1 Game Theory for Shielding Personal Data Against Privacy Attacks on Anonymity

Zhiyu Wan, Vanderbilt University Medical Center, Nashville, TN, Contact: zhiyu.wan@vanderbilt.edu

Person-specific biomedical data are now widely collected, but its sharing raises privacy concerns, specifically about the re-identification of seemingly anonymous records. Formal re-identification risk assessment frameworks can inform decisions about whether and how to share data; current techniques, however, focus on scenarios where the adversaries use only one resource. This matters because recent attacks show that adversaries can access multiple resources, combining them in a stage-wise manner, to enhance the chance of an attack's success. In this work, we represent a re-identification game that can be applied to assess risk and suggest an optimal data sharing strategy based on a privacy-utility tradeoff. We report on experiments with genomic datasets to show that most data can be effectively shared with low re-identification risk using game-theoretic models.

2 A Partially Observable Stochastic Game Model of Entry and Exit for Fast Food Industry

Yanling Chang, Texas A&M University, College Station, TX, Contact: yanling.chang@tamu.edu

Business cycle describes the periodic growth and decline of a nation's economy and has huge impact on investment decisions of corporations. However, business cycle cannot be directly observed and companies have to make their decisions based on their beliefs about economy state from various indicators such as GDP, unemployment rate. We develop a partially observable stochastic game model for the market entry and exit problem and design an estimation procedure to examine how companies make investment according to partially observed business cycle. The method is illustrated with the data of hamburger market in Canada (1970-2005) for fast food industry.

3 A Game and Control Framework for Modeling and Mitigating Advanced Persistent Threats

Shana Moothedath, Iowa State University, Ames, IA, Contact: mshana@iastate.edu

Advanced Persistent Threats (APTs) are sophisticated attacks mounted by intelligent and resourceful adversaries who gain access to a targeted system and gather critical information over an extended period of time. APTs consist of multiple stages each of which involves strategic interaction between the APT and the targeted system. While this strategic interaction can be viewed as a game, the stealthiness, adaptiveness, and unpredictability of APTs imply that the information structure of the game and the strategies of the APT are not readily available. In this talk, we will present a game-theoretic approach to characterize the trade-off between effectiveness for detecting APTs and resource efficiency. Our model is grounded on APT data gathered using the Refinable Attack Investigation (RAIN) flow-tracking framework.

CC - Room 102
Matrix/Tensor Valued Data Mining Methods and Applications
General Session

Session Chair
Yang Chen, University of Michigan, Ann Arbor, MI

1 Statistics Inferences on Image Data via Deep Neural Networks

Jian Kang, University of Michigan, Ann Arbor, MI

Regression models for matrix or tensor values have been developed to study the associations between the image data and other variables of interests. In this talk, I will present a series of regression models for image data analysis where the model parameters are constructed through deep neural networks (DNN). Compared with the existing solutions, our methods are more flexible in capturing the complex patterns among the images, of which the noise level and the spatial dependence appear to be heterogeneous across different regions of the images. I will discuss the parameter estimation and inference procedures along with the theoretical properties of our proposed methods. I will show that the new methods outperform the existing ones through both simulations and different image data examples.

2 Multi-linear Tensor Autoregressive Models

Zebang Li, Han Xiao, Rutgers University, Piscataway, NJ, Contact: hxiao@stat.rutgers.edu

Contemporary time series analysis has seen more and more tensor type data from many fields. In the first part of the talk, we propose a multi-linear autoregressive model for tensor-valued time series (TenAR). Comparing with the traditional VAR approach, the TenAR model preserves the tensor structure and has advantages in terms of interpretability, dimension reduction and computation. We propose to use the alternating algorithms to obtain the LSE and MLE. The performance of the models and methods is demonstrated by theoretical studies and simulated and real examples.
In the second part of the talk, we consider the TenAR model under co-integration. We investigate the MLE under a separable error covariance structure and provide asymptotic results for the co-integration vectors, as well as the projection onto the co-integration space.

3 Two-sample Hypothesis Testing for Multiple-Network Data

Yinqiu He, University of Wisconsin-Madison, Madison, WI

Multiple-network data has attracted increasing attention recently, where the data are recorded as symmetric matrices, and each matrix encodes an individual network structure. Such data arises frequently in various scientific fields such as the analyses of brain connectivity and gene interactions. In these studies, it is of great interest to compare the means of two populations of networks. In this work, we propose a hypothesis testing procedure when we are interested in a given area of networks that may have multiple signals functioning together. We establish asymptotic results for the proposed test under general moment conditions and validate the test under a variety of popular network models. We further demonstrate the efficacy of the proposed test under simulation studies and the analysis of a brain dataset.

4 Local Spatio-temporal Analysis of Global Climate Data from Argo Profiling Floats

Mikael Kuusela, Carnegie Mellon University, Pittsburgh, PA, Contact: mkuusela@andrew.cmu.edu

Statistical analysis of modern observational climate data is challenging due to their complex spatio-temporal structure and large size. Analyzing these data using local statistical models has proved to be a successful strategy for handling both the complexity and computational challenges.
For example, climatological anomalies can be mapped using locally stationary Gaussian processes, which yields computationally tractable nonstationary fields without the need to explicitly model the nonstationary covariance structure. In this talk, I will first introduce the relevant local modeling and analysis techniques and then describe our recent work on using these methods to produce new data-driven estimates of various key properties of the global climate system based on temperature and salinity profiles observed by Argo floats in the upper 2,000 m of the global ocean.

Advances in Time series Modeling and Forecasting Using Deep Learning Methods

General Session

Session Chair

Jie Han, University of Texas, Arlington, TX

Session Chair

Shouyi Wang, University of Texas at Arlington, Arlington, TX

1 Long-term Forecasting of Time Series with Graph Convolutional Networks

Ali Sarabi, Arizona State University, Tempe, AZ, Contact: asarabi1@asu.edu

Time series forecasting has long been a challenging task that has piqued the interest of academics in various fields. This problem becomes more difficult as model predictions become less accurate over time. Furthermore, we frequently see hierarchical structures between different time series in real-world applications, which cannot be overlooked. Graph Neural Network (GNN) has demonstrated strong capability in dealing with these relational dependencies. In this paper, we propose a generic deep neural network to improve the accuracy of time-series forecasting in the long term. Our model employs graph convolution to extract the inter-series temporal correlation properties and Long Short-Term Memory (LSTM) cells to extract intra-temporal relationships and make both short-term and long-term predictions.

2 Deep Learning-based Anomaly Detection in Multivariate Time Series Data

Yeseul Choi, Soomin Lee, Dongil Kim, Chungnam National University, Daejeon, Korea, Republic of.

Anomaly detection system aims to identify unusual events that do not conform to expected distribution. The system is one of the important tasks for several domains such as industries and network securities. We propose a method to detect anomalous data in multivariate time series data. The proposed method employs CNN-based autoencoder structures and uses 2-dimensional input shape. We used several open datasets and a real-world dataset for empirical studies. In experiments, we compared the performance of the proposed method with the performance of several models for anomaly detection as baselines. The experimental results showed that the proposed method had better performance than benchmark methods

3 The Explainable Neural Networks for Nowcasting

Wonkeun Jo, Dongil Kim, Chungnam National University, Daejeon, Korea, Republic of. Contact: jowonkun@naver.com

Nowcasting is one of the major issues in machine learning. The useful non-linear combination of the neural network that helps extract the feature vectors make it hard to explain the model. The neural additive model that was recently researched shows the possibility of the explain the reason for how to predict the nowcasting target. Since NAM-NC is conducted based on GAM, we can explain why the model nowcasts the target value. According to the pilot experiment, NAM-NC can predict the next step in the time series and also explain the reasonable contribution of the feature net. Also, we apply the hard-sharing to NAM-NC, decreasing the memory complex cost of our model. The hard-tied feature net of NAM-NC still extracts the meaningful vector from the real-world time series. NAM-NC shows competive performance as much as than other SOTA neural networks in real-world problems.

Advances in Predictive and Forecasting Techniques with Healthcare and Business Applications

General Session

Session Chair

Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel.

Session Chair

Gonen Singer, Bar-Ilan University, Ramat Gan, Israel.

1 Adaptive Cost-sensitive Learning Approach in Neural Networks for Medical Applications

Gonen Singer, Ohad Volk, Bar-Ilan University, Ramat Gan, Israel. Contact: gonen.singer@biu.ac.il

We design a new Adaptive Cost-Sensitive Learning (AdaCSL) algorithm for binary classification problems. Our algorithm adaptively adjusts the loss function such that the classifier bridges the difference between the class distributions of subgroups of samples in the training and test data sets with similar predicted probabilities (i.e., local training-test class distribution mismatch). We present empirical evidence that a deep neural network used with the proposed AdaCSL algorithm yields better results on several medical data sets compared to other alternative approaches. The proposed AdaCSL algorithm can be used for medical applications, in which large variability may occur between subjects in training and test data sets.

2 Employee Retention: What is the Value of Turnover Contagion? A Bilevel Optimization Approach

Iris Forma[1], Hila Chalutz Ben-Gal[2], Gonen Singer[3], [1]Afeka Tel-Aviv College of Engineering, Tel-Aviv, Israel; [2]Afeka Tel-Aviv College of Engineering, Tel-Aviv, Israel; [3]Bar-Ilan University, Ramat Gan, Israel. Contact: irisf@afeka.ac.il

The growing practice of flexible work following the COVID-19 pandemic is likely to have a significant impact on management and human resource (HR) practices. We propose a novel bi-level mathematical programming model that can serve as a decision support tool for firms in real-life settings to address employee retention challenges via hybrid and flexible work plans, in the context of turnover contagion. We show that the model provides an exact solution based on a mixed integer formulation. We present a computational analysis based on changing candidate behaviors in response to firm's strategy, then we demonstrate its applicability to a real-world dataset and we present initial results.

3 Innovative Mathematical Tools for Post-traumatic Epilepsy Using Multimodal Data

Dominique Duncan, University of Southern California, Los Angeles, CA

The Epilepsy Bioinformatics Study for Antiepileptogenic Therapy (EpiBioS4Rx), is a multisite collaboration collecting MRI, EEG, and blood samples. The development of epilepsy after a traumatic brain injury is a multifactorial process and crosses multiple modalities. Before these data can be analyzed, a central platform is needed to standardize these data and provide tools for searching, viewing, annotating, and analyzing them. We have built a centralized data archive that will allow the broader research community to access these shared data in addition to mathematical tools to identify and validate biomarkers of epileptogenesis in imaging and electrophysiology data.

4 An Application to Optimize the Schedule of MRI

David Freud, Amir Elalouf, Bar Ilan University, Ramat Gan, Israel.

The Magnetic Resonance Imaging (MRI) is a vital diagnostic tool, yet MRI scanners are in short supply and are utilized around the clock. The MRI scheduling problem is a single-machine scheduling NP-hard problem. Our proposal is to address this problem using a novel application of a pseudo-polynomial algorithm. We assume the scanner to have required periodic maintenance time, and that each patient can be allocated to an alternative facility with a differential allocation cost, limited by a fixed budget constraint.

Sunday, 8AM–9:15AM

Efficient Statistical Methods for Uncertainty Quantification

General Session

Session Chair

Ozge Surer, Northwestern University, Evanston, IL

1 Efficient Gaussian Process Regression with Kernel Packets

Haoyuan Chen, Liang Ding, Rui Tuo, Texas A&M University, College Station, TX, Contact: ruituo@tamu.edu

We develop an exact and scalable algorithm for one-dimensional Gaussian process regression with Matern correlations whose smoothness parameter is a half-integer. The proposed algorithm only requires operations and storage both linear in the sample size. The proposed method is based on a novel theory for Matern correlation functions. We find that a suitable rearrangement of these correlation functions can produce a compactly supported function, called a "kernel packet". Using a set of kernel packets as basis functions leads to a sparse representation of the covariance matrix that results in the proposed algorithm. Simulation studies show that the proposed algorithm, when applicable, is significantly superior to the existing alternatives in both the computational time and predictive accuracy.

2 Bayesian Uncertainty Quantification for Low-rank Matrix Recovery

Simon Mak, Duke University, Durham, NC, Contact: sm769@duke.edu

We consider the problem of uncertainty quantification for an unknown low-rank matrix X, given a partial and noisy observation of its entries. This quantification of uncertainty is essential for many real-world problems, including image processing, satellite imaging, and seismology, providing a principled framework for validating scientific conclusions and guiding decision-making. We propose a new Bayesian modeling framework, called BayeSMG, which parametrizes the unknown matrix via its underlying row and column subspaces. This Bayesian subspace parametrization enables efficient posterior inference on matrix subspaces, which represents interpretable phenomena in many applications. We demonstrate the effectiveness of BayeSMG over existing methods in numerical experiments, image inpainting, and a seismic sensor network application.

3 Model Mixing with Bayesian Additive Regression Trees

John Yannotty[1], Matthew Pratola[2], Thomas Santner[3], [1]The Ohio State University, Columbus, OH, [2]The Ohio State University, New Albany, OH, [3]The Ohio State University, Columbus, OH

In modern computer experiments, one often encounters the situation where many plausible models of a physical system are considered, each implemented as a simulator. An important question in such a setting is determining the best simulator, or best combination of simulators, to use for prediction or inference. Bayesian model averaging (BMA) and stacking are relevant statistical modeling approaches typically used to account for model uncertainty. In the context of multi-simulator computer experiments, BMA or stacking can be used to combine a set of plausible simulators using a weighted average, where the weights are independent of the input space. Bayesian model mixing (BMM) extends these ideas to capture the localized behavior of each simulator by allowing the weights to depend on the inputs. In our approach, we propose a BMM model using Bayesian Additive Regression Trees.

4 Batch Sequential Calibration of a Computationally Intensive Simulation Model Using Parallel Computing

Ozge Surer[1], Matthew Plumlee[1], Stefan Wild[2], [1]Northwestern University, Evanston, IL, [2]Argonne National Laboratory, Lemont, IL, Contact: ozgesurer2019@u.northwestern.edu

In a standard Bayesian calibration, one builds a cheaper emulator as a proxy to an expensive-to-evaluate simulator using data from simulation experiments, and then leverages Markov chain Monte Carlo sampling algorithms to obtain draws from the posterior distribution of unknown/uncertain parameters. To train an emulator, one needs a design of parameters and their corresponding simulation outputs. Space-filling designs are widely used in the literature to generate designs. The region occupied by a density of parameters inside a hypercube can be very small in higher dimensions, and space-filling designs can miss the high probability regions. In this study, we propose a sequential Bayesian experimental design that can be used to provide more precise inference by better selecting the design points.

Data Analytics in Developing Quality Management Theory and Practices

General Session

Session Chair

Heng (John) Xie, California State University, Sacramento, CA

Session Chair

Xinyu Wei, California State University, Chico, Chico, CA

1 **Applying Text Mining Methods to Identify Health Perceptions of College Students**

Heng (John) Xie[1], Xiaoni Zhang[2], [1]California State University, Sacramento, Sacramento, CA, [2]University of Alabama at Birmingham, Birmingham, AL, Contact: heng.xie@csus.edu

Developing a healthy lifestyle is important at a young age as it impacts a person's future health and well-being. A habit could also be a risk factor for developing chronic disease. However, behavior change is not easy. We use text mining methods to examine published papers on healthy behaviors in college students and synthesize prior findings. Our goals are to identify effective interventions that could produce long-term benefits for a person and has the potential to be accepted and adopted by others. We want to raise awareness of the detrimental effect of chronic disease and educate college students about well-being, disease prevention, and a healthy lifestyle. We summarize prior interventions and propose suggestions and strategies for health promotion for college students.

2 **Relationships Among Healthcare Operations Measurements and Patient Satisfaction**

Xinyu Wei[1], Xianghui (Richard) Peng[2], Victor R. Prybutok[3], [1]California State University, Chico, Chico, CA, [2]Penn State Erie The Behrend College, Fairview, PA, [3]University of North Texas, Denton, TX, Contact: xwei1@csuchico.edu

Effective measurement of healthcare outcomes remains of interest to healthcare professionals, healthcare executives, and academics. This study examines and compares different healthcare operations measurements provided by regulatory agencies and healthcare associations. This research examines the relationships between these measurements and patient satisfaction. The findings contribute to the health care operations literature and reveal the need for a structured and consistent measurement because such consistency can enhance temporal and organizational comparisons.

3 **A Sustainability Focused Organizational Framework**

Lu Xu[1], Ying Cao[2], Xinyu Wei[3], Xianghui Peng[2], Victor Prybutok[4], [1]University of North Georgia, Oakwood, GA, [2]Penn State Erie The Behrend College, Erie, PA, [3]California State University, Chico, Chico, CA, [4]University of North Texas, Denton, TX, Contact: lu.xu@ung.edu

This study integrates quality management (QM) and supply chain management (SCM) to create a sustainable organizational framework. The literature review on QM, SCM, and sustainable SCM allowed identifying research gaps. One outcome from integration of theory was proposal of a testable research model and a survey to test that model. This study contributes to theory development and provides managerial insights.

4 **Customers' Perceptions of Quality Management in Electric Vehicle Rental Business in The USA**

Edwin (Yuchen) Wang[1], Richard (Xianghui) Peng[2], Adeela Gulzari[3], Victor R. Prybutok[4], [1]Kean University, Union, NJ, [2]Penn State Erie, Erie, PA, [3]University of North Texas, Denton, TX, [4]University of North Texas, Denton, TX

To limit household energy consumption and carbon emissions, the promotion of clean and fuel-efficient vehicles, such as electric vehicles (EV), especially in the surge of international gasoline prices, is thriving. Along with the upward trend of EV, the quality of this type of automobile, the service before & after the purchase or rental, and the infrastructure become the concerns of many consumers.

This research centers on the relationship between perceived service quality, perceived functional quality, willingness to pay, and the rental intention of EV with the partial least squares method, using the survey data collected in the southern USA. The results provide information about the preferences of customers that can be used in the implementation of a proper quality management approach, thereby ensuring that customers receive the quality they expect when renting EV.

Sunday, 8AM–9:15AM

SA07

CC - Room 107
Risk Analysis
Contributed Session

Session Chair
Mehdi Dadfarnia, National Institute of Standards & Technology, Bethesda, MD

1 Reliability Inference of Spacecraft Power Systems with Imperfect Information

Marc Eskew[1], M. Elisabeth Pate-Cornell[2], Victoria Li[1], Donovan Tokuyama[1], Ashten Prechtel[1], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA, Contact: esq601@gmail.com

The objective of this work is to model the reliability of a critical component in spacecraft power systems with no direct observations of the individual component performance. Based on data from NASA/JPL missions, Markov Chain Monte Carlo modeling is used to infer probability distributions of reliability parameters of interest. Using these estimates, this model provides credible intervals of reliability and probability of failure of power systems for future missions and allows updating from continued missions or testing.

2 Project Control Looking Forward: Making Sense of Project Performance Indicators Under Uncertainty and Ambiguity

Byung-Cheol Kim, Penn State Behrend, Erie, PA, Contact: buk70@psu.edu

Project managers need to look forward, not backward, in order to drive a project forward. This presentation discusses the predictive performance tracking problem (PPTP) in the context of project control. Tracking bias arises when a project backtracks (digging into visible numbers), rather than embracing the uncertain future, creating a consistent tendency of overshooting or undershooting the true project position at completion. The PPTP is framed as a signal-noise separation problem and a risk-driven debiasing simulation model is used to investigate the nature, characteristics, and implications of the tracking biases of standard key performance indicators (KPIs) in project control. Results from the predictive tracking simulation are integrated into a set of decision support tools for real-time adjustment of the KPIs as a predictive measure.

3 Discrete Approximations for Large Scale Markov Systems

Zhengqi Lin, Rutgers University, Newark, NJ, Contact: zhengqi.lin@rutgers.edu

We consider the construction of finite-state approximations of continuous state-space Markov systems. When the dimension of the state space increases, the amount of data required for numerical analysis grows exponentially. We introduce a state discretization method using particle generation and selection to overcome this issue. The method uses the dynamics equation to generate new particles and probability metrics for the selection of a suitable subset of particles. Furthermore, we demonstrate the approximation errors are kept small for the estimation of the dynamic measure of risk and associated control problems, without the exponential growth of the number of particles.

4 A Systematic Review of Approaches to Evaluate the Operational Risks and Benefits of Condition Monitoring

Mehdi Dadfarnia, National Institute of Standards & Technology, Gaithersburg, MD, Contact: mehdi.dadfarnia@nist.gov

Industrial users increasingly use condition monitoring systems (CMSs) to detect, diagnose, or prognosticate asset faults and failures. Such capabilities mitigate operational risks and enhance asset reliability but come at a cost. Pinpointing a CMS's benefits to a particular industrial asset is not trivial. A prior successful implementation does not imply future success, as monitoring depends on the asset's structure, operating conditions, and often closed-box machine learning algorithms that the CMS utilizes. Many studies have considered decision-making approaches for CMS-related investments and balancing their risks and benefits, though no widely accepted procedures exist. This talk surveys CMS evaluation approaches, yields definitions for terms relevant to their evaluation, and elucidates the existing approaches' possibilities, gaps, and limitations.

Data Mining Flash Session I

Flash Session

Session Chair

Margret V. Bjarnadottir, University of Maryland, College Park, MD

1 Mode Melding in Misspecified Gaussian Mixtures

Xumei Xi, Cornell University, Ithaca, NY, Contact: xx269@cornell.edu

We study Gaussian mixture models where the number of components may be misspecified. We focus on the special case of fitting a 2-Gaussian mixture to a single Gaussian. We reveal an intriguing phenomenon called Mode Melding, where the two modes of the likelihood function merge and attain an error rate faster than the minimax bound. On the algorithmic side, we study a quasi-Newton algorithm suitable for optimizing the ill-conditioned likelihood. Perhaps unexpectedly, a naive implementation fails spectacularly, precisely in the event of Mode Melding. Leveraging a fine-grained characterization of Mode Melding, we design an improved algorithm that is guaranteed to converge linearly and robustly.

2 Missing Data? Four Imputation Strategies and How They Impact Model Performance

Jennifer Priestley[1], Martin Brown[2], Duleep Don[1], [1]Kennesaw State university, Kennesaw, GA, [2]Kennesaw State University, Kennesaw, GA

We present our study which evaluates differences in model performance using 4 imputation techniques across 3 levels of missingness among predictor variables in logistic regression. Imputation techniques include median imputation, multiple imputation by chained equations (MICE), single center imputation from multiple chained equations (SICE), and denoising autoencoder (DAE). The dataset comes from a global credit bureau and includes firmographic information and payment performance for 6 million commercial entities. Results indicate that risk modeling is heavily impacted by imputation technique across varying levels of missingness. Model performance is evaluated using AUC and K-S test.

3 Big Data Analytics Adoption: An Extension of UTAUT Model

Vatsal Paghadal, Md Golam Kibria, University of Toledo, Toledo, OH

Grounded in the UTAUT model, management fads and fashions and social learning theory/neo institutional theory this study proposes a model determining the role of Performance expectancy, effort expectancy, social influence and facilitating conditions on of organizational big data analytics intention and firm performance. It also explores the moderating role of Mindfulness in effect of UTAUT model constructs on behavioral intention and role of voluntariness in effect of behavioral intention on quality of innovation. Measurements have been developed based on literature review and Q-sorting and the proposed model is ready to be tested utilizing a structural equation modeling (SEM).

4 A Graphical Multi-fidelity Gaussian Process Model, with Application to Emulation of Expensive Computer Simulations

Yi Ji[1], Simon Mak[2], Derek Soeder[3], J-F Paquet[3], Steffen A. Bass[3], [1]Duke University, Durham, NC, [2]Duke University, Durham, NC, [3]Duke University, Durham, NC, Contact: yi.ji@duke.edu

We present a novel Graphical Multi-fidelity Gaussian Process (GMGP) model that uses a directed acyclic graph to model dependencies between multi-fidelity simulation codes. It is an extension to the Kennedy-O'Hagan model for problems where different codes cannot be ranked in a sequence from lowest to highest fidelity. We also present a scalable recursive formulation and a non-linear extension to the GMGP model. The advantages of the GMGP model over existing methods are demonstrated via an application to heavy-ion collisions emulation, which shed light on the origins of the Universe shortly after the Big Bang.

5 A Data-driven Approach to Modeling Assortment Optimization: The Tractable Case of Similar Substitutes

Nanxi Zhang, Shanghai University of Finance and Economics, Shanghai, China. Contact: sufenanxizhang@163.sufe.edu.cn

We propose a data-driven approach to model assortment optimization problem. Two empirical observations from Taobao data motivate our work: one is that most customers browse very few items before they make a purchase; the second is that customers consideration sets are small intervals in a sorting of items. We build a choice model framework with these observations which subsumes some popular choice models as special cases. To justify our framework, we use hotel transaction data to fit different models and compare their performance. Finally, we give algorithms for assortment planning problems under our framework and implement our data-to-model-to-optimization approach on customer data on JD.com.

6 Improving Conversation Analytics Through Hyperparameter Tuning with and Without Labels

Cecilia Ying, Stephen Thomas, Queen's University, Kingston, ON, Canada. Contact: 18yly@queensu.ca

Conversation Analytics (CA) is used for extracting insights from chatbot logs to help companies understand their customers' frequent concerns and trending topics. Many human-annotated messages used for training CA tools are incorrectly and inconsistently labelled, resulting in unreliable metrics for model evaluation. We propose a hybrid hyperparameter tuning approach to address this. We leverage the Cophenetic Correlation, a performance metric for unsupervised hierarchical clustering, with the Adjusted Mutual Information when labels are available. We conclude that this hybrid approach is more effective than using just one of the two methods for model evaluations.

7 Knot Selection for B-spline Regression via Trimmed Regularizer

Shotaro Yagishita[1], Jun-ya Gotoh[2], [1]Chuo university, Bunkyo-ku, Tokyo, Japan; [2]Chuo University, Bunkyo-ku, Tokyo, Japan.

We propose a nonconvex regularizer and an algorithm for selecting knots at the same time as estimating the B-spline regression model. More specifically, starting with the constraint to directly designate the number of knots to be used, we present an (unconstrained) regularized least square reformulation, which is equivalent to the cardinality-constrained formulation. The obtained formulation is further modified so that we can employ a proximal gradient-type algorithm. Numerical experiment demonstrates how our approach performs on several data sets.

8 Scalable Distributed Computing Systems for Incremental Machine Learning in Big Data Applications

Dhaval Salwala[1], Seshu Tirupathi[1], Brian Quanz[2], Wesley Gifford[2], Stuart Siegel[2], [1]IBM Research Europe, Dublin, Ireland; [2]IBM Thomas J. Watson Research Center, Yorktown Heights, NY, Contact: dhaval.vinodbhai.salwala@ibm.com

Terabytes of daily raw data generated by IoT sensors are indispensable for investigating time-series problems like short-term forecasting of the target variable, and failure predictions. Pure batch learning algorithms can be challenging with this high frequency and high-volume data as concept drifts would require frequent retraining of the deployed models leading to significant downtimes. Therefore, incremental models or coupled batch-incremental models are gaining increasing importance to handle these problems. In this talk, we will present a distributed computing system that can scale to perform incremental learning for big data and efficiently perform a parameter search in big data applications to dynamically generate the most efficient incremental modelling pipelines with every stream of new incoming data, followed by synthetic and real world use cases.

9 Flash Paper

Shulei Wang, 1</sup

Self-supervised metric learning has been a successful approach for learning a distance from an unlabeled dataset. The resulting distance is broadly useful for improving various distance-based downstream tasks, even when no information from downstream tasks is utilized in the metric learning stage. To gain insights into this approach, we develop a statistical framework to theoretically study how self-supervised metric learning can benefit downstream tasks in the context of multi-view data.

10 Closing Demographic Pay Gaps

Margret V. Bjarnadottir[1], David Anderson[2], David Gaddis Ross[3], [1]University of Maryland, College Park, MD, [2]Villanova University, Villanova, PA, [3]University of Florida, GAINESVILLE, FL, Contact: mbjarnad@umd.edu

Employers are under increasing pressure to address pay inequity, however, managers have few tools at their disposal to help them. We design and implement an algorithm that measures whether an employer has a pay gap, suggests salary adjustments to close it, and establishes a quantitative framework for determining whether a pay gap is "statistically closed," all while supporting the employer's own goals with respect to equity, culture, and incentives in its pay structure. Our work not provides a solution to management personnel for a problem of growing social and practical importance, and demonstrates how the OM toolkit may be applied to improve human resources management.

Applications and Implications of AI in Social Interactions

Joint Session

Session Chair

Yifan Yu, University of Washington, Seattle, WA

1 Covid-19 Pandemic Heard Disproportionate Female Voices in News

Zhihan Li[1], Juan Wang[2], Wendao Xue[3], Yifan Yu[3], Yong Tan[3], [1]Cornell University (Cornell Tech Campus), New York, NY, [2]Chongqing University, Chongqing, China; [3]University of Washington, Seattle, WA, Contact: zl629@cornell.edu

Studies on gender inequality during the COVID-19 pandemic have found women's burden and contribution in the crisis. The long-lasting gender gap in media coverage, therefore, is expected to narrow. However, we find that the gender gap enlarged, by analyzing 146,203 online news on the coronavirus from January 20, to April 30, 2020. Gender gap is measure by both coverage gap, the difference between number of times males and females are mentioned in news, and source gap, the difference between number of times males and females are quoted. We observe a jump in both coverage gap and source gap on March 11, when the COVID-19 cases in the U.S. has reached 1000. We utilize Synthetic Control Method and Regression Discontinuity in Time to identify such effects and mechanisms.

2 Whose Words to Believe? The Polarity of Customer Reviews on Apparel Rental Platforms

Yu Kan, Uttara Ananthakrishnan, University of Washington, Seattle, WA

Customer reviews make a difference. This is especially true for online fashion retailers. Countless research has shown that positive reviews can increase sales. However, due to the heterogeneity among customers, their opinions inevitably differ from each other. If the reviews contain positive and negative emotions, how will they affect the sales? Will the extent of polarity in reviews affect sales? In this paper, we partner with a subscription-based apparel rental platform and leverage large-scale customer and product level data to investigate these questions. We employ Bidirectional Encoder Representations from Transformers (BERT) to identify entities mentioned in each review and corresponding sentiment. We show that the contradictory opinions in reviews affect rentals under different circumstances.

3 How to Identify Lonely People with Social Media Data and Help Them Cope?

Chengyue Huang[1], Alice Wang[2], Weiguo (Patrick) Fan[1], [1]University of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, Contact: cyhuang@uiowa.edu

Given the unprecedent social isolation caused by the pandemic, loneliness is a growing mental health issue. However, not all lonely people respond to the undesired situations equally. Some actively cope with it, while others may cope with it negatively. Therefore, to help people cope with loneliness, it's important to identify lonely people and to analyze their optimism/pessimism attitudes towards future. In this research, we examine how loneliness and optimism jointly affect behaviors with social media data from Reddit by leveraging NLP techniques. We collected thousands of posts from loneliness-related subreddits and classified posts into four groups. With MANOVA analysis, we found the lonely and optimistic groups express stronger social motivations compared to other groups (non-lonely and optimistic, non-lonely and pessimistic, lonely and pessimistic groups)

4 How Recommender Systems Shape Online Investor Behaviors

Ruiqi Zhu[1], Yu Jeffrey Hu[2], Cheng He[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technologuy, Atlanta, GA, [3]University of Wisconsin-Madison, Madison, WI, Contact: rich.zhu@scheller.gatech.edu

The impact of recommender systems on online investors' behaviors is rarely documented. Financial products are inherently different from consumer products in terms of quality uncertainty and purchase stages. In this paper, we employ regression discontinuity design to causally examine the effect of recommender systems on online investor behaviors, more specifically in the context of mutual fund investment. The results show that (1) funds featured by recommender systems receive a significantly higher number of purchases; (2) the recommendation effect is heterogeneous across different types of mutual funds and investors with different characteristics. Furthermore, (3) the holding period of recommended and non-recommended funds is heterogeneous across diverse investors. In addition, we examine the mechanisms and implications.

1 On-line Order Batching for Robot-based Order Picking Systems Using Deep Reinforcement Learning

Bhoomica Mysore Nataraja, Zumbul Atan, Ivo Adan, Eindhoven University of Technology, Eindhoven,

Netherlands. Contact: b.m.nataraja@tue.nl
Recent advancements in robotics and automation have enabled warehouses in the e-commerce era to adopt new ways to cope with highly volatile customer demands with shorter deadlines. Uniquely, we consider an autonomous robot-based order picking system that fulfils orders from a multi-deep gravity flow rack in an online environment. For such a system, we study the online order batching problem with an objective to minimize the weighted earliness and tardiness. We formulate a Semi-Markov decision process to represent the problem that allows us to create a deep reinforcement learning (DRL) agent. The DRL agent can produce feasible solutions superior to the benchmark heuristics in most tested cases. We demonstrate that the learning agent shows potential performance under fluctuating order environments making it suitable for online retailing of fast-moving consumer goods.

2 Machine Learning Based Problem Space Reduction in Stochastic Programming Models: An Application in Biofuel Supply Chain Network Design

Kolton Keith[1], Krystel Castillo[2], Adel Alaeddini[1], [1]University of Texas at San Antonio, San Antonio, TX, [2]University of Texas-San Antonio, San Antonio, TX, Contact: kolton.keith@utsa.edu

Biofuels derived from feedstock offer a sustainable alternative to meeting energy needs. Stochastic programming models in this area often incur a heavy computational burden. The present work proposes a hybrid strategy that uses machine learning to reduce computational complexity of stochastic programming models via problem space reduction. First, randomly generated reduced-space versions of the problem are solved to generate a set of solution data. Next, a supervised machine learning algorithm is called to predict a potentially beneficiary problem space from which a near-optimal solution can be obtained. Finally, the mixed integer linear program will select the optimal solution from the reduced space suggested. The numerical experiments show the proposed solution procedure yields quality solutions with reduced computational burden.

Improving Healthcare One Bit at a Time: Using Data Science to Revolutionize the Industry

General Session

Session Chair

Geoffrey Fairchild, Los Alamos National Laboratory, Los Alamos, NM

1 Real-time Characterization of Emerging SARS-CoV-2 Variants Globally

Kaitlyn Johnson, The Rockefeller Foundation, DC

Understanding in real-time when, whether, and how emerging SARS-CoV-2 variants pose a threat is critical for tailoring responses. The characteristics of a novel variant can affect public health guidelines, vaccine roll-out, treatment recommendation, and individual risk assessment. The Pandemic Prevention Institute has developed a weekly report that provides scientists, decision-makers, and the public with real-time variant characterization. Using a global sequencing repository coupled with epidemiological data, we systematically assess the risk posed by a novel variant by estimating its fitness advantage, checking for bias in the lag-time of sequence submission, and assessing its impact on cases. In this talk, I will discuss some of the approaches we have taken to parse signals from noise to improve our early understanding of SARS-CoV-2 variants as they emerge.

2 The Road to Data-Centric Machine Learning in Healthcare

Jason Fries, Stanford University, Stanford, CA

The high cost of building and sharing labeled training data is one of the largest barriers to using supervised machine learning in medicine. One approach to addressing this challenge is *weakly supervised learning*, where instead of manually labeling data, domain experts create training labels programmatically using imperfect labeling rules. Programmatic labeling takes a data-centric view of machine learning, and focuses on novel methods to curate, transform, and shape training data to improve model performance. In this talk, I describe our recent successes using weakly supervised learning and other data-centric techniques to build medical applications across a range of modalities, including structured medical records, clinical text, and medical imaging.

3 Identifying Asymptomatic Spreaders of Antimicrobial Resistant Pathogens in Hospital Settings

Sen Pei, Columbia University, NY

Antimicrobial resistant organisms (AMROs) can colonize people without symptoms for long periods and spread unnoticed to other patients. Here, we study methicillin-resistant Staph. aureus (MRSA), a prevalent AMRO, in 66 Swedish hospitals using an agent-based model informed by real-world hospitalization records. We develop and validate an individual-level inference approach that estimates the colonization probability of individual hospitalized patients. For both model-simulated and historical outbreaks, the proposed method supports the more accurate identification of asymptomatic MRSA carriers than other traditional approaches. In addition, in silica control experiments indicate that interventions targeted to inpatients with a high-colonization probability outperform heuristic strategies informed by hospitalization history and contact tracing.

4 NEEDS TITLE

Sara Del Valle, Los Alamos National Laboratory, Los Alamos, NM

The COVID-19 pandemic has highlighted a need for better understanding of countries' vulnerability and resilience to not only pandemics but also disasters, climate change, and other systemic shocks. In this talk, I will present a data-driven framework for studying countries' vulnerability and resilience to incident disasters across multiple dimensions of society. To illustrate this methodology, we leverage the rich data landscape surrounding the COVID-19 pandemic to characterize observed resilience for several countries (USA, Brazil, India, Sweden, New Zealand, and Israel) as measured by pandemic impacts across a variety of social, economic, and political domains. This work also highlights key gaps in our current understanding about vulnerability and resilience and a need for data-driven, context-specific assessments of disaster vulnerability in the future.

Decision Support for Competitive Security Applications

General Session

Session Chair

William Caballero, AFIT, Air Force Academy, CO

1 A Behavioral Approach to Repeated Bayesian Security Games

William Caballero[1], Jake Cooley[1], David Banks[2], Phillip R. Jenkins[3], [1]United States Air Force Academy, Colorado Springs, CO, [2]Duke University, Durham, NC, [3]Air Force Institute of Technology, Wright-Patterson Air Force Base, OH, Contact: william.caballero@afacademy.af.edu

Security games are a potent policymaking tool however, whereas canonical models effectively allocate limited resources, they generally do not consider adaptive, boundedly rational adversaries. Thus, we develop a repeated game framework in which a boundedly rational adversary is characterized by a behavioral-economic theory of learning, i.e., experience-weighted attraction learning. Realistic uncertainty about the competition is modeled by adopting the perspective of adversarial risk analysis. Using Bayesian reasoning, these games are decomposed into multi-arm bandit problems. A collection of cost-function-approximation policies are set forth, and their effectiveness is shown via extensive empirical testing on a defense-related case study.

2 Strategic Network Inspection with Imperfect Detection Technology

J. Haden Boone, Mathieu Dahan, ISyE Georgia Tech, Atlanta, GA, Contact: jboone31@gatech.edu

We consider a two-player zero-sum network inspection game, in which a limited number of detectors are coordinated according to a probability distribution to detect multiple attacks from a strategic opponent. Detection is assumed to be imperfect and is modeled with a probability that an attack of each network component is successfully detected from each detector location. This probability is determined from the detection technology utilized and the properties of the network. We analytically characterize Nash equilibria of the game in which the defender (attacker) attempts to minimize (maximize) the number of undetected attacks under the condition that each network component is detected from one detector location. We utilize the results on the disjoint case to provide approximate solutions to the general case using a greedy partitioning strategy.

3 Information Security Investments Against Multiple Boundedly-Rational Attackers: An Adversarial Risk Analysis Approach

Ashley Peper[1], Eric B. DuBois[2], Laura Albert[1], [1]University of Wisconsin-Madison, Madison, WI, [2]CNA, Arlington, VA, Contact: apeper2@wisc.edu

We use integer programming techniques to inform defensive decision-making in mitigating the risk from multiple boundedly rational adaptive adversaries. We extend adversarial risk analysis frameworks to consider a maximum reliability path interdiction problem with a single defender and multiple attackers who have different goals and levels of strategic sophistication.

4 Rumor Propagation and Clarification on Social Media During Crisis Events

Puneet Agarwal[1], Ridwan Al Aziz[2], Kyle J. Hunt[3], Jun

Zhuang[3], [1]California Polytechnic State University, San Luis Obispo, CA, [2]State University of New York-Buffalo, Buffalo, NY, [3]University at Buffalo, Buffalo, NY, Contact: pagarw05@calpoly.edu

Online social media allow for the delivery of important information at extreme speeds. Unfortunately, due to the unmoderated nature of social media, rumors and fake news have plagued the networks of platforms such as Twitter. Rumors and fake news are spread across social media when information integrity is crucial to the safety of the public, such as during crisis events. During these events, timely and credible information is of the utmost importance to those affected by the disasters, and those following the disaster-related news. In this study, we model the strategic behaviors of the official agencies and social media users during rumor transmission using two novel game-theoretic models. The objective of this study is to analyze the impact of rumor clarification and verification strategies of the agencies on the decisions of social media users during rumor propagation.

Artificial Intelligence for Transportation Cyber-Physical Systems Analytics

General Session

Session Chair

Mohamadhossein Noruzoliaee, University of Texas Rio Grande Valley, Edinburg, TX

1 System Optimal Vehicle Platooning Control for Eco-Driving at Signalized Intersection Built upon Hybrid MPC System, Online Learning and Distributed Optimization

Hanyu Zhang, Lili Du, University of Florida, Gainesville, FL, Contact: hanyu.zhang@chem.ufl.edu

This study develops a system optimal platoon-centered control for eco-driving (PCC-eDriving) at signalized intersections, which aims to guide a mixed flow platoon to smoothly approach, split as needed, and then sequentially pass intersections, while reducing sharp deceleration and red idling. The PCC-eDriving is enabled by a hybrid model predictive control (MPC) system, including three MPC for platoon trajectory control and a mixed-integer nonlinear program for optimal platoon splitting decision. The feasibility and stability of the hybrid MPC system are mathematically proved to ensure the system performance. Besides, we design an online adaptive curve learning algorithm to learn vehicle driving uncertainties. The numerical experiments validate the merits of the PCC-eDriving in improving traffic efficiency and reducing energy consumption.

2 Detection and Mitigation of Cyber Threats in Smart Traffic Signal Control System

Yiheng Feng, Purdue University

Connected vehicle (CV) technology brings both opportunities and challenges to the traffic signal control system. The vulnerabilities in communications between vehicles and infrastructure may increase the risks of cyber threats. In this talk, I will introduce our recent work that integrates machine learning models with transportation engineering domain knowledge to analyze the cybersecurity of the smart traffic signal control system in the V2X environment, including threat modeling, mitigation solutions, and test and evaluation.

3 Learning-based Optimization of Large-scale Combinatorial Problems in Transportation

Zhongxia Yan, Massachusetts Institute of Technology, Cambridge, MA, Contact: zxyan@mit.edu

Combinatorial problems abound in transportation and cyberphysical systems. Despite recent efforts by machine learning (ML)-based methods to solve problems such as the traveling salesman problem (TSP), vehicle routing problem (VRP), and others, scalability and solution quality remains a key issue for ML-based methods. In this talk, we discuss a general learning-augmented framework for solving large-scale VRPs. The method iteratively improves the solution by identifying appropriate subproblems and obtaining improvements by calling a black box subsolver. Our method accelerates state-of-the-art VRP solvers by 10x to 100x on VRPs of sizes 500 to 3000 while generalizing to a variety of distributions, variants, and solvers. We additionally discuss recent results in lifelong multi-agent path finding (MAPF), another combinatorial problem in cyberphysical systems.

Interpretable Models in Healthcare

General Session

Session Chair

Elisa Frances Long, UCLA Anderson School of Management, Los Angeles, CA

Session Chair
Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA

1 Estimating Treatment Effects from Observational Data Using a Hidden Markov Model

Tongqing (Angelina) Chen[1], John R. Birge[2], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL, Contact: john.birge@chicagobooth.edu

Estimating treatment effects from observational data is complicated by unobserved confounders and other selection issues. Hidden Markov models can be applied to represent these unobserved conditions. This talk will describe an approach to solve the resulting maximum likelihood estimation problem and conditions for identifiability of the underlying effects.

2 Interpretable Machine Learning: Application to Triage and Reassessment Guidelines for Ventilator Rationing

Julien Grand-Clément[1], Carri Chan[2], Vineet Goyal[3], Elizabeth H. Chuang[4], [1]ISOM Department, HEC Paris, Paris, France; [2]Columbia Business School, New York, NY, [3]Columbia University, New York, NY, [4]Albert Einstein College of Medicine, New York, NY, Contact: grand-clement@hec.fr

Algorithms for sequential decision-making in healthcare often suffer from a lack of interpretability. Decision trees have gained interest in recent years, due to their performances and their interpretability. We present a model to compute interpretable sequential policies that have a tree structure, called tree policies. We apply our model to learn triage and reassessment guidelines for ventilator allocations to patients affected by Sars-Cov-2. We find that official New York state guidelines, based on risk scores, may not outperform First-Come-First-Served guidelines, because they are not adjusted to the specifics of Sars-Cov-2. Our simple tree policies improve upon First-Come-First-Served guidelines and New York State guidelines by reducing the number of excess deaths associated with various hypothetical levels of ventilator shortage.

3 Improving Prediction of Opioid-involved Overdosed Deaths with Multivariate Spatiao-temporal Hawkes Process

Che-Yi Liao[1], Gian-Gabriel P. Garcia[2], Kamran Paynabar[3], Mohammad Jalali[4], [1]Georgia Tech, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]ISyE Georgia Tech, Atlanta, GA, [4]Harvard University, Boston, MA, Contact: cliao48@gatech.edu

Public health surveillance efforts, critical to planning for policy interventions, can be enhanced by decision support tools that identify emerging trends from data. One of the most severe public health crises in US history, surveillance of the opioid crisis has been complicated by ever-changing drug overdose trends across many geographic regions and population groups. In this work, we propose an interpretable Multivariate Spatio-Temporal Hawkes Process with a dynamic network structure (D-MSTHP). D-MSTHP can model these complex interactions by quantifying the influence of each overdose on future overdoses across space, time, and substance. Using overdose death data from Massachusetts, we show that D-MSTHP outperforms popular predictive models applied in this field, with the additional interpretable structure to facilitate inference of emerging trends.

4 Waiting Time Prediction with Invisible Customers

Yoav Kerner[1], Ricky Roet-Green[2], Arik Senderovich[3], Yaron Shaposhnik[2], Yuting Yuan[2], [1]Ben Gurion University of the Negev, Beer Sheva, Israel; [2]University of Rochester, Rochester, NY, [3]University of Toronto, Toronto, ON, Canada.

We study the problem of predicting in real time customers' expected waiting time in partially visible service systems. We apply a theoretical analysis to a novel queueing model that highlights the technical challenge in obtaining an analytical solution. Subsequently, we use the solution as an element of a data-driven machine learning approach to solve the problem in general. We conduct extensive numerical experiments using the simulated data inspired by the literature and real data from a large outpatient hospital.

1 In-group Bias in Treatment: Does RAS Play a Role?

Jianing Ding, Susan F. Lu, Karthik Kannan, Purdue University, West Lafayette, IN, Contact: ding246@purdue.edu

More than surging clinical performance, robotic-assisted surgery (RAS) tends to increase objectivity in treatment process. In this work, we examine RAS's effect on ameliorating treatment bias induced by patient-physician concordance, which is identified as one of priorities to alleviate surgical disparities. We first examine the effect of RAS on clinical outcomes, controlling physician's self-selection behavior in choosing treatment methods. Then we investigate the patient-physician concordance bias in clinical outcomes and reveal the synergy of RAS implementation on alleviating such bias. Ultimately, we focus on the access to RAS and explore how physician and patient heterogeneity affect the adoption of RAS. As our study suggests RAS reduces treatment bias in clinical performance, future healthcare management might leverage RAS on alleviating treament bias.

2 Primary Care, Health Screenings, and Disease Management Outcomes: An Empirical Investigation

Yingchao Lan[1], Aravind Chandrasekaran[2], Jane Iversen[3], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]The Ohio State University, Columbus, OH, [3]The Ohio State University, columbus, OH, Contact: yingchao.lan@unl.edu

Overuse of resource-intensive services such as unplanned hospitalization and emergency room (ER) visits and underuse of primary care and health screenings contributes to soaring healthcare expenditures in the United States. Despite calls for more investments in primary care, there is lack of empirical evidence on how levels of access to primary care and preventive health screenings can affect patient's use of resource-intensive healthcare services. Leverating a unique diabetic patient claim dataset across United States and implementation of accountable care organizations initiative, we created a quasi-experiment with a difference-in-difference identification strategy to study the impact of primary care access through ACOs. We find that improved access to primary care is associated with more diabetes screening and better disease management performance.

3 Continuity of Care Increases Physician Productivity in Primary Care

Harshita Kajaria-Montag[1], Michael Freeman[2], Stefan Scholtes[1], [1]University of Cambridge, Cambridge, United Kingdom; [2]INSEAD, Singapore, Singapore. Contact: hk437@cam.ac.uk

To date, much research effort has been spent on establishing the impact of continuity of care (COC) in the primary care setting on patient outcomes and secondary care utilization. However, no work has looked at how reductions in COC can also have a detrimental effect on the productivity of primary care service provision itself. In this paper, we show causally that patients who are seen by their regular primary care provider (i.e., who receive COC), return for a subsequent primary care visit on average 15% later than a patient who does not. This effect increases for older patients and patients with comorbidities. A counterfactual analysis suggests that an increase in COC to the top decile would have led to a 5.2% reduction in consultations.

4 The Effect of Episode-based Payments on Cost and Quality: An Empirical Investigation

Austin McCandlish[1], Turgay Ayer[2], Bilal Gokpinar[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, [3]UCL School of Management, London, United Kingdom.

Unlike fee-for-service (FFS) payments which reward volume, episode-based payments (EBPs) are designed to encourage efficient use of resources by issuing a single payment for an entire episode of care. There is, however, limited empirical research on whether and to what extent EBPs lower costs or improve quality of care, particularly in the private insurance market where FFS dominates. We examine a statewide all-payer EBP program implemented in Arkansas using a large claims database of privately insured patients. We evaluate the effect of the EBPs on episode-level costs across different clinical episodes with a difference-in-difference approach. We also explore operational implications of EBPs in terms of cost-savings and quality improvements.

Data-driven Research in Health Care

General Session

Session Chair

Paola Martin, University of Texas at Austin, Austin, TX

Session Chair

Jingyao Huang, the University of Texas at Austin, Autsin, TX

1 **Combining Pre-approval Clinical Trials and Post-approval Spontaneous Adverse Event Reporting for Improved Safety Signaling**
John M. Silberholz[1], Fernanda Bravo[2], Yunliang Chen[3], [1]University of Michigan Ross School of Business, Ann Arbor, MI, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]UC Berkeley, Berkeley, CA
A classical question in pharmacovigilance is how to combine pre-approval RCTs and post-approval surveillance data to increase the power for side effect detection. A key step is to learn the degree to which the observational data is biased before one can combine it with unbiased clinical trial data. In this work, we propose a model that uses information about common toxicities to help de-bias the observational data on rare toxicities through the correlation of bias among different toxicities (e.g., correlation due to co-reported drugs, indications, and patient health). Using Bayesian statistics, we analyze the benefit of "cross"-debiasing and identify the situation where such benefit is largest. Numerical experiments using real data from the FDA Adverse Event Reporting System (FAERS) suggest significant values of using cross-debiasing to improve drug safety signaling.

2 **Impact of the Kidney Transplant Risk Index on Kidney Accept/Decline Decisions**
Paola Martin[1], Diwakar Gupta[2], Jingyao Huang[3], [1]University of Texas at Austin, Austin, TX, [2]University of Texas, Austin, TX, [3]the University of Texas at Austin, Autsin, TX, Contact: jingyao.huang@mccombs.utexas.edu
The Kidney Donor Risk Index (KDRI) plays a key role in determining transplant surgeons' accept/decline (A/D) decisions for deceased-donor kidneys. However, the KDRI only includes donor characteristics but does not consider candidates' features. In this talk, we propose a new measure of transplant risk, coined the Kidney Transplant Risk Index (KTRI), which considers both donors' and recipients' characteristics. Using historical national transplant data, we develop a highly-accurate A/D model and quantify the impact of using KTRI, instead of KDRI, on the number of kidneys that will be accepted by transplant surgeons and candidates. Moreover, we evaluate the potential societal benefits of using KTRI instead of KDRI.

3 **A Comparison Between Process-flow Simulators and Black-box Prediction Models in Health Care**
Yao Li[1], Simrita Singh[2], Jan A. Van Mieghem[3], [1]Kellogg School of Management, EVANSTON, IL, [2]Kellogg School of Management at Northwestern University, San Jose, CA, [3]Northwestern University, Evanston, IL, Contact: yao.li@kellogg.northwestern.edu
In health care systems, length of stay (LOS) is an important operation measure. Two methods are commonly used to predict LOS: a detailed process-flow simulator and a black-box prediction model. The authors compare the two types of predictors and investigate the value added from knowledge of process flows and time distributions. The authors also investigate how to mine process knowledge from current EHR data.

4 **A Supply Chain Look at Opioid Crisis**
Iman Attari, Jorge Mejia, Jonathan Eugene Helm, Indiana University, Bloomington, IN, Contact: iattari@iu.edu
Over the past two decades, the opioid crisis has escalated into a national public health emergency by claiming the lives of more than 400,000 people, exceeding those attributed to guns or car accidents during the same period. While much of the current research has addressed the opioid epidemic from the perspective of prescription monitoring and end-point distributions, little is known about how structural characteristics in the broader pharmaceutical industry environment, in terms of supply chain structure and market contribute to or mitigate the prevalence of opioid addiction. This study examines supply chain levels above the providers to determine deeper, supply chain-based connections with opioid abuse.

Advances in Empirical Healthcare Operations

General Session

Session Chair

Song-Hee Kim, Seoul National University, Gwanak-gu, Korea, Republic of.

Session Chair

Wilson Lin, University of Southern California, Arcadia, CA

1 Impact of Telehealth on Appointment Adherence in Ambulatory Care

Masoud Kamalahmadi, Christos Zacharias, Howard Gitlow, University of Miami, Coral Gables, FL, Contact: mkamalahmadi@miami.edu

Telehealth services grew massively popular amid the COVID-19 pandemic, but their operational implications for healthcare organizations are not well-understood. We study the effect of telehealth on patients' adherence to medical appointments in ambulatory care. Using data from a large medical system, we find that telehealth improves appointment adherence. We discuss the mechanisms of the effect and its implications for managers and policy makers.

2 The Impact of Online Self-scheduling on Patient Access to Hospital Services

Lesley Meng[1], Hummy Song[2], Christian Terwiesch[2], [1]Yale School of Management, Yale University, New Haven, CT, [2]University of Pennsylvania, Philadelphia, PA, Contact: lesley.meng@yale.edu

Recent innovation in healthcare access has led to the launch of online patient platforms where patients are now able to digitally schedule and manage their own medical appointments within a health system. In many large academic medical centers, digital scheduling has become the default method for patients to request and schedule appointments, and many medical appointments are now made this way. In this study, we examine the impact of online self-scheduling access on patient scheduling and visit behavior at a large academic medical center.

3 The Role of Physician Integration in Alternative Payment Models: The Case of the Comprehensive Joint Replacement Program

Christopher J. Chen[1], Kraig Delana[2], [1]Indiana University Kelley School of Business, Bloomington, IN, [2]University of Oregon, Eugene, OR, Contact: kdelana@uoregon.edu

In this paper, we empirically examine the role of both horizontal and vertical integration of orthopaedic surgeons in driving heterogeneity in the impact of the Comprehensive Joint Replacement (CJR) alternative payment program. Using a quasi-experimental difference-in-differences approach, we find hospitals with high horizontal and vertical integration see an increase in both hospital costs and complication rates of 3.17% and 1.18, respectively, while others see either a decrease or no-change in these measures. Moreover, we present evidence that these changes in performance measures are driven by changes in physician care decisions regarding length-of-stay and discharge disposition. Our findings provide novel insights into hospital-physician relationships, which are relevant for policymakers, payors, and healthcare providers.

4 Does Telehealth Reduce Rural-urban Care-access Disparities? Evidence from Covid-19 Telehealth Expansion

Shujing Sun, Guihua Wang, The University of Texas at Dallas, Richardson, TX

Using a unique set of national healthcare claims data, we investigate the effect of telehealth expansion policy on rural-urban healthcare-access disparities. Leveraging a difference-in-differences design, we compare the total number of visits to urban and rural providers before and after telehealth expansion. We find an enlarged disparity in rural-urban healthcare access, with the rural-urban gap in total patient visits increasing by 3.9% due to telehealth expansion. We then examine the underlying mechanisms that drive the enlarged disparity. Our findings are important to policy makers, healthcare providers, and researchers seeking to understand the broad implications of telehealth expansion on rural-urban disparities and further promoting and integrating remote care delivery into the healthcare system.

Sunday, 8AM–9:15AM

CC - Room 125

Delegated Sequential Search

General Session

Session Chair

Shouqiang Wang, 1</sup

1 To Whom the Offer Prioritizes? A Joint Optimization of Offer Sequence and Offer Deadline

Wenjie Tang[1], Zhenyu Hu[2], [1]University of Vienna, Vienna, Austria; [2]National University of Singapore, Singapore, Singapore. Contact: wenjie.tang@univie.ac.at

We consider a setting where a proposer makes an offer to a sequence of responders, each of whom concurrently searches for alternative offers and has to respond to the proposer's offer by the respective deadline. Taking into account responders' reactions, the proposer needs to maximize her value-to-go through the choice of sequence of responders and corresponding deadlines. We provide a full characterization of the optimal deadlines. Moreover, we solve for the optimal sequence in two special cases. Finally, we investigate the efficiency of a greedy policy that always prioritizes the highest-utility responder, and provide a lower bound for the proposer's expected payoff when the size of alternative offers is deterministic.

2 The when and How of Delegated Search

Sasa Zorc[1], Ilia Tsetlin[2], Sameer Hasija[3], Stephen E. Chick[4], [1]University of Virginia, Darden School of Business, Charlottesville, VA, [2]INSEAD, Singapore, Singapore; [3]Insead, Singapore, Singapore; [4]INSEAD, Fontainebleau, France. Contact: zorcs@darden.virginia.edu

Firms often outsource search processes such as the acquisition of real estate, technologies, or talent, which then involves designing contracts to attenuate the ill effects of agency. We model this problem via the dynamic principal-agent framework, embedding the standard sequential search model. The optimal contract pays a fixed per-period fee, plus a bonus for finding a suitable alternative. The bonus size is defined a priori and decreases over time, while the range of values deemed suitable expands over time. We also consider the choice between searching in-house and outsourcing. This decision is shown to hinge on the speed-quality tradeoff. The age-old aphorism "if you want it done right, do it yourself" holds, as in-house search is optimal if quality is prioritized. Yet, in the context of our model, we establish an addendum: "if you want it done fast, hire someone else."

3 Information Design of a Delegated Search

Zhenyu Hu[1], Shouqiang Wang[2], Yangge Xiao[1], [1]National University of Singapore, Singapore, Singapore; [2]The University of Texas at Dallas, Richardson, TX

We study a delegated sequential search problem, where an agent is in charge of the search but only a principal can observe and evaluate each search result. Once the search ends, the principal and agent split the payoff. The principal designs an information policy to strategically provide some information about the search results over time. We show that the optimal policy makes a binary recommendation in each period, which the agent will voluntarily follow. Specifically, the principal specifies a threshold in each period, decreasing over time, such that the agent is recommended to continue the search if and only if the payoff from the search is below that threshold. These thresholds are higher than those that would be used if the agent has full access to the search results, suggesting that the principal can induce a higher search intensity by leveraging her informational advantage.

4 Optimal Presentation of Alternatives

Zeya Wang, Morvarid Rahmani, Karthik Ramachandran, Georgia Institute of Technology, Atlanta, GA, Contact: zeya.wang@scheller.gatech.edu

In many contexts such as technology and management consulting, clients seek the expertise of providers to find solutions for their problems. When there are multiple alternatives that could potentially solve the client's problem, providers can lead the client's exploration by choosing which alternative(s) to present and in what sequence. In this paper, we develop a dynamic game-theoretic model where the provider chooses how to present alternative solutions, and the client chooses which solution to try. Our analysis reveals that it is generally optimal for the provider to offer alternatives sequentially. Following a failed trial, the provider should readily offer a new alternative if the client's capability is either very high or very low. Otherwise, the provider should allow the client to try the same solution multiple times, especially when the project duration is long.

Qualitative Value of Information: Theory and Applications
General Session

Session Chair
Michael C. Runge, USGS Eastern Ecological Science Center, Laurel, MD

1 Developing a Qualitative Measure of the Value of Information
Michael C. Runge[1], Clark S. Rushing[2], James E. Lyons[1], Madeleine A. Rubenstein[3], [1]USGS Eastern Ecological Science Center, Laurel, MD, [2]University of Georgia, Athens, GA, [3]USGS National Climate Adaptation Science Center, Reston, VA, Contact: mrunge@usgs.gov
The value of information is a central concept in decision analysis, used to quantify how much the expected outcome of a decision would be improved if epistemic uncertainty could be resolved prior to committing to a course of action. Quantitative analysis of the value of information demands predictions as a function of actions and sources of uncertainty, but what if such predictive tools are not available? In this presentation, we propose a novel qualitative measure of the value of information (QVOI), grounded in the algebra of the expected value of perfect information (EVPI), but requiring less of experts and analysts. The QVOI calculation decomposes EVPI into a contribution representing the relevance of the uncertainty to the decision and a contribution representing the magnitude of uncertainty; qualitative constructed scales are then proposed for each contribution.

2 Prioritizing Research Needs for Migratory Bird Management Under Climate Change Using Qualitative Value of Information
Clark Rushing[1], Madeleine Rubenstein[2], James Lyons[3], Michael C. Runge[3], [1]University of Georgia, Athens, GA, [2]USGS National Climate Adaptation Science Center, Reston, VA, [3]USGS Eastern Ecological Science Center, Laurel, MD, Contact: clark.rushing@uga.edu
We demonstrate how qualitative value of information (QVoI) can be used to prioritize research in decision contexts characterized by high degrees of complexity and uncertainty. We used QVoI to evaluate 11 hypotheses about the effects of climate change on migratory birds and prioritize research needs to improve land acquisition decisions to protect these species. Reducing uncertainty about how climate change will influence the spatial distribution of priority species was identified as the highest priority for future research due to both the value of this information for improving decisions and the feasibility of reducing uncertainty. By providing a rigorous and transparent approach to prioritizing research, QVoI is a valuable tool for prioritizing research and improving management decisions in settings where quantitative value of information is not possible.

3 Qualitative Value of Information Provides a Transparent and Repeatable Method for Identifying Critical Uncertainty Regarding the use of Prescribed Fire
Michelle L. Stantial[1], Abby Lawson[2], Auriel Fournier[3], Peter Kappes[4], Chelsea Kross[3], Michael C. Runge[1], Mark Woodrey[4], James Lyons[1], [1]USGS Eastern Ecological Science Center, Laurel, MD, [2]USGS New Mexico Cooperative Fish and Wildlife Research Unit, Department of Fish, Wildlife and Conservation Ecology, New Mexico State University, Las Cruces, NM, [3]Forbes Biological Station–Bellrose Waterfowl Research Center, Illinois Natural History Survey, Prairie Research Institute, University of Illinois at Urbana-Champaign, Havana, IL, [4]Coastal Research and Extension Center, Mississippi State University, Biloxi, MS, Contact: mstantial@usgs.gov
Conservation decisions are often made under uncertainty, and adaptive management can balance achieving conservation objectives with reducing epistemic uncertainty. However, quantitative evaluation of uncertainty may require more resources than are available in the early stages of conservation planning. We demonstrate a qualitative value of information (QVoI) analysis requiring few resources to efficiently prioritize uncertainty for adaptive management. We developed conceptual models to identify sources of uncertainty and articulate hypotheses about prescribed fire to benefit marshbirds in the Gulf of Mexico. We used QVoI to prioritize the sources of uncertainty based on their magnitude, relevance for decision making, and reducibility. We found that uncertainties related to fire return intervals and burn season were the highest priorities for managers.

4 Value Added Conservation: Prioritizing Critical Uncertainties for Rosy-finch Conservation in a Warming World
Abby Lawson[1], Janice Gardner[2], Michelle Stantial[3], Clark Rushing[4], [1]US Geological Survey New Mexico Cooperative Fish and Wildlife Research Unit, Las Cruces, NM, [2]Sageland Collaborative, Salt Lake City, UT, [3]US Geological Survey Eastern Ecological Science Center, Laurel, MD, [4]University of Georgia, Athens, GA, Contact: ajlawson@nmsu.edu
While nearly all wildlife management decisions involve some degree of uncertainty, those involving data-deficient species pose unique challenges. For imperiled species in particular, data deficiency can prevent managers from knowing

how to direct limited resources to provide the maximum conservation benefit. Rosy-finches are a group of three cold-adapted passerine species that breed in alpine ecosystems that are difficult to access and monitor, resulting in extreme data deficiency. Here we describe the use of qualitative value of information (QVoI) to identify research priorities to improve conservation planning for Rosy Finches. Results are being implemented by an interagency Rosy-Finch working group and will help streamline research and monitoring, avoid duplication, and reduce uncertainties related to conservation interventions.

AI for Cybersecurity

General Session

Session Chair

Soumyadeep Hore, Tampa, FL

Session Chair

Ankit Shah, University of South Florida, Tampa, FL

1 A Machine Learning and Optimization Approach to Optimal Alert Investigation

Jalal Ghadermazi, Ankit Shah, University of South Florida, Tampa, FL

A Cyber Security Operations Center (CSOC) is tasked with investigating alerts generated from the Intrusion Detection Systems (IDS) in a timely manner. CSOCs often fall short of alert handling expectations due to two main reasons. First, the rule-based triage mechanism of the IDS does not comprehensively consider the organization-specific factors such as asset and mission criticality. Second, the analyst expertise is not matched with the alert type for efficient investigation. In this talk, we address the above shortcomings with an intelligent approach to achieving optimal alert investigation that considers organization-specific factors and analysts' capabilities. Experimental results show that with our approach, which combines machine learning and optimization, alerts are investigated in a timelier manner when compared to the current practices at the CSOCs.

2 The Potential of AI in Cybersecurity

Soumyo D. Moitra, Pittsburgh, PA

This paper discusses potential applications of AI for enhancing cybersecurity. AI is a good fit to cybersecurity problems as AI is ideally suited to analyze big data, complex decision-making spaces, and situations where there is ambiguity. High level algorithms for some examples are presented including cost modeling of cybersecurity systems and the evaluation of the effectiveness of security systems. The perspective is that of decision support through expert systems.

3 Cyber-physical System Monitoring Using Explainable Artificial Intelligence

Iida Haghnegahdar, SUNY, Binghamton, NY

Manufacturing systems are increasingly faced with attacks not only by traditional malicious actors such as hackers and cyber-criminals but also by some competitors and nations engaged in corporate espionage. Artificial intelligence (AI) as one of the new approaches has emerged to overcome the increasing complexity and sophistication of cybersecurity attacks in manufacturing. These defensive and control-based AI method implements various machine learning algorithms for different types of controls, such as intrusion detection and malware detection. However, the growing adoption of advanced deep learning algorithms is turning these AI-based controls into black box systems. In this study, the authors propose an action for the explainability of the AI-based cybersecurity controls in research and practice for Additive manufacturing.

4 A Reinforcement Learning Approach to Maintaining the Level of Operational Effectiveness of a Cyber Security Operations Center Under Adverse Conditions

Ankit Shah[1], Rajesh Ganesan[2], [1]University of South Florida, Tampa, FL, [2]George Mason University, Fairfax, VA

The level of operational effectiveness (LOE) is a color-coded performance metric that is monitored by the Cyber Security Operations Center (CSOC). It is determined using the average time to analyze alerts in every hour of shift operation. Adverse events can cause low LOE as the alert arrival rate exceeds the investigation rate. Upon exhausting all the analyst resources, the only option available to a CSOC manager is to discard alerts for restoring the LOE of the CSOC. This talk presents an intelligent strategy, powered by reinforcement learning (RL), to maintain the LOE under adverse conditions. The RL-based strategy, which is developed using a dynamic optimization model, has the following desiderata: (i) maximize utilization of analysts and (ii) minimize the number of alerts to discard. Our experiment results show that the RL strategy outperforms the other strategies.

Sunday, 8AM–9:15AM

CC - Room 128

Global and Planetary Health

Joint Session

Session Chair

Rebecca Alcock, Madison, WI

Session Chair

Justin J. Boutilier, University of Wisconsin - Madison, Fitchburg, WI

1 Cost-effectiveness of Seroprevalence Based Covid-19 Vaccination Strategies in India

Sripad K. Devalkar[1], Sarang Deo[1], Abhishek Reddy[1], Nimalan Arinaminpathy[2], Sandip Mandal[3], Hiral Shah[4], [1]Indian School of Business, Hyderabad, India; [2]Imperial College London, London, United Kingdom; [3]Independent Consultant with ICMR, New Delhi, India; [4]Imperial College London, London, United Kingdom.

Given the considerable heterogeneity and uncertainty in the transmission of COVID-19 in urban and rural areas of India, identifying and prioritising vaccination strategies based on cost-effectiveness evidence can aid in understanding how to allocate limited supply and resources. In this work, we determine the cost-effectiveness of seroprevalence-based vaccination strategies by combining epidemiological and supply chain modeling. We develop a supply chain model based on the resources available to support COVID-19 vaccination and determine the appropriate allocation of these resources to support different seroprevalence-based vaccination strategies to estimate the cost of vaccine administration. We use an epidemiological model of transmission dynamics to determine health outcomes for the vaccination strategies and estimate their cost-effectiveness.

2 Health Clinic Electrification in LMICs via a Novel Renewable Energy Network

Rebecca Alcock[1], Justin J. Boutilier[2], [1]University of Wisconsin–Madison, Madison, WI, [2]University of Wisconsin - Madison, Fitchburg, WI, Contact: ralcock@wisc.edu

More than one billion people worldwide receive healthcare in a facility without electricity. Energy inequities in healthcare have many consequences, including increased mortality and higher incidence of disease. To address this, we are investigating a vehicle-to-grid system that will equip resource-limited health clinics with the electricity needed to keep them running, while enabling mobile health services via access to electric bicycles. This talk will focus on the pilot project at a community garden in Madison, WI, and the current state of the mathematical frameworks used for sizing the system.

3 Designing a Personalized Community-based Approach to Diabetes Care

Katherine B. Adams[1], Justin J. Boutilier[2], Yonatan Mintz[3], Sarang Deo[4], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin - Madison, Fitchburg, WI, [3]University of Wisconsin Madison, Madison, WI, [4]Indian School of Business, Hyderabad, India. Contact: kbadams@wisc.edu

Diabetes is a global health priority, especially in lower-middle-income countries, where over 50% of premature deaths are attributed to high blood glucose. Several studies have demonstrated the feasibility of using Community Health Worker (CHW) programs to provide affordable and culturally tailored solutions for early detection and management of diabetes. We propose an optimization framework to personalize CHW visits to maximize glycemic control at a community-level. We present structural and computation results using real data from India.

4 Ensemble Machine Learning Methods to Improve Burden Estimates for Wasting

Mayukh Ghosh[1], Zohreh Raziei[2], Chintan Amrit[1], Ozlem Ergun[2], Srinivasan Radhakrishnan[3], [1]University of Amsterdam, Amsterdam, Netherlands; [2]Northeastern University, Boston, MA, [3]Northeastern University, Amsterdam, Netherlands.

Wasting, an acute form of malnutrition, increases a child's risk of infection and death and reduces their ability to learn and be productive. Reliable estimates of annual severe acute malnutrition (SAM) are required for policy decisions and planning. In the absence of incidence data, the SAM burden is estimated as a function of only prevalent cases and the incidence correction factor for which a single factor (1.6) is recommended globally. However, obtaining a reliable estimate is challenging as the incidence varies among sites thereby often leading to underestimation of the SAM burden. In this study, in collaboration with UN WFP, we propose novel multivariate ensemble classification models to predict and validate the burden of SAM in the Sahel region of Africa. We then present a comparative evaluation of the performance of our chosen algorithms.

Epidemic Modeling, Prediction, and Control

Tutorial Session

Session Chair

Pradeep Kumar Pendem, University of Oregon, Eugene, OR

1 **Epidemic Modeling, Prediction and Control**

Ujjal Kumar Mukherjee[1], Sridhar Seshadri[2], [1]University of Illinois, Urbana-Champaign, Champaign, IL, [2]University of Illinois, Champaign, IL

The COVID-19 pandemic has disrupted almost every facet of life globally and has posed new challenges to policymakers and questions to researchers. In this article, we discuss some of the key considerations and challenges in modeling epidemics, predicting their diffusion within and across populations and evaluating their control policies. Epidemic prediction is challenging due to the uncertain nature of its spatial and temporal diffusion, co-evolution of latent confounding factors, sparsity of signals particularly during the initial stages of a pandemic and the complex interactions of the individual- and group-level behaviors with mitigating policy interventions. We explain, illustrate and comment on the strengths and weaknesses of the commonly used epidemic models. We classify the existing models on methodologies used such as compartmental models versus agent-based models, nature of model uncertainties considered such as deterministic versus stochastic models and factors included in the models such as network effects, disease characteristics and control actions. We highlight some of the common behavioral traits exhibited by individuals and discuss the theoretical sources of such behavior. Based on our work, we illustrate the formulation of a specific compartmental model that accounts for asymptomatic spread of COVID-19 and the effect of control actions such as testing and lockdowns. We also demonstrate the nature of optimal actions based on analytical and agent-based simulation methodology. Finally, we conclude by discussing lessons learned from the COVID-19 pandemic to better manage any future pandemic.

Airline Network Design on STEAM and OR Education Contents

Joint Session

Session Chair

Shio Kawagoe, 1</sup

Session Chair

Yudai Honma, The University of Tokyo, Meguro-Ku, Japan.

1 **Workshop Design for STEAM Education by Cooperating with Industry**

Shio Kawagoe, The University of Tokyo, Tokyo, Japan.

In response to the drastically changing society, the practice of STEAM (Science, Technology, Engineering, Arts, and Mathematics) education is being promoted internationally. The Office for the Next Generation (ONG) has organized various STEAM education programs based on engineering research. In this study, we designed workshops by cooperating with the airline for junior and senior high school students to learn the relationship between science and technology and society. The questionnaire survey results indicate that the workshops efficiently make the students understand "each STEAM subject" and "the social roles and the significance of science and technology."

2 **Development of an Evaluation Method for STEAM Education-based Learning in High School**

Mizuki Yamada, The University of Tokyo, Japan.

According to the recent curriculum guideline, the importance of cross-curricular learning has been addressed in Japan. With establishment of project-based learning activities in high schools, there is a need to develop lesson designs for project-based learning with STEM (Science, Technology, Engineering, and Mathematics) approaches and their evaluation methods to enhance STEAM Education.

The present study aims to develop a lesson design and evaluation method for project-based learning with STEAM approaches that is introduced into schools through the project UTokyoGSC conducted by the University of Tokyo. UTokyoGSC has been developing education programs, which utilizes a science and technology human resource development program for high school students initiated by Office for the Next Generation at the University of Tokyo.

3 **Development of Excel Materials for or Education Through Airline Network Design**

Yudai Honma[1], Saori Nakai[2], Hiroko Watanabe[2], [1]The University of Tokyo, Meguro-Ku, Japan; [2]The University of Tokyo, Tokyo, Japan. Contact: hiroko@iis.u-tokyo.ac.jp

Airline network design is considered a network optimization while considering various conflicting objectives, so it is an excellent educational theme for OR. In this study, we have developed an Excel education material that delivers the essence of this topic to junior and senior high school students.

4 Importance of STEAm and or Educations for Airline Companies

Taito Sato, Saki Inohata, Yuta Watari, Hiroshi Iseki, Hiroshi Ohata, Hideki Ochiai, Japan Airlines Co., Ltd., Tokyo, Japan.

Sustainability is an important issue shared by society as a whole. It is no different for airline companies that connect cities around the world. We are continuously examining how to balance economic activities and environmental protection, and how to deliver appropriate messages to society. With this background, Japan Airlines actively promotes educational activities for junior and senior high school students, who are the future leaders of the next generation. In particular, we have focused on STEAM and OR educations to acquire a broad perspective and have developed both educational materials and workshop events on the theme of "aviation" in cooperation with the University of Tokyo. This presentation will introduce the content and motivation of such efforts.

Digital Platforms

General Session

Session Chair

Christopher S. Tang, University of California-Los Angeles

Session Chair

Yiting Deng, University College London, London, United Kingdom.

1 The Effects of Driver Supply on Demand in the Ride-sharing Market: A Field Experiment

Zack Wang[1], Qiyuan Wang[2], Song Yao[3], Tat Y. Chan[1], [1]Washington University, St. Louis, MO, [2]The Hong Kong Polytechnic University, Hong Kong, China; [3]Washington University in St. Louis, St. Louis, MO, Contact: chongbo.wang@wustl.edu

We study the effects of driver supply on demand in the ride-sharing market by running a natural field experiment for a platform. We manipulate drivers' subsidies to influence the supply, and use subsidies as an instrument to identify the impacts on demand. We find that increasing the number of drivers at work by 1% will increase the number of customer orders by 2.0% and, conditional on the orders, reduce the cancellation rate by 0.5%. These results also imply a long-term impact on customers' repeating orders and churns. We find that, for a 1% increase in the number of drivers working in afternoon or night, the aggregate customer lifetime value of the platform will increase by 1.6% or 0.5%, respectively. The findings suggest that, to improve the revenue, the platform can focus on hiring drivers or incentivizing current drivers work for longer hours.

2 Planogram Design in the Presence of Store Brands and Shelf Display Fees

Yasin Alan[1], Mumin Kurtulus[2], Alper Nakkas[3], [1]Vanderbilt University - Owen Graduate School of Management, Nashville, TN, [2]Vanderbilt University, Nashville, TN, [3]University of Texas at Arlington, Arlington, TX, Contact: yasin.alan@vanderbilt.edu

We examine how store brands (SBs) and display fees, which manufacturers pay retailers for prime shelf space, affect retailers' planogram decisions (i.e., placement of products on shelves). We consider a game-theoretic model with one retailer and two national brand (NB) manufacturers. The NB manufacturers determine their wholesale prices and how much they are willing to pay for the prime shelf space, while the retailer makes assortment and planogram decisions and sets retail prices. Our study generates three insights. First, the common practice of giving the prime shelf space to a high sales volume product can be suboptimal for the retailer. Second, the retailer can carry the SB in its assortment to increase its display revenue. Third, display fees can increase the NB manufacturers' profits.

3 Informal Payments and Doctor Engagement in Online Health Community: An Empirical Investigation Using Generalized Synthetic Control

Qili Wang[1], Liangfei Qiu[1], Wei Xu[2], [1]University of Florida, Gainesville, FL, [2]Renmin University of China, Beijing, China. Contact: qili.wang@warrington.ufl.edu

Online health communities are growing rapidly as more individuals seek health information online. Given the importance of doctor engagement, some online health communities have introduced informal payments to doctors to encourage knowledge sharing. We leverage the launch of a gifting feature by a leading online health community as a natural experiment that exogenously provides doctors with extra monetary incentives. We find that the introduction of the gifting feature negatively affects doctors' responses to medical consultations. Our results indicate a crowding-out effect of informal payments on doctors' intrinsic motivation to engage in such consultations. Moreover, our consultation-level analysis suggests that monetary and nonmonetary gifts play distinct roles in motivating doctors' responses.

4 The Effect of Surge Pricing on Driver Behavior in the Ride-sharing Market: Evidence from a Quasi-experiment

Wei Miao[1], Yiting Deng[1], Wei Wang[2], Yongdong Liu[3], Christopher S. Tang[4], [1]University College London, London, United Kingdom; [2]University of International Business and Economics, Beijing, China; [3]UCL School of Management, University College London, London, United Kingdom; [4]University of California-Los Angeles, Los Angeles, CA, Contact: yiting.deng@ucl.ac.uk

Surge pricing has been used to coordinate supply and demand in the ride-sharing industry; however, its causal effects on driver behavior remain unclear. This motivates us to examine how surge pricing causally affects driver earnings and labor supply by leveraging a unique quasi-experiment, in which a leading ride-sharing company in China introduced surge pricing in two cities at different times. Using a difference-in-differences design with the causal forest method, we find that surge pricing increased a driver's weekly revenue. We then decompose the driver's weekly revenue into "intensive margin" and "extensive margin" factors, and identify two countervailing effects at play: a cherry-pickingeffect and a competition effect. Finally, we find considerable heterogeneity across drivers, and that the benefit of surge pricing was unevenly distributed across drivers.

Operations Management and Social Development

General Session

Session Chair

Andre Du Pin Calmon, Scheller College of Business, Georgia Institute of Technology, Atlanta, GA

Session Chair

Christopher Dalton Parker, American University, Washington

1 Improving Cash-constrained Smallholder Farmers' Revenue: The Role of Government Loans

Wen Hong (Kenneth) Pay[1], Somya Singhvi[2], Yanchong (Karen) Zheng[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]USC Marshall School of Business, Los Angeles, CA, Contact: yanchong@mit.edu

The need for immediate cash inhibits smallholder farmers from maximizing their revenue by forcing them to sell their produce at suboptimal times. This paper develops a model to examine how cash constraints influence farmers' selling decisions, as well as to analyze the efficacy of loan programs in improving revenue outcomes. The model results are validated with field data from agricultural markets in India.

2 The Operational Origins of Child Labor in Cocoa Production

Andre Du Pin Calmon[1], Andreas Gernert[2], Dan Andrei Iancu[3], Luk N. Van Wassenhove[4], [1]Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, [2]Kühne Logistics University, Hamburg, Germany; [3]Stanford University, Stanford, CA, [4]INSEAD, Fontainebleau Cedex, France. Contact: andre.calmon@gatech.edu

Child labor is a major issue in chocolate value chains. In Ghana and Ivory Coast, most farmers employ child labor in cocoa production. Our work examines, both empirically and analytically, how several aspects of cocoa farmers' operations, such as production decisions, farmer wealth, and access to loans, can exacerbate (or mitigate) child labor use. Our empirical approach leverages detailed surveys of cocoa farmers. We find, for example, that the availability of loans does not increase the use of child labor in very low-income farmers. Conversely, the availability of loans for higher-income (but still poor) farmers might increase the use of child labor. Based on our empirical findings, we build an analytical model that describes the various tradeoffs cocoa farmers face. We use this model to investigate the value of different interventions that aim to mitigate child labor.

3 Blockpower: Using Compensated Relational Voting to Increase Black Voter Turnout

Karthik Balasubramanian[1], Chris Parker[2], [1]Howard University School of Business, Washington, [2]American University, Washington, DC, Contact: chris.parker@american.edu

BlockPower is a non-profit that pays citizens of majority-Black neighborhoods up to $500 to train people they already know to increase voter turnout. We describe BlockPower and explain how we are testing for increases in voter turnout. We also describe other opportunities to collaborate on research.

4 The Impact of Streak-based Performance Evaluation in Crowdsourcing Contests for Skilled Microtasks

Olumurejiwa A. Fatunde[1], Joann de Zegher[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT Sloan, Cambridge, MA

Crowdsourcing is increasingly used to organize distributed work, including skilled tasks. This paper explores incentive design for distributed-task platforms by studying a platform which serves as an intermediary in the supply chain for medical knowledge. Using data on 5,418 crowdsourcing contests for medical diagnosis, we examine how evaluation metrics shape participants' decisions and performance. We assess the impact of evaluating participants using the longest "streak" of correct answers, rather than an accuracy-based metric. Streak evaluation increases volume of quality responses and speed of achieving consensus, largely through dramatically increased engagement. These findings are relevant in settings where rewards for performance streaks are used to boost motivation; we find that they also boost performance.

Ebru Korular Bish, University of Alabama, Tuscaloosa, AL

Session Chair

Sait Tunc, Virginia Tech, Blacksburg, VA

1 Correlation Improves Group Testing

Yujia Zhang[1], Jiayue Wan[2], Peter Frazier[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, [3]Cornell University, Ithaca, NY

Large-scale screening enabled by group testing is a powerful tool for controlling infectious diseases like COVID-19. While past analyses of group testing typically assume samples in a pool are independent, we observe that placing samples from a social group into the same pool correlates a pool's samples, so that a positive pool likely contains multiple positive samples. We show that, under the classic two-stage Dorfman procedure, correlated pooling increases sensitivity and also tends to require fewer tests per positive identified. Such improvement in sensitivity and efficiency in turn improves group testing's power in achieving epidemic control. Thus, correlation is an important consideration for policy-makers: it makes screening more attractive for epidemic control (as opposed to lockdown) and it suggests that sample collection should maximize correlation.

2 Presenter

Sait Tunc, Virginia Tech, Blacksburg, VA

3 Optimal COVID-19 Vaccination Facility Location

Jingyuan Hu, Elisa Frances Long, Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA, Contact: jingyuan.hu.phd@anderson.ucla.edu

Socioeconomic disparities in COVID-19 vaccination rates are partially attributable to poor vaccination site selection. We formulate a COVID-19 vaccination location problem as a large-scale mixed-integer program, selecting from >58,000 pharmacies and >30,000 dollar stores nationwide. The optimal solution allocates 37% of vaccinations to dollar stores, achieving a 62% reduction in travel distance, and reduces racial disparities as measured by a newly constructed Gini coefficient.

Supply Chain Financing and Operational Decisions

General Session

Session Chair

Karca D. Aral, Syracuse University, Syracuse, NY

1 Effects of Financial Constraint Relaxation on Supply Chain Financing Choices and Operational Decisions

Sridhar Seshadri, UNIVERSITY OF ILLINOIS URBANA-CHAMPAIGN, IL

Aggregate planning in supply chain management enables firms to make operational investments subject to financial constraints, to resolve the trade-off between capacity and inventory. Limited research empirically examines the how financial constraints affect these decisions. In this study, we bridge the gap and investigate how firms plan on their capacity and inventory when financial constraints are relaxed. To alleviate the endogeneity stemming from unobserved factors driving the relation and to identify a causal link, we leverage staggered state-wise implementations of interstate branching deregulation across U.S. as quasi-experiments. We find that banking deregulation improves firms' access to credit market and generates heterogenous effects on financing choices and operational decisions across firms.

2 Shareholder Scrutiny, Managerial Flexibility, and Inventory Management

Karca D. Aral, Syracuse University, Syracuse, NY

We study how shareholder scrutiny may affect key operations decisions pertaining to inventory. For identification, we exploit the quasi-natural experiment provided by the staggered adoption of constituency statutes which provided executives the flexibility to invest in building long-term operational capacity. Using a staggered difference-in-differences approach, we find that, after the reforms, firms incorporated in constituency states increased inventory by 5.2% relative to firms not incorporated in constituency states. We also find that the increase in inventory is gradual and persists over time, suggesting a strategic shift in long-term service levels. These changes are associated with a positive increase in firm value. A battery of validity and robustness tests strongly mitigates the concern that alternative channels could explain our findings.

Service Systems and Customer Behaviour

General Session

Session Chair

Tingliang Huang, Carroll School of Management, Boston College, Newton, MA

1 Order Ahead for Pickup: Promise or Peril?

Luyi Yang[1], Yunan Liu[2], Ke Sun[3], [1]University of California, Berkeley, Berkeley, CA, [2]North Carolina State University, Raleigh, NC, [3]Beijing University of Chemical Technology, Beijing, China.

Mobile technologies have increasingly enabled customers to order ahead at quick-service restaurants. As customers who order ahead travel to the service facility to pick up their order, their order also advances in the food-preparation queue. It is widely believed that the order-ahead scheme reduces customers' total wait time and therefore attracts more orders (i.e., yields higher throughput) than if customers must order onsite. We build queueing-game theoretic models to study the throughput implications of the order-ahead scheme.

2 The Impact of Consumer Complaint Relevance on Product Recalls: An Empirical Investigation of the Automobile Industry

Weihan Jia[1], Yufei Huang[1], Xingjie Wei[2], [1]Trinity Business School, Trinity College Dublin, Dublin, Ireland; [2]University of Leeds, Leeds, United Kingdom. Contact: yufei.huang@tcd.ie

This paper studies the impact of consumer complaint relevance on the timing of product recall decisions. Using a car recall data set from NHTSA (National Highway Traffic Safety Administration) in the USA, we first implement text mining methods to analyze consumer complaint relevance by measuring the similarity between the car defects and the content in consumer complaints. We then examine how consumer complaint relevance impacts the timing of recall decisions. We find that when the level of consumer complaint relevance is higher, a recall decision is made faster. Such a relationship becomes stronger when a defected component is used in different car models or when the car models are older.

3 Whether and when Grocery Stores Should Adopt Time-based Pricing: Competition and Negative Congestion Externality

Christopher S. Tang[1], Onesun Steve Yoo[2], Dongyuan Zhan[3], [1]University of California-Los Angeles, Los Angeles, CA, [2]UCL School Of Management, University College London, London, United Kingdom; [3]University College London, London, United Kingdom. Contact: d.zhan@ucl.ac.uk

Considering consumer's congestion aversion, we examine "whether and when" brick-and-mortar grocery stores should adopt intra-day time-based pricing. We develop a two-stage dynamic duopoly game in which each store can make sequential adoption timing and pricing decisions pricing. Our equilibrium analysis reveals that both stores should eventually adopt time-based pricing in equilibrium. Additionally, despite the fact that cautious adoption offers an "informational advantage" by postponing the adoption time, at most one store will adopt the cautious approach in equilibrium.

Interestingly, we find that adoption of time-based pricing can soften the intensity of the competition to raise prices and boost retailer profits. We examine the implications of the equilibrium transition to time-based pricing on demand smoothing, consumer welfare, and social welfare.

4 Service Networks with Open Routing and Procedurally Rational Customers

Tingliang Huang[1], Andrew E. Frazelle[2], Yehua Wei[3], [1]BC, Boston, MA, [2]The University of Texas at Dallas, Richardson, TX, [3]Duke University, CHAPEL HILL, NC

We investigate the implications of procedurally rational customers on service networks where customers visit multiple stations but can choose the order in which to visit the stations. Self-interested customers populate various service systems, and these customers may not be fully rational. Customers' form of reasoning and its consequences for system performance affect the planning decisions of service providers.

1 Assortment and Price Optimization Under MNL Model with Price Range Effect

Stefanus Jasin[1], Chengyi Lyu[2], Andrew Vakhutinsky[3], Huanan Zhang[2], [1]University of Michigan, Ann Arbor, [2]University of Colorado Boulder, Boulder, CO, [3]Oracle Labs, Burlington, Contact: huanan.zhang@colorado.edu

In this paper, we study the assortment and price optimization problems under the MNL model with price range effect, where the utility of a product is affected by the relative position of its price with respect to the highest and the lowest prices in the offer set. This model is motivated by the so-called Range Theory popularized in the behavioral economics and psychology literature. It addresses the limitation of a single-point interpretation of reference price, which ignores the impact of all other distributional information. We investigate the pure assortment problem, the pure pricing problem, and the joint assortment and pricing problem under the MNL model with price range effect. For each model, we first identify the structure of the optimal policy, and then we propose tractable algorithms that either output the optimal solution in polynomial time or admit an FPTAS.

2 Offline Personalized Pricing with Censored Demand

Zhengling Qi[1], Jingwen Tang[2], Ethan Xingyuan Fang[3], Cong Shi[2], [1]The George Washington University, Potomac, MD, [2]University of Michigan, Ann Arbor, MI, [3]Duke University, Durham, NC, Contact: xingyuan.fang@duke.edu

We study a personalized pricing problem with demand censoring in an offline data-driven setting. In this problem, a firm is endowed with a finite amount of inventory, and faces a random demand that is dependent on the offered price and the covariates (from products, customers, or both). Any unsatisfied demand that exceeds the inventory level is lost and unobservable. Our objective is to use the offline dataset to find the optimal personalized pricing rule so as to maximize the expected revenue. Through the lens of causal inference, we propose a novel data-driven algorithm that is motivated from survival analysis and doubly robust estimation. We derive a finite sample regret bound to justify the proposed offline learning algorithm and prove its robustness. Thorough numerical experiments demonstrate the value of factoring in demand censoring for personalized pricing.

3 Learning Fair Machine Learning Models with ROC Constraints by Semi-infinite Programing

Qihang Lin[1], Yao Yao[2], [1]University of Iowa, Iowa City, IA, [2]The University of Iowa, Iowa City, IA

Machine learning technologies have been increasingly used in high-stakes decision making, which raises a new challenge of avoiding unfair and discriminatory decisions for protected classes. Among various criteria of fairness, the one based on ROC curve is the strongest as it requires the model to generate the same distribution of prediction scores on the protected classes and the entire population. Using the ROC-based fairness metric as a constraint, training a fair machine learning model can be formulated as a semi-infinite program. We propose a new first-order method for this problem and establish its convergence analysis. The applications of our methods include the fairness-aware learning problems arising from health care and operations management.

4 Transfer Learning, Cross Learning, and Co-learning of Unknown Product Demands

Lei Li[1], Qi Annabelle Feng[1], George George

Shanthikumar[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, WEST LAFAYETTE, IN, Contact: li2851@purdue.edu
Making inventory decision under limited demand data can be challenge. We apply operational data analytics (ODA) framework to develop prescriptive solutions under transfer learning, cross learning and co-learning of the demands. This approach features data integration model and validation model, and demonstrates superior performance for small samples.

Closed Loop SCM

General Session

Session Chair

Paolo Letizia, University of Tennessee

1 Impact of Competitor Store Closures on a Major Retailer

M. Serkan Akturk[1], Michael Ketzenberg[2], [1]Clemson University, Clemson, SC, [2]Texas A&M University, College Station, TX, Contact: makturk@clemson.edu
We use a proprietary data set from a national US department store chain to investigate the impact of competitor store closures on a major retailer. We find that store sales increase with respect to a store's proximity to closed competitor locations. More interestingly, we find that online channel sales also increase in geographic locations where competitors close stores and where our focal retailer has store locations in close proximity to the markets it serves. This latter finding highlights the important role that stores play in the online channel. Stores provide a level of shopping assurance generally not available online and support customer webrooming and showrooming to mitigate purchase uncertainty. Stores are also integral to omnichannel services like return-to-store wherein stores provide a convenient nearby location to make a free return.

2 Input Material Reduction Incentives vs. Scrap Recycling for Closed Loop Supply Chains

Tolga Aydinliyim[1], Eren Basar Cil[2], Nagesh N. Murthy[2], [1]Baruch College, CUNY, New York, NY, [2]University of Oregon, Eugene, OR, Contact: erencil@uoregon.edu
In this paper, we consider a setting wherein a buyer procures standard-sized forgings from a supplier, and performs machining, which yields final components and significant scrap. Adopting a principal-agent framework, we investigate coordination implications while accounting for potential information asymmetry issues, and find that improved recycling may or may not mitigate decentralization cost.

3 Pricing and Returns in the Era of Big Tech: Implications of Information Asymmetry Reversal

Kiarash M. Hassani, Murray Lei, Anton Ovchinnikov, Queen's University, Kingston, ON, Canada. Contact: 18kmh4@queensu.ca
We present a model to optimize the return policy of a monopolistic seller, who may have better information about consumers' tastes than the customers themselves. We analyze how return policy, tech-enabled superior information, and return hassle cost affect the firm's profit and consumer surplus. The results show that without returns, collecting information up to the consumer's information doubles the profit compared with the case that the firm has no information, but being fully-informed brings no additional value. When costless returns are allowed, more information results in more profit, but the value of information is decreasing in salvage value, and when the firm is fully informed, it is always profitable to allow returns. Finally, in some situations, Pareto-improvement exists.

4 How Does Product Customization Affect Consumer Returns? An Empirical Analysis

Anupam Agrawal[1], Christoph Fuchs[2], Paolo Letizia[3], [1]Texas A&M University, College Station, TX, [2]University of Vienna, Vienna, Austria; [3]University of Tennessee, Knoxville, TN, Contact: pletizia@utk.edu
Product customization has been shown to reduce returns. However, there are different types of customization: horizontal, which involves the change of color or shape of a product component, vertical, which is related to the selection of a quality level for a product component, and personalization, which consists of the engraving of a text on the product. In this work, we empirically study how the different types of customization affect product returns.

Behavior in Services

General Session

Session Chair
Pnina Feldman, Boston University, Boston, MA

1 Cooperation in Heterogeneous Teams

Mouli Modak[1], Yaroslav Rosokha[2], Masha Shunko[3], [1]Chapman University, Orange, CA, [2]Purdue University, West Lafayette, IN, [3]University of Washington, Seattle, WA, Contact: modak@chapman.edu

We study a project management system in which heterogeneous tasks arrive stochastically and are processed by a team of heterogeneous workers. In particular, workers specialize in one type of task, which, in our model, translates into a lower cost of effort while processing that type of task. The effort chosen by the servers determines the payoff after the task is processed. Our paper compares the behavior of workers when the sequence of tasks are visible versus not visible.

2 Not All Lines are Skipped Equally: An Experimental Investigation of Line-sitting and Express Lines

Abdullah Althenayyan[1], Sezer Ulku[2], Shiliang Cui[2], Luyi Yang[3], [1]Columbia University, Columbia Business School, New York, NY, [2]Georgetown University, McDonough School of Business, Washington, DC, [3]University of California, Berkeley, Orinda, CA, Contact: aalthenayyan27@gsb.columbia.edu

We study how customers respond to priority in queues. In addition to express lines, the most common forms of priority schemes, we also consider line-sitting which is the practice of hiring others (line-sitters) to wait in line and has become more prevalent in a variety of contexts.

3 Evaluating Experienced and Prospective Queues: A Behavioral Investigation

Sera Linardi, Jing Luo, Leon Valdes, University of Pittsburgh, Pittsburgh, PA, Contact: lvaldes@katz.pitt.edu

Contrary to rational queuing predictions, empirical evidence suggests that waiting disutility does not decrease neatly over time. However, it remains unclear whether and how the experience of wait impacts such disutility. Similarly, how queue characteristics such as speed, length, and total waiting time affect waiting disutility remains unclear. In this paper, we conduct a controlled experiment to study, in observable queues, how do (i) the experience of wait and (ii) the characteristics of the residual queue affect the estimated cost of obtaining service. Our results show that the effect of experienced wait depends on the characteristics of both the queue and the individual. We also find that, in contrast to rational models, the length and service speed of the residual queue affect individuals' costs additively, not multiplicatively.

4 Exploring Consumer Responses to Time Limits

Pnina Feldman[1], Ella Segev[2], Michelle A. Shell[3], [1]Boston University, Boston, MA, [2]Ben-Gurion University of the Negev, Beer Sheva, Israel; [3]Boston University, Dover, MA, Contact: pninaf@bu.edu

Service providers often request that customers limit their consumption of experiential goods - particularly during periods of congestion. This research seeks to shed light on trade-offs between customer satisfaction, desired operational efficiencies, and general welfare by improving our understanding of how customers respond to voluntary time limits in discretionary service environments.

1 An Adaptive Superfast Inexact Proximal Augmented Lagrangian Method for Smooth Nonconvex Composite Optimization Problems

Arnesh Sujanani, Renato Monteiro, Georgia Institute of Technology, Atlanta, GA, Contact: asujanani6@gatech.edu

This work presents an adaptive superfast proximal augmented Lagrangian (AS-PAL) method for solving linearly-constrained smooth nonconvex composite optimization problems. At each iteration, AS-PAL inexactly solves a possibly nonconvex proximal augmented Lagrangian subproblem with prox stepsize chosen aggressively large so as to speed up its termination. An adaptive ACG variant of FISTA, namely R-FISTA, is then used to possibly solve the above subproblem. AS-PAL then adaptively updates the prox stepsizes based off the possible failures of R-FISTA. An interesting feature of AS-PAL is that it does not require knowledge of the parameters underlying the problem. We demonstrate the speed and efficiency of our method through extensive computational experiments which show that AS-PAL can be more than 10 times faster than all the other state-of-the-art codes.

2 Equilibrium Computation of Generalized Nash Games: A New Lagrangian-based Approach

Jong Gwang Kim, Purdue university, West Lafayette, IN, Contact: kim2133@purdue.edu

This paper presents a primal-dual method, based on a new form of Lagrangian, for computing an equilibrium of generalized Nash equilibrium problem (GNEP) where each player's feasible strategy set depends on the other players' strategies. We establish the equivalence between a saddle point of the Lagrangian and an equilibrium of the GNEP. We then propose a simple algorithm that is globally convergent to the saddle point. Our method has novel features over existing approaches; it does not require any boundedness assumptions and is the first development of an algorithm to solve a general class of GNEPs in a distributed manner. Numerical experiments on test problems demonstrate the effectiveness of the proposed method.

3 An Interior Point Method for Nonlinear Optimization Problems with Noise

Shima Dezfulian, Jorge Nocedal, Andreas Waechter, Northwestern University, Evanston, IL, Contact: shimadezfulian2023@u.northwestern.edu

We propose an interior-point algorithm for solving nonlinear constrained optimization problems in which the objective and constraints values and gradients are contaminated by non-diminishing noise. We identify the key components of the classical algorithm that should be modified to achieve noise-tolerance. We establish that the iterates converge into a neighborhood of stationary points and demonstrate the efficiency of the method with numerical experiments.

Robust Decision-making in Healthcare

General Session

Session Chair

Arkajyoti Roy, The University of Texas at San Antonio, San Antonio, TX

1 Equitable Anesthesiologist Scheduling Under Demand Uncertainty Using Multi-objective Programming

Kai Sun[1,2], Minghe Sun[1], Deepak Agrawal[3], Ronald Dravenstott[4], Frank Rosinia[2], Arkajyoti Roy[1], [1]The University of Texas at San Antonio, San Antonio, TX, [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]American Airlines, Fort Worth, TX, [4]The University of Texas Health Science Center at San Antonio, San ANtonio, TX, Contact: kasun@syr.edu

This work addresses an anesthesiologist scheduling (AS) problem under uncertainty. The goal is to plan and deploy providers to meet clinical demand and institutional protocols. A data-driven two-step sequential AS framework is developed using a mixed-integer multi-objective program. Step 1 designs shifts to minimize excessive clinical time using conditional value-at-risk constraints to account for demand uncertainty. Step 2 assigns shifts to providers considering optimal and equitable workload distribution and the number of required providers. An ⍰-constraint solution method is applied for multi-objective optimization, and an iterative solution method is developed to improve workload equity in clinical applications. Two case studies, the budget and hiring planning and the monthly AS, are addressed in a large anesthesiology department via the AS framework.

2 Risk-averse Radiotherapy Planning to Account for Auto-segmentation Errors

Ruiqi Li[1], Justin J. Boutilier[2], Niko Papanikolaou[1], Neil Kirby[1], Arkajyoti Roy[3], [1]UT Health San Antonio, San Antonio, TX, [2]University of Wisconsin - Madison, Fitchburg, WI, [3]The University of Texas at San Antonio, San Antonio, TX

To incorporate uncertainty in deep learning (DL) based auto-segmentation models into radiotherapy planning, we propose a data-driven conditional value-at-risk (CVaR) framework. First, we apply hybrid techniques, including Monte Carlo dropout and deep ensemble to estimate uncertainty in the segmentation model. Second, we propose an optimization model that employs an expected linear-quadratic objective and multiple CVaR constraints on the predicted tumor and organ contours and the prediction uncertainties. Preliminary results on a set of clinical lung cancer patients show improvements in target dose coverage and healthy organ sparing, reducing the toxicity caused by errors in auto-segmentation models.

3 Value of Intermediate Imaging in Adaptive Robust Radiotherapy Planning to Manage Radioresistance

Arkajyoti Roy[1], Shaunak Dabadghao[2], Ahmadreza Marandi[3], [1]The University of Texas at San Antonio, San Antonio, TX, [2]Eindhoven University of Technology, Eindhoven, Netherlands; [3]Eindhoven University of Technology, Tilburg, Netherlands. Contact: arkajyoti.roy@utsa.edu

In radiotherapy, uncertainties in tumor radioresistance and its progression can degrade deterministic treatments. While a robust methodology can overcome this, it often produces overly conservative or suboptimal decisions, especially when there are changes in time. We develop an adaptive radiotherapy planning framework that reduces over-conservatism yet remains robust to uncertainties. Intermediate imaging is used to update the uncertainty at each stage. While additional imaging reduces uncertainty, it accrues costs such as extra radiation to organs, which deters continuous imaging. We probe this trade-off in uncertainty and observation cost by computing and comparing two-stage, three-stage, and four-stage robust models, as well as deterministic approaches. All models are evaluated on a clinical prostate case.

4 Optimal Interventions in Robust Optimization with Time-dependent Uncertainties

Shaunak Dabadghao[1], Arkajyoti Roy[2], Ahmadreza Marandi[3], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]The University of Texas at San Antonio, San Antonio, TX, [3]Eindhoven University of Technology, Tilburg, Netherlands.

Uncertainties can be time-dependent, particularly in areas such as cancer radiotherapy planning, where the condition of the patient can change during the course of the treatment. It is crucial to intervene and observe the condition of the system prior to adapting the decisions. But observations are costly, and the timing of observations is directly impacted by time-dependent uncertainties. We develop optimal intervention policies for robust optimization models that employ time-dependent uncertainty sets. We provide heuristic procedures to compute adaptive robust solutions from the models. We evaluate practicality of the developed results and show that they perform better than naive models. The proposed methodology is generic and can be applied to other time-dependent uncertain processes.

Learning and Optimization in Dynamic Environments

General Session

Session Chair

Apurv Shukla, Columbia University, New York, NY

1 Is Separately Modeling Subpopulations Beneficial for Sequential Decision-making?

Ilbin Lee, University of Alberta, School of Business, Edmonton, AB, Canada.

In recent applications of Markov decision processes (MDPs), it is common to estimate model parameters from data. In healthcare and other applications, data are collected from different entities, such as patients. Thus, one faces the question of whether to model subpopulations separately. For instance, there may be a subpopulation whose disease status progresses faster than others, and for such a group, estimating a separate model and applying the resulting treatment plan can improve their outcomes, which aligns with the precision medicine paradigm. This work provides theoretical results and empirical methods for deciding whether to model subpopulations separately. We also present how to use our results to select the best stratification among many. We illustrate our results and methods using random instances and a medical decision-making problem from the literature.

2 Lower Bounds for Reinforcement Learning in Non-ergodic MDPs

Apurv Shukla, Columbia University, New York, NY

We derive instance-dependent lower bounds for learning average-cost criterion, non-ergodic tabular Markov Decision Processes (MDPs). The lower-bound is established in both asymptotic and non-asymptotic regimes. The results are characterized through a series of examples illustrating how structurally-different MDPs have significantly different complexity.

3 Sampling-based Safe Reinforcement Learning for Dynamic Systems

Westley Suttle[1], Krishna Kosaraju[2], Sivaranjani Seetharaman[3], Vijay Gupta[4], Ji Liu[1], [1]Stony Brook University, New York, IN, [2]Clemson University, Clemson, IN, [3]Purdue University, West Lafayette, IN, [4]Purdue university, West Lafayette, IN, Contact: gupta869@purdue.edu

Designing controllers that guarantee properties like safety and stability in complex systems when the dynamics are unknown is a challenging problem. Recent advances in control theory and reinforcement learning (RL) incorporate hard constraints on the controls proposed by RL algorithms to assure safety or stability in such systems, but lose the convergence guarantees enjoyed by classical RL and suffer increased computational burdens. In this talk, we describe a sampling-based approach to constraint satisfaction that allows us to learn RL controllers that enjoy classical convergence guarantees while maintaining desirable properties like stability, robustness, or safety of the system under disturbances. Our approach naturally integrates with the notion of control barrier functions to guarantee such properties, but applies to more general constraints as well.

Robust and Stochastic Decision Making

General Session

Session Chair

Chen Li, Singapore.

1 Robust Explainable Prescriptive Analytics

Li Chen[1], Melvyn Sim[1], Xun Zhang[2], Minglong Zhou[1], [1]National University of Singapore, Singapore, Singapore; [2]Shanghai Jiao Tong University, Shanghai, China. Contact: chen_l@u.nus.edu

We propose a new robust explainable prescriptive analytics framework that minimizes a risk-based objective function under distributional ambiguity by leveraging the data of the uncertain parameters affecting the decision model and the side information that have some predictive power on those uncertainties. The framework solves for an explainable response policy that transforms the side information directly to implementable decisions. We adopt the data-driven robust satisficing framework to address the issue of overfitting when the empirical distribution is used for evaluating the risk-based objective function. We introduce a new tractable safe approximation when the constraints are biaffine in the outcome variables and the side information. We provide a simulation study on allocating taxis to different demand regions in response to the weather information.

2 Single-scenario Facet Preservation for Stochastic Mixed-integer Programs

Aysenur Karagoz, David Mildebrath, Andrew J. Schaefer, Rice University, Houston, TX

When solving the extensive form of a two-stage stochastic mixed-integer linear program (SMIP), valid inequalities for a single-scenario polyhedron can provide significant improvements. However, it is important to assess the strength of a single-scenario valid-inequality for the extensive form. To this end, we introduce a class of two-stage SMIPs where the single-scenario facets are facet-defining for the extensive form. Particularly, we study when a SMIP preserves single-scenario facet-defining inequalities. To answer this question, we examine the matrix and recourse structures and provide examples illustrating the necessity and sufficiency relation between recourse structures and preserving single-scenario facets. We further show that under mild assumptions some matrix and recourse structures are sufficient for preserving single-scenario facets.

3 Quantum Control Pulse Optimization with Uncertain Hamiltonian Controllers

Xinyu Fei[1], Lucas Brady[2], Jeffrey Larson[3], Sven Leyffer[4], Siqian Shen[1], [1]University of Michigan, Ann Arbor, MI, [2]NASA Ames Quantum Artificial Intelligence Laboratory, Mountain View, CA, [3]Argonne National Laboratory, Argonne, IL, [4]Argonne National Laboratory, Lemont, IL, Contact: xinyuf@umich.edu

Quantum control aims to manipulate quantum systems toward desired states or operations. We consider binary optimal quantum control under uncertain Hamiltonian controllers. We propose a chance-constrained formulation to guarantee high fidelity of the control performance and solve the CVaR approximation via two approaches. One is an interpolated approximation for the non-differentiable objective function, and the other is a two-step minimization algorithm. We apply sum-up-rounding techniques to obtain binary controls and extend the model by introducing an exact penalty function to handle the additional SOS1 property. We conduct numerical studies on examples in quantum pulse optimization. The results demonstrate that (i) our algorithms can obtain high-quality control results; (ii) the CVaR model improves solution robustness under controller uncertainty.

4 Data Driven Bunker Refueling Under Price Uncertainty

Qinghe Sun[1], Ying Chen[2], Mabel Chou[1], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore.

Bunker refueling decisions in international shipping are high-stake operational decisions. Each ship is analogous to a mobile storage facility rotating among different markets, procuring bunker fuels at different ports to propel itself throughout its voyage, while grappling with fluctuating bunker fuel prices over time and geographical locations. In this paper, we propose a set of data-driven structure prescriptive (SP) approaches to address this problem, marrying the strength of modern machine learning, with the structural insights obtained from traditional OR modeling and optimization.

1 **Efficient Algorithm for Solving Robust Counterparts of LP Problems Under Budgeted Uncertainty**
Odellia Boni, Evgeny Shindin, Harold Ship, IBM Research, Haifa, Israel. Contact: odelliab@il.ibm.com
We consider the case of an uncertain linear optimization problem subject to budgeted uncertainty, meaning the uncertain parameters are dependent. Such uncertainty occurs in many real-life scenarios. Moreover, it is used in a standard approximation of scalar chance constraints. To create a tractable robust counterpart for the case of budgeted uncertainty we need to introduce many additional variables and constraints to the original problem, which may render it too large. However, many of these are typically inactive at the optimal robust solution. We present a simplex based algorithm that finds an optimal robust solution with minimal number of additional variables and constraints.

2 ***MSPLib*: A Library of Problems for Benchmarking SDDP**
Bonn Kleiford Seranilla[1], Nils Loehndorf[2], [1]University of Luxembourg, Esch-sur-Alzette, Luxembourg; [2]University of Luxembourg, Luxembourg, Luxembourg. Contact: bonn-kleiford.seranilla@uni.lu
We present MSPLib - a library of multistage stochastic programming problems to measure the computational performance of different implementations of stochastic dual dynamic programming (SDDP). MSPLib contains various instances of large real-world problems as well as synthetic problems ranging from easy to difficult variations. We use the library to test prevailing implementations - including QUASAR, SDDP.jl, and MSPPy.

3 **A New Tool for Solving Uni-parametric Linear Programs, Convex Quadratic Programs, and Linear Complementarity Problems**
Nathan Adelgren, Princeton University, Princeton, NJ, Contact: na4592@princeton.edu
We introduce a new technique for solving uni-parametric versions of linear programs, convex quadratic programs, and linear complementarity problems in which a single parameter is permitted to be present in any of the input data. We demonstrate the use of our method on a small, motivating example and present the results of a small number of computational tests demonstrating its utility for larger scale problems.

4 **Interval Linear Programming: An Additional Function of Interest**
Mohsen Mohammadi[1], Monica Gentili[2], Milan Hladik[3], Raffaele Cerulli[4], [1]Northwestern University, Evanston, IL, [2]University of Louisville, Louisville, KY, [3]Charles University, Prague, Czech Republic; [4]University of Salerno, Fisciano, Italy.
In this talk, we consider the problem of finding the range of an additional function over the set of all possible optimal solutions of a linear program with interval right-hand sides. We show the relevance of the problem in practice, address its computational complexity, and discuss some of its theoretical properties. Moreover, we propose several heuristics to solve the problem and analyze their quality and efficiency.

1 **Layer VQE: A Variational Approach for Combinatorial Optimization on Noisy Quantum Computers**
Xiaoyuan Liu[1], Anthony Angone[2], Ruslan Shaydulin[3], Ilya Safro[4], Yuri Alexeev[5], Lukasz Cincio[6], [1]Fujitsu Research of America, Inc., Sunnyvale, CA, [2]Clemson University, Clemson, SC, [3]JPMorgan Chase & Co., Lemont, IL, [4]University of Delaware, Newark, DE, [5]Argonne National Lab, Chicago, IL, [6]LANL, Los Alamos, NM
Combinatorial optimization on near-term quantum devices is a promising path to demonstrating quantum advantage. In this paper, we propose an iterative Layer VQE (L-VQE) approach, inspired by the Variational Quantum Eigensolver (VQE). We evaluate quantum optimization heuristics on the

problem of detecting multiple communities in networks, for which we introduce a novel qubit-frugal formulation. We show that L-VQE is more robust to finite sampling errors and has a higher chance of finding the solution as compared with standard VQE approaches. Our simulation results show that L-VQE performs well under realistic hardware noise.

2 Polyhedral Structure of Exact Penalty Constants in Quadratic Unconstrained Binary Optimisation

Rodolfo Quintero Ospina, Lehigh University, Bethlehem, PA

In recent years, the study of Quadratic Unconstrained Binary Optimization (QUBO) problems has regained importance because it provides a unified framework to model and solve many combinatorial optimization problems (COPT); in particular, several quantum computing algorithms can be used to solve QUBO models. In this flash talk, we propose a polyhedral characterization of the penalty constants that arise when exact penalization methods are used to reformulate linear and quadratic integer programs as a QUBO problem. We obtain new general existence results and explicit constructions that allow recovering previous reformulations and techniques used in the literature.

3 Preconditioned Inexact Infeasible Quantum Interior Point Method for Linear Optimization

Zeguan Wu, Mohammadhossein Mohammadisiahroudi, Xiu Yang, Tamás Terlaky, Lehigh University, Bethlehem, PA, Contact: zew220@lehigh.edu

Quantum Interior Point Methods (QIPMs), due to its potential to solve optimization problems significantly faster, attracted significant interest recently. Generally, QIPMs use Quantum Linear System Algorithms (QLSAs) as a replacement for classical linear system solvers. However, the performance of QLSAs depend on the condition number of the linear systems arising from QIPM, which are typically $O(1/\mu^2)$. To improve conditioning, a preconditioned QIPM based on the optimal partition estimation is developed. We improve the condition number of the linear systems to be solved to $O(1/\mu)$ and improve the preconditioned QIPM's dependence on the duality gap by $O(1/\mu^{.5})$.

4 A Faster Interior-point Method for Semidefinite Programming

Swati Padmanabhan, University of Washington, Seattle, WA, Contact: pswati@uw.edu

Semidefinite programs (SDPs) are a fundamental class of optimization problems with important recent applications in approximation algorithms, quantum complexity, robust learning, algorithmic rounding, and adversarial deep learning. This paper presents a faster interior point method to solve generic SDPs with variable size n x n and m constraints in time $O(\sqrt{n}\cdot (mn^2 + m^\omega + n^\omega) \cdot \log (1/\epsilon))$, where ω is the exponent of matrix multiplication and ϵ is the relative accuracy. In the predominant case of m≥n, our runtime outperforms that of the previous fastest SDP solver, which is based on a cutting plane method.

5 Cost Optimization of Smart Manufacturing Systems by Charging and Discharging Scheduling of Electric Trucks

Lata Pandurang Karmali[1], Nasim Nezamoddini[2], Amirhosein Gholami[3], [1]Oakland University, Rochester, MI, [2]Oakland University, Rochester, MI, [3]NULL, Binghamton, NY, Contact: lkarmali@oakland.edu

Majority of supply chains in any manufacturing industry relies on heavy trucks for transportation that leads to greenhouse gas emissions and cost fluctuation. Electric vehicles are a key component in transportation to reduce these challenges. This paper proposes a deterministic model that optimizes cost in manufacturing plants while reducing emissions caused by their transportation systems. This is enabled by utilizing electric trucks and scheduling of their charging and discharging activities in a smart manufacturing. The results show that the proposed framework not only supports penetration of renewable energy resources in manufacturing, but also saves transportation costs.

6 PAC Reinforcement Learning for Predictive State Representations

Wenhao Zhan, Princeton University, Princeton, NJ

In this paper we study online Reinforcement Learning (RL) in partially observable dynamical systems. We focus on the Predictive State Representations (PSRs) model, which is an expressive model that captures other well-known models such as Partially Observable Markov Decision Processes (POMDP). PSR represents the states using a set of predictions of future observations and is defined entirely using observable quantities. We develop a novel model-based algorithm for PSRs that can learn a near optimal policy in sample complexity scaling polynomially with respect to all the relevant parameters of the systems. Our algorithm naturally works with function approximation to extend to systems with potentially large state and observation spaces. We show that given a realizable model class, the sample complexity of learning the near optimal policy only scales polynomially with respect to the statistical complexity of the model class, without any explicit polynomial dependence on the size of the state and observation spaces. Notably, our work is the first work that shows polynomial sample complexities to compete with the globally optimal policy in PSRs. Finally, we demonstrate how our general theorem can be directly used to derive sample complexity bounds for special models including m-step weakly revealing and m-step decodable tabular POMDPs, POMDPs with low-rank latent transition, and POMDPs with linear emission and latent transition.

7 Stochastic Inverse Optimization

John R. Birge[1], Xiaocheng Li[2], Chunlin Sun[3], [1]University of Chicago, Chicago, IL, [2]Imperial College Business School, London, United Kingdom; [3]Stanford University, Stanford, CA, Contact: xiaocheng.li@imperial.ac.uk

The inverse linear optimization considers the problem of inferring the objective coefficient of a linear program through the observation(s) of the constraints and the optimal solution. We consider a stochastic setting where the objective coefficient follows some unknown distribution and the goal becomes to infer the distribution from observations of constraints and the optimal solution. We consider two settings for the stochastic inverse optimization: a Gaussian setting where the objective coefficient follows von Mises-Fisher distribution, and a delta-corruption setting where the objective coefficient distribution concentrates on one vector with high probability and is arbitrarily corrupted otherwise. We devise Bayesian algorithms for parameter estimation and develop theoretical guarantees for the recovery of the true parameter.

8 Scalable Algorithms for Densest Subgraph

Farouk Harb, University of Illinois at Urbana Champaign, Champaign, IL, Contact: eyfmharb@gmail.com

In this talk, we'll briefly recap some recent results on the densest subgraph problem for large scale graphs. The problem has a classical max-flow reduction and an LP. However, for large scale graphs, simple iterative algorithms perform much better in practice than theoretically fast algorithms based on network-flow or LP solvers. We will reference some of the iterative algorithms available like Greedy++, the Frank-Wolfe-based algorithm, and quickly introduce our new scalable iterative algorithm.

1 Pyros: A Generalized Robust Cutting-Set Algorithm for Nonlinear Two-Stage Adjustable Robust Optimization

Jason Sherman[1], Natalie Isenberg[2], John Siirola[3], Carl Laird[4], Chrysanthos Gounaris[5], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Brookhaven National Laboratory, Upton, NY, [3]Sandia National Laboratories, Albuquerque, NM, [4]Carnegie Mellon University, Pittsburgh, PA, [5]Carnegie Mellon University, Pittsburgh, PA, Contact: jasherma@andrew.cmu.edu

We present PyROS, a Python-based meta-solver for nonlinear, nonconvex two-stage adjustable robust optimization problems. Based on a generalized robust cutting-set algorithm, PyROS may be accessed through the open-source algebraic modeling language Pyomo. PyROS supports recourse decisions via various types of decision rules, and user-defined or a multitude of pre-implemented uncertainty set classes. We report latest advances in the implementation of PyROS and computational results for a two-stage optimal power flow problem—with uncertain renewable energy generation capacities—to demonstrate the utility of PyROS for systems of practical relevance.

2 Performance Evaluation of Algebraic Modeling Languages Under Practical use Cases

Merve Merakli[1], Carl Laird[2], Kevin C. Furman[3], Bashar L. Ammari[4], Sai Kompali[4], Yufeng Qian[4], [1]ExxonMobil, Spring, TX, [2]Carnegie Mellon University, Fayetteville, AR, [3]ExxonMobil, Houston, TX, [4]Carnegie Mellon University, Pittsburgh, PA

Increased interest in high level algebraic modeling languages (AMLs) has resulted in extensible open-source tools. However, this extensibility and implementation in high-level languages can raise performance concerns. While AML performance comparisons exist in the literature, most of the work does not address common meta-algorithmic use cases - for example, repeated resolves with different parameter values, cut additions, and sub-model solves frequently utilized in matheuristics and exact solution algorithms. In this presentation, we compare the performance of several AMLs under common use cases with large-scale problems. The case studies selected for comparison include, for example, a maritime inventory routing problem, a modified facility location problem, a linear-quadratic control problem, and optimization of trained neural networks.

3 Pyomo.doe: An Open-source Package for Model-based Design of Experiments in Python

Jialu Wang[1], Alexander Dowling[2], [1]Notre Dame University, Notre Dame, IN, [2]University of Notre Dame, Notre Dame, IN, Contact: jwang44@nd.edu

Selecting, calibrating, and validating predictive science-based models often remain an art in practice. Model-based design of experiments (MBDoE) leverages science-based models to maximize information gain from experiments while minimizing time and resource costs. We introduce Pyomo. DOE, an open-source package for MBDoE. Pyomo.DOE uses a nonlinear sensitivity analysis code k_aug to quickly approximate the Fisher information matrix, improving the computational time by more than one order of magnitude. In addition, Pyomo.DOE leverages a new two-stage stochastic program to facilitate the gradient-based optimization framework. Two case studies show how MBDoE formalism quickly identifies model identifiability challenges, and the power of Pyomo.DOE to estimate the value of experimental modifications a priori for large-scale partial PDAE models.

4 PAO: A Python Library for Adversarial Optimization

William E. Hart, Sandia National Laboratories, Berlin, MA

We describe PAO, a Python-based package for Adversarial Optimization. The goal of PAO is to provide a general modeling and analysis capability for bilevel, trilevel and other multilevel optimization forms that express adversarial dynamics. PAO integrates two different modeling abstractions. First, PAO algebraic models extend the modeling concepts in the Pyomo algebraic modeling language to express problems with an intuitive algebraic syntax. Second, PAO compact models express objective and constraints in a manner that is typically used to express the mathematical form of these problems (e.g. using vector and matrix data types). PAO defines custom Multilevel Problem Representations (MPRs) that simplify the implementation of solvers for bilevel, trilevel and other multilevel optimization problems.

1 High Probability Iteration and Sample Complexity Bounds for Adaptive Optimization Algorithms via Stochastic Oracles

Billy Jin, Katya Scheinberg, Miaolan Xie, Cornell University, Ithaca, NY, Contact: mx229@cornell.edu

We consider an adaptive step-size algorithm for continuous optimization under a stochastic setting where the function values and gradients are available only through inexact probabilistic zeroth and first-order oracles. Unlike the stochastic gradient method and its many variants, the algorithm does not use a pre-specified sequence of step sizes but adjusts the step size adaptively according to the estimated progress. The probabilistic oracles capture standard settings including expected loss minimization and zeroth-order optimization. Moreover, our framework allows the function and gradient estimates to be biased. The proposed algorithm is simple to describe, easy to implement and is close in spirit to standard line search. Under reasonable conditions on the oracles, we derive high probability tail bounds on the iteration and sample complexity of the algorithm.

2 Global Convergence of Sub-gradient Method for Low-rank Matrix Factorization

Jianhao Ma, Salar Fattahi, University of Michigan, Ann Arbor, MI, Contact: fattahi@umich.edu

We study the performance of sub-gradient method (SubGM) on a nonconvex formulation of low-rank matrix recovery, where the goal is to recover a low-rank matrix from a limited number of measurements, a subset of which may be grossly corrupted with noise. We study a scenario where the rank of the true solution is unknown and over-parameterized instead. Such over-parameterization may lead to overfitting, or adversely affect the performance of the algorithm. We prove that SubGM with small initialization is agnostic to both over-parameterization and noise in the measurements. In particular, we show that small initialization nullifies the effect of over-parameterization on the performance

of SubGM, leading to an exponential improvement in its convergence rate, even under arbitrarily large and arbitrarily dense noise values.

3 SQP Methods for Inequality Constrained Stochastic Optimization

Baoyu Zhou[1], Frank E. Curtis[2], Daniel Robinson[1], [1]Lehigh University, Bethlehem, PA, [2]lehigh university, Bethlehem, PA

We introduce an algorithm for minimizing a stochastic objective function subject to deterministic nonlinear equality and inequality constraints. Such problems arise in various important applications including machine learning and data science. Under common assumptions, we prove the convergence in expectation from remote starting points for the proposed algorithm. The results of numerical experiments demonstrate the practical performance of our proposed method.

4 Adaptable Businesses: A Mixed Integer Approach for Modeling the Food Service Sectors' Resilience Tactics in Face of Disruptions

Grace Jia[1], Xiangyang Guan[2], Chaoyue Zhao[3], Cynthia Chen[3], [1]UNIVERSITY OF WASHINGTON, SEATTLE, WA, [2]University of Washington, Seattle, WA, [3]UNIVERSITY OF WASHINGTON, Seattle, WA, Contact: gracejia@uw.edu

The food services sector, i.e., restaurants, grocery stores, and convenience stores, brings the community together, participates in economic activities, and satisfies human needs. As COVID-19 shows, food-related businesses are vulnerable to disruptions such as labor shock, supply shock, demand shock, infrastructure damage, regulations, etc. This work develops a mixed-integer nonlinear programming model with scenario designs to study how the businesses adapt to different disruptions, identify bottlenecks in current operations, and develop adaptation strategies.

1 Dual Descent ALm and ADMM

Kaizhao Sun[1], Andy Sun[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]MIT, Catonsville, MD, Contact: ksun46@gatech.edu

We investigate a new class of dual updates within the augmented Lagrangian framework, where the key feature is to reverse the update direction in the traditional dual ascent. When the dual variable is further scaled by a fractional number, we name the resulting scheme scaled dual descent (SDD), and otherwise, unscaled dual descent (UDD). We propose SDD-ADMM for nonlinear equality-constrained multi-block problems, and contribute to the literature by establishing O(□$^{-4}$), O(□$^{-3}$), and O(□$^{-2}$) *first-order* iteration complexities for SDD-ADMM under different assumptions. We also propose UDD-ALM for weakly convex minimization over affine constraints, which complements the best-known results for the class of problems considered.

2 Global Complexity Bound of a Proximal ADMm for Linearly-Constrained Non-Separable Nonconvex Composite Programming

Weiwei Kong, U.T. Battelle, LLC (ORNL), Oak Ridge, TN, Contact: wwkong92@gmail.com

In this talk, we present a dampened proximal alternating direction method of multipliers (DP.ADMM) for solving linearly-constrained nonconvex optimization problems where the smooth part of the objective function is nonseparable. Each iteration of DP.ADMM consists of: (ii) a sequence of partial proximal augmented Lagrangian (AL) updates, (ii) an under-relaxed Lagrange multiplier update, and (iii) a novel test to check whether the penalty parameter of the AL function should be updated. Under some mild regularity conditions, we describe how DP.ADMM obtains a first-order stationary point of the constrained problem in O(□^{-3}) iterations for a given numerical tolerance □>0. One of the main novelties of the method is that the convergence of the method is obtained without requiring any rank assumptions on the constraint matrices.

3 Proximal-primal-dual Algorithms for Nonconvex Optimization Problems

Jiawei Zhang[1], Zhi-quan Luo[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Shenzhen Research Institute of Big Data, The Chinese University of Hong Kong, Shenzhen, China. Contact: jwzhang@mit.edu

In this talk, we first answer the open problem of how to design an algorithm achieving the benchmark iteration complexity *O*(1/□^{2}) for constrained nonconvex problems with linear equality constraints and convex inequality constraints. To this aim, we propose a smoothed proximal augmented Lagrangian method and its multi-block version. Using a proximal-primal-dual framework and some novel error bounds, we prove that our algorithm can converge with an $O(1/\square^2)$ iteration complexity for the problems with polyhedral constraints and compact, convex constraints. In addition, we introduce the extension of our algorithm to distributed optimization and minimax problems, achieving the $O(1/\square^2)$ iteration complexity for decentralized training over distributed samples and features and robust optimization.

4 Low-order Methods for Nonlinear Constrained Nonconvex Optimization

Yangyang Xu, Rensselaer Polytechnic Institute, Troy, NY

Many applications involve nonlinear functional constraints that prohibit easy projections. These problems are often high dimensional. Traditional methods such as the Newton's method are usually too expensive. In this talk, I will present low-order optimization methods. For applications where function values and first-order derivatives are accessible, we propose first-order methods; for problems where only function values are available, we propose zeroth-order methods. Oracle complexity results will be shown under certain regularity conditions. Numerical results will also be shown on solving classical optimization problems and machine learning problems.

Topics in Sequential Models Under Uncertainty

General Session

Session Chair

Sebastian Perez Salazar, Georgia Institute of Technology, Atlanta, GA

1 Tightness Without Counterexamples: A New Approach and New Results for Prophet Inequalities

Jiashuo Jiang[1], Will Ma[2], Jiawei Zhang[3], [1]New York Uniersity, New York, NY, [2]Columbia University, New York, NY, [3]New York University, New York, NY, Contact: jzhang@stern.nyu.edu

Prophet inequalities consist of many beautiful statements that establish tight performance ratios between online and offline allocation algorithms. Typically, tightness is established by constructing an algorithmic guarantee and a worst-case instance separately, whose bounds match as a result of some "ingenuity". In this paper, we instead formulate the construction of the worst-case instance as an optimization problem, which directly finds the tight ratio without needing to construct two bounds separately. Through this analysis, our paper provides a unified framework that derives new results and recovers many existing ones. For example, we show that the "oblivious" method of setting a static threshold due to Chawla, Devanur, and Lykouris (2021) is, surprisingly, best-possible among all static threshold algorithms, for any number k of starting units.

2 Icu Management with Proactive Patient Transfer

Chia-Hao Chang, Vineet Goyal, Columbia University, New York, NY, Contact: cc4626@columbia.edu

Managing patient flow in hospitals has always been a crucial subject for hospital operation. In hospitals, regular patients stay in wards whereas severely ill ones are treated in the Intensive Care Units (ICUs). However, recent evidence from machine learning shows that proactive patient transfer to the ICU may increase overall patients' well-being. Due to the scarcity of ICUs and uncertainties of patient dynamics, nonetheless, effective management of the ICUs is paramount. In this work, we consider a discrete-time Markov model where a central planner decides the number of patients to be proactively transferred. We propose a state-dependent threshold policy and compare it with other heuristics by several numerical simulations.

3 Non-Adaptive Stochastic Score Classification

Rohan Ghuge[1], Anupam Gupta[2], Viswanath Nagarajan[3], [1]University of Michigan, Ann Arbor, MI, [2]Carnegie Mellon University, Pittsburgh, PA, [3]University of Michigan, Ann Arbor, MI

In the stochastic score classification problem, there are several binary tests, where each test i is associated with a probability p_i of being positive and a cost c_i. The score of an outcome is a weighted sum of all positive tests, and the range of possible scores is partitioned into intervals corresponding to different classes. The goal is to perform tests sequentially so as to identify the class at the minimum expected cost. We provide the first constant-factor approximation algorithm for this problem, improving over a previous logarithmic approximation ratio. Moreover, our algorithm is non adaptive: it just involves performing tests in a fixed order until the class is identified. We also perform computational experiments on random instances, and observe that the cost of our algorithm is typically within 50% of an information-theoretic lower bound on the optimal value.

4 **Online Resource Allocation for Electric Vehicle Battery Swapping Service**

Ziyang Liu, Rajan Udwani, UC Berkeley, Berkeley, CA, Contact: ziyang_liu@berkeley.edu

We study the online decision making in electric vehicle battery swapping service. When adversarial customers arrive at the service facility sequentially, the facility determines whether to provide a battery for swapping to save customer's time or provide the regular charging service. Moreover, the matching eligibility depends on both the battery resources and the customers. We propose novel algorithms that address the heterogeneity of battery resources and the uncertainty in future arrivals.

Transportation-enabled Services

General Session

Session Chair

Hai Wang, Singapore Management University, Singapore, Singapore.

Session Chair

Hao Hao, Carnegie Mellon University, Pittsburgh, PA

1 **Commuting Service Platform: Concept and Analysis**

Xuegang Ban, University of Washington, Seattle, WA

Platform (app)-based ride-hailing services have recently transformed urban mobility by connecting drivers (supply) directly with travelers (demand). For commuting to work or school, however, individual travelers' travel decision making can be heavily influenced by employers or work places. In this talk, we propose the commuting service platform (CSP) to serve urban commuting, which also connects commuters and their employers, thus revealing their interactions when commuting decisions are concerned. We present CSP as a two-sided market, its conceptual service modes, and the analysis methods. We also model the impact of the locations of homes and worksites to the analysis of CSP, and summarize major factors that may impact the performance of a CSP.

2 **Optimization of Customer Service Area and Driver Dispatch Area for On-demand Food Delivery Services**

Jingfeng Yang, Singapore Management University, Singapore.

Recently, on-demand food delivery platforms have connect drivers, restaurants, and customers in real time and are drastically changing food delivery services. In this paper, we focus on the area size optimization problem, in which the platform dynamically coordinates the balance between supply and demand by adjusting the radius of its customer service and driver dispatch areas. Leveraging a real dataset from a food delivery platform, we propose a data-driven optimization framework that combines machine learning methods for order delivery time estimation and mathematical programming for the optimization of the two areas at the same time. The objective is to maximize the total number of orders served with minimal impact on the average order delivery time. Experiments using real-world data show that our framework outperforms several benchmarks in current practice.

3 **Prescriptive Analytics for Wildfire Suppression**

Jacob Wachspress[1], Alexandre Jacquillat[2], [1]Operations Research Center, MIT, Cambridge, MA, [2]MIT Sloan School of Management, Cambridge, MA, Contact: jacobwac@mit.edu

We propose an optimization approach to support wildfire suppression operations. The model brings together prioritization and routing decisions to minimize future fire damage as well as crew assignment costs. Accordingly, the model is formalized via a double set partitioning formulation over time-space networks, with linking constraints ensuring that crew supply meets wildfire suppression demand. To solve it, we develop a double column generation algorithm with tailored stabilization strategies. Our algorithm can scale to realistic instances faced in practice, and can thus guide wildfire suppression efforts at the regional and national levels. Results show that out optimization approach can outperform several benchmarks—in particular, they show the benefits of integrating the endogeneity of wildfire growth and crew assignments decisions.

4 **Multimodal Transportation Alliance Design with Endogenous Demand: Large-scale Optimization for Rapid Gains**

Kayla Spring Cummings[1], Vikrant Vaze[2], Ozlem Ergun[3], Cynthia Barnhart[4], [1]Massachusetts Institute of Technology, Allston, MA, [2]Dartmouth College, Hanover, NH, [3]Northeastern University, Boston, MA, [4]Massachusetts Institute of Technology, Cambridge, MA, Contact: vikrant.s.vaze@dartmouth.edu

We design a prescriptive pricing alliance to power collaborations between fixed-route transit agencies and on-demand mobility providers. We formulate a fare-setting model to jointly optimize discounted fares across both networks under endogenous traveler route choice resulting in a large-scale, non-convex, mixed integer program. We develop a new solution heuristic combining tailored coordinate descent, parsimonious anchor point selection, and non-convex piecewise linear interpolation. Computationally, our approach significantly outperforms state-of-the-art benchmarks. Practically, our pricing alliance improves outcomes over non-cooperative counterfactuals from both operators' self-interested perspectives while also improving system utilization and lowering prices for low-income residents and long-distance commuters.

1 **A Simulation Model for the Railcar Retrieval Problem**
Atefe Sedaghat[1], Amir Gharehgozli[2], Maryam Hamidi[3], Roger William Baugher[4], [1]Lamar University, Beaumont, TX, [2]California State University Northridge, Northridge, CA, [3]Lamar University, Beaumont, TX, [4]TrAnalytics, LLC, Johns Creek, GA, Contact: asedaghat@lamar.edu
This paper develops an AnyLogic simulation model to study the railcar retrieval problem (RRT) that focuses on retrieving the railcars required for the next train. The railcars are stored in several tracks and retrieving some of them needs reshuffling. The objective function is to minimize the total time and the performances of different policies are evaluated using a real-world case study.

2 **How Blockchain and Uber Freight Services Can Help Disrupted Logistics Network**
Lanqing Du[1], Jinwook Lee[2], [1]Drexel University, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, Contact: ld695@drexel.edu
Since COVID, labor shortages have substantially influenced conventional transportation and supply chain management activities. When faced with interruption and its associated ripple impact, third-party logistics (3PL) services are critical logistical fulfillment options. And blockchain-enabled information transparency will aid in the development of information resilience. In this research, we investigate related decision-making problems in a disrupted logistics network, where nodes represent facilities with varying degrees of disruption and edges indicate a shipment volume between two nodes. Key findings from numerical experiments on real-world data will be presented.

1 **The Dynamic Pickup and Allocation with Fairness Problem**
Gal Neria, Michal Tzur, Tel Aviv University, Tel Aviv, Israel.

We consider the problem of determining a vehicle route that visits pickup points (PPs), from which the vehicle collects supplies, and demand points (DPs) to which these supplies are delivered. The supply quantities at the PPs are uncertain, and the information on their value arrives gradually over time. We model it as a stochastic dynamic routing and resource allocation problem, with the aim of delivering as many goods as possible while obtaining equitable allocations to the DPs. We present a Markov decision process formulation, however, it suffers from the curse of dimensionality. Therefore, we develop a solution framework that presents a novel combination of operations research and machine learning. A numerical experiment with 11 to 100 site instances, based on data from the Berlin Foodbank and random datasets, confirms that our solution method performs very well.

2 Diversion and Treatment Policies for Opioid use Disorder: A Discrete Event Simulation Approach

Veronica M. White[1], Laura Albert[2], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Middleton, WI, Contact: vmwhite@wisc.edu

The opioid crisis has led to a rapid increase of opioid-related deaths, overdoses, and arrests, that have strained many organizations, systems, and personnel in hospitals, treatment facilities, and police departments. We introduce a discrete event simulation to evaluate various intervention policies to estimate a community's opioid-related outcomes over time by modeling opioid users' pathways. We use public and community-sourced data to populate the case study based in Dane County, Wisconsin. We then compare our case study's simulated outcomes of implementing various community interventions. The analysis sheds light on the combination of policies that has the best potential to lower opioid-related deaths, overdoses, and arrests.

3 Revisiting School District Design: A Stream-based Approach

Aysu Ozel[1], Karen Smilowitz[2], Lila K. S. Goldstein[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: aysuozel@u.northwestern.edu

We revisit the school districting problem, introducing a new stream-based approach that can incorporate multiple assignment decisions simultaneously. In particular, the students in small geographic units are assigned to a set of schools (e.g., elementary, middle, high school, specialized education programs) with a single composite variable. This leads to a compact optimization model that considers metrics such as transportation cost and equitable access while meeting community-driven needs. The formulation builds on decades of advancements in such models, while allowing flexibility to adapt to local conditions. We present a case study from a partnership with a community redesigning student assignment to address historic inequities.

Societal and Welfare Impacts of Information Systems

General Session

Session Chair

Abhishek Ray, George Mason University, West Lafayette

1 The Advertising Big Picture: Analyzing The Cross-platform Synergies Between Tv and Online Advertising

Ilango Guru Muniasamy[1], Mohammed Alyakoob[2], Hossein Ghasemkhani[1], [1]Purdue University, West Lafayette, IN, [2]University of Southern California, New York, CA, Contact: igurumun@purdue.edu

We study the interaction effects between TV advertising and online advertising in driving consumers' decisions to make online purchases. We match a rich dataset of an automobile company's online advertising and activities of users on the company's website, with a granular dataset of TV ad spending by the company and its competitors in the users' geographical locations. Our findings suggest that TV advertisements amplify the probability of an online purchase by users who are exposed to online advertisements of the company.

2 Brand Mentions and News Engagement: An Empirical Investigation of The Roles of News Format and Narrativity

Debashish Ghose[1], Susan Mudambi[1], Subodha Kumar[2], [1]Temple University, Philadelphia, PA, [2]Fox School of Business, Temple University, Philadelphia, PA, Contact: dghose@temple.edu

Social media continues to grow into a major provider of news but competition for user attention is intense, encouraging the use of attractive headlines. News editors need to carefully choose which brands to feature and how to talk about them. We investigate the roles of brand mentions, news format (traditional or satirical), and news narrativity in garnering engagement. Endogeneity corrected analyses of a curated dataset comprised of 50k traditional and satirical stories that originated from the same newsroom reveal that while brand mentions in headlines do encourage engagement, human brand mentions have a stronger effect than product brands. This effect is stronger for satirical news than traditional news. Narrative structures of staging, plot progression, and cognitive tension encourage engagement for satirical news but not traditional news.

3 Does Pre-login Search Matter? Evidence from a Mobile Commerce Platform

Jordan He[1], Luna Zhang[2], David Zhang[1], Yuliang Yao[1], [1]Lehigh University, Bethlehem, PA, [2]University of Washington Tacoma, Tacoma, WA, Contact: qih320@lehigh.edu

An increasing number of consumers enjoy shopping in mobile commerce. When consumers use a mobile app, they can choose whether to log in with their accounts or not. In this paper, we argue that pre-login search can play a critical role in affecting consumers' purchase decisions, although it has largely been overlooked in the Information Systems literature. Using clickstream data, we examine whether and how pre-login search effort affects the likelihood of purchase. Our results show that pre-login search behaviors are as important as post-login search behaviors to consumers' purchase decisions. We also demonstrate that consumers purchase probability increases at a diminishing rate with an increasing search effort during both pre- and post-login periods.

Testing Network Correlation Efficiently via Counting Trees

Sophie Yu, Duke University, Durham, NC

We propose a new procedurefor testing whether two networks are edge-correlated through some latent vertexcorrespondence. The test statistic is based on counting the co-occurrences ofsigned trees for a family of non-isomorphic trees. Our algorithms significantlyimprove the prior work in terms of statistical accuracy, running time, andgraph sparsity.

Tight Guarantees for Multi-unit Prophet Inequalities and Online Stochastic Knapsack

Jiashuo Jiang, Hong Kong University of Science and Technology, Hong Kong.

Prophet inequalities are a useful tool for designing online allocation procedures, with widespread adoption in mechanism design and general online allocation problems in online advertising, healthcare scheduling, and revenue management. In this paper, we characterize the optimal procedure to obtain tight LP bounds and consequently improve the best-known guarantee for k-unit prophet inequalities for all k>1. We also consider the more general online stochastic knapsack problem. We introduce a new ``best-fit'' procedure with an improved guarantee which we also show is tight over LP upper bound.

The Fragility of Optimized Bandit Algorithms

Lin Fan, Stanford University, Stanford, CA

Much of the literature on optimal design of bandit algorithms is based on minimization of expected regret. It is well known that designs that are optimal over certain exponential families can achieve expected regret that grows logarithmically in the number of arm plays, at a rate governed by the Lai-Robbins lower bound. We show that when one uses such optimized designs, the regret distribution necessarily has a very heavy tail, specifically, that of a truncated Cauchy distribution. This makes such designs highly fragile from a statistical viewpoint, the consequences of which we explore.

Digitizing Spare Parts Supply Chain via 3D Printing - An Operational Cost Analysis

Yue Zhang[1], William McCall[2], Jing-Sheng Jeannette Song[3], [1]Pennsylvania State University, University Park, PA, [2]Xerox, Chapel Hill, NC, [3]Duke University, Durham, NC

The case includes a sourcing problem and a manufacturing problem for an original equipment manufacturer, demanding sourcing recommendations for a variety of parts used in high voltage equipment, and decisions on the manufacturing strategy for a part used in a water monitoring system. The case promotes qualitative and quantitative understanding of 3D printing vs. traditional manufacturing via the lens of operational cost. It can be used for discussing the impact of 3D printing on supply chains, and for graduate/undergraduate course to introduce make-to-stock/order, queueing, lifecycle analysis.

Moneyball for Murderball: Using Analytics to Construct Lineups in Wheelchair Rugby

Craig Fernandes[1], Timothy Chan[1], Albert Loa[1], Nathan Sandholtz[2], [1]University of Toronto, Toronto, ON, Canada; [2]Brigham Young University, Provo, UT

This case follows a new assistant coach of Canada's national wheelchair rugby team who is tasked with optimizing their lineups using descriptive (data analysis), predictive (regression) and prescriptive (optimization) techniques. It was developed from discussions with the national team coach and sport scientists. Students build proficiency in developing an end-to-end solution approach using appropriate software for a complex real-world problem. This case can be utilized in both OR and statistics courses, with material that covers both introductory and advanced modeling topics.

To Catch a Thief: Explainable AI in Insurance Fraud Detection

Antoine Desir[1], Ville Satopaa[1], Eric Sibony[2], Laura Heely[3], [1]INSEAD, Fontainebleau, France; [2]Shift Technology, Paris, France; [3]Atypical Partner, London, United Kingdom.

This case introduces the concept of explainable artificial intelligence through the lens of InsurTech unicorn Shift. Students are asked to take the position of a senior operations professional, whose algorithm is used by leading global insurers such as Generali France and Mitsui Sumitomo to fight fraudulent claims. The case focuses on company-level strategic decisions and algorithm-level decisions. With an anonymized dataset of more than 10,000 claims and a guided coding exercise in statistical computing softwares R and Python, students are able to backtest their strategies on historical data.

Elections Management: Exploring the Complexity of Polling Place Consolidation

Adam Schmidt, UW-Madison, Madison, WI

Every election, officials plan for unpredictable election conditions, which requires inter-related decisions. This case has students study the impact of polling place consolidation on voter participation, equity, and cost effectiveness by predicting the performance of polling places using a mathematical queueing model. The case will improve students ability to study queueing systems and assess decisions from the viewpoint of multiple stakeholders. The case is presented in three parts and is to be completed by small student groups coupled with larger group discussions over one course period.

1 Going The Distance: The Impact of Commute on Gender Diversity in Public Service Positions

Dawson Kaaua[1], Vanitha Virudachalam[2], [1]Georgetown University, Washington, DC, [2]Gies College of Business, UIUC, Champaign, IL, Contact: dawson.kaaua@georgetown.edu

Women have been shown to prefer jobs with a better work-life balance across many fields. Given that serving as a state political representative requires a significant amount of travel between one's home district and the state capitol, this suggests that long commute times may reduce the number of women that seek political office in the United States. We investigate whether this is true and, if so, potential policies to mitigate this effect.

2 A Data-driven Approach to Routing Images in a Virtual Radiology Network

Vijay Mehrotra[1], Shivani Shukla[1], Theo Mefford[2], [1]University of San Francisco, San Francisco, CA, [2]University of San Francisco, San Francisco, CA, Contact: vmehrotra@usfca.edu

In a virtual radiology network, images are captured in many different medical facilities and then routed to radiologists in a variety of remote locations. From an operations management perspective, there are two primary factors that make the design and control of such networks challenging. First of all, there are typically several hundred unique types of images and several hundred different radiologists, each of whom is eligible to handle a unique subset of image types. Secondly, images can be queued to multiple radiologists in parallel even though it will ultimately be handled by the first radiologist who begins working on it. In this paper, we propose logic to route images to radiologists to optimize system performance, and demonstrate how our method outperforms current practices.

3 The Psychology of Virtual Queue: When Waiting Feels Less like Waiting

Kejia Hu[1], Xun Xu[2], Ao Qu[3], [1]Vanderbilt University, Nashville, TN, [2]California State University, Dominguez Hills, Carson, CA, [3]Massachusetts Institute of Technology, Cambridge, MA

In this study, we examine the impact of the practice of virtual queue (VQ) on customer complaints and satisfaction via empirical evidence from 0.72 million online customer reviews of U.S. major casual-dining chain restaurants. Using difference-in-difference regressions facilitated by propensity score matching, we find that VQ significantly reduces customers' complaints about pre-process waiting and increases their overall satisfaction but does not increase their in-process waiting complaints. In addition, we find that when the providers adopt VQ, the positive effects are relatively immediate, rather than lagged. Further, the VQ effects are amplified if the providers are perceived to offer low value or have high substitutability.

4 Cents of Urgency: How Opening An Urgent Care Center Affects Emergency Department Arrivals?

Simin Li[1], Achal Bassamboo[2], Martin Lariviere[2], [1]Tulane University, New Orleans, LA, [2]Northwestern University, Evanston, IL

How a nearby urgent care center (UCC) affect emergency department arrivals is inconclusive in literature. In this project, we use a clean quasi-experiment setting to show that: 1) 21% semi to nonurgent patients, 5% urgent patients are diverted to UCC; 2) diverted urgent patients requires no hospitalization, which indicates a sophisticated self-selection of healthcare facilities among the patients; 3) the provider to disposition time among urgent and semi-urgent patients decrease by 13%, which improves hospital's throughput measures; 4) these effects are mostly persistent.

1 Distributionally Robust Time Series Analysis with Martingale Constraints

Jose Blanchet[1,2,2], [1]Columbia University, Dallas, [2]Stanford, Palo Alto, CA

We optimal min-max linear prediction for linear time series (including ARMA(p,q)). We generalize the prediction equations by considering adversarial perturbations in a Wasserstein neighborhood of a baseline model but adding martingale constraints. We show the existence of a Nash equilibrium, strong duality, and provide efficient algorithms for computing it. If the baseline model is Gaussian, we show that the optimal adversarial martingale is also Gaussian. The min-max non-parametric prediction / estimation problem can be efficiently computed within a Wasserstein ball subject to martingale constraints.

2 Load Balancing on Truly Sparse Graphs

Kavita Ramanan, Brown University, Providence, RI, Contact: kavita_ramanan@brown.edu

We will consider the behavior of load balancing networks on truly sparse networks, developing tractable approximations for their hydrodynamic limits and using them to provide insight into performance analysis.

3 On Quantum Algorithms for Random Walks in the Nonnegative Quarter Plane

Mark S. Squillante[1], Vasileios Kalantzis[1], Shashanka Ubaru[1], Lior Horesh[2], [1]IBM Research, Yorktown Heights, NY, [2]IBM TJ Watson, Ossining, NY, Contact: mss@us.ibm.com

We consider the problem of computing the stationary distribution of a general class of random walks in the nonnegative quarter plane, with a focus on efficient quantum computing solutions. We devise quantum algorithms for computing the stationary distribution and establish significant speedups under different conditions, including quadratic speedup over the classical cyclic reduction algorithm, exponential improvement over so-called quantum walk algorithms, and addressing for the first time a well-known computational bottleneck of quantum walk algorithms.

4 Square-Root Voting: Related Stochastic Processes and Limiting Regimes

David D. Yao, Wenpin Tang, Columbia University, New York, NY

The square-root voting rule was first proposed by Lionel Penrose, that each member country of a world assembly (such as UN) be given a number of votes equal to the square root of its population. The idea has become newly relevant in the POS (proof of stake) scheme of digital currency (e.g., Ethereum) and other decentralized voting mechanisms. Focusing on the processes representing the total wealth over time and each participant's share, we derive their limiting distributions and related concentration inequalities.

1 Optimal Dividend Strategy Under Model Uncertainty

Prakash Chakraborty, Pennsylvania State University, State College, PA, Contact: prakashc@psu.edu

We consider a diffusive model for optimally distributing dividends, while allowing for Knightian model ambiguity concerning the drift of the surplus process. We show that the value function is the unique solution of a non-linear Hamilton-Jacobi-Bellman variational inequality. In addition, this value function embodies a unique optimal threshold strategy for the insurer's surplus, thereby making it the smooth pasting of a non-linear and linear part at the location of the threshold. Furthermore, we obtain continuity and monotonicity of the value function in addition to continuity of the threshold strategy with respect to the parameter that measures ambiguity of our model.

2 Presenter

Imon Banerjee, Purdue University

Markov decision processes (MDPs) have wide applications in engineering and machine learning, forming a key component in many reinforcement learning problems. In this work, we consider the estimation of the transition probabilities of finite-state finite-action MDPs, and develop a minimax sample complexity bounds for nonparametric estimation of these transition probability matrices. Unlike most studies, which have been in the online setup, we consider offline MDPs. Our results are quite general since we do not assume anything specific about the logging policy. Instead, the dependence of our statistical bounds on the logging policy comes out in form of a natural mixing coefficient. We finally demonstrate the validity of our results under various known policies like stationary, Markov, and episodic policies.

3 Adopting to Changing Environment: Dynamic Bandits with Stochastic Structure

Poyraz Bozkurt[1], Harsha Honnappa[2], Ruihao Zhu[3], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, [3]Purdue Krannert School of Management, Chicago, IL, Contact: pbozkurt@purdue.edu

Motivated by the dynamic/non-stationary nature of many real-world market settings, we study dynamic multi-armed bandit (MAB) problem with stochastic temporal structures that satisfies: (i) the amount of changes is linear in T time periods; (ii) the expected reward of an arm follows a stochastic process. Many existing MAB algorithms fail to perform well in the dynamic settings, where the expected reward of each arm changes over time. In our formulation, the expected reward of each arm follows a Reflected Brownian Motion (RBM) model that governs the temporal structure of the reward distributions. Due to the dynamic nature of rewards, an agent has to continuously keep exploring in order to adapt to the changing environment. Our formulation is a special case of the restless MAB problem.

4 Generalized Regret Analysis of Thompson Sampling Using Fractional Posteriors

Prateek Jaiswal, Texas A&M University, College Station, TX, Contact: jaiswalp@tamu.edu

Thompson sampling (TS) is one of the most popular and earliest algorithms to solve stochastic multi-armed bandit problems. We consider a variant of TS, named □-TS, where we use a fractional or □-posterior (□ (0,1)) instead of the standard posterior distribution. For □-TS we compute near-optimal problem-dependent and problem-independent frequentist regret bounds for general prior and reward distributions (with bounded support). Our key contribution is to deliver the near-optimal frequentist regret bounds under a very mild regularity condition on the prior distribution that only requires the prior to place positive mass in an appropriate Rényi neighborhood of the true reward distribution. Moreover, our analysis does not require additional structural properties such as closed-form posteriors or conjugate priors.

Causal Inference, Robustness, and Reinforcement Learning

General Session

Session Chair

Shuangning Li, 1</sup

1 Sensitivity Analysis of Individual Treatment Effects: A Robust Conformal Inference Approach

Ying Jin, Stanford University, Stanford, CA, Contact: ying531@stanford.edu

We propose a model-free framework for sensitivity analysis of individual treatment effects (ITEs). For any unit, our procedure reports a number that quantifies the minimum strength of confounding needed to explain away the evidence for ITE.Under the marginal sensitivity model, we characterize the distributional shift between the observations and the counterfactuals. We first develop a general method for predictive inference under distributional shifts; we then leverage this to construct covariate-dependent prediction sets for counterfactuals. These prediction sets (resp. approximately) achieve marginal coverage if the propensity score is known (resp. estimated). We devise another procedure attaining coverage conditional on the training data that is sharp in certain problems. We verify the new methods via simulation studies and apply them to real datasets.

2 Empirical Gateaux Derivatives for Causal Inference

Angela Zhou, University of Southern California, Los Angeles, CA, Contact: angela-zhou@berkeley.edu

We study a constructive procedure for estimating Gateaux derivatives for statistical functionals, with attention to causal inference. We study a statistical setting where probability distributions need also to be estimated from data. We begin with a case study of counterfactual mean estimation. This helps concretize by allowing us to study rates of numerical approximation that preserve statistical performance; our concretizations improve facial validity of numerical derivative approaches and highlight tradeoffs for researchers and practitioners. Next we study applications to optimization functionals, : we can evaluate influence function bias corrections by evaluation of the functional at valid (perturbed) distributions. We show how this approach is relevant to constrained off-policy evaluation in infinite-horizon settings.

3 Distributionally Robust Q-learning: Formulation, Algorithm, and Sample Complexity

Shengbo Wang, Stanford University, Stanford, CA, Contact: shengbo.wang@stanford.edu

We consider a reinforcement learning setting in which the deployment environment is different from the training environment. We propose a synchronous distributionally robust (DR) tabular Q-learning algorithm that learns the DR Q function under the worst distributional perturbation of the environment within a relative entropy uncertainty set. We utilize the strong duality theory for the DR Q function and design an unbiased randomized multi-level Monte-Carlo scheme to estimate the distributionally robust error using this dual formulation. Assuming access to a generative model, we prove that the worst-case sample complexity to achieve ⍰ algorithmic error is upper bounded by Õ(|S||A|(1-⍰)^{-5}⍰^{-2}). Simulation studies further validate our theoretical results.

4 Optimal Policy Evaluation Using Kernel-Based Temporal Difference Methods

Yaqi Duan, Massachusetts Institute of Technology, Cambridge, MA, Contact: yaqid22@gmail.com

We study kernel methods for value function estimation of an infinite-horizon discounted Markov reward process (MRP). We use empirical process theory to derive a non-asymptotic upper bound on the estimation error with explicit dependence on the eigenvalues of the kernel operator, as well as the instance-dependent variance of the Bellman residual error. In addition, we prove minimax lower bounds over sub-classes of MRPs, which shows that our rate is optimal in terms of sample size n and effective horizon $H=(1-⍰)^{-1}$. Whereas existing worst-case theory predicts cubic scaling (H^3) in the effective horizon, our theory reveals that there is in fact a much wider range of scalings, depending on the kernel, the stationary distribution, and the variance of the Bellman residual error. Notably, it is only (near-)parametric problems that can ever achieve the worst-case cubic scaling.

Arda Vanli, FAMU-FSU College of Engineering, Tallahassee, FL

1 RCA Knowledge Transferring for Machine Learning Based Multiclass Compressor Anomaly Classification

Pooyan Mobtahej, Sadra Naddaf-Sh, Maryam Hamidi, Hassan Zargarzadeh, Xinyu Liu, José M. Vega-Guzmán, Lamar University, Beaumont, TX, Contact: pmobtahej@lamar.edu

A gas compressor system consists of different components, where any defects in components could cause a costly system failure. Therefore, early diagnosis of failures in a compressor is essential to reduce the risk of system shutdown and increase reliability. This research proposes a hybrid anomaly detection approach by leveraging both Root Cause Analysis (RCA) and supervised Machine Learning based algorithms for feature selection, component failure detection, and unseen anomalies classification captured in historical multivariate time-series records of components. Ten-fold cross-validation is conducted to evaluate the performance of trained models. Best performance is achieved through A decision tree-based approach with a 99.99% AUC score in the multiclass anomaly detection setting on the test set.

2 Bridging Reliability and Operations Management for New Product Introduction in Nonstationary Condition

Tongdan Jin, Texas State University, San Marcos, TX

Nowadays many firms have handled the manufacturing, maintenance, and repair of capital goods under an integrated product-service paradigm. However, in literature reliability-redundancy, maintenance planning, and spares logistics are often optimized separately, resulting in local optimality. We discuss the challenges and opportunities of consolidating these decisions for attaining superior system availability. Specific interest is focused on the new product introduction phase in which firms face a variety of uncertainties, such as installed base, usage, reliability, and intermittent demand. The goal is to call for tackling the reliability-maintenance-inventory allocation problem under a nonstationary condition.

3 Extracting Failed Equipment Taxonomy from Unstructured Maintenance Records with Confidence

Abhijeet Sandeep Bhardwaj[1], Dharmaraj Veeramani[2], [1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI

Maintenance records generated while inspection of breakdown event contain rich information in unstructured free-text format. The effort for manual review and analysis of voluminous maintenance records is prohibitive, and hence, in real-world industrial practice, the unstructured data are typically not leveraged in systematic ways to support failure diagnosis. An important facet of failure diagnosis is the ability to identify the complete equipment taxonomy of sub-components that malfunctioned during a breakdown event. To address this opportunity, in this work we propose a comprehensive methodology to automatically analyze unstructured maintenance records in an unsupervised manner to extract the complete equipment taxonomy corresponding to each maintenance event along with a confidence score for each predicted result.

4 Predictive Models for Covid-19 Survival Analysis from Blood Test Data

Seyedreza Abazari[1], Arda Vanli[1], Rahil Mazloumi[2], Farnaz Nafarieh[2], Amir Aghsami[2], Fariborz Jolai[2], [1]FAMU-FSU College of Engineering, Tallahassee, FL, [2]University of Tehran, Tehran, Iran, Islamic Republic of. Contact: sabazari@fsu.edu

The purpose of this study is to compare the efficacy of various machine learning algorithms for survival analysis of Covid-19 based on several blood test characteristics. In particular, Cox Proportional Hazards models with survival response data are compared to Logistic Regression with binary response data for classification and variable selection performance. Further comparisons are made against Random Forest, Support Vector Machine, Decision Tree, Adaptive Boosting and K Nearest Neighbors classification methods for predicting the survival probabilities. Algorithms are trained and tested on a blood sample dataset which consists of blood's clinical indicators and information of 306 infected patients. According to our findings, age is the most critical feature and LD, Leukocytes and CRP are highly correlated

Data Quality Assurance for Industrial Internet

General Session

Session Chair

Yingyan Zeng, Blacksburg, VA

Session Chair

Ran Jin, Virginia Tech, Blacksburg, VA

1 Contextual Bandit Guided Data Farming for Deep Neural Networks in Manufacturing Industrial Internet

Yingyan Zeng[1], Parshin Shojaee[1], Syed Hasib Syed-Hasib-Akhter Faruqui[2], Adel Alaeddini[3], Ran Jin[1], [1]Virginia Tech, Blacksburg, VA, [2]Northwestern, Evanston, IL, [3]University of Texas at San Antonio, San Antonio, TX, Contact: adel.alaeddini@utsa.edu

Deep Neural Networks (DNNs) have shown superior performance in supervised learning in Industrial Internet applications. However, the performance of DNNs relies on large and high-quality data sets with appropriate distributions. Inspired by the theory of Design of Experiments, we propose a Contextual Bandit-based Representation Design (CBRD) to generate data suitable for training DNNs. The CBRD combines the offline experimental design criteria as the arms of a contextual bandit model for DNN training in a joint and interactive way for online batch data. A real case study of the Aerosol Jet Printing process is used to demonstrate the merits of the CBRD method.

2 A Task-Driven Privacy-preserving Data-sharing Framework for Industrial Internet

Parshin Shojaee[1], Muntasir Wahed[2], Yingyan Zeng[1], Avi Seth[2], Ran Jin[1], Ismini Lourentzou[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Blacksburg, VA, Contact: ilourentzou@vt.edu

Despite the Industrial Internet promise of training and deployment acceleration, and the potential to optimize decision processes via sharing rich datasets, adoption is impacted by increased information privacy concerns, limiting interoperability. In addition, not all shared data are equally useful or well-suited across all downstream tasks. While prior work has largely explored privacy-preserving mechanisms, it remains non-trivial how to design data selection mechanisms that model the similarity of data owners to better facilitate partnership.
In this work, we propose PriED, a task-driven data-sharing framework that combines privacy-preserving generative models to facilitate proxy-data exchange, and a dynamic data selection strategy trained with reinforcement learning. We demonstrate performance gains on a real semiconductor manufacturing case study.

3 Monitoring Runtime Metrics of Fog Manufacturing via a Qualitative and Quantitative (QQ) Control Chart

Yifu Li[1], Lening Wang[2], Dongyoon Lee[3], Ran Jin[4], [1]University of Oklahoma, Norman, OK, [2]Ford, Detroit, MI, [3]Stony Brook University, Stony Brook, NY, [4]Virginia Tech, Blacksburg, VA

Fog manufacturing combines Fog and Cloud computing in a manufacturing network to provide efficient data analytics and support real-time decision-making. Detecting anomalies, including imbalanced computational workloads and cyber-attacks, is critical to ensure reliable and responsive computation services. We propose a qualitative and quantitative (QQ) control chart to monitor system anomalies through identifying the changes of monitored runtime metric relationship (quantitative variables) under the presence of dynamic offloading (qualitative variable) using a risk-adjusted monitoring framework. Both the simulation and Fog manufacturing case studies show the advantage of the proposed method compared with the existing literature under the dynamic offloading influence.

4 Ensemble Active Learning by Contextual Bandits for AI Incubation in Manufacturing

Yingyan Zeng[1], Xiaoyu Chen[2], Ran Jin[3], [1]Virginia Tech, Blacksburg, VA, [2]University of Louisville, Louisville, KY, [3]Virginia Tech, Blacksburg, VA, Contact: yingyanzeng@vt.edu

The poor data quality of high-speed, large-volume data collected by Industrial Cyber-physical System (ICPS)s has posed significant challenges to the online updating of artificial intelligence (AI) models. Additionally, it is labor-intensive to annotate all streaming samples. Active learning methods have been proposed to acquire informative samples. However, existing acquisition criteria cannot well balance the trade-off between the exploration and exploitation of the input variable space. We propose an ensemble active learning method by contextual bandits (CBEAL), which incorporates a set of active learning agents designed for exploration or exploitation by a weighted combination and dynamically adjusted the weight based on the usefulness of its decisions. The effectiveness of CBEAL is validated in a numerical simulation study and a manufacturing case study.

Ashif Iquebal, 1</sup

1 Multi-block Parameter Calibration in Computer Models

Cheoljoon Jeong[1], Albert Berahas[2], Eunshin Byon[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: ebyon@umich.edu

Parameter calibration aims to estimate unobservable parameters employed in a computer model by utilizing physical process responses and computer model outputs. Existing studies calibrate all parameters simultaneously using an entire dataset. However, in certain applications, some parameters are associated with only a subset of data. This study provides a multi-block calibration approach that considers such heterogeneity. Unlike existing studies that build emulators for the computer model response, we consider multiple loss functions, each for a block of parameters that use the corresponding dataset and estimate the parameters using a nonlinear optimization technique. The superiority of our approach is demonstrated through numerical studies and a building energy simulation case study.

2 Active Learning for Classification with Imperfect Labels

Pouya Ahadi[1], Kamran Paynabar[2], [1]ISyE Georgia Tech, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: pouya.ahadi@gatech.edu

In an active learning problem, query samples will be annotated using some oracles. In most cases, these labels include noise due to the noisy oracles. Moreover, uncertain samples are more likely to receive imperfect labels from those labelers. Learning with highly imperfect labeled data points will result in an inaccurate classifier. Some existing approaches use repeated labeling methods that require annotating one sample multiple times. These approaches may label fewer distinct samples due to the limited sampling budget, and thus the classifier might not be well-trained. We propose a novel method for active learning problems to construct a robust classification model. We assign each query sample to a proper labeler to mitigate the effect of label noise on the classifier.

3 Online Exploration-exploitation Trade-off in Active Learning Regression

Upala Junaida Islam, Ashif Iquebal, Arizona State University, Tempe, AZ, Contact: uislam@asu.edu

Active learning reduces the required number of data labeling, the generalization error, and the overall cost of gathering high-fidelity experimental data by actively and intelligently choosing the data to learn from. Active learning in regression problems needs to explore the search space to learn the gist of the overall structure of the underlying function and exploit the regions where the function is unpredictable with limited data. We present an active learning regression approach to learn unknown black-box functions by balancing the exploration-exploitation trade-off online. We propose a Bayesian hierarchical model using Dirichlet Process prior to the trade-off factor in the process. Applied to case studies, it shows faster convergence compared to pure exploration and exploitation strategies.

4 Towards Developing an Autonomous Experimentation Platform (AEP) Through Bayesian Model Averaging (BMA) and Surprise-reacting Experiment Policy

Ahmed Shoyeb Raihan[1], Imtiaz Ahmed[2], [1]West Virginia University, Morgantown, WV, [2]West Virginia University, Morgantown, WV, Contact: ar00065@mix.wvu.edu

AEPs are futuristic manufacturing platforms which can sequentially search the material design space (MDS) and find parameters with targeted properties. Traditional approaches often over-exploits and under-explores the MDS without considering model uncertainty. This work incorporates BMA in the model framework guiding the experiments through surprise-reacting and EI-based strategies. Our approach accounts for model uncertainty identifying the most promising regions in the MDS effectively.

Data Analytics in Healthcare Application

General Session

Session Chair

Shujin Jiang, Purdue University, West Lafayette

Session Chair

Jian Liu, University of Arizona, Tucson, AZ

1 Bayesian Spatial Analysis of Socioeconomic Determinants on Covid-19 Mortality: An Application to the State of California

Rasim M. Musal[1], Tahir Ekin[1], Tevfik Aktekin[2], [1]Texas State University, Austin, TX, [2]University of New Hampshire, Durham, NH, Contact: rm84@txstate.edu

This presentation illustrates a spatio-temporal model in the context of biweekly Covid-19 mortality in the state of California. We illustrate multiple models in exploring the factors that affect Covid-19 mortality including vaccination rates, ICU utilization by Covid patients, and various social determinants of health. In particular, we develop exploratory models to assess a static baseline Besag York Mollie model and extend it. In addition to interaction, spatial and interaction effects we incorporate a time series component. This can help healthcare authorities to understand the changes in the disease ecology and assess effect of strategies or explore particular areas of interest that behave better/worse than would be expected under risk neutrality.

2 Improving Health Trajectory Estimation with Generative Iterative Multiple Imputation

Senne Van Steelandt[1], Anahita Khojandi[1], Rama Vasudevan[2], [1]University of Tennessee, Knoxville, TN, [2]Oak Ridge National Laboratory, Oak Ridge, TN

Generative models present a powerful approach to generate realistic health trajectories for individual patients, however, the physiological time-series used to train these models often contain a high degree of sparsity. Various studies on time series prediction have demonstrated that these missingness patterns can be exploited to improve model performance, but these techniques fail when applied in the context of trajectory estimation. We address this issue by developing a novel on-training imputation technique for predicting health trajectories through generative models. Using a synthetic and a real-world clinical dataset (MIMIC-III), we show that we achieves state-of-the-art performance in generating realistic health trajectories, and we provide further insights on our technique's performance under varying missingness patterns and degrees of sparsity.

3 Predicting Case-mix Resident Census in Nursing Homes: A Multivariate Count Time Series Forecasting Method

Shujin Jiang[1], Mingyang Li[2], Yuehwern Yih[1], Nan Kong[1], [1]Purdue University, West Lafayette, IN, [2]University of South Florida, Tampa, FL, Contact: jiang557@purdue.edu

We study the problem of forecasting nursing home (NH) resident census from various resident acuity groups. The census data are nonstationary, count time series data with potential correlation in groups. We compare prediction results of autoregression models, vector autoregression models, univariate dynamical generalized linear models, and multivariate dynamical count mixture models using a back-testing method. We conduct case studies based on five years' Minimum Data Set (MDS) data from Indiana NHs. We provide computational insights into nonstationary resident census forecasting and justify the superiority of the proposed multivariate dynamical count time series models.

Evolution of Electricity Market Design

General Session

Session Chair

Evangelia Spyrou, National Renewable Energy Laboratory, Golden, CO

Session Chair

James Hyungkwan Kim, [1</sup]

1 Improving Congestion Management in Integrated Balancing Markets

Marie Girod[1,2], Efthymios Karangelos[3], Yannick Perez[1], [1]Laboratoire de Génie Industriel, CentraleSupélec, Université Paris Saclay, Paris, France; [2]RTE, Paris, France; [3]University of Liege, Liege, Belgium. Contact: marie.girod@rte-france.com

European markets integration is currently undergoing a major new stage with the creation of common markets of manually activated balancing reserve. In the design of these balancing markets, the method for computing cross-border capacity has several limitations. We provide an improved capacity management process using a flow-based methodology and a network representation forecast one hour before real-time. We develop a model that simulates a manual balancing process and evaluates its impact on network congestion. Using this model, we estimate the impact of the current and the proposed cross-border capacity computations on both market welfare and network congestion.

2 A New Risk Assessment and Management Paradigm in Electricity Markets

Panagiotis Andrianesis[1], Dimitris Bertsimas[2], Michael C. Caramanis[1], William W. Hogan[3], [1]Boston University, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Harvard University, Belmont, MA, Contact: panosa@bu.edu

We present early results of an ARPA-E funded project under the PERFORM - Performance-based Energy Resource Feedback, Optimization, and Risk Management - program, which develops innovative management systems that represent the relative delivery risk of each asset, like wind farms, and balance the collective risk of all assets across the grid. We propose a New Risk Assessment and Management Paradigm designed to overhaul Electricity Markets by efficiently addressing uncertainty in the forthcoming massive renewable generation and electrification of fossil fuel reliant energy uses. We present methodologies constituting a risk-driven paradigm to achieve higher adoption of stochastic resources and a more efficient and reliable system operation, and we provide proof of concept on the Southwest Power Pool territory.

3 Hybrid Plant Design in Highly Congested Regions: Implications for Market Design and Transmission Development

James Hyungkwan Kim, Dev Millstein, Julie Mulvaney-Kemp, Ryan Wiser, Lawrence Berkeley National Laboratory, Berkeley, CA, Contact: hyungkwankim@lbl.gov

Transmission congestion can reduce the value of output from hybrid (renewable+storage) plants. These value penalties now occur in some portion of every Independent System Operator (ISO) regions. Partly in response to these congestion penalties and the overall hybrid value decline occurring in higher penetration ISOs, there is interest in both developments of hybrid plant design and the development of new transmission infrastructure. We found differences between the identified optimal configurations in the congested regions and supporting market design to enhance the value of the hybrid plants. Also, we recognized the impact of transmission expansion on the optimal hybrid configuration in the congested region where estimating future electricity costs will depend on the mix and configuration of hybrid plants and the transmission development level.

Policy-enabling Models in the Power Sector

General Session

Session Chair

Afzal Siddiqui, Stockholm University, Stockholm, Sweden.

1 Assessing the Potential of Demand Response as a Source of Flexibility in Low-carbon Power Systems: Insights from the French Case

Julien Ancel[1], Olivier Massol[2], [1]Climate Economics Chair, Paris, France; [2]IFP School & City, University of London, Rueil-Malmaison, France.

Long disregarded in power systems, demand side participation is now expected to provide the flexibility required to operate RES-dominated power systems. In light of this, a crucial question remains unanswered: what is the exact potential of Demand Response (DR)? To investigate it, we develop an analogy between load-shedding and load-shifting technologies and hydropower units and use it to examine the optimal operation of a low carbon power system. The resulting multi-stage stochastic linear programming problem is solved using the Stochastic Dual Dynamic Programming (SDDP) technique. As an application, we consider the French case and examine the role of DR on the current system as well as on alternative future configurations. Our findings show that DR susbtantially reduces the cost of a power system provide new insights regarding the economics of these technologies.

2 Basis-oriented Time Series Aggregation

Sonja Wogrin, David Cardona-Vasquez, Udo Bachhiesl, Graz University of Technology, Graz, Austria.

Due to the increasing share of variable renewable energy sources in power systems, models for policy guidance have become more computationally demanding, even making some intractable for realistic systems; thus, arises the need for techniques that improve computational efficiency. One such technique is temporal aggregation via clustering and representative periods; in general, however, the underlying optimization model is completely ignored in the temporal aggregation process, often leading to aggregations that might have good clustering performance, which does not necessarily translate into good optimization results. We analyze how information about the mathematical basis of the optimization model can be used to improve the temporal aggregation when used for aggregated optimization models and present preliminary results of a case study.

3 When a Power Purchase Agreement Reduces Social Welfare

Joseph Edward Duggan[1], Ramteen Sioshansi[2], [1]University of Dayton, Grove City, OH, [2]The Ohio State University, Columbus, OH, Contact: sioshansi.1@osu.edu

We investigate the incentive, market-behavior, and welfare effects of a proposed profit guarantee and associated power purchase agreement (PPA), which was introduced to ensure that generating firms remain viable through periods of higher-than-normal costs. We develop and analyze a stylized Nash-Cournot model of a wholesale electricity market to examine the incentive effects of the proposed PPA. We find that the proposed PPA has incentive impacts that are contrary to its stated aim. The PPA incentivizes uneconomic firms to remain in the market when otherwise they would exit and incentivizes the shutdown of otherwise economically viable firms to restrict output, increasing prices. The theoretical results of the Nash-Cournot analysis are illustrated with a numerical case study, which shows the deleterious consumer and social-welfare effects of this incentive scheme.

4 Bitcoin or No Bitcoin?

Yihsu Chen[1], Andrew L. Liu[2], [1]University of California, Santa Cruz, Santa Cruz, CA, [2]Purdue University, Lafayette, IN, Contact: yihsuchen@ucsc.edu

In response to the crackdown by government elsewhere, energy-intensive bitcoin rigs have searched for other energy sources to support their operations. There is a growing interest in some regional electricity markets in the US to host them. However, concerns about their impact on the market emerge as they are, in fact, a prosumer that can either sell power to or purchase power from the grid. We study their impacts on the wholesale market using a two-stage stochastic programming approach formulated as a complementarity problem. We show that their presence can effectively induce additional capacity if they act as a consumer in favorable conditions.

EV Fleet Optimization and Grid Ineractions

General Session

Session Chair

Nawaf Nazir, 1</sup

Session Chair

Chase Dowling, 1</sup

1 An Energy Management System for EV Fleets

Tami Monge, Jamie Hussman, Robert Spragg, NextEra Mobility, San Francisco, CA, Contact: tamara.monge@nexteraenergy.com

Individual electric vehicles have much lower energy costs per mile than their internal combustion counterparts (in most fueling contexts), but fleets of EVs are subject to peak demand effects that can send energy costs soaring. NextEra Mobility has developed an Energy Management System (EMS) that curtails those effects, preserving EVs' cost advantage. The EMS ingests vehicle routes, charger dwell periods, utility tariffs, weather forecasts, and on-site energy resources and passes them to a model predictive controller, which optimizes the charging schedules to minimize the total cost of the electricity used by the fleet. We have developed the EMS by simulating a diverse set of real-world scenarios in preparation for production operation later this year. In this talk we will discuss our approach to solving the optimization problem and findings from the simulations.

2 Algorithms for Electric Vehicle Valuation in Grid Services

Joshua Jaworski[1], Ningkun Zheng[2], Bolun Xu[2], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY, Contact: jjj2146@columbia.edu

Electric vehicles can adjust their charging schedule in response to time-of-use tariffs or spot electricity market prices to reduce the charging cost and aid power grid operation. This talk introduces a computation-efficient algorithm for optimizing electric vehicle charging schedules to provide grid services. The algorithm is based on dynamic programming and uses an analytical approach to update the value function. The proposed approach is convenient and computationally efficient to incorporate price uncertainties and nonlinear battery models such as state-of-charge dependent power ratings and efficiencies, and the calculated value functions provide a base for EV fleet aggregation.

3 Centering Equity in The Design of EV Charging Infrastructure

Hafiz Anwar Ullah Khan[1], Yury Dvorkin[1], Burcin Unel[2], [1]New York University, Brooklyn, NY, [2]New York University, NYC, NY, Contact: hak369@nyu.edu

Access to and affordability of electric vehicle charging infrastructure (EVCI) are the two prominent barriers for EV adoption. In this talk, we identify such socio-demographic features that correlate with the current distribution of EV charging stations in New York City, demonstrating a heavy skew against low-income, Black-identifying, and disinvested neighborhoods. We use this data-driven analysis to design equitable charging tariffs for public EVCI. The designed framework incorporates economic welfare, social costs of environmental and public health impacts, and demographic characteristics. The results demonstrate that charging tariffs can be efficient and promote distributional equity, underscoring the need for policy frameworks that incorporate equity and justice in the rollout of EVCI.

4 Unlocking the Value of Electric Vehicle Fleets as Grid Assets

Eilyan Bitar[1], Feras Al Taha[1], Tyrone Vincent[2], [1]Cornell University, Ithaca, NY, [2]Colorado School of Mines, Golden, CO, Contact: eyb5@cornell.edu

To transform electric vehicles (EVs) into dispatchable resources that provide energy/ancillary services to the grid, it is essential to quantify their capacity to supply energy and defer charging based on their heterogeneous charging requirements. While the aggregate charging flexibility of an EV fleet can be expressed as a Minkowski sum of convex polytopes, it is generally intractable to compute exactly. We propose novel methods to compute accurate inner and outer approximations of the aggregate flexibility set by solving modestly-sized linear programs. We illustrate our methods using real-world EV fleet data.

Auctions and Market Design Flash Talks

Flash Session

Session Chair

Cagil Kocyigit, University of Luxembourg, Luxembourg, Luxembourg.

Session Chair

Robert Day, University of Connecticut, Storrs, CT

1 Flash Paper

Robert Day, University of Connecticut, Storrs, CT

2 Innovations in Auction Design

Benjamin Lubin, Boston University, Boston, MA

We will preview the content of the session, which will include 4 excellent papers on mechanism design in an auction context. A particular emphasis in this year's session will be on advances in bidder preference elicitation and bidder feedback.

3 Flash Paper

Sven Seuken, University of Zurich, Zuerich, Switzerland.

4 Flash Paper

Yunus C. Aybas, Stanford University, Stanford, CA, Contact: aybas@stanford.edu

We will preview the content of the session, which will include 4 excellent papers on Information Design.

5 Robust Mechanism Design

Cagil Kocyigit, University of Luxembourg, Luxembourg, Luxembourg.

This talk focuses on the use of techniques from robust optimization to investigate how the decisions of a mechanism designer are affected by distributional ambiguity.

6 Supporting Democratic Innovation: Fairness, Representativeness, and Transparency for Citizens' Assemblies

Paul Gölz, Carnegie Mellon University, Pittsburgh, PA, Contact: pgoelz@cs.cmu.edu

Globally, there has been a recent surge in *citizens' assemblies*, which are a form of civic participation in which a panel of randomly selected constituents contributes to questions of policy. Since panels should be demographically representative, and since they should be randomly selected, the selection process poses challenges of fairness, efficiency, predictability, and transparency. I will describe multiple pieces of work in which we support nonprofit organizations in hosting citizens' assemblies.

7 Obviously Strategyproof Single-Minded Combinatorial Auctions

Carmine Ventre, King's College London, London, United Kingdom.

We consider the setting of combinatorial auctions when the agents are single-minded and have no contingent reasoning skills. We are interested in mechanisms that provide the right incentives to these imperfectly rational agents, and therefore focus our attention to obviously strategyproof (OSP) mechanisms. These mechanisms require that at each point during the execution where an agent is queried to communicate information, it should be "obvious" for the agent what strategy to adopt in order to maximise her utility. In this paper we study the potential of OSP mechanisms with respect to the approximability of the optimal social welfare.

8 Flash Paper: Serverless Computing

Ian Kash, 1</sup

In serverless computing, customers provide code to run and conditions which trigger the invocation of the code. They pay only for the time the code is running with the cloud provider managing resources. I'll discuss ongoing work on pricing caching policies in this context.

9 Uniformly Bounded Regret in Dynamic Fair Allocation

Santiago Balseiro[1], Shangzhou Xia[2], [1]Columbia University, Armonk, NY, [2]Columbia University, New York, NY, Contact: sx2182@columbia.edu

We study a dynamic allocation problem in which sequentially arriving resources need to be allocated to fixed agents with additive utilities. Most works on dynamic resource allocation aim to maximize the utilitarian welfare of the agents, which may result in unfair concentration of resources at select agents while leaving others' demand under-fulfilled. We consider the egalitarian welfare objective instead, which aims at balancing the efficiency and fairness of the allocation. We propose a new policy consisting of infrequently re-solving the fluid problem, which attains uniformly bounded regret against the hindsight optimum.

Sustainability in Agriculture
General Session

Session Chair
Erkut Sonmez, University of Nebraska Lincoln, Lincoln, NE

1 **Dynamic Irrigation Management Under Temporal and Spatial Variability**
Erkut Sonmez[1], Baris Ata[2], Derek Heeren[1], [1]University of Nebraska Lincoln, Lincoln, NE, [2]University of Chicago, Chicago, IL
Recent studies report that agricultural productivity must improve significantly in the near future to meet the increase in demand due to rapid growth of the world population. One way to improve agricultural productivity is to increase irrigation. However, fresh water scarcity, increasing production costs, and the climate change necessitate sustainable and efficient methods for irrigation. This paper studies dynamic irrigation management under uncertainty taking into account temporal variability and spatial soil heterogeneity of the field. Our results reveal that proposed (s, S)-type irrigation policies can improve farmers' expected net benefit and water savings significantly over the commonly used irrigation policies in practice

2 **Feeding the Hungry in the Midst of a Pandemic: How to Build Resilience in Food Bank Operations**
Luv Sharma, Yingru Han, Olga Perdikaki, Pelin Pekgun, University of South Carolina, Columbia, SC, Contact: luv.sharma@moore.sc.edu
In this study, we investigate the role of a critical operational factor in influencing the *ramp-up in distributional capacity* for food banks in the face of emergencies like the Covid-19 pandemic and help build resiliency in operations.

3 **Optimization of Crop Insurance Policy Selection and Fertilizer Management with Water Quality Impacts**
Gorkem Emirhuseyinoglu, Sarah M. Ryan, Iowa State University, Ames, IA, Contact: gorkem@iastate.edu
Weather conditions and market prices are the major uncertainties affecting farm revenue. Farmers apply N to the soil to compensate for its nutrient deficiencies and increase the yield output. However, N leaching through subsurface flow threatens water quality. In the US, federal crop insurance and income support policies defined in the Farm Bill are the primary ongoing financial tools mitigating farmers' financial risk. In addition to providing financial security for farmers, these programs also affect fertilizer management decisions and have unintended consequences for water quality. We build a stochastic program, including CVaR as a risk measure, to find optimal crop insurance choices and N application rates under a range of risk preferences. The results inform the design of support policies and insurance products to improve economic and environmental outcomes.

Evaluating Technology and Resource Tradeoffs in Energy System Planning
General Session

Session Chair
Neha Patankar, North Carolina State University, West Windsor, NJ

1 **Multiagent Optimization for Coordinated Transmission-distribution System**
Saumya Sakitha Sashrika Ariyarathne[1], Harsha Gangammanavar[2], Jianhui Wang[3], [1]Southern Methodist University, Dallas, TX, [2]Southern Methodist University, Dallas, TX, [3]Southern Methodist University, Dallas, TX, Contact: sariyarathne@smu.edu
In this talk, we present a multiagent optimization model and solution method for coordinating market transactions between the centralized transmission system (TS) and multiple distribution systems (DS). We consider DS operations including generation using distributed energy resources such as rooftop solar and convex relaxations of power flows. Our model concurrently optimizes these operations at individual DS while keeping their competitive

advantages over the other systems. The optimization model at individual also captures the environmental impact of DS operations. The exchange of electricity between the TS and a DS is governed by a linear inverse demand function. We will present the results from computational experiments with our multiagent optimization model.

2 Incorporating Energy Equity and Environmental Justice into Wind Power Siting

Jeffrey A. Bennett[1], Jonathan D. Ogland-Hand[1], Erin Middleton[1], Jessi Eidbo[1], Matthew Prorok[2], Brian Ross[2], Sean Yaw[3], Richard S. Middleton[1], [1]Carbon Solutions LLC, Bloomington, IN, [2]Great Plains Institute, Minneapolis, MN, [3]Montana State University, Bozeman, MT, Contact: jeffrey.bennett@carbonsolutionsllc.com

Although wind is now the least expensive form of new energy generation, its continued deployment faces siting barriers. In this talk, we introduce a tool, *SimWIND^{PRO}*, that supports wind farm siting while concurrently optimizing wind resource potential, transmission costs, and energy equity and environmental justice. We then present a case study in the context of Midcontinent Independent System Operator's (MISO) western region that includes some of the best wind resources in the United States. Our results show that transmission routing is significantly increased when considering energy equity considerations such as traditional fossil fuel communities and environmental impacts such as The Nature Conservancy's Site Renewables Right.

3 A Data-driven Approach to Identify Household Demand Flexibility to Supply a New Power Market Risk Product

Yijiao Wang[1], Li He[2], Mengmeng Cai[2], Shawn Li[3], Elina Spyrou[2], Benjamin Field Hobbs[1], [1]Johns Hopkins University, Baltimore, MD, [2]National Renewable Energy Laboratory, Golden, CO, [3]Johns Hopkins University, Baltimore, MD, Contact: ywang303@jhu.edu

At least two critical gaps prevent the efficient management of delivery risk in electricity markets. First, flexibility of distributed energy resources (DERs) is underutilized. Second, system flexibility is mostly used for reliability purposes and not for economic hedging of delivery risk. In an ongoing project, we propose a new power market risk product. The novel product allows uncertain resources to hedge reliability risks (production imbalances) by procuring system-wide flexibility including flexibility by residential sector load management. Texas household-level smart thermostat data is being studied to identify potential residential load shifting opportunities.

4 Land Tradeoffs in the American West Under Uncertain Future Scenarios

Neha Patankar, Princeton University, Princeton, NJ

In the electricity sector, system stakeholders have multiple priorities that are often ignored by existing power system capacity expansion models (CEMs). Non-modeled priorities, such as the ecological impacts or regional equity of a given transition plan, have significant impacts on the pace and scale of the switch to zero-carbon electricity. These priorities lead to parametric and structural uncertainty in the CEMs. Our analysis employs a model of the Western Interconnection to explore electricity generation pathways for achieving 100% carbon-free electricity supply for the American West by 2045. We show that the Modeling to Generate Alternative (MGA) methodology performs better under parametric uncertainties while MGA's ability to address structural uncertainty depends highly on the type of non-modeled priority.

Data Driven Decisions: New Paradigms

General Session

Session Chair

Omar Mouchtaki, Columbia University, New York, NY

Session Chair

Omar Besbes, Columbia University, New York, NY

1 Contextual Search in the Presence of Adversarial Corruptions

Akshay Krishnamurthy[1], Thodoris Lykouris[2], Chara Podimata[3], Robert Schapire[1], [1]Microsoft Research, New York, NY, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Harvard University, Allston, MA

We study contextual search which captures settings such as feature-based dynamic pricing. Standard formulations of this problem assume that agents act based on a homogeneous response model. In practice, some responses may be adversarially corrupted. Existing algorithms heavily depend on the assumed response model being accurate for all agents and have poor performance in the presence of even a few such arbitrary misspecifications. We initiate the study of contextual search when some of the agents can behave in ways inconsistent with the underlying response model. In particular, we provide algorithms that attain near-optimal regret in the absence of adversarial corruptions and their performance degrades gracefully with the number of such agents, providing the first results for contextual search in any adversarial noise model.

2 Near-Optimal Decision-Aware Reinforcement Learning

Hamsa Sridhar Bastani[1], Osbert Bastani[2], Tsai-Hsuan Chung[1], Vahid Rostami[3], [1]Wharton School, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Macro-Eyes, Seattle, WA, Contact: hamsab@wharton.upenn.edu

We propose decision-aware reinforcement learning via a novel Taylor expansion of the optimal decision loss to provably align the objective of our prediction models with the objective of the downstream sequential optimization problem. Importantly, our approach only requires a simple re- weighting of the training data, allowing it to easily be incorporated into complex modern data science pipelines, yet producing sizeable efficiency gains. We apply our framework to optimize the distribution of essential medicines and vaccines in collaboration with policymakers in Sierra Leone; highly uncertain demand and limited budgets currently result in excessive unmet demand. Out-of-sample results demonstrate that our end-to-end approach can significantly reduce unmet demand across 1200+ health facilities throughout Sierra Leone.

3 Nonstationary Bandit Learning via Predictive Sampling

Yueyang Liu[1], Benjamin Van Roy[1], Kuang Xu[2], [1]Stanford University, Stanford, CA, [2]Stanford Graduate School of Business, Stanford, CA, Contact: yueyl@stanford.edu

Although Thompson sampling is widely used in stationary environments, it does not effectively account for nonstationarities. To address this limitation, we propose predictive sampling, a policy that balances between exploration and exploitation in nonstationary bandit environments. It is equivalent to Thompson sampling when specialized to stationary environments, but much more effective across nonstationary environments because it deprioritizes investment in acquiring information that will quickly lose relevance. To offer insight in the efficacy of predictive sampling, we establish a regret bound. This bound highlights dependence on the rate at which new information arrives to alter the environment. In addition, we conduct experiments on bandit environments with varying information arrival rates and observe that predictive sampling outperforms Thompson sampling.

4 Beyond i.i.d.: Data-driven Decisions in a Heterogeneous Environment

Omar Besbes[1], Will Ma[2], Omar Mouchtaki[1], [1]Columbia University, New York, NY, [2]Columbia University, Cambridge, MA, Contact: om2316@gsb.columbia.edu

The assumption that samples are identically and independently distributed (i.i.d.) is classical and central in the data-driven algorithms literature. This assumption can be questioned in many applications as the collected data is rarely associated with identical distributions. We first propose a general framework for offline data-driven decision-making in a heterogeneous environment in which the stream of historical samples is generated by distributions which lie in a heterogeneity ball and centered around an unknown distribution. We develop asymptotic performances of data-driven policies when the number of samples goes to infinity and the heterogeneity radius goes to 0. We show that for different problems and heterogeneity balls, different performances may arise and we derive new connections with distributionally robust optimization.

1 Equity in Resident Crowdsourcing: Measuring Under-reporting Without Ground Truth Data

Zhi Liu[1], Nikhil Garg[2], [1]Cornell University, Ithaca, NY, [2]Cornell Tech, New York, NY, Contact: zl724@cornell.edu

Modern city governance relies heavily on crowdsourcing to identify problems in real-time. A major concern in these systems is that residents do not report problems at the same rates. However, measuring such under-reporting is a difficult task, as distinguishing between low reporting rates and low ground-truth incident rates is challenging. We develop a method to identify heterogeneous reporting rates, without using external ground truth data. Our insight is that rates on *duplicate* reports about the same incident can be leveraged, to turn the question into a standard Poisson rate estimation task. We apply our method to over 100,000 resident reports made to the NYC Department of Parks and Recreation, finding that there are substantial spatial and socio-economic disparities in reporting rates, even after controlling for incident characteristics.

2 Approximate Submodularity in Network Design Problems

Levi DeValve[1], Sasa Pekec[2], Yehua Wei[2], [1]University of Chicago, Chicago, IL, [2]Duke University, Durham, NC

We study network design problems, with a focus on flexibility design (i.e., allocating subsets of limited resources to multiple demand classes) as a motivating case. Using a primal-dual approach, we establish that the flexibility design problem possesses a novel structural property. The property, which we call cover modularity, can be interpreted as an approximate form of submodularity, in the sense that local changes in the objective function can be used to bound global changes. We use this structure to analyze a class of greedy heuristics and establish the first constant factor approximation guarantee for solving the general flexibility design problem. We further demonstrate existence of a cover modular structure in a general class of linear programming formulations, indicating applicability of our approach to a wide range of network design problems.

3 Optimal Auction Design with Deferred Inspection

Ali Makhdoumi, Duke University, Durham, NC

In auctioning digital goods, the platforms have the ability to monitor the payoff of bidders and adjust their payments accordingly. In this talk, we model the design of such auctions and use tools from convex analysis and calculus of variation to find the optimal mechanism. We then explain how the analysis can be applied to other auction design settings where ``local incentive compatibility'' does not imply ``global incentive compatibility''.

4 Promotion Display when Customers Search: A Structural Estimation of Click-then-purchase Behavior in Online Retail

Yi Chen[1], Jing Dong[2], Fanyin Zheng[2], [1]HKUST, Hong Kong, Hong Kong; [2]Columbia University, New York, NY

Promotions are among the most important operational levers for retail platforms to attract customers and improve revenue. For most platforms, since customers first click on a product before making the purchase decision, the platform can choose to display the promotion before or after the click. In this work, we study the impact of promotion display for online retail platforms when customers search. Utilizing a large-scale dataset which contains detailed customer click and purchase information, we estimate a search and purchase model. The estimated model allows us to evaluate different promotion display schemes, propose an easy-to-implement heuristic policy for promotion display, and demonstrate through counterfactual analysis that our heuristic policy can substantially improve the revenue for some product categories.

1 Learning to Persuade on the Fly: Robustness Against Ignorance

You Zu[1,2], Krishnamurthy Iyer[3,2], Haifeng Xu[4,5], [1]University of Minnesota, Minneapolis, MN, [2]UNIVERSITY OF MINNESOTA, Minneapolis, MN, [3]University of Minnesota, Saint Paul, MN, [4]University of Virginia, Charlottesville, VA, [5]University of Virginia, Charlottesville, VA, Contact: zu000002@umn.edu

We consider a repeated persuasion setting where a sender seeks to persuade a stream of myopic receivers to choose the sender's preferred actions by selectively sharing information about a state drawn i.i.d. from an unknown distribution. We study the sender's problem of making persuasive recommendations to achieve low regret against the benchmark where the state distribution is commonly known. We propose a signaling algorithm that is persuasive (whp) across all rounds and achieves $\Omega(\sqrt{T\log T})$ regret, where T is the horizon length. The core philosophy behind the design of our algorithm is to leverage robustness against the ignorance of the state distribution. We prove that no algorithm can achieve regret better than $\Omega(\sqrt{T})$ even if the persuasiveness requirements were significantly relaxed.

2 Costly Signaling with Heterogeneous Outside Options

Itai Ashlagi[1], Faidra Monachou[2], Afshin Nikzad[3], [1]Stanford University, Stanford, CA, [2]Harvard University, Cambridge,

MA, [3]University of Southern California, Palo Alto, CA, Contact: monachou@stanford.edu

We study optimal mechanism design in a continuum model of continuous agent types and discrete object qualities, where a planner maximizes social welfare. Each agent has a type (representing her willingness to pay for quality) and a heterogeneous outside option (independently drawn from her type). Our first result considers publicly observed outside options. We show that the optimal incentive-compatible, individually rational mechanism determines a participation threshold for each outside option; an agent with type below that threshold is assigned to her outside option, while an agent with type above that threshold is offered either a single common object quality or a lottery of consecutive common object qualities, possibly pooled with her outside option. Our second result shows that the same mechanism is also optimal in a setting with downward-private outside options.

3 Optimal Test Design with Limited Commitment

Yingkai Li[1], Boli Xu[2], [1]Yale University, New Haven, CT, [2]Northwestern University, Evanston, IL

We study a model where a worker sequentially interacts with multiple employers. The worker's type is unknown to both the worker and the employers, and the employers can schedule tests for privately learning the worker's type. Upon receiving the signals, the employers can decide whether to give an offer and the worker decides whether to accept. Crucially, although the signals are private information for each employer, all other employers can infer the worker's type through the publicly observed actions. We show that in equilibrium, an employer may strategically reject overqualified workers, or lower the hiring standard to make an offer to unqualified workers, so as to lower the worker's belief about his continuation value upon rejecting the offer. We apply this framework to analyze various aspects of labor markets such as the welfare impact of the privacy on job search history.

4 Online Bayesian Recommendation with No Regret

Yiding Feng[1], Wei Tang[2], Haifeng Xu[3], [1]Microsoft Research, Cambridge, MA, [2]Washington University in St. Louis, St.Louis, MO, [3]University of Virginia, Charlottesville, VA, Contact: w.tang@wustl.edu

We introduce and study the online Bayesian recommendation problem for a platform, who can observe a utility-relevant state of a product, repeatedly interacting with a population of myopic users through an online recommendation mechanism. For each user with her own private preference and belief, the platform commits to a recommendation strategy to utilize his information advantage on the product state to persuade the self-interested user to follow the recommendation. Using the Stackelberg regret as the regret notion, our first result is an online policy that achieves O(loglog T) regret, where T is the number of rounds. This regret on its dependency on T is tight. Finally, by formulating the platform's problem as optimizing a linear program with membership oracle access, we present our second online policy that achieves regret O(poly(m log T)) where m is the number of states.

Session Chair
Boris Hanin, 1</sup

1 Deep Learning Theory at Limits

Cengiz Pehlevan, Harvard SEAS

A strategy for gaining insight into the complexity of deep learning is to study non-trivial yet tractable limits. I will describe our work on three such limits with a focus on results on representation learning and inductive biases.

2 Overparameterization Improves Robustness to Covariate Shift in High Dimensions

Ben Adlam, Google Brain, Cambridge, MA

A significant obstacle in the development of robust machine learning models is *covariate shift*. Despite its prevalence, a theoretical understanding has remained lacking. We examine the exact high-dimensional asymptotics of random feature regression under covariate shift and present a precise characterization of the limiting test error. Our results motivate a natural partial order over covariate shifts that provides a sufficient condition for determining when the shift will harm (or even help) test performance. We find that overparameterized models exhibit enhanced robustness to covariate shift, providing one of the first theoretical explanations. Additionally, our analysis reveals an exact linear relationship between the in-distribution and out-of-distribution generalization performance, offering an explanation for this surprising recent observation.

3 Learning Sparse Functions with Neural Networks

Theodor Misiakiewicz, Stanford

We consider the problem of learning sparse functions (a function that depends on a latent low-dimensional subspace) with two-layer neural networks (NN). This setting is of interest since neural networks routinely tackle high-dimensional datasets and it is still poorly understood when and how SGD-trained NNs can adapt to latent low-dimensional structure without suffering from the curse of dimensionality.
We consider training a 2-layer NN with online SGD in the mean-field scaling. We show that the SGD trajectory can be well approximated for constant time by a dimension independent dynamics, which we call DF-PDE. In particular, if the DF-PDE converges in constant time to zero test error, so does online SGD. We apply this characterization to sparse functions on the hypercube and show that a hierarchical property —the merged-staircase property— is necessary and nearly sufficient for learning in this regime.

4 Transition to Linearity of General Neural Networks with Directed Acyclic Graph Architecture

Libin Zhu, UCSD

We show that feedforward neural networks corresponding to arbitrary directed acyclic graphs undergo transition to linearity as their "width" approaches infinity. The width of these general networks is characterized by the minimum in-degree of their neurons, except for the input and first layers. Our results identify the mathematical structure underlying transition to linearity and generalize a number of recent works aimed at characterizing transition to linearity or constancy of the Neural Tangent Kernel for standard architectures.

1 Pigeonhole Design: Balancing Sequential Experiments from an Online Matching Perspective

Jinglong Zhao[1], Zijie Zhou[2], [1]Boston University, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA

We study an online experimental design problem, the "Online Blocking Problem." In this problem, experimental units with heterogeneous covariate information arrive sequentially and must be immediately assigned into either the control or the treatment group, with an objective of minimizing the total discrepancy, which is defined as the minimum weight perfect matching between the two groups. To solve this problem, we propose an experimental design method, the "Pigeonhole Design." The pigeonhole design first partitions the covariate space into smaller spaces, which we refer to as pigeonholes, and then, when the experimental units arrive at each pigeonhole, balances the number of control and treatment units for each pigeonhole. We show effectiveness of the pigeonhole design by comparing against the match-pair design and the completely randomized design.

2 Active Learning in the Predict-then-optimize Framework

Paul Grigas, UC Berkeley, Berkeley, CA, Contact: pgrigas@berkeley.edu

We develop the first active learning methods in the predict-then-optimize framework. Our active learning methods are the first to be directly informed by the decision error induced by the predicted parameters, which is referred to as the Smart Predict-then-Optimize (SPO) loss, or a tractable surrogate thereof. In particular, we develop two practical active learning algorithms — a margin-based algorithm and an importance weighting algorithm — with theoretical (e.g., generalization) guarantees. Furthermore, we prove bounds on the label complexity, the number of samples whose labels are acquired, and show that these bounds can be better than the naive supervised learning approach that labels all samples under a natural and previously studied low-noise condition. We also demonstrate numerical evidence showing the practical value of our proposed algorithms.

3 Distributionally Robust End-to-end Learning with Side Information

Luhao Zhang[1], Jincheng Yang[2], [1]The University of Texas at Austin, Austin, TX, [2]The University of Chicago, Chicago, IL

We consider data-driven decision-making under uncertainty with side information, in which exogenous covariates data are available to reveal partial information about random problem parameters and thus facilitate better decisions. The decision maker's goal is to find an optimal end-to-end policy that directly outputs a decision for any new context. We propose a distributionally robust formulation based on the causal transport distance, which preserves the conditional information structure of random problem parameters given the value of covariates. We derive a dual reformulation and study its regularization effect. We prove that the infinite-dimensional policy optimization admits a finite-dimensional convex programming equivalent reformulation. This result renders a new class of optimal policy for adjustable robust optimization.

4 **Robust Two-stage Optimization with Covariate Data**

Bart Paul Gerard Van Parys, MIT Sloan School of Management, Cambridge, MA

We consider a generalization of two-stage decision problems in which the second-stage decision may be a function of a predictive signal but can not adapt fully to the realized uncertainty. We will show how such problems can be learned from sample data by considering a family of noise regularized sample average formulations. Furthermore, our regularized data-driven formulations admit convex distributionally robust counterparts which enjoy desirable out-of-sample performance guarantees. Finally, we show that all derived data-driven formulations can be solved efficiently using canonical stochastic gradient algorithms.

Misinformation and Platform Design

General Session

Session Chair

Z. Jessie Liu, Johns Hopkins

1 **Prevalence and Propagation of Fake News**

Banafsheh Behzad[1], Susan E. Martonosi[2], [1]California State University, Long Beach, Long Beach, CA, [2]Harvey Mudd College, Claremont, CA, Contact: banafsheh.behzad@csulb.edu

In recent years, scholars have raised concerns on the effects that unreliable news, or "fake news," has on our political sphere, and our democracy as a whole. For example, the propagation of fake news on social media is widely believed to have influenced the outcome of national elections, including the 2016 U.S. Presidential Election, and the 2020 COVID-19 pandemic. What drives the propagation of fake news on an individual and the network levels, and which interventions could effectively reduce the propagation rate? Our model disentangles bias from truthfulness of an article and examines the relationship between these two parameters and a reader's own beliefs.

2 **People are More Likely to Believe and Share Fake News on Smartphones (vs. PCs)**

Z. Jessie Liu[1], Minzhe Xu[2], Yang Yang[3], [1]Johns Hopkins University, Baltimore, MD, [2]Iowa State University, Ames, IA, [3]University of Florida, Gainesville, FL, Contact: jzliu@jhu.edu

Are smartphone users, compared with PC (desktop or laptop) users, more or less likely to believe and share fake (but not true) news, and why? This project explored this question by analyzing a dataset that includes 97,765 Twitter replies to 5,802 source tweets. Our data analysis showed a significant and positive smartphone effect on one's receptivity to misinformation. We further tested possible mechanisms in two lab experiments, which revealed that this device effect is driven by smartphone users' lack of deliberation, but *not* due to the difference in screen size or individual traits (such as age or education) associated with using smartphones vs. PCs. Instead, we showed that the lack of deliberation is a result of environmental distractions brought about by the portability of smartphones.

3 **Debunking Misinformation in Advertising**

Jessica Fong, University of Michigan, MI

We study the efficacy of debunking messages in reducing the impact of misinformation on purchase behavior, and whether such messages correct consumers' misinformed beliefs - an ideal outcome from a policy-maker's perspective - or merely reinforce correct beliefs, as predicted by biased Bayesian updating. We implement a conjoint experiment that measures willingness-to-pay under exposure to real-world misinformation and debunking messages. Focusing on three product categories where misinformation is prevalent, we find that debunking can repair the decrease in willingness-to-pay caused by misinformation by correcting misinformed beliefs. We discuss incentives for firms to debunk or introduce products that conform to misinformation.

4 **Fake Sales and Ranking Algorithms in Online Retail Marketplace with Sponsored Advertising**

Fei Long[1], Yunchuan Liu[2], [1]The University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of Illinois, Champaign, IL, Contact: Fei_Long@kenan-flagler.unc.edu

We study the optimal algorithm decisions of a platform on ranking products sold by sellers--who may use fake sales to boost the rankings of their products--and the impact on consumers and sellers. We design a model of an online retail marketplace with competing sellers. The platform decides whether to tolerate fake sales and whether to rank its organic results based on sellers' qualities or popularities. The sellers decide whether to buy fake sales and how much to bid for sponsored advertising on the platform. We show a platform may strategically tolerate or even encourage popularity-boosting fake sales by a seller when the seller's quality level is extreme relative to competitors. Furthermore, fake sales may benefit consumers by increasing price competition and may also benefit competing sellers by reducing the high-quality seller's dominance.

Sustainable Collaborative Service Systems

General Session

Session Chair

Sina Shokoohyar, Stillman School of Business - Seton Hall University, South Orange, NJ

Session Chair

Vahid Ghomi, Penn State Mont Alto, Highspire, PA

1 Improving Supply Chain Resilience Through Investment in Flexibility and Innovation

Vahid Ghomi[1], Vahid Nooraei[2], Sina Shokoohyar[3], Mansoor Shekarian[4], Mahour Parast[4], Farnaz Ghazi Nezami[5], [1]Penn State Mont Alto, Waynesboro, PA, [2]North Carolina Agriculture and Technical State University, Waynesboro, PA, [3]Stillman School of Business, Seton Hall University, South Orange, NJ, [4]North Carolina A&T State University, Greensboro, NC, [5]Kettering University, Flint, MI

We examine how organizations improve resilience and their response to SC disruptions through investment in flexibility and innovation. There are several approaches and conceptualizations of flexibility and innovation in the literature. Nevertheless, how flexibility and innovation can enhance an organizational response to disruptions has not received much attention. We extend the research in SC resilience by investigating the relationships between flexibility, innovation, and resilience under disruption risk. The findings show that innovation and flexibility have a positive impact on resilience. By developing a novel multi-objective mixed-integer linear programming, the findings reveal that disruption risks affect resilience and firms' ROI, so investing in improvements in flexibility and innovation decreases the impact of disruptions.

2 A Systematic Quantitative Review of Sustainable Transportation Case Studies

Sina Shokoohyar[1], Amirsalar Jafari Gorizi[2], Vahid Ghomi[3], Weimin Liang[4], Hak J. Kim[5], [1]Stillman School of Business, Seton Hall University, South Orange, NJ, [2]American University, Washington, D.C., DC, [3]Penn State Mont Alto, Highspire, PA, [4]Saint Joseph's University - Erivan K. Haub School of BusinessSaint Joseph's University - Erivan K. Haub School of Business, Philadelphia, PA, [5]Hofstra University, Hempstead, NY, Contact: aj2917a@student.american.edu

Following the COVID-19 epidemic and a slew of new climate change supply chain disruptions, a holistic approach to sustainable transportation is required. This study looked at 358 case studies and divided them into twenty categories based on the mode of transportation and eleven categories based on the authors' principal concerns. Keyword analysis and topic modeling revealed three distinct tendencies in the cohort. The findings were divided into four categories: in-vehicle improvements, built-environment elements, human factors, and planning and regulations, with a corroborating look at the benefits of the United States' infrastructure bill.

3 Shared Mobility in Post-COVID Era: New Challenges and Opportunities

Sajjad Shokouhyar[1], Sina Shokoohyar[2], Anae Sobhani[3], Amirsalar Jafari Gorizi[4], [1]Shahid Beheshti University, Tehran, Iran, Islamic Republic of; [2]Seton Hall University, South Orange, NJ, [3]University of Hartford, West Hartford, CT, [4]American University, Washington, DC

4 Economic and Environmental Evaluation for Production System Design in Controlled Environment Agriculture

Guiping Hu, Saiara Samira Sajid, Iowa State University, Ames, IA

The world population is anticipated to reach 9.7 billion by 2050 and to meet the growing food demand, controlled environment agriculture has evolved as a paradigm shift in agriculture. Significant advancement has been made in the design and production of controlled environment agriculture in the past few decades. It should be noted that currently opportunities and obstacles co-exist with the design and management of vertical farming. Some key benefits of vertical farming are improved crop yields, protection from extreme weather conditions, water savings, and efficient use of lands. On the contrary, high labor and fixed cost, immature technology, and high energy consumption are among the challenges yet to be addressed. Thorough evaluation of the economic and environmental performance of the production system is of paramount importance. Analyses are designed such as carbon footprint, energy consumption, net present cost (NPC) with the Levelized cost of energy (LCOE), and analysis of demand-supply to guide the evaluation and decision making in system design for the controlled environment agriculture.

5 Consumer Preference Towards the Green Services in the Electronics Industry: A Social Media Approach

Sanaz Ghorbanloo[1], Sajjad Shokouhyar[1], Sina Shokoohyar[2], [1]Shahid Beheshti University, Tehran, Iran, Islamic Republic of; [2]Seton Hall University, South Orange, NJ, Contact: sina.shokoohyar@shu.edu

Green services, also known as environmentally friendly services, have become a key driver for many consumers in the electronics industry. In recent years, consumers have often considered the company's environmental footprint before purchasing products and services. Hence, this study looks at the consumer sentiment around sustainability in the environment and how that impacts consumers' preference toward sustainable services. The research method of this paper follows a quantitative and qualitative content analysis using sentiment analysis techniques that provided a lexicon-based approach based on Twitter data. The study data showed that "raw materials", "energy consumption", "waste management", "eco-packaging", "use of recycled plastic", "manage greenhouse gases", and "carbon emission" is the most significant priority of consumers.

Digital Finance and Technology

General Session

Session Chair

Agostino Capponi, Columbia University, New York, NY

1 Speedex: A Scalable, Parallelizable, and Economically Efficient Distributed Exchange

Geoffrey Ramseyer, Stanford University, Stanford, CA, Contact: geoff.ramseyer@cs.stanford.edu

SPEEDEX is adecentralized exchange (DEX) that lets participants securely trade assetswithout giving any party undue control. SPEEDEX offers several advantages overprior DEXes. It achieves high throughput—over 200,000 transactions per secondon 48-core servers, even with tens of millions of open offers. SPEEDEX runsentirely within a Layer-1 blockchain. It eliminates internal arbitrageopportunities and eliminates some common types of front-running attacks. Itskey design insight is its use of an Arrow-Debreu exchange market structure thatfixes the valuation of assets in a given block of transactions. This designfurthermore makes trade operations commutative and hence efficientlyparallelizable. SPEEDEX is scheduled for deployment in one of the largest Layer-1 blockchains.

2 The Evolution of Blockchain: From Public to Private Mempool

RUIZHE JIA[1], Agostino Capponi[1], Ye Wang[2], [1]Columbia University, New York, NY, [2]ETH Zurich, Zurich, Switzerland. Contact: RJ2536@COLUMBIA.EDU

We study the economic incentives behind the adoption of private pools. Validators may choose to not monitor private pools to preserve rents extracted from arbitrageurs, hence creating execution risk for users. Private pools neither eliminate frontrunning risk nor reduce transaction fees. The welfare of validators increases, but the welfare of arbitrageurs goes down. A private pool leads to higher aggregate welfare compared to a public pool only blockchain. Empirically, we find that Flashbots private pools increase arbitrageurs' cost-to-revenue ratio by a third.

3 Proof-of-Work Cryptocurrencies: Does Mining Technology Undermine Decentralization?

Sveinn Olafsson, Stevens Institute of Technology, Hoboken, NJ

Does the proof-of-work protocol serve its intended purpose of supporting decentralized cryptocurrency mining? To address this question, we develop a game-theoretical model where miners first invest in hardware to improve the efficiency of their operations, and then compete for mining rewards in a rent-seeking game. We argue that because of hardware constraints faced by miners, centralization in mining is lower than indicated by both public discourse and recent academic work, and that centralization is countercyclical with respect to mining reward. Furthermore, our results highlight that advancements in hardware efficiency do not necessarily lead to larger miners increasing their advantage, but may rather allow smaller miners to expand and new miners to enter. We show that our model predictions are consistent with a detailed empirical analysis of the Bitcoin network.

4 Differential Liquidity Provision in Uniswap V3 and Implications for Contract Design

Francisco Marmolejo Cossío, Harvard University, Cambridge, MA, Contact: fjmarmol@seas.harvard.edu

Decentralized exchanges (DEXs) facilitate trading assets on-chain without the need of a trusted third party. Amongst these, constant function market maker DEXs such as Uniswap handle the most volume of trades between ERC-20 tokens. In Uniswap v3, liquidity providers (LPs) are given the option to differentially allocate liquidity to be used for trades that occur within specific price intervals. We formalize the profit and loss that LPs can earn in simplified trade dynamics and are able to compute optimal liquidity allocations for liquidity providers who hold fixed price trajectory beliefs. We use this tool to shed light on the design question regarding how v3 contracts should partition price space for permissible liquidity allocations. Our results suggest that a richer space of potential partitions can simultaneously benefit both LPs and traders.

Decarbonization in the Water Sector

General Session

Session Chair

Christian Hernandez-Negron, 1</sup

Session Chair

Erin Baker, 1</sup

1 Assessment of the Impact of Farm-scale Renewables on the Carbon Footprint of Center-pivot Irrigation

Nyarko Nanaadom, Western New England University, mmm, AZ

Small Town and Rural (STAR) communities in the United States depend heavily on center-pivot irrigation, which is supplied primarily by grid-connected or diesel-powered pumps. The purpose of this research is to understand how farm-scale renewables can reduce the carbon footprint of center-pivot irrigation. The Global Change Analysis model (GCAM) is used to model the outcome of how much greenhouse gas emissions could be saved if center-pivot irrigation were powered with farm-scale renewables, including green ammonia technologies.

2 Decarbonizing the Water Sector - What Can We Learn from the Energy Sector?

Aaron J. Simon[1], Seth Snyder[2], [1]Carbon Direct, New York, NY, [2]Northwestern University, Chicago, IL

Decarbonizing water and wastewater treatment is an enormous challenge, and also an engineering opportunity. The water sector will benefit from decarbonization of the energy sector because water treatment requires energy and because the water sector can learn from the energy sector's experience. In this talk, we explore the nexus between water and energy, the coupled challenges of decarbonizing both, the differences in scale between water, energy and carbon flows, and case studies from the energy sector. We place decarbonization strategies into a consistent framework that spans sectors.

3 Optimal Management of Food, Energy and Water System in the Presence of Uncertainties

Tianye Wang, George Washington University, Washington, DC, Contact: twang87@email.gwu.edu

This research examines the impact of uncertainties in water supply and the demand for electricity on the nexus of food, energy and water systems (FEWS). Specifically, we develop a suite of optimization models that consider the FEWS as a spatially distributed multi-agent system (MAS) of cities, hydropower plants, irrigation areas, and the policymaker. The uncertainties are addressed using scenarios in a two-stage stochastic process. The methodology is applied to a stylized representation of the Columbia River Basin (CRB) to test its effectiveness particularly in the prescription of the optimal agent responses in the system and to inform policymaking.

Faster Algorithms for Steiner Tree and Related Problems: From Theory to Practice

Daniel Rehfeldt, Technische Universität Berlin, Berlin,

Germany.
The Steiner tree problem in graphs (SPG) is a classic NP-hard problem. This thesis advances the state of the art in solving SPG and well-known relatives, often found in real-world applications. Based on new theoretical results (e.g., polyhedral descriptions and complexity), the thesis introduces an exact solver for SPG and 14 related problems. The solver is on each of the 15 problem classes significantly faster than previous solvers. The solver is available with source code for academic use (https://scipjack.zib.de/) and is used in industry, for example for the planning of fiber-optic networks.

Causal Inference for Social and Engineering Systems

Anish Agarwal, Massachusetts Institute of Technology, Newton, MA
What will happen to Y if we do A? A variety of meaningful questions can be formulated this way: What if a patient is given a new therapy? What if data center operator introduces a new congestion control protocol? We explore answering such counterfactual questions using observational data and/or very limited experimental data. Two key challenges are: (i) counterfactual prediction in the presence of latent confounders; (ii) estimation with modern datasets which are high-dimensional, noisy, and sparse. The main framework we introduce is connecting causal inference with tensor completion with missing not at random data. The efficacy of our framework is shown on high-impact real-world applications.

Data-Driven Operations in Changing Environments

Ruihao Zhu, Massachusetts Institute of Technology, Cambridge, MA
Recent advances in data science technologies have enabled big-data analytics for operations management problems. Currently, most existing works in this field critically assume the operational environments remain unchanged throughout. However, real-world operational environments are often time-varying and dynamically evolving. In this thesis, we study three different scenarios of operations management in changing environments.

Learning and Earning Under Noise and Uncertainty

Su Jia, CMU, Pittsburgh, PA
Sequential decision-making under uncertainty is central to a range of operations and marketing problems. In the face of an unknown environment, the decision-maker needs to strike a balance between learning the known environment (“learning”) and selecting nearly optimal decisions (“earning”). The trade-off between learning and optimization can be modelled as the Multi-Armed Bandits (MAB) problem, which has attracted significant attention from a range of communities in recent years, including machine learning, operations research and marketing. While most of the fundamental problems in this area have been theoretically well-understood, these algorithms have been rarely deployed in practice. In contrast, while marketing research on sequential decision-making has been focused on the practical side, their results are usually empirical and lacking of rigorous analysis. This thesis serves as a preliminary step towards filling this gap. We will consider practical sequential decision-making problems arising from some of the most fundamental marketing areas including survey design, pricing and content recommendation, and provide theoretical insights via provable performance guarantees

Managing Innovation, Collaboration, and User Behavior: Insights from Behavioral Operations

General Session

Session Chair

Maria R. Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL

1 How Mobile App Updates Affect User Engagement: Empirical Evidence from Mobile App Releases

Alejandro Hernandez De la Lanza, Maria R. Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL, Contact: alejandro.lanza@kellogg.northwestern.edu
We investigate how to schedule app updates to enhance user engagement, the key driver of app success.

2 Collaboration in Sequential Projects

Ruth Beer[1], Anyan Qi[2], Ignacio Rios[2], [1]Baruch College, CUNY, New York, NY, [2]The University of Texas at Dallas, Richardson, TX, Contact: ruth.beer@baruch.cuny.edu
We explore the decisions of two workers choosing between exerting effort towards a collaborative joint project where their respective tasks need to be completed sequentially, or an outside option. The optimal policy prescribes that when the incentive to finish early is high enough, both workers forgo the outside option and finish the project as early

as possible. On the other hand, a behavioral experiment shows that completing the project takes 60% longer than prescribed by the optimal policy. We analyze the behavioral drivers of this result, and we propose mechanisms to "nudge" workers' behavior.

3 Computer Vision to Measure Product Design Visual Similarity

Egbert Amoncio[1], Tian Chan[2], Cornelia Storz[3], [1]Goethe University Frankfurt, Frankfurt, Germany; [2]Emory University's Goizueta Business School, Atlanta, GA, [3]Goethe University Frankfurt, Frankfurt, Germany. Contact: amoncio.egbert@its.uni-frankfurt.de

Computer vision (CV) enables computers to "see" and "understand" images. We propose that the Structural Similarity Index Measure (SSIM) can be used to quantify the visual similarity across product designs. To test this idea, we first apply SSIM to measure the visual similarity of pairs of designs over a corpus of 400,000 U.S. design patent images granted from 1976 to 2020. We then validate the measure with a validation survey involving 382 online observers. Finally, using the validated similarity measure, we show new and rigorous evidence that aesthetic knowledge spillovers are geographically localized. We discuss how the ability to leverage CV to measure similarity over images opens new avenues of research, and we provide open access to the code and data.

4 The Impact of AI Monitoring on Service Consumption: A Theoretical and Empirical Analysis

Zhaohui (Zoey) Jiang[1], Yao Cui[2], [1]Tepper School of Business, Carnegie Mellon University, Pittsburgh, PA, [2]Cornell University, Ithaca, NY, Contact: zhaohuij@andrew.cmu.edu

With recent technological advancement, many companies introduce AI as a part of their service, e.g., using AI devices to guide consumer behaviors. In this paper, we study the impact of such AI monitoring on consumer service usage. We develop a game-theoretic model featuring the heterogeneous impact of AI monitoring on consumers with different skill levels. We partner with an international car sharing company and design a randomized field experiment to empirically test hypotheses generated from the model. We show theoretically and verify empirically that consumers with either low or high skill levels (as opposed to a medium skill level) benefit more from AI monitoring. We further leverage these findings to provide policy recommendations to companies that are introducing such AI monitoring devices.

5 The Distributional Impact of Fatigue on Performance

Hessam Bavafa[1], Jonas Oddur Jonasson[2], [1]Wisconsin School of Business, Madison, WI, [2]MIT Sloan School of Management, Somerville, MA

Little is known about how people-centric factors affect the shape of service time distributions, despite distributional statistics (variance or quantiles) being key drivers of system performance in many service industries. We investigate, empirically, the impact of within-shift worker fatigue on the average, variance, and quantiles of service times. We find that the average service time increases by 5% throughout the course of an average shift. Furthermore, the workers become less consistent with fatigue; service time variance increases by 39% during a normal shift. In addition to an upward shift in mean service times, both the upper and lower tails of the distribution have more weight for fatigued workers.

The Offline Socio-economic Impacts of Online Interventions

General Session

Session Chair

Yash Babar, University of Wisconsin-Madison, Madison, WI

1 The Impact of E-scooters on Retail Visits: Empirical Analysis Using Graph Neural Networks

Ruichun Liu, Unnati Narang, UIUC, Champaign, IL, Contact: narang.unnati@gmail.com

Shared micromobility services have expanded rapidly in recent years. Within micromobility, electric scooters (e-scooters) account for 63% of the trips. However, not much is known about the effects of e-scooters. This research examines the effects of e-scooters on visits to retailers. The results from a difference-in-differences analysis show that e-scooters significantly increase visits to restaurants. We also find a stronger effect for previously less visited restaurants and non-chain restaurants, suggesting that e-scooters facilitate the discovery of less known restaurants by consumers. To analyze the mechanisms, we use spectral convolutional graph neural networks. E-scooter trips to restaurants are shorter and slower than other trips (e.g., grocery), suggesting that use of e-scooters for leisure and restaurant discovery could explain our results.

2 The Impact of Early Digital Movie Releases on Box Office Revenue: Evidence from the Korean Market

Yangfan Liang[1], Gordon Burtch[2], Daegon Cho[3], Michael D. Smith[4], [1]Pittsburgh, PA, [2]Boston University, Boston, MA, [3]KAIST, Seoul, Korea, Republic of; [4]Carnegie Mellon University, Pittsburgh, PA

Most movies in the United States are first released exclusively via theaters for 2-3 months. These lengthy theatrical exclusivity windows have come under pressure with the rise of digital distribution channels, sparking debate between movie studios and theater owners about the possible impact of shortened exclusivity windows on box-office revenue and overall movie profitability. Our work informs this debate by examining early home digital release that have taken place in the South Korean movie market. By utilizing a triple differences design, we observe a statistically and economically insignificant decline in theatrical revenue from early home release, equivalent to a ~0.8% drop in the first eight weeks' theatrical revenue. We also estimate that early home release increases the marginal profit to studios over the first eight weeks of movie release by ~12%.

3 Entry of Online Grocery Delivery Services in the U.S. and Widening of the Nutritional Inequalities

Hyeonsik Shin, Taha Havakhor, Min-Seok Pang, Temple University, Philadelphia, PA, Contact: hshin@temple.edu

This paper examines the effect of third-party online grocery delivery services (OGDS) on the obesity rate. By exploiting the nationwide quasi-experimental setting of Instacart's staggered entries at the US county-level in 2004-2017, we find that the entry of Instacart lowers the obesity rate by 0.64 percentage points and, however, that this impact becomes greater for the high-income counties. Further analyses show that the Instacart entry leads to large grocery stores more concentrated in few zip-codes, widening nutritional inequality gaps between the wealthy and the poor. This study contributes to the information systems (IS) literature by providing robust empirical evidence that points to the role of digital platforms in exacerbating societal inequalities. Policy implications such as lowering barriers to use of OGDS for the low-income population are discussed.

4 E-Access versus Physical Access: An Analysis of the Rural Health Care Program

Eric Xu, University of Minnesota, Minneapolis, MN

While our current conception of telemedicine has existed for half a century, beginning with the Space Technology Applied to Rural Papago Advanced Health Care (STARPAHC), only recent telecommunication advancements have increased the pace of adoption amongst patients and practitioners. Therefore, we examine the impact of telemedicine adoption on primary care use, specifically examining the conditions by which telehealth consultations become a substitute for in-person care or a compliment to in-person care. Using a unique dataset of insurance claims for primary care visits, we examine in-person, asynchronous, and synchronous primary care visits.

JWM - Room 201

The Frontier of Collaborative Design

General Session

Session Chair

Alison Olechowski, University of Toronto, Toronto, ON, Canada.

1 Model-robust Experimentation Strategy for Estimation of Expensive Black-box Functions with Mixed Quantitative and Qualitative Factors

Gautham Sunder[1], Christopher Nachtsheim[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: sunde153@umn.edu

Design of experiments is an indispensable tool during product development for characterizing the relationship between product features and key product quality metrics and for identifying the optimal product configuration. The model-robust experimentation strategy proposed in this study was inspired by our collaboration with a large medical device manufacturer on hyperparameter tuning of deep neural networks while developing an automated quality inspection system. The proposed adaptive experimentation strategy is a hybrid between Response Surface Optimization (RSO) and Bayesian Optimization (BO) methods. Our simulation study illustrates that the proposed experimentation strategy is more efficient than BO methods for estimating a locally second-order black-box function and has comparable performance to BO methods when the black-box function is nonlinear.

2 Analysis of Communication Patterns in Engineering Product Design Via Enterprise Social Networks

Alison Olechowski, University of Toronto, Toronto, ON, Canada.

Enterprise social network messaging sites are becoming increasingly popular for team communication in engineering and product design. These digital communication platforms capture detailed messages between members of the design team and are an appealing data set for researchers who seek to better understand communication in design. This exploratory study investigates whether we can use enterprise social network messages to model communication patterns throughout the product design process. We apply a variety of Natural Language Processing techniques to a data set comprising of 250,000 messages sent by 32 teams enrolled in a 3-month intensive product design course. Our study delivers implications for engineering idea convergence and divergence, effective team communication, and development of shared understanding.

3 Data-driven design: Managing Beyond the Hype

Julie Johnson, University of Waterloo, Waterdown, ON, Canada.

Recent literature on data-driven design describes how big data and machine learning algorithms are dramatically changing design as well as the organizations in which design is practiced. Despite this promise, there is still much that we don't know about how new data-driven design processes are evolved and adopted by design teams and organizations. The goal of this research is to discover how design management should adapt to this paradigm shift. We provide a survey of research to date, identify its limitations, and identify opportunities for future investigation.

4 Technology Affordances and Collaborative, Cloud-based Cad

Tucker Marion[1], Alison Olechowski[2], Satish Nambisan[3], [1]Northeastern University, Boston, MA, [2]University of Toronto, Toronto, ON, Canada; [3]Case Western Reserve University, leveland, OH, Contact: t.marion@neu.edu

Modern CAD platforms enable synchronicity, where actions move at the same rate, and exactly together. For those studies evaluating specific CAD tools, little research has focused on synchronicity, collaboration and cloud characteristics. Recent research has begun to use a technology affordance lens to examine innovation and knowledge creation in large-scale collaboration networks. Technology affordances are relational and denote action possibilities offered by a set of technology features to meet the goals of an individual, group or organization. The aim of our research is to develop a conceptual framework for mid-level affordances of cloud-based CAD that links specific engineering challenges within knowledge-based theory on collaborative networks.

Session Chair

Yicheng Song, University of Minnesota, Minneapolis, MN

1 Frequency-biased Diffusion: Disproportionate Reception of Rare Categories of Events in Social Networks

Alice Jayoung Jang, Virginia Tech, Blacksburg, VA, Contact: ajjang@vt.edu

The quality of information that diffuses in social networks is a current concern. While the previous research has focused on the lack of accuracy of information in social networks, we focus on another dimension of quality, namely, representativeness of overall mix of information that diffuses in social networks. We conducted randomized online laboratory experiments of information diffusion with multi-step social networks. We find that the further someone is down a diffusion chain, the more the mix of information that they receive is biased toward rarer categories of events. We name the disproportionate exposure to rarer categories of events "frequency-biased diffusion". We also show that this systematic bias risks de-emphasizing the importance of empirically common categories of events and over-emphasizing the importance of empirically rare categories of events.

2 Emojis Predict Dropouts of Remote Workers: An Empirical Study of Emoji Usage on Github

Xuan Lu[1], Wei Ai[2], Zhenpeng Chen[3], Yanbin Cao[3], Qiaozhu Mei[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Maryland, Ann Arbor, MI, [3]Peking University, Beijing, China. Contact: luxuan@umich.edu

Emotions at work have long been identified as critical signals of work motivations, status, and attitudes, and as predictors of various work-related outcomes. When more and more employees work remotely, these emotional signals of workers become harder to observe through daily, face-to-face communications. The use of online platforms to communicate and collaborate at work provides an alternative channel to monitor the emotions of workers. This paper studies how emojis, as non-verbal cues in online communications, can be used for such purposes and how the emotional signals in emoji usage can be used to predict future behavior of workers.

3 A Concept-based Hierarchical Method for Cross-document Modeling and Predictions

Yu Qin, Paul J. Hu, Olivia R. L. Sheng, University of Utah, Salt Lake City, UT, Contact: yu.qin@eccles.utah.edu

The rapidly proliferated information technology has fueled the creation of voluminous and often fragmented information that is essential to various business purposes. Although abundant, such information is difficult to use and interpret, due to several limitations of existing analytics methods. Toward that end, cross-document modeling is crucial. It leverages natural language processing to extract essential information and identify nonobvious relationships from textual documents. In this study, we propose a two-stage concept-based hierarchical deep learning method to extract and model important concept information from relevant but fragmented source documents, which enables downstream predictive analytics for business applications. We use a financial scenario to illustrate the value and use of our method, in comparison with several benchmark methods.

4 Understanding Instructor Performance in Digital Education with a Hierarchical Bert Model

Wen Wang, Carnegie Mellon University, Fornebu

With the development of technology, online education has been growing rapidly over the past decade. Despite its economic and societal importance, there is little empirical research that assists in understanding instructor performance in digital education. In our paper, we conduct a systematic study to evaluate instructors' online teaching style and their instructional materials using a unique dataset that consists of 1,085 online courses collected from Coursera. Our results show that instructors' verbal cues and their course structure design are both significantly associated with instructors' performance evaluation. We then propose a hierarchical BERT model to predict instructors' performance in digital education. Our proposed model captures the hierarchical structure within each course as well as the deep semantic features extracted from the course content.

Supply Chain Optimization at Amazon

General Session

Session Chair

Chun Ye, Amazon.com

1 A Practical Approach to Model the Impact of Origin and Destination Flows Variability in a Logistics Network

Julie Poullet[1], Jochen Koenemann[2], Cristiana L. Lara[1], [1]Amazon, Seattle, WA, [2]University of Waterloo, Waterloo, ON, Canada. Contact: jpoullet@amazon.com

Supply chain networks of e-commerce retailers are subject to high variability. This variability is both inherent to their business, such as demand volume driven by customers, and a result of actual operations, such as fulfillment decisions driven by capacity awareness and inventory availability. Such variability negatively impacts costs, as most resources are scheduled weeks in advance. Specifically, it creates large linehaul cost headwinds for the middle mile network: variability in lane volume leads to expensive last-minute truck adhocs and cancellations. We develop a practical approach to incorporate Amazon fulfillment variability to strategical planning decisions. We propose a methodology to study how such variability impacts different network designs and derive insights for designing more resilient networks with respect to operational variability.

2 Tenet Based Network Design

Yuan Li[1], Xiaoyan Si[1], Shahbaaz Mubeen[1], Yijiang Li[2], [1]Amazon, Seattle, WA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: yyuanli@amazon.com

Amazon's growing outbound networks came with exponentially increasing complexities and challenges for both operations and plannings. To continue offering superior customer experience at the best speed, selections, and prices, we need to break the complexity spirals. To do so we investigate several network connection tenets that impose more structures to the network. We illustrate trade-offs considered in practice, evaluated through optimizations/simulations.

3 A Base Cost Distribution Model to Control Towards Source to Sink Target Flow Ratios

Qi Chen, Amazon, Bellevue, WA

We present a probabilistic model for controlling aggregate target flow ratios from a set of sources to a set of sinks, through the application of offset costs to influence a higher-granularity discrete decision oracle operating on individual flow packets. We evaluate model performance against varying levels of orthogonality in net background control influences to the decision oracle. We also describe a coupled lower level corrector to close the control gap.

4 **Dimension Reduction and Inference in Strategic Planning Through ML**
Zhikun Gao[1], Chun Ye[2], [1]Amazon, Seattle, WA, [2]Amazon.com, Seattle, WA
In planning a delivery network, finer network design assumptions would lead to better accuracy of cost and utilization metrics estimation. However, at early stage, the granularity of assumption is coarse. Thus, it requires us to estimate the key business metrics (e.g. cost and speed) of a network only from its high-level design assumptions. We propose a ML model to identify impactful drivers to key business metrics and use them to construct a consolidated network, which abstracts away lower-level details. This method reduces the complexity of planning a network, meanwhile estimates the key metrics at a suitable degree of accuracy. As a result, the key metrics can be evaluated directly from early planning stage to provide directional guidance for detailed builds plan.

Life as a PhD Student
Panel Session

Session Chair
Sofia Perez-Guzman, Rensselaer Polytechnic Institute, Troy, NY

1 **Moderator**
Sofia Perez-Guzman, Rensselaer Polytechnic Institute, Troy, NY
Deciding to start a Ph.D. is not an easy task. Yet, many of us decide to trust our abilities and knowledge to take that step and enroll in the program of interest. While everyone's path is unique, for the most part, life as a Ph.D. student is challenging and requires hard work, sacrifice, and perseverance. It makes one wonder why to pursue this path? How to overcome the challenges faced during these years? Is it worth the sacrifice? This panel is intended to cover all these questions about life as a Ph.D. student, hearing opinions from current and former Ph.D. students.

2 **Panelist**
Milan Preet Kaur, Rensselaer Polytechnic Institute, Troy, NY

3 **Panelist**
John Ayaburi, Colorado School of Mines, Golden, CO

4 **Panelist**

Planning for Sustainable Energy
Contributed Session

Session Chair
An Pham, University of Michigan/Center for Sustainable Systems, Ann Arbor, MI

1 **Designing Sustainability Transitions Towards a Net-zero Emissions and Circular Future**
Vyom Thakker, Bhavik R. Bakshi, The Ohio State University, Columbus, OH, Contact: thakker.8@osu.edu
Industry and governments are pledging to achieve sustainability and circularity targets to mitigate climate change by as early as 2030. However, recent reports suggest that most of these institutions are unable to make solid action plans for achieving these targets. This is partly due to the oversight of potential innovations, emerging technologies and policy interventions. The objective of this work is to perform planning optimization to obtain eco-innovation roadmaps to meet sustainability targets, while minimizing investment costs and carbon budget utilization. The constraints account for long term planning, evolution of eco-innovation readiness of adoption, and changing background emissions over the time horizon. The framework generates a 'gantt chart' to describe an optimal investment strategy, for innovations in the plastic packaging industry.

2 **Achieving Power Sector Carbon Neutrality in a Low-cost Renewable Era**
Gang He, Stony Brook University, Stony Brook, NY

Clean power transition is at the center to achieve mid-century carbon neutrality goals. The cost of solar and wind has plummeted in the past decade, and solar and wind electricity has been achieving grid parity. Low-cost renewables offer new perspectives for energy system decarbonization that was less visioned before. In this talk, Dr. He will discuss the pathways of clean power transition and their system impacts using high-resolution models, to reflect the need for integrating variable renewable energy and phasing out coal to achieve carbon neutrality in the power sector at a low-cost renewables era.

3 The Value of Advanced Planning for a Negative Emissions Power System

An Pham[1], Michael Craig[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: anph@umich.edu

Few studies examine the impact of planning for negative emission systems (NES) to achieve aggressive mitigation pathways under different timelines. We fill this critical gap by quantifying power system consequences of planning for NES at two different points along decarbonization pathways - beginning in 2020 and in 2050. We use an optimization-based capacity expansion model applied to the Eastern Interconnection (EI) and Electric Reliability Council of Texas (ERCOT). We show that planning for NES in 2020 lowers annual cost by $14 billion or 2% ($2 billion or 2%) in EI (ERCOT) compared to planning for NES in 2050. The value of planning for NES early increases when technological constraints are more stringent. Our results suggest planning for NES in 2020 compared to 2050 yields little cost saving, indicating that utilities should continue planning for net-zero systems by 2050.

JWM - Room 206

Simulation Optimization and Output Analysis

General Session

Session Chair

David J. Eckman, Texas A&M University, College Station, TX

1 On Constructing Confidence Sets for Multi-objective Stochastic Optimization

Susan R. Hunter[1], Raghu Pasupathy[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN

We consider the context of multi-objective stochastic optimization; that is, multi-objective optimization when the objective functions can only be observed with stochastic error in presence of a dataset of size n. We seek frequentist, asymptotically valid in n, (1-alpha) confidence sets on the efficient set (in the decision space) and the Pareto set (in the objective space). Toward this end, we discuss the construction of an appropriate Central Limit Theorem (CLT) in infinite dimensions, as well as its translation into a finite-dimensional object that can be computed.

2 Finding a Portfolio of Best Systems for Subjective Constraints

Yuwei Zhou[1], Sigrun Andradottir[2], Seong-Hee Kim[2], [1]University of Chicago, Chicago, IL, [2]ISyE Georgia Tech, Atlanta, GA, Contact: Yuwei.Zhou@chicagobooth.edu

We consider the problem of finding a portfolio of systems with the best primary performance measure among finitely many simulated systems as stochastic constraints on secondary performance measures are relaxed. By finding the best systems under a variety of constraint thresholds, the decision maker can identify a robust solution with respect to the constraints or consider the trade-off between the primary performance measure and the level of feasibility of the secondary performance measures. Given that there is no change in the underlying simulated systems, we propose an indifference-zone procedure that recycles simulation observations. We prove that the proposed procedure identifies the portfolio of the best systems with at least a pre-specified probability and show that it saves observations compared with repeatedly applying existing procedures.

3 Simulation Optimization with Censored Streaming Data

Roberto Szechtman, Naval Postgraduate School, Monterey, CA

We consider online optimization of physical systems with censored information. As realizations of the system materialize, the information gathered to-date is used to optimize the system's execution. The information available is incomplete in two ways: (i) the system's parameters are initially unknown, but can be estimated from physical realizations; and (ii), the system's inputs may be censored. We motivate this framework with a variety of examples, and establish convergence results for policies that take advantage of uncensored estimators.

4 Confidence Bands for Shape-Constrained Performance Measures of Simulation Models

David J. Eckman[1], Matthew Plumlee[2], Barry L. Nelson[2], [1]Texas A&M University, College Station, TX, [2]Northwestern

University, Evanston, IL, Contact: eckman@tamu.edu

Many grey-box simulation models give rise to performance measures possessing known functional properties, such as monotonicity, Lipschitz continuity, or convexity. We introduce a framework that accommodates and exploits such forms of functional information to infer the performances of unsimulated solutions. In particular, we use mathematical programming to construct upper and lower bounds on the unknown performance measure. Asymptotically, these lower and upper bounds achieve a desired level of confidence uniformly over the solution space and are consistent pointwise. These ideas are illustrated in a series of examples and compared to existing approaches.

Teaching/DEIC/MIF: Inclusive Pedagogy Experiences in Teaching OR/MS courses

General Session

Session Chair

Ruben Proano, 1</sup

1 Integrating Social Justice into Engineering Classes

Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA

Multiple studies call for engineering education to integrate the social aspect of engineering into classroom instruction. Yet, there is uncertainty regarding whether integrating these social topics into engineering curriculum will support or detract from learning of technical concepts. We evaluate how reframing technical assessments to include social justice concepts impacts student learning, and investigate how well students can integrate social justice into engineering decision making. We use a within subject design in which students were exposed to both conditions (questions with and without social justice context) we evaluate how social justice framing impacts overall student learning of technical topics. The majority of students showed an increase in critical thinking skills related to evaluating the social justice implications of technical decisions.

2 Inclusion and Equity in an Online Management Science Course

Kenneth E. Murphy, University of California Irvine, Irvine, CA, Contact: murphyke@uci.edu

DEI initiatives in academic institutions seek to expand opportunity, raise awareness, and enhance skills to meet the challenges of an increasingly diverse world. How do the concepts of equity and inclusion apply in the instruction of math modeling courses? This presentation provides working definitions for these constructs in the context of OR/MS course delivery. We present student perceptions of course inclusivity and equity based on data gathered in a medium-sized online management science course. We then consider the relationship between these metrics and engagement and outcome variables with the goal of informing on tangible actions for instruction and course administration.

3 A Scaffolding Module for Teaching Undergraduate Data Analytics Inclusive of Limited Prior Backgrounds in Programming and Analytics

Mihir Mehta, Pennsylvania State University, State College, PA

Undergraduate students with a little background in programming and data analytics often face challenges in learning problem-solving skills. To help all students become better problem-solvers, we developed a scaffolded assignment that leverages publicly available data sets. In this presentation, we describe our scaffolding module implementation. We designed active incremental learning exercises to assist with project completion. We highlighted similarities between different types of datasets. We helped students to develop essential analytics skills useful for areas such as manufacturing, retail, and finance, through this engaging and positive learning-based implementation.

4 Promoting Inclusion Through Effective Groupwork

Susan E. Martonosi, Harvey Mudd College, Claremont, CA

Active learning techniques have been shown to improve learning for all students, and particularly for students from underrepresented groups. In this talk, I will focus on active learning groupwork that I use in my undergraduate classes. I will discuss three important principles that guide my use of groupwork to promote inclusion: 1) Everybody should have a role; 2) The task should be properly scaffolded. 3) A collaboration mindset should be cultivated. These principles will be illustrated through successful (and less-than-successful) classroom examples.

Keji Wei, Sabre, Grapevine, TX

1 Resilient Airline Scheduling to Minimize Delay Risks

Deniz Simsek, Northwestern University, Evanston, IL

Airlines tend to design their flights schedules with the primary concern of the minimization of operational costs. However, the recently emerging idea of resilient scheduling defined as staying operational in case of unexpected disruptions and adaptability should be of great importance for airlines as well due to the high opportunity costs caused by the flight cancellations and passenger inconvenience caused by delays in the schedule. In this study, we integrate resilient airline schedule design, aircraft routing and fleet assignment problems with uncertain non-cruise times and controllable cruise times. We follow a data-driven method to estimate flight delay probabilities to calculate the airport congestion coefficients required for the probability distributions of non-cruise time random variables. We formulate the problem as a bi-criteria nonlinear mixed integer mathematical model with chance constraints. The nonlinearity caused by the fuel consumption and CO_2 emission function associated with the controllable cruise times in our first objective is handled by second order conic inequalities. We minimize the total absolute deviation of the aircraft path variability's from the average in our second objective to generate balanced schedules in terms of resilience. We compare the recovery performances of our proposed schedules to the minimum cost schedules by a scenario-based posterior analysis.

3 A Cloud-based Low Altitude Surveillance System for Advanced Air Mobility Operations: Cost-benefit Analysis for The State of Ohio

Esrat Farhana Dulia, Kent State University, Kent, OH

Advanced Air Mobility (AAM) will enable emerging aircraft to operate efficiently in lower altitude airspace in the near future. To detect and track AAM traffic, a Low Altitude Surveillance Information Clearinghouse (LASIC) can serve a vital role as a cloud-based data collection, monitoring, and distribution center, where AAM operators handling different AAM use cases — passenger and cargo transportation, medical delivery etc. — will subscribe to receive relevant AAM traffic data to plan their operations. In this work, we present a framework for the LASIC of Ohio and perform a cost-benefit analysis. The insights gained justify investment in this infrastructure, showing that LASIC will generate revenues from subscriptions for investors and benefit AAM operators and policymakers.

4 Iterative Exact and Heuristic Algorithms for Airline Timetable Development

Ritesh Ojha, Georgia Institute of Technology, Atlanta, GA

Airline companies operate flights in markets (defined as origin-destination pairs) to satisfy customer demand as much as possible with available resources (i.e aircrafts). Designing a flight timetable for even one major airline is an enormous undertaking. In this research, we formulate the airline timetable development problem over a time-expanded network. Key decisions in the model are represented by flight-arc variables, which determine the fleet type and departure time of an aircraft. Overall, these departures must meet given demand for every market, and must satisfy airport operating hours, minimum inter-departure times, and overnight aircraft parking constraints. We develop a multi-phase integer-programming based solution approach that works with relatively smaller integer programs in every phase to yield high quality feasible solutions (flight timetables) for practically-sized instances. Preliminary results are illustrated using data available from the Bureau of Transportation Statistics.

Multimodal Strategies for Mitigating Congestion from Urban Parcel Delivery Integrating Drones, Non-motorized Vehicles and Trucks

Ang Li[1], Mark M. Hansen[2], Bo Zou[3], [1]University of California-Berkeley, Emeryville, CA, [2]University of California-Berkeley, Berkeley, CA, [3]University of Illinois, Chicago, IL

The explosive growth in e-commerce, the increasing urgency of de-carbonization, the rapid advances in UAV technology, and the continuous disruptive development of the gig economy create needs and opportunities for dramatic improvements in urban package delivery. To mitigate the congestion impact from truck and van traffic, as well as reduce costs and travel times, last-mile delivery should in many cases be shifted toward non-motorized modes and UAV. In this research, we propose a suite of multimodal, congestion-sensitive strategies for urban delivery, by integrating traditional motorized vehicles, non-motorized modes, and UAV. We first conceptualize and optimize the integrated delivery strategy combining different types of vehicles, then incorporate congestion effects into the integrated delivery strategy.

SA87

JWM - Room 209
Management of Electronic Waste
Contributed Session

Session Chair
Gazi Duman, University of New Haven, West Haven, CT

1 On Robust Optimization, Blackouts and The Law

Dirk Lauinger[1], François Vuille[2], Daniel Kuhn[3], [1]EPFL, Lausanne, Switzerland; [2]Etat de Vaud, Lausanne, Switzerland; [3]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, Switzerland. Contact: dirk.lauinger@epfl.ch

Vehicle-to-grid is the idea of meeting the growing demand of electricity storage, e.g., for frequency regulation with batteries of parked electric vehicles. Frequency regulation providers promise to charge or discharge their batteries whenever the grid frequency deviates from its nominal value. They must honor their promises for all frequency deviation trajectories that satisfy certain properties prescribed by EU law. We encode the law in a robust optimization model and find that the penalties for non-compliance with market rules are currently too low. This suggests that "crime pays".

2 Planning a Circular Economy System for Electric Vehicles Using Network Simulation

Sidi Deng[1], Yuehwern Yih[1], John W. Sutherland[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: deng100@purdue.edu

This study develops a stochastic activity network to simulate a circular economy system for rebuilding/renewing used electric vehicles and extracting maximum value from end-of-life components and materials. The designed process chain coordinates and synergizes concomitant procedures such as disassembly, processing, and reassembly. The network framework integrates a process planning model and a cost-benefit model to consider both system productivity and its pricing strategy. The results provide evidence for the technical viability of the proposed system design from an operational viewpoint and suggest its promising economic potential in industrial practice.

3 Battery Energy Storage Systems: When Does Heterogeneity Work?

Joonho Bae, Roman Kapuscinski, John M. Silberholz, University of Michigan Ross School of Business, Ann Arbor, MI, Contact: baejh@umich.edu

With the rapid development of technology and the increased availability of batteries (e.g., retired batteries from electric vehicles), battery operators often have the option of investing in heterogeneous systems that can be built from battery modules with different types, ages, and capacity ratings. What complicates this decision is the fact that the projected benefits from a heterogeneous battery portfolio fluctuate considerably due to many factors such as battery degradation. We consider contingency applications (e.g., backup battery power system) where the battery operator commits to provide energy in an emergency under the presence of uncertainty. This paper uses analytical modeling to systemically characterize the benefits of heterogeneity in battery systems and establish general lessons.

4 Electronic Waste Prediction for Circular Economy: A Novel Grey Forecasting Model

Gazi M. Duman[1], Elif Kongar[2], Surendra Gupta[3], [1]University of New Haven, West Haven, CT, [2]Fairfield University, Fairfield, CT, [3]Northeastern University, Boston, MA, Contact: gduman@newhaven.edu

Electronic waste is today one of the fastest growing municipal solid waste streams in the US. Accurate e-waste predictions that municipalities can utilize to build appropriate reverse logistics infrastructures play an important role in waste collection, recycling and disposal operations. The literature offers a wide range of approaches that investigate e-waste estimation. Among these, Grey Modeling has drawn attention due to its ability to provide meaningful results with even small-sized data. The proposed non-linear grey Bernoulli model with convolution integral improved by Particle Swarm Optimization demonstrates superior accuracy over alternative models. Furthermore, Fractional Order Accumulation method is applied to increase the precision of the forecast. A case study utilizing Washington State e-waste data is provided for comparative analysis.

Plenary Session

Welcome

Brad Weaber[1], Radhika Kulkarni[2], Elena Gerstmann[3], [1]INFORMS Annual Meeting Host, Brad Weaber Consulting Group, LLC, Washington, DC, [2]INFORMS President, SAS Institute Inc. (retired), Durham, NC, [3]INFORMS Executive

Director, Catonsville, MD

Opening Remarks

Sheldon H. Jacobson, General Chair, University of Illinois, Urbana, IL

1 Do Simpler Machine Learning Models Exist and How Can We Find Them?

Cynthia Rudin, Duke University, Durham, NC

While the trend in machine learning has tended towards building more complicated (black box) models, such models are not as useful for high stakes decisions - black box models have led to mistakes in bail and parole decisions in criminal justice, flawed models in healthcare, and inexplicable loan decisions in finance. Simpler, interpretable models would be better. Thus, we consider questions that diametrically oppose the trend in the field: for which types of datasets would we expect to get simpler models at the same level of accuracy as black box models? If such simpler-yet-accurate models exist, how can we use optimization to find these simpler models? In this talk, I present an easy calculation to check for the possibility of a simpler (yet accurate) model before computing one. This calculation indicates that simpler-but-accurate models do exist in practice more often than you might think. Also, some types of these simple models are (surprisingly) small enough that they can be memorized or printed on an index card.

Heavy-tailedness, Dependence and Robustness in Econometrics, Economics and Finance

General Session

Session Chair

Rustam Ibragimov, Imperial College Business School, London, United Kingdom.

1 The Bias of the Gini Coefficient

Victor de la Pena, Department of Statistics, Columbia University, Fairfield, CT

In this talk, I will present a formula for the exact biasof the sample Gini coefficient.

2 A Machine Learning Attack on Illegal Trading

Artem Prokhorov, University of Sydney Business School, Woodcroft, Australia.

We design an adaptive framework for the detection of illegal trading behavior. Its keycomponent is an extension of a pattern recognition tool, originating from the field of signalprocessing and adapted to modern electronic systems of securities trading. The new methodcombines the flexibility of dynamic time warping with contemporary approaches from extremevalue theory to explore large-scale transaction data and accurately identify illegal trading patterns.Importantly, our method does not need access to any confirmed illegal transactions fortraining. We use a high-frequency order book dataset provided by an international investment firm to show that the method achieves remarkable improvements over alternative approaches inthe identification of suspected illegal insider trading cases.

3 Change Point Detection in Time Series Using Mixed Integer Programming

Alexander Semenov, University of Florida and St. Petersburg State University, Shalimar, FL

We use recent advances in mixed integer optimization (MIO) methods to develop a framework for identification and estimation of structural breaks in time series. The framework requires a transformation of the the classical structural break detection problem into an Mixed Integer Quadratic Programming problem. MIO is capable of finding provably optimal solutions to this problem using a well-known optimization solver. The framework allows to determine the unknown number of structural breaks. In addition to that, we demonstrate how to accommodate a specific required number of structural breaks, or a minimal required number of breaks. We demonstrate the effectiveness of our approach through extensive numerical experiments on synthetic and real-world data.

4 Intergenerational Transmission of Tail Inequality in Incomes

Joseph Gatus[1], Rustam Ibragimov[2], Paul Kattuman[3], [1]Goldman Sachs, London, United Kingdom; [2]Imperial College Business School, London, United Kingdom; [3]University of Cambridge, Cambridge, United Kingdom. Contact: pak13@cam.ac.uk

It is known that over the last many decades income inequality has increased substantially. It is also known that much of the increase has been in the upper tail of the income distribution. It would be useful to know to what extent the increase in upper tail income inequality is inter generationally transmitted. The tail index of the income distribution is a summary measure of inequality among top incomes. We examine the direction and extent to which the intergenerational mobility estimated for the United Kingdom using the British Household panel survey accounts for the changes the tail index of the income distribution of the parent's generation to the tail index of the income distribution of the child's generation. We elucidate the methodological contribution and discuss findings and implications for the evolution of upper tail income inequality.

5 New approaches to Robust on Market (Non-) Efficiency, Volatility Clustering and Nonlinear Dependence

Rustam Ibragimov, Imperial College Business School, London, United Kingdom.

Many financial and economic variables, including financial returns, exhibit nonlinear dependence, heterogeneity and heavy-tailedness. These properties may make problematic the analysis of (non-)efficiency and volatility clustering in economic and financial markets using traditional approaches that appeal to asymptotic normality of sample autocorrelation functions of returns and their squares. This paper presents new approaches to deal with the above problems. We provide the results that motivate the use of measures of market (non-)efficiency and volatility clustering based on (small) powers of absolute returns and their signed versions. We further provide new approaches to robust inference on the measures in the case of general time series, including GARCH-type processes. The approaches are based on robust t-statistics tests and new results on their applicability are presented. In the approaches, parameter estimates (e.g., estimates of measures of nonlinear dependence) are computed for groups of data, and the inference is based on t-statistics in the resulting group estimates. This results in valid robust inference under heterogeneity and dependence assumptions satisfied in real-world financial markets. Numerical results and empirical applications confirm the advantages and wide applicability of the proposed approaches.

1 Strategic Competitive Positioning: An Unsupervised Structural Hole-based Firm-specific Measure

Myunghwan Lee, Gene Moo Lee, Hasan Cavusoglu, Marc David L. Seidel, University of British Columbia, Vancouver, BC, Canada. Contact: myunghwan.lee@sauder.ubc.ca

Our research proposes structural hole-based strategic competitive positioning (SCP) measures to capture a firm's competitive and strategic positioning. Drawing on the network theory and structural holes concept, we operationalize SCP measures using a machine learning approach called doc2vec, creating a similarity matrix of all existing U.S. publicly traded firms. This enables us to construct firm-level measures of strategic competitive positioning. To show the effectiveness of the proposed measures, we provide illustrative examples and conduct a case study on the imprinting effect of IPOs on short- and long-term firm performance. This paper makes a significant methodological contribution to the information systems and strategic management literature by proposing a network theory-based approach to measure firm-level competition and strategic positioning.

2 Impact of Viewers Targeting on Viral Marketing in Social Network Service

Youhyun Lee, University of Florida, Gainesville, FL, Contact: youhyun.lee@ufl.edu

The research investigate the answer of following question. Can targeting viewers contribute to spread a branded post in Social network service more broadly? Targeting viewers means a marketing campaign considers followers' interests when it decides to pay for an influencer to seed a branded post.

3 Cookie Intermediates: Does Competition Leads to More Privacy? Evidence from the Dark Web

Arion Cheong[1], D. Daniel Sokol[1], Tawei Wang[2], [1]California State University at Fullerton, Irvine, CA, [2]DePaul University, Chicago, IL

In this study, we focus on firms voluntarily share their customer information with third parties and the corresponding consequences. Specifically, we collect first-party cookies of U.S. firms that are identified as a digital online platform and examine how they share customer information through these first-party cookies. Based on this sample, we then analyze how the market structure of an industry sector affects the level of personal information leakage on the darkweb. The results show that firms in less concentrated markets share more customer information with third-party entities and experience more customer privacy information leakage than the firms in more highly concentrated markets. Further, we demonstrate that the data sharing activities with data brokers with more highly concentrated market share result in less customer personal information leakage. Our result suggests that the market structure and the level of competition are two factors that should be considered for policy decision-making. regarding privacy policy.

Machine Learning in Finance

General Session

Session Chair

Xin He, City University in Hong Kong, Hong Kong, China.

1 Data Driven Wealth Management

Sikun Xu[1], Ali Hirsa[2], Miao Wang[2], Federico Klinkert[3], [1]Washington University in St. Louis, St. Louis, MO, [2]Columbia University in the City of New York, New York, NY, [3]ASK2.AI, New York, NY, Contact: sikun@wustl.edu

In this research we established a data driven system for wealth management. The wealth management system consists of four major modules: security selection, asset allocation, portfolio optimization and risk management. It utilizes a large variety of data including fund performance, alternative data, macroeconomic indicators, etc., to assist dynamic and robust portfolio decisions. We designed a dynamic, explainable and automated pipeline of machine learning and deep learning models to process the large amount of hetero-structured data. We tested our system in the U.S. mutual fund market and in comparison to traditional wealth management methodologies, we are able to achieve superior performance.

2 Portfolio Choice for Online Loans and Implications for Platforms

Zonghao Yang[1], Moris Simon Strub[2], Ram Gopal[3], Xiao Qiao[1], [1]City University of Hong Kong, Hong Kong, China; [2]Southern University of Science and Technology, Shenzhen, China; [3]University of Warwick, Coventry, United Kingdom. Contact: zonghao.y@my.cityu.edu.hk

Using over one million LendingClub loans, we investigate the suitability of online loans as an investment. We introduce generalized portfolio policies, where we propose a nonlinear portfolio policy based on a shallow neural network. The nonlinear loan portfolio outperforms the naïve equal-weight portfolio and earns competitive rates of return to that of the S&P 500 while showing limited comovement. Our results indicate that online loans are an attractive novel asset class for investors. Platforms may consider embedding a dual-layer portfolio framework in a robo-advising system, which would expand the access of sophisticated loan portfolios to a broad set of investors.

3 The Factor Model Failure Puzzle

Carter Davis[1], Brian Boyer[2], Fahiz Baba-Yara[1], [1]Kelley School of Business, Indiana University, Bloomington, IN, [2]BYU Marriott School of Business, Provo, UT, Contact: ckd1@iu.edu

Despite the weak theoretical assumptions needed to guarantee the existence of a factor model that prices the cross-section of stock returns we show in a meta-analysis of fifteen state-of-the-art models that none of these models can price the mean-variance efficient portfolio of the other fourteen. No one model effectively describes the cross-section of US equities. Our results highlight the need to benchmark new factor models against each other, rather than traditional test assets. When markets are incomplete, an infinite number of stochastic discount factors price assets, but empirically, we have yet to find just one. We refer to this as the*factor model failure puzzle*. We present a theoretical model with many weak anomaly trading signals and show that slight methodological deviations lead to different factor models that all fail as observed empirically.

4 Attention Based Dynamic Graph Neural Network for Asset Pricing

Ajim Uddin, Xinyuan Tao, Dantong Yu, New Jersey Institute of Technology, Newark, NJ, Contact: au76@njit.edu

Networks among firms (sectors) play an essential role in asset valuation. These networks are dynamic and continuously evolve in response to market micro and macro changes. This paper develops an end-to-end graph neural network model to capture the implication of dynamic network structure in asset pricing. First, we apply the graph attention mechanism to learn dynamic network structures of the equity market over time and then use a recurrent convolutional neural network to diffuse and propagate firms' fundamental information into the learned networks. The superiority of our model is demonstrated in both return prediction and portfolio Sharpe ratio. The dynamic network learned from our model represents general market conditions over time and explains the equity network systemic risk previously identified in the literature.

1 **Column Generation Based Load Builder Engine for Walmart's First-mile Transportation Network**
Kunlei Lian[1], Ming Ni[1], Liqing Zhang[2], Mingang Fu[3], Ti Zhang[4], Yu Zheng[1], [1]Walmart, Bentonville, AR, [2]Walmart, Humble, TX, [3]Walmart, Palo Alto, CA, [4]Walmart, Sunnyvale, CA, Contact: ming.ni@walmart.com
Tens of thousands of shipments need to be moved from geographically dispersed suppliers to distribution centers daily on Walmart's first-mile transportation network. Efficiently consolidating shipments into bigger loads allows Walmart to earn preferred rates, reduce operational costs and improve overall supply chain efficiency. We present an in-house developed optimization engine that employs column generation (CG) to create promising candidate loads and identify the optimal loads. Upon transforming the problem into the CG framework, the main problem identifies shipment dual values, which are then utilized by various tailored heuristic/metaheuristic algorithms to solve the pricing problem efficiently.

2 **Powering Walmart's Spark Driver Assignment: Driver Matching 2.0, a Scalable Service Design with Machine Learning and Optimization**
Xi Chen, Walmart, Sunnyvale, CA
Spark delivery service is Walmart's last mile delivery solution. This paper presents a novel system design that provides efficient and customized offer assignment to Spark drivers with the help of machine learning (ML) and optimization, and with a robust system design that can scale to serve all Spark-enabled markets. The optimization engine forms the backbone of the system that searches for the global optimal driver assignments, while multiple ML services are incorporated into the system to model driver preference and driver real time activity. A distributed high-performance system is designed to provide reliability, scalability and maintainability to our driver assignment system. After launching the system on large scale, an encouraging improvement in multiple performance metrics have been observed, with few to none engineering concerns.

3 **Optimizing Outbound Multi-stop Routing Plan for Walmart Grocery Network**
Xiaojie Wang, Tiantian Nie, Fereydoun Adbesh, Ti Zhang, Walmart, Sunnyvale, CA
Creating routing plans that satisfy both safety and operational requirements moving pallets from distribution centers (DCs) to stores is essential and challenging when considering commodities that vary from dry to perishable and scale of the problem. To address the routing and load planning automatically, optimally and simultaneously, a set of algorithms were developed and deployed in a hosting application - Load Planner (LP). This talk focuses on demonstrating the related techniques considering stores' time window, department of transportation (DOT) rules, and feasible load design requirements, etc. Our LP algorithm obtains routing solutions that show a 3.7% reduction in miles and a 3.7% reduction in the number of routes compared to the original solver system with 4 DCs and one month of data.

1 **Improving Cyber Resilience of Critical Assets Network**
Kam-Fung Cheung, Barney Tan, The University of New South Wales, Sydney, Australia. Contact: kf.cheung@unsw.edu.au
The COVID-19 pandemic accelerates the digitisation of businesses, while its associated cyber threats affect various industries such as logistics and retail. The unavailable critical assets due to successful cyberattacks undermine an organisation's profit, thus there is an urgency in enhancing cyber resilience of the critical assets network, i.e., the backbone network, in the organisation. This paper proposes a novel model based on eigenvector centrality to identify (hidden) critical assets in an organisation and improve their resilience by adding redundant links among them. With the case study of a retail company, managerial

insights on enhancing cyber resilience in the critical assets network such as designing backup strategies and managing shadow IT systems.

2 Provider-firm Cybersecurity Investment Spillover: Implications for the Supply Chain

Hooman Hidaji, University of Calgary, Calgary, AB, Canada. Contact: hooman.hidaji@haskayne.ucalgary.ca

As cybersecurity threats become more prevalent and IT supply chains more intertwined, providers and firms need to invest in cybersecurity to secure their supply chains. A critical managerial problem is the level and interaction of the cybersecurity investments by the providers and firms. While some provider investments substitute potential firm investment, others are complementary to the firm investment. We use a general-form model to study this problem. We find that provider investment incentivizes firm investment only if the provider investment has a positive spillover on firm investment, and that downstream competition negatively impacts this effect. Interestingly, in the case of substitutable (complementary) provider-firm investment spillover, increased provider investment benefits firm profit only if downstream externality is positive (negative).

3 Critical Infrastructure Risk Assessment at Scale

Jason Reinhardt[1], Derek Koolman[2], Jeffrey Munns[3], Lauren Wind[3], Merideth Secor[2], [1]Sandia National Laboratories, Livermore, CA, [2]Cybersecurity and Infrastructure Security Agency, Arlington, VA, [3]SPA, Alexandria, VA, Contact: jason.reinhardt@associates.cisa.dhs.gov

The Cybersecurity and Infrastructure Security Agency (CISA) has the mission to lead the National effort to understand, manage, and reduce risk to our cyber and physical infrastructure. CISA has developed a representation of critical infrastructure (CI) as a functional graph of interconnected nodes based on the National Critical Functions (NCFs) to enable risk analysis at the national scale. A Risk Architecture (RA) is being created that uses the NCF dependency structure in a risk analytic framework. The RA employs a matrix formalism approach for risk analysis of disparate and interconnected CI at scale. This talk will introduce the NCF structure and the RA, describe the matrix formalization used, and discuss examples.

4 Effect of Executive Qualification on Information Security Risk

Hau Tran[1], Linh Le[2], Anh Ta[3], [1]University of North Texas, Denton, TX, [2]Penn State Behrend, Erie, PA, [3]University of Nebraska Omaha

This study empirically investigates whether the presence of a Chief Information Officer (CIO) on the board of directors reduces firms' information security risks, measured by the incidence of cyberattacks. In addition, the study shows that the qualification of CIOs also plays a role in managing information security incidents. The findings extend the literature about the role of the top management team in mitigating information security risks.

Big Data Applications in Global Operations and Management

General Session

Session Chair

Xiaojin Liu, Virginia Commonwealth University, Richmond, VA

Session Chair

Pankaj Kumar, Virginia Tech

1 Know Your Users Before You Spend: A Data-driven Optimization Approach to Enhance User Engagement Using Visual Analytics

Mayukh Majumdar[1], Subodha Kumar[2], Chelliah Sriskandarajah[3], [1]University of San Diego, San Diego, CA, [2]Fox School of Business, Temple University, Philadelphia, PA, [3]Texas A&M University, College Station, TX

Social media platforms have become an increasingly popular channel for firms to advertise their products via social media posts. How to effectively develop posts with compelling features and understand what users prefer to engage thus become important tasks. Even though post development using social media analytics by utilizing budget efficiently is essential for firms, it has not been examined rigorously in the literature. To bridge this important gap, we propose a novel optimization framework for analyzing and publishing social media posts across multiple platforms for a planning horizon under a firm's limited budget. Our framework and the findings have important implications for firms aiming to improve their social media presence.

2 Correlation-Enhanced Deep Learning and Its Applications in Operations Management

Hu Yang[1], Kedong Chen[2], [1]Central University of Finance and Economics, Beijing, China; [2]Old Dominion University,

Norfolk, VA, Contact: kchen@odu.edu
Deep learning is gaining popularity in operations management (OM) research. However, traditional deep learning (DL) methods such as long short-term memory (LSTM) and Gated Recurrent Unit (GRU) cannot well handle spatially correlated data in prediction. Interrelationships between regions constitute an important feature in real-world OM data and problems. To improve prediction accuracy, we take spatial correlation into consideration and propose correlation-enhanced deep learning as an extension to traditional DL models. We apply the proposed method to practically critical OM problems and illustrate its applications. We demonstrate a superior prediction performance after using correlation-enhanced deep learning.

3 Data Science-driven Monitoring of Slug-flow Process in Crystallization Synthesizing

Yanjun Qian, Virginia Commonwealth University, Richmond, VA

In continuous chemical manufacturing, the slug-flow process plays an important role in crystallization synthesizing and provides better process control and reproducibility. However, it is challenging to maintain the uniformity of the crystal size when scaling-up slugs. Thanks to the advances in in-line imaging technologies, we can apply state-of-the-art data science methods to improve flow control for better crystallization quality. We first adopt image processing and deep learning to detect all the slugs along with the crystals inside them. Then, their sizes and shapes are analyzed by statistical methods to model the slug flow behaviors. With the in-line monitoring and modeling, the proposed work will lead to a controller to scale up slug-flow without sacrificing slug and crystal size uniformity.

4 How Do Online Signals of Social Identity Affect Businesses in the Restaurant Industry?

Ali Adeli[1], Yash Babar[2], Gordon Burtch[3], [1]The University of Memphis, Memphis, TN, [2]University of Wisconsin-Madison, Madison, WI, [3]Boston University, Boston, MA, Contact: amadeli@memphis.edu

Flags, posters, photos, stickers, and other pieces of shop décor can all signal the social identity of shopkeepers. Past research has shown that these sorts of offline identity cues can have large consequences on consumer behavior. Recently, digitization has led most brick-and-mortar establishments to present an online business profile. Whereas social identity may be inferred as a byproduct of casual inspection in the offline space, with online presentations, businesses gain greater control over what, when, and how they signal social identity information. Both Google and Yelp have introduced identity signaling features into their platforms, enabling establishments to post explicit indicators of owner race, gender, and minority allyship. In this work, we ask whether, when, and how these identity-signaling features impact Restaurants and other eating places.

1 Learning from Imbalanced Data with Triplet Adversarial Samples

Jaesub Yun[1], Jong-Seok Lee[2], [1]Sungkyunkwan University, SUWON-SI, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of. Contact: yunjaesub@gmail.com

Class imbalance is one of the most challenging problems in the field of machine learning. To address this issue, we present a novel synthetic sample generation method that incorporates both the triplet loss and the adversarial attack scheme. The former is intended to create a synthetic sample that is similar to original minority class samples, whilst the latter is to place the synthetic sample close to its decision boundary. Both aim to increase classification performance by strengthening minority class generalization. The proposed method outperformed the state-of-the-art algorithms on artificial and real-world datasets, demonstrating better classification performance.

2 Out-of-distribution Detection Using Angular Margin Loss and Regularization Between Output and Penultimate Layers of Neural Networks

TaeWook Kim[1], Jong-Seok Lee[2], [1]Sungkyunkwan University, Suwon, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of. Contact: redxtar@skku.edu

Discriminating out-of-distribution (OOD) samples from in-distribution ones is important in terms of the safe use of machine learning models. This research proposes a novel training scheme for neural networks to detect OOD. The proposed method employs the angular margin loss as a learning objective and regularization between output and penultimate layers of a neural network. The former is to create discriminative embedding features and the latter is to make gentle prediction surfaces near decision boundaries in the created embedding space. Both intend to eventually prevent overconfident predictions. Numerical experiments showed that our method improved the OOD detection of a classifier while preserving its classification performance.

3 A Convolutional-LSTM Architecture Inspired Track Association Algorithm for Marine Vessels

Md Asif Bin Syed[1], Imtiaz Ahmed[2], [1]West Virginia University, Morgantown, WV, [2]West Virginia University, Morgantown, WV, Contact: ms00110@mix.wvu.edu

Tracking multiple moving objects in real-time in a dynamic threat environment is important in national security and surveillance. In this work, we have implemented the Conv-LSTM for the association of the Marine vessels using the time series features collected by an Automatic Identification system.In order to implement the Deep learning Algorithm, the data must first be preprocessed for missing values before being fed into the Conv-LSTM architecture. Then the Conv-LSTM architecture has been used for the Classification of the input data. For the benchmarking, We have compared our algorithm with other time series classification algorithms. Given the imbalanced characteristics of AIS data, the F1 score is used to evaluate the performance of the Conv-LSTM. The result demonstrates that the Conv-LSTM outperforms in the classification of AIS datasets.

Data Mining Flash Session II

Flash Session

Session Chair

Ziwei Su, Northwestern University, Evanston, IL

1 OR in Practice: Opportunities, Challenges, and Best Practices

Filippo Focacci, Decision Brain, Paris, France.

We bring together a group of OR enthusiasts from business owners, to practitioners to academic researchers to share their perspectives on adoption of OR in today's challenging economic environment. In this flash paper we will dig into global disruptions and how OR-based methods and systems can and are being used to support organizations in maneuvering through uncertainty.

2 A Deep RL Framework for Reach-avoid Zero-sum Games and Its Application to Viability Kernel and Backward Reachable Set

Jingqi Li[1], Donggun Lee[2], Somayeh Sojoudi[3], Claire Tomlin[1], [1]University of California, Berkeley, Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA, [3]University of California, Berkeley, El Cerrito, CA, Contact: jingqili@berkeley.edu

We consider the reach-avoid zero-sum game problem, where the goal is to find a set in the state space such that the system starting at a state therein could be controlled to reach a given target set without violating constraints under the worst-case disturbance. We solve the problem by designing a new value function with a contracting Bellman backup, where the super-zero level set recovers the reach-avoid set. We prove that the proposed method can be adapted to compute the viability kernel and the backward reachable set. Finally, we adopt the Conservative Q-Learning to alleviate the curse of dimensionality issue such that a conservative approximation to the reach-avoid set can be learned.

3 Extending and Improving Iterative Kernel-based Regressions Using Tensor Processing and Local Models

Ben Hen[1], Ángela Fernández[2], Neta Rabin[1], [1]Tel-Aviv University, Tel-Aviv, Israel; [2]Universidad Autónoma de Madrid, Madrid, Spain. Contact: netara@tauex.tau.ac.il

Iterative kernel-based regression constructs a multi-scale representation of the train data, where the modes are the average residuals. We describe several extensions of this model. For dealing with data that has non-uniform noise, we compute a point-dependent stopping criterion. Localization in the frequency is achieved by combining the iterative regression with Emperical Mode Decomposition (EMD). Processing of tabular datasets is done by operating on the row and column spaces of the data. Experimental prediction and forecasting results are demonstrated on real world dataset.

4 Analyzing Self-presentation Text on Linkedin: Who is Noble, Who is Humble?

Vivian Simon[1], Neta Rabin[1], Hila Chalutz Ben-Gal[2], [1]Tel Aviv University, Tel Aviv, Israel; [2]Tel Aviv Afeka Academic College of Engineering, Tel Aviv, Israel. Contact: hilab@afeka.ac.il

The growing practice of AI enabled recruitment systems via social networks has become a major component of talent recruitment tools. Data overflow of personal information may result in conscious or unconscious bias. Efforts have been made to eliminate such bias but further investigation is needed. We analyze candidates' textual self-presentation utilizing ML methods on a training dataset of 14K LinkedIn profiles. Our results indicate that some features have significant influence on gender gaps of textual self-presentation. Our research methods may be adopted by AI-enabled recruitment tools to improve the diversity of candidates and reduce bias.

5 Nonparametric Empirical Bayes Prediction in Mixed Models

Trambak Banerjee, University of Kansas, Lawrence, KS

We develop a novel framework, EBPred, for empirical Bayes prediction in mixed models. The predictions from EBPred rely on the Best Predictor of the random effects, which are constructed without any parametric assumption on the distribution of the random effects and offer a natural extension to the BLUP when the true random effect distribution is not Normal. We develop theory to show that the corresponding predictions from EBPred are asymptotically optimal in terms of mean squared error for prediction. Extensive simulation studies demonstrate that EBPred outperforms existing predictive rules in mixed models and the efficiency gain is substantial in many settings.

6 Data-Driven Robust Optimization with Conformal Prediction

Chancellor Johnstone[1], Eugene Ndiaye[2], Bruce Cox[3], [1]Air Force Institute of Technology, Dayton, OH, [2]Georgia Institute of Technology, Atlanta, GA, [3]Air Force Institute of Technology, Dayton, OH

One method of incorporating uncertainty into making optimal decisions is through robust optimization (RO), which minimizes the worst-case scenario over uncertainty sets. Conformal prediction is a method for uncertainty quantification that works with any prediction methodology and provides information on the uncertainty around some data point of interest, under fewer assumptions that traditional uncertainty sets. We discuss previous work to connect robust optimization and conformal prediction, practical issues, current work to solve these issues and potential methodological applications. This topic is a work in progress.

7 Knowledge Graphs and Covid-19: Challenges, Opportunities and Successes

Mayank Kejriwal, University of Southern California, Marina del Rey, CA

The impacts of the COVID-19 pandemic have had not just health, but also socio-political and economic ramifications. Improvements in Artificial Intelligence (AI), cheap computation, and availability of open datasets present both an opportunity and novel challenges in applying AI to complex real-world problems, such as COVID-19. In this flash talk, I will briefly review an innovative applied AI technology called a knowledge graph (KG) that can robustly facilitate a wide range of information and analytical needs. As evidenced by creative implementations in industry and academia, KGs have already played an important role in the fight against COVID-19, but face many challenges (and opportunities).

8 Rate-Optimal Contextual Online Matching Bandit

Yuantong Li[1], Chi-Hua Wang[2], Guang Cheng[3], Will Wei Sun[2], [1]University of California, Los Angeles, Los Angeles, CA, [2]Purdue University, West Lafayette, IN, [3]University of California, Los Angeles, Los Angeles, CA, Contact: yuantongli@ucla.edu

Two-sided online matching platforms have been employed in various markets. However, agents' preferences in present market are usually unknown and must be learned from data. With the growing availability of side information involved in the decision process, modern online matching methodology demands the capability to track preference dynamics for agents based on their contextual information. This motivates us to consider a novel Contextual Online Matching Bandit prOblem (COMBO), which allows dynamic preferences in matching decisions. In this paper, we propose a Centralized Contextual - Explore Then Commit (CC-ETC) algorithm to adapt to the COMBO.

9 Soft-Cascading Assortment Bandits

Hyun-jun Choi, Min-hwan Oh, Seoul National University, Seoul, Korea, Republic of. Contact: nschj1@snu.ac.kr

We propose a new sequential assortment selection problem, soft-cascading assortment bandits. The decision-making agent offers a user a cascade of slates where each slate is a set of items. A distinct feature is allowing the user to leave the system completely when there are no attractive items, which is prohibited in the existing cascade bandit models. The feedback of user choice is given by a multinomial logit choice model. We propose a UCB algorithm for this problem with provable guarantees. The empirical experiments support the theoretical claims.

10 Stochastic Simulation Calibration of Inexact Computer Models

Ziwei Su[1], Matthew Plumlee[2], [1]Northwestern University,

Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: ziwei.su@northwestern.edu
Stochastic simulation models generate random samples designed to emulate a system or process. To help align the simulation model with the target process, data is used to calibrate the model. Calibration is especially difficult when the model is inexact, meaning that there is always a difference between the model and the target process (model discrepancy). Much of the existing literature on calibration under model discrepancy focus on deterministic models. Calibration for stochastic models is harder as the discrepancy is now a difference between distributions. In this talk, I will discuss recent developments in stochastic simulation calibration of inexact computer models that address the challenges of simultaneous parameter and discrepancy estimation.

1 The Effect of Emoji on Intervention for Misinformation

Seonjun Kang[1], Yeongin Kim[2], Victoria Yoon[1], [1]Virginia Commonwealth University, Richmond, VA, [2]Virginia Commonwealth University, Glen Allen, VA, Contact: kangs10@vcu.edu
With the development of social media, we can quickly obtain information from a variety of sources. However, as social media also promotes the spread of misinformation, the damage caused by distorted facts is also increasing rapidly. Therefore, social media platforms have been intervening to prevent the spread of misinformation. For example, Facebook shows a label on top of a photo or video of a misinformation article and displays a link to a fact-checker's assessment. However, emojis accompanying online articles that capture other users' emotional reactions to the article undermine the label's effectiveness. Drawing on cognitive dissonance theory, emotions as social information theory, and social influence theory, we study the effect of emojis on the trust in the intervention and the online article believability.

2 Contagion of Investor Sentiment in Online Investment Communities: Evidence from Dynamic Visuals on Stocktwits

Ming Gu, University of California, Irvine, Irvine, CA
We study the associations of GIFs with user-declared stock sentiment, trading behavior, and future stock returns at the firm-day level. On firm-days with GIF postings, we find higher net bullish sentiment, higher retail order imbalance, and short sale volume; and initial positive abnormal returns followed by a longer-term reversal. The GIF associations with sentiment, return overreaction, and short sale volume are stronger on firm-days with popular GIFs, with GIFs with declared sentiment, with GIFs from influencers, and in firms with higher retail ownership. Retail buys and retail sells separately, and not order imbalance, are stronger in firms with higher retail ownership. Our findings suggest that dynamic visuals in social media postings are associated with greater investor attention and higher bullish sentiment, resulting in net buying and overpricing.

3 Is that Decision Fair? A Formal Model to Assess an Individual's Belief on the Fairness of a Decision

Chenglong Zhang[1], Young U. Ryu[2], Varghese S. Jacob[2], [1]Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]University of Texas-Dallas, Richardson, TX, Contact: chenglong.zhang@utdallas.edu
The concept of fairness has been addressed by many disciplines. However, prior studies have not formally represent individuals' view of a fair decision mathematically nor determined how to represent the degree to which a decision is viewed as fair by individuals. Based on the concept that "fairness is in the eye of the beholder," we provide a framework to formally represent individuals' view of the fairness of a decision using the scheme in Dempster and Schafer's theory of evidence. This allows us to capture the strength of the individual's fairness belief and represent the person's indifference to the outcome of the decision. We further illustrate how a decision-maker can use the knowledge of the fairness beliefs of a group of individuals to make an optimal decision on the fairness criteria. We also used data from Tweeter and Youtube to validate and operationalize our model.

1 Using Artificial Intelligence to Mitigate Human Errors in Nuclear Power Plants: A Case in Operation and Maintenance

Bhavya Reddy Kolta[1], Ezgi Gursel[2], Anahita Khojandi[2], Mahboubeh Madadi[3], Jamie Coble[2], Vivek Agarwal[4], Vaibhav Yadav[4], Ronald Laurids Boring[4], [1]San Jose State University, San Jose, CA, [2]University of Tennessee, Knoxville, TN, [3]San Jose State University, San Jose, CA, [4]Idaho National Laboratory, Idaho Falls, ID, Contact: bhavyareddy.kotla@sjsu.edu

Human errors(HEs) are an important concern in safety-critical systems such as nuclear power plants(NPPs). HEs attributed to many deadly accidents and outage incidents. Despite increased automation in NPPs, HE remain unavoidable. Hence, HE detection is as important as prevention. In this study, we develop an unsupervised anomaly detection technique based on generative adversarial networks(GANs). GAN trained to detect mismatches between continuously-recorded sensor and manually-collected surveillance data; tested on both real-world and external dataset obtained from testbed. Results benchmarked against unsupervised anomaly detection algorithms, like one-class support vector machine and isolation forest. Results indicate improved anomaly detection performance by proposed GAN, showing promise for future development of AI-based HE detection systems.

2 Hierarchical Knowledge Transfer Networks for Traffic Accident Forecasting on Heterogeneous Spatio-temporal

Bang An[1], Amin Vahedian Khezerlou[2], Xun Zhou[3], Nick Street[3], Li Yanhua[4], [1]Iowa University, Iowa City, IA, [2]Northern Illinois University,, DeKalb, IL, [3]University of Iowa, Iowa City, IA, [4]Worcester Polytechnic Institute, Worcester, MA, Contact: bang-an@uiowa.edu

Traffic accident forecasting is a significant problem for transportation management and public safety. However, this problem is challenging due to the spatial heterogeneity of the environment and complex factors resulting in accidents. Recent traffic accident prediction methods have attempted to use deep learning models to improve accuracy. However, most of these methods focus on small-scale and homogeneous areas and fail to handle heterogeneity in large regions. To address these limitations, this paper proposes a novel Hierarchical Knowledge Transfer Network model to capture irregular heterogeneity patterns better. Extensive experiments on a real-world accident dataset from the state of Iowa demonstrate that the proposed model can accurately capture underlying heterogeneous patterns and greatly improve prediction performances

3 A Discrete Search Game with Multiple Hidden Objects

Thuy Bui, Thomas Lidbetter, Rutgers Business School, Newark, NJ, Contact: tb680@business.rutgers.edu

Consider a zero-sum game between a Hider and a Searcher. The Hider places m objects in m of n boxes ($n>m$). The Searcher picks an infinite sequence corresponding to the order in which the boxes are searched. Every time the Searcher looks in box i, if the target is there, he finds it independently with overlook probability p_i and pays a cost of c_i. The game concludes when k $(1 \le k \le m)$ objects are found. The payoff of the game is the expected cost paid until the Searcher finds k objects. We consider the case where the parameters p_i are all equal and the parameters c_i are all equal 1. We give a full solution to this game for any arbitrary number of boxes n and number of objects m, k. We also prove the existence of a pure optimal strategy and construct the pure optimal strategy for some cases.

4 Acqui-hiring or Acqui-quitting: Post-M&A Turnover Prediction via a Dual-fit Model

Denghui Zhang[1], Howard Zhong[2], Jingyuan Yang[3], [1]Rutgers Business School, Newark, NJ, [2]ESCP Business School, Paris, France; [3]George Mason University, Fairfax, VA, Contact: dhzhangai@gmail.com

Gaining highly skilled human capital is one of the primary reasons for corporate mergers and acquisitions (M&A), especially for knowledge intensive industry. However, the inevitable tensions brought by the divergent cultures and organizational misalignment during M&A process result in high talent turnover rate and ultimately integration failure. Hence, it is imperative to understand and prepare for potential effects of M&A on employee turnover. To this end, we propose a novel dual-fit heterogeneous Graph Neural Network model to predict talent turnover trend by taking into account complex relationship among the acquirer firm, acquiree firm, and the acquired employees. Specifically, we design a dual-fit model comprised of both the firm-level and employee-firm fit. Extensive evaluations on large-scale real-world data demonstrate the effectiveness of our approach.

Tinglong Dai, Johns Hopkins University, Baltimore, MD

1 Operationalizing Physician-in-the-Loop Treatment Recommendations

Michael Lash[1], Tinglong Dai[2], [1]University of Kansas, Lawrence, KS, [2]Johns Hopkins University, Baltimore, MD, Contact: michael.lash@ku.edu

Artificial intelligence has become increasingly prevalent in shaping healthcare decisions. However, because healthcare providers (esp., physicians) are ultimately responsible for these decisions, human involvement in the decision-making process is required. In this paper, we model and analyze a physician-in-the-loop AI treatment recommendation system. We characterize the conditions under which physicians might choose to use or not use AI systems. We also consider trust, the patient's perceived benefit, and the trade-offs between the two.

3 Human and AI Collaboration - Incorporating Artificial Intelligence as an Enablement into Adverse Event Identification for Pharmacovigilance

PROMIT ROY[1], Yufei Huang[2], [1]Trinity College Dublin, Dublin, Ireland; [2]Trinity Business School, Trinity College Dublin, Dublin, Ireland. Contact: royp@tcd.ie

Traditionally, Adverse Event (AE) detection and monitoring for Drug Safety in Pharmacovigilance involve many manual processes. Trained experts have to go over a huge amount of text-based information collected from patients, healthcare professionals and the engaged public. The process is time- and cost-intensive with low speed and varied accuracy. Recently, Artificial Intelligence (AI) and Machine Learning (ML), have been adopted into the process to collaborate with human experts to extract potential AEs via natural language processing and text mining. In this study, we use a large data set from an international pharmaceutical company to identify the viability of using an AI and ML in real-time AE detection and evaluate its impact on effectiveness and efficiency. We observe a significant improvement in both speed and accuracy in AE detection and monitoring.

2 Jumpstarting Online Interactions to Promote Smoking Cessation- Analyzing the Role of Seed Users in an Online Health Community

Xiangyu Wang, University of New South Wales (UNSW), Sydney, Australia.

When starting a new online community, a useful practice is to recruit "seed users" to create content and encourage participation from community members. However, in the context of online health communities (OHCs), where users with similar health concerns interact, the impact of interacting with seed users on members' health outcomes remains unknown. Using data from an OHC for smoking cessation, we found that support from seed users predicts member abstinence. In addition, seed users who were former smokers were more effective in supporting others to quit. The analysis of posting behaviors also revealed differences between the support provided by seed users who were former smokers vs. current smokers. Outcomes of this study can aid the design of a supportive OHC and the promotion of smoking cessation.

1 Optimally Assigning Army Recruiters

Timothy Lambert[1], Lihui Bai[2], [1]United States Army and the University of Louisville, Louisville, KY, [2]University of Louisville, Louisville, KY

In 2021, the United States Army Recruiting Command (USAREC) had approximately 9000 recruiters actively seeking to bring young men and women into the United States Army. The requirement was to contract a combined 93520 future soldiers into both the Regular Army and Army Reserve. However, USAREC fell over 20000 contracts short of that requirement. Although this presentation will not explore environmental factors that may have resulted in some of the shortfall, it will show that realigning recruiters can provide opportunities to increase contracts. This presentation presents an integer linear program, Optimally Assigning

Army Recruiters, using recruiting station locations and production rates to provide an optimal assignment of Army recruiters that maximizes market potential.

2 **Educational Wargaming for Operational Energy**

Nicholas Ulmer, United States Navy, Pacific Grove, CA

Naval Postgraduate School developed and played an educational DND-style game with an ultimate goal of providing an enriching experience of how operational energy is a critical component of military force development. The purpose of the game was explained to players as a visceral sense of winning or losing based on the operational energy decisions made in two phases of gameplay. They achieve this through connecting procurement and technology investment decisions to operational consequences. The focus has been on education and provocation vice analysis. However, comments from students afterwards provide evidence of lasting impression, understanding, and appreciation for the complexity of operational energy in warfare

1 **Optimal On-demand Order Assignment Through Dynamic Surge Pricing in Online Meal-delivery Markets via Deep Reinforcement Learning**

Azadeh Gharibreza Yazdi[1], Vadim Sokolov[2], Elise Miller-Hooks[1], [1]George Mason University, Fairfax, VA, [2]George Mason University, Fairfax, VA, Contact: agharibr@gmu.edu

Meal delivery companies connect customers to restaurants by assigning orders to crowd-sourced drivers. During peak demand periods, there may be insufficient at-will drivers available. The meal delivery company may wish to provide incentives through surge prices to encourage drivers to take new jobs. In this presentation, we propose a deep reinforcement learning method to derive optimal surge pricing policies during demand surges in this dynamic, stochastic multi-agent setting.

2 **Dynamic Routing of Drones for Last-Mile Delivery with Demand Uncertainty**

Linxuan Shi[1], Zhengtian Xu[2], Miguel Lejeune[3], [1]The George Washington University, Washington, DC, [2]The George Washington University, Washington, [3]George Washington University, Arlington, VA, Contact: shilx@gwmail.gwu.edu

Drones, given their advantage in avoiding ground obstacles and congestion, are projected as a promising means of transportation for the shipping and delivery market. This study aims at conceptualizing and modeling the use of drone fleets for urban logistics, including parcels, meals, groceries, among others. We focus on the dynamic deployment problem of a drone fleet for last-mile delivery by considering stochastic demand arrivals with heterogeneity and uncertainty in the delivery items' weights, pickup/drop-off locations, and delivery windows. A two-stage stochastic programming model is formulated and solved through an ad-hoc solution algorithm. The first stage accounts for the system-level considerations regarding fleet deployment, followed by the second stage delineating the interactions between the stochastic demand and dispatching decisions of drones.

3 **Strategies for Assigning Delivery Jobs with Uncertain Ready Times to At-will Couriers**

Weiwen Zhou[1], Elise Miller-Hooks[1], Sagar Sahasrabudhe[2], [1]George Mason University, Fairfax, VA, [2]Grubhub, Chicago, IL, Contact: wzhou5@gmu.edu

This presentation proposes a dynamic order assignment and courier routing problem that arises in a stochastic, dynamic meal delivery environment with uncertainty in upcoming orders, handling times and availability of couriers who sign in and out from the delivery platform at will. A stochastic, discrete event simulator is developed to replicate real meal delivery operations and an ejection chain neighborhood-embedded tabu search heuristic is proposed for its solution.

Decision-making, Utilization, and Outcomes in Emergency Departments

General Session

Session Chair
Gabriel Zayas-Caban, University of Wisconsin Madison, Madison, WI

Session Chair
Valerie Odeh-Couvertier, University of Wisconsin, WI

1 Average Response Curves for Treatment Time in the Emergency Department

Sebastian Alejandro Alvarez Avendano, University of Wisconsin, Madison, WI, Contact: alvarezavend@wisc.edu

We estimate average responses curves for treatment time in the Emergency Department. Extending treatment time is a promising solution for improving admission decisions. Providing support for this solution, however, is difficult because this intervention (treatment) is a continuous time-to-event; is strongly influenced by unmeasured patient health needs; and may be only modifiable up to a shift in the realized time. We show that average responses curves for treatment time cannot be identified nonparametrically due to unmeasured confounding from patient health needs. We thus use a parametric model that includes a latent variable for health needs and a threshold regression model for the admission process.

2 Temporal Analysis of Frequent Emergency Department Visits: A Machine Learning Approach

Lloyd Fernandes[1], Hyojung Kang[1], Seokgi Lee[2], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]Youngstown State University, Youngstown, OH, Contact: lloydf2@illinois.edu

Frequent emergency department (ED) users account for only 4.5 - 8% of all ED patients but 21 - 28 % of all ED visits. Identifying patients who use the ED often can help hospitals identify and address such patients through a more streamlined care management system and reduce the burden on EDs. The objective of this study is to build a prediction model that can identify ED frequent users based on their past electronic health records. We implement various machine learning techniques to make effective use of the temporal nature of the electronic health record and use natural language processing based embedding techniques to encode high dimensional diagnosis codes.

3 Association Between Advanced Image Ordered in The Emergency Department and Subsequent Imaging for Abdominal Pain Patients

Valerie Odeh-Couvertier, University of Wisconsin, WI

Abdominal pain is associated with high rates of emergency department (ED) imaging utilization and revisits. A better understanding is needed on when the decision to image is justified. We evaluated associations between ED imaging on subsequent outpatient imaging and revisits among abdominal pain patients discharged from the ED. Imaging in the ED was associated with lower imaging utilization and revisit to an ED after discharge, suggesting that ED imaging may replace downstream imaging.

4 Impact of Ridesharing Entry on Hospitals' Emergency Department (ED) Admissions

Saeed Piri, University of Oregon, Eugene, OR

In this paper, we examine the impact of information technology (IT)-enabled ridesharing platforms on healthcare demands, specifically at hospitals' emergency departments (EDs). We consider the rollout of ridesharing platforms over time in distinct locations and analyze changes in Emergency Department (ED) hospital admissions. Employing a difference-in-differences design, we analyze HCUP (Healthcare Cost and Utilization Project) data from the state of Florida, that has patient-level arrival and treatment data for 42 million emergency department patient encounters. We find that the availability of ridesharing services has a positive and significant effect on ED arrivals, indicating enhanced accessibility. To identify the heterogeneous impact of ridesharing, we repeated our analysis in different patient sub-populations. Our results indicate the most significant effect applies to young, middle-aged, low-income, and non-critical patients. Additionally, in a post-hoc analysis, we find a significant increase in ED service time for patients with less critical conditions and no change in length of visit for critical patients. The rise in ED demand due to ridesharing entry can have two distinct implications for emergency departments. On the one hand, ridesharing entry addresses the access barrier when the patient's condition is non-critical, but ED usage is necessary. This is a positive impact of ridesharing services availability, especially since it helps low-income communities the most. Therefore, hospitals and ridesharing companies can collaborate to address the challenge of healthcare access. On the other hand, ridesharing entry may exacerbate already overcrowded EDs by facilitating non-critical and unnecessary ED usage, which can be an adverse effect. In this case, effective patient triage to identify those with urgent needs may become even more essential after ridesharing entry.

Healthcare OM under a Pandemic
General Session

Session Chair
Vedat Verter, Michigan State University, East Lansing, MI

1 Managing Hospital Resources Amid a Pandemicfor Improving Regional Health Outcomes

Vedat Verter[1], Beste Kucukyazici[1], Angelos Georghiou[2], Bahman Naderi[3], Anand Nair[4], [1]Michigan State University, East Lansing, MI, [2]University of Cyprus, Nicosia, Cyprus; [3]Amazon Web Cervices, Marina del rey, CA, [4]Michigan State University, East Lansing, MI, Contact: verter@msu.edu

During the early week of the COVID-19 pandemic, surge capacity was managed by transferring patients among different hospitals within the same health network, repurposing ORs as ICU beds and cancelling elective surgeries. Using publicly available data from Michigan, we develop an analytical framework to study how these policies can be implemented individually, or in combination, in order to optimize the pandemic response in a region, while delivering care to uninfected patients.

2 Managing Medical Equipment Capacity with Early Spread of Infection in a Region

Apurva Jain, Swapnil Rayal, University of Washington, Seattle, WA, Contact: apurva@uw.edu

We develop a model for a regional decision-maker to analyze the requirement of medical equipment capacity in the early stages of a spread of infections. We use a stochastic differential equation to capture the growth of infections in a community spread and shutdown model. We develop results to determine shutdown time, to show how to compensate for limited medical equipment capacity, and to show how capacity-sharing across regions can deliver a peak-timing benefit beyond traditional risk pooling.

3 Countermeasures Against Challenges of Vaccine Production Capacity Building

Fuminori Toyasaki[1], Hongmei Sun[2], [1]York University, Toronto, ON, Canada; [2]York University, Kanata, ON, Canada. Contact: toyasaki@yorku.ca

Vaccines have helped defeat several pandemics and epidemics in human history. In the recent COVID-19, vaccines have been developed at unprecedented speed, enabling effective vaccines to help defeat the pandemic. Despite the significant contribution of vaccination to global health, the low vaccine coverage rate has usually been a severe concern internationally. This study sheds light on vaccine capacity management by answering the following research questions:
1. What types of government procurement contracts can align the interests of the government and the vaccine manufacturer to coordinate the vaccine supply chain and improve the supply of vaccines?
2. Can a high-competent vaccine developer always send an outsourced vaccine manufacturer a credible signal for its true competence when information asymmetry exists between the two parties?

Operations Research with Impactful Applications in Healthcare
General Session

Session Chair
Lauren Lindley Czerniak, 1</sup

1 Uncertainty in Patient Condition and Treatment Pathways in a Tiered Ambulance Allocation Model

Eric G. Stratman[1], Laura Albert[2], Justin J. Boutilier[3], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Middleton, WI, [3]University of Wisconsin-Madison, Fitchburg, WI, Contact: egstratman@wisc.edu

Changes in federal regulation allow eligible emergency medical patients to be treated at the scene of an incident or an alternative destination other than an emergency department. These new treatment pathways can reduce emergency medical service (EMS) expenditure and enhance the quality of care; however, the pathways available to a patient are uncertain until EMS personnel arrive at the scene of the incident and assess the patient. We develop a tiered EMS resource allocation model for a system with uncertainty in patient condition. The model optimally allocates resources considering the information known following the phone triage and the recourse actions that may be taken once the patient's true condition and treatment pathways are known. We demonstrate the value of these new treatment pathways and flexible EMS fleet strategies.

2 Optimal Prioritization and Discharge Policies for Medicaid Waiver Services

Yuqing Chen[1], Qiushi Chen[1], Can Zhang[2], [1]Pennsylvania State University, University Park, PA, [2]Duke University, Durham, NC, Contact: ykc5346@psu.edu

Medicaid waiver programs provide critical services for patients with developmental disabilities to support the care in home and community-based settings. Due to both a rapid increase in demand and limited resources for such services, the current waiting time is extensive and detrimental to the patients. Prior studies have focused on identifying either optimal prioritization or discharge policies in managing the waitlist, whereas joint decisions of both have not been extensively studied. We propose a Markov Decision Process (MDP) modeling framework for examining jointly optimal prioritization and discharge decisions and studying how the option of early discharge can lead to different structures of prioritization decisions.

3 Identifying Individuals at Risk of Vision Threatening Diabetic Retinopathy

Erik Rosenstrom, Julie Simmons Ivy, Maria Mayorga, North Carolina State University, Raleigh, NC, Contact: erosens@ncsu.edu

Diabetic retinopathy (DR) is a complication from diabetes which can become vision threatening (VTDR) and cause blindness. In the US, an estimated 899,000 diabetic adults have VTDR despite it being preventable with timely treatment. VTDR is difficult to catch due to the slow progression and dependence on patients' care seeking behavior. Here we address these challenges by leveraging 20+ years of electronic health records to construct and extend ensemble classifiers to (i) identify patients that will develop VTDR within the next year and (ii) to identify those that will develop DR in the next year. We can achieve high recall (>80%) for both classification tasks. In practice this classifier can personalize care coordination to improve utilization and timing without any additional patient actions.

4 Closed-form (R,S) Inventory Policies for Hospital Pharmacies Experiencing Supply Chain Disruptions

Lauren L. Czerniak, Mark S. Daskin, Mariel S. Lavieri, Burgunda V. Sweet, Jenn Leja, Matthew A. Tupps, Karl Renius, University of Michigan, Ann Arbor, MI, Contact: czernl@umich.edu

Hospital pharmacy managers make decisions for thousands of different perishable drugs that experience supply chain disruptions. This makes (a) quick to solve and (b) easy to implement inventory policies of utmost importance in this application area. We derive closed-form solutions for a perishable lost-sales (R,S) periodic review inventory system with supply chain disruptions. We perform a numerical analysis to (i) illustrate the impact of ignoring perishability and supply chain disruptions, (ii) show the importance of accounting for the length and time between supply chain disruptions, (iii) demonstrate the consequences of selecting simplicity over model accuracy, and (iv) study the influence of stochastic demand.

Discharges and Readmissions
Contributed Session

Session Chair
Fatma Pakdil, Eastern Connecticut State University, Willimantic, CT

1 Joint Admission and Discharge Control with Readmissions

Zhiyuan Lou[1], Jingui Xie[2], Taozeng Zhu[3], [1]Technical University of Munich, Heilbronn, Germany; [2]Technical University of Munich, Heilbronn, Germany; [3]Dongbei University of Finance and Economics, Dalian, China. Contact: zhiyuan.lou@tum.de

Admission and discharge decisions play essential roles in hospital intensive care unit (ICU) bed capacity management. In this model, we formulate the readmission of patients as an endogenous process that relies on previous discharge decisions. We develop a model to consider early discharge decisions and admission control jointly, including emergency diversion and elective scheduling. By applying the riskiness index, we can reformulate the problem as a sequence of convex mixed-integer problems and solve it efficiently. We use the MIMIC-III data to validate our model. The numerical study shows that the capacity overload risk is under control by applying our model. We also compare the effects of different admission and discharge policies.

2 How a Dedicated Post-discharge Unit Can Reduce Hospital Congestion and Costs

Maryam Khatami[1], Jon M. Stauffer[2], Mark Alan Lawley[2], [1]Indiana University, Bloomington, IN, [2]Texas A&M University, College Station, TX, Contact: mkhatami@iu.edu

Depending on the patient's condition, up to 60% of inpatients are transferred to post-acute care facilities. They may experience several days of non-medical inpatient stay until the hospital finds a facility that fits their needs, contributing to overcrowding in upstream units. We study the feasibility of creating a "post-discharge-unit" (PDU) for ready-for-discharge patients experiencing transfer delays. We use a multistage stochastic program to address the PDU capacity planning issue. Our results, using data from a large hospital, show that a PDU can reduce costs and improve access to inpatient beds. Compared to current practice in our partner hospital, a PDU could increase access to inpatient beds by up to 13% and result in 2-21% cost savings. Also, PDU capacity in hospitals with a larger number of patients waiting for transfer is more sensitive to variation in PDU costs.

3 Using Machine Learning Methods to Develop Risk-adjusted Prediction Models in Healthcare

Sonia Jahangiri, Nasibeh Azadeh-Fard, Rochester Institute of Technology, Rochester, NY, Contact: sj1374@rit.edu

In-hospital mortality, hospital length of stay (LOS), and readmission are the most significant measures for evaluating the performance of the healthcare system. We use the Nationwide Readmission Database (from the Agency for Healthcare Research and Quality) consisting of approximately 35 million patient data, to develop a novel risk-adjusted prediction model that integrates clinical and non-clinical data. The most significant variables were selected using the combination of Boruta and Random Forest techniques. Then, different machine learning methods were used to build a risk-adjusted model to predict the risk of readmission, LOS, and in-hospital mortality.

4 The Length of Stay and Readmissions of Pneumonia Patients: An Analysis Using NRd in HCUP Between 2010 and 2018

Fatma Pakdil[1], Steve Muchiri[1], Nasibeh Azadeh-Fard[2], [1]Eastern Connecticut State University, Willimantic, CT, [2]RIT, Rochester, NY, Contact: pakdilf@easternct.edu

Hospital length of stay (LOS) and readmissions are commonly considered major patient outcomes for measuring quality and cost of healthcare services. This paper examines the relationship between the readmissions and LOS of pneumonia patients using the Nationwide Readmission Database provided by the Healthcare Cost and Utilization Project (HCUP) between 2010 and 2018. This study analyzes the relationship between LOS and 30-day readmissions of pneumonia patients. Obtaining a further understanding of the relationships between LOS and readmission rates of pneumonia patients may provide insightful knowledge for policy and decision-makers.

1 Lessons Learned from Applying Multi-criteria Decision-making Methods to Early-stage Pharmaceutical Development Decisions

Deepak Veeraraghavan, Strategic Decisions Group,

Düsseldorf, Germany. Contact: vdeepak@sdg.com
Multi-criteria decision-making (MCDM) methods have been shown to be well suited to support early-stage pharmaceutical development decisions. In 2019, the authors applied value-based thinking and MCDM methods to prioritize early-stage development assets at Bayer Pharmaceuticals. In this presentation, the authors reflect on the implications of this new approach and present lessons for decision analysts and decision makers in the pharmaceutical industry. They discuss best practices for developing a set of fundamental objectives, operationalizing those objectives, and taking steps to de-bias the organizational decision-making process.

Decision Modelling in Supply Chain Management

General Session

Session Chair
Jonathan W. Welburn, RAND Corporation, Santa Monica, CA

1 **Value of Customer Preference Information in Supply Chain Network Design**
Austin Saragih[1], Milena Janjevic[2], Jarrod D. Goentzel[2], Gilberto Montibeller[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Loughborough University, Loughborough, United Kingdom.
Understanding shifting customer preferences and cost complexities are essential to designing successful supply chains. However, acquiring all customer and operational information is costly during the design phase. This study provides a strategic framework to evaluate the appropriate amount of information needed a priori in supply chain network design. We analyze the value of full information (VOFI) and partial information (VOPI) and their acquisition costs. We identify the optimal strategy for information acquisition over spatial areas against its marginal cost.

2 **Presenter**
Jonathan W. Welburn, RAND Corporation, Santa Monica, CA

3 **Forecasting Demand for Optimal Inventory with Long Lead Times: An Automotive Aftermarket Case Study**
Norman Keith Womer[1], Christopher Anderson[2], [1]University of Missouri-St Louis, Saint Louis, MO, [2]University of Missouri-St Louis, Saint Louis, MO, Contact: womerk@umsl.edu
Accuracy in predicting customer demand is essential for inventory policy under periodic review, long lead-time, and a target fill rate. This study uses stock control metrics to evaluate the forecast by different simple to more complex predictive analytical techniques. We show how traditional forecast error measures are inappropriate for inventory control, despite their frequent use. We do so, by evaluating demand forecast performance looking at holding cost, stock out cost, and customer service levels. We also evaluate an econometric autoregressive model of demand for the parts manufacturer. This study adds to the limited case study research on demand forecasting under long lead times using stock control metrics, dynamic model updating, and the Prais-Winsten method of estimating demand.

Behavioral Operations in the Public Sector

General Session

Session Chair
James Fan, Naval Postgraduate School, Seaside, CA

1 **Behavioral Responses to Nonprofit Performance Metrics: Efficiency vs. Impact**

Hasti Rahemi[1], Gloria Urrea[2], Leon Valdes[3], [1]University of Colorado Boulder, Boulder, CO, [2]University of Colorado Boulder, Superior, CO, [3]University of Pittsburgh, Pittsburgh, PA, Contact: hasti.rahemi@colorado.edu

Donors seek to evaluate the performance of nonprofit organizations (NPOs) before making donation decisions. The most commonly studied performance metric is Program Spending Ratio (PSR), which captures an NPO's expenditure on their programs as a fraction of their total expenses. However, PSR might do more harm than good, as it contributes to the NPO's starvation cycle. Therefore, we study whether and how NPOs can use additional metrics to communicate their performance to donors and reduce their reliance on PSR. Specifically, we investigate two performance metrics—impact and cost effectiveness—and how they interact with PSR information. Using a series of experiments, we shed light on whether and how donors' willingness to donate to an NPO is affected by these additional metrics.

2 Association Between Time and Monetary Donation

Chao Wu, Mahyar Eftekhar, Arizona State University, Tempe, AZ, Contact: eftekhar@asu.edu

Charities are cautioned against providing volunteer opportunities to potential donors because volunteers are considered as unreliable source of labor supply, and volunteering is assumed to crowd out monetary donation. In this study, we examine the causal relationship between individuals' volunteering and their subsequent donation decisions through two sets of experiments.

3 New Workers or New Tasks? An Augmented Reality Field Experiment with Public Sector Maintenance Officers

James Fan[1], Jelle de Vries[2], Clay Greunke[3], Perry McDowell[3], [1]Naval Postgraduate School, Seaside, CA, [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]Naval Postgraduate School, Monterey, CA, Contact: james.fan@nps.edu

We investigate the benefits of augmented reality guidance for a sophisticated maintenance procedure in a controlled field experiment at the Center for Naval Aviation Technical Training. Using naval maintenance officers as participants, we explore the interaction between guidance modality, worker experience, and task-switching.

4 Effects of Horizons, Delays and Magnitudes on the Time Preferences of US Agricultural Producers and Land-Grant University Students

Diya Ganguly[1], Paul Feldman[2], Paul Ferraro[3], Kent Messer[4], [1]University of Delaware, DE, [2]Texas A&M University, College Station, TX, [3]Johns Hopkins University, Baltimore, MD, [4]University of Delaware, Newark, DE

Economic experiments often utilize convenience samples that involve student participants. We aim to examine if students serve as good model participants for decision -making by farmers. Using large-sample field experiments with agricultural producers and university students from the same states we compare time and risk preferences across these two samples. To elicit time preference, we use the convex time budget methods to understand decisions in delayed payoffs, at the individual level. We compare differences in magnitude, delay, and horizon effects between student and producer populations. To elicit risk preferences, we use Eckel and Grossman's (2002) risk elicitation method and compare constant relative risk aversion estimates across student and producer populations.

Choosing Opponents in Tournaments
Tutorial Session

Session Chair
Mabel Chou, National University of Singapore, SG, SG, Singapore.

1 **Choosing Opponents in Tournaments**
Nicholas G. Hall[1], Zhixin Liu[2], [1]Ohio State University, Columbus, OH, [2]University of Michigan-Dearborn, Dearborn, MI
We consider the design of tournaments that use a preliminary stage, followed by several rounds of single elimination play. Many sports, including for example most U.S. major sports, use this format. The tournament design problem involves determining the sequence of matchups re-quired to determine a winner. This problem has been extensively studied within the literature of operations research and economics. The conventional design of the single elimination rounds is a "bracket" based on a prior ranking or seeding of the players. However, this design suffers from several deficiencies, insofar as natural expectations about the results of the design are not satis-fied. First, the expectation that higher ranked players having a higher probability of winning is not satisfied. Second, the probability that the top two players meet is not maximized. Third, there is the widely observed issue of tanking or shirking at the preliminary stage, where there are disincentives for a player to win. Fourth, top ranked players randomly incur unfortunate matchups against other players, which introduces an unnecessary element of luck. Finally, the use of a conventional fixed bracket is limiting, in that it fails to allow players to consider infor-mation that develops during the tournament. Our proposed solution involves allowing higher ranked players at the single elimination stage to choose their next opponent at each round. Us-ing data from 1,902 men's professional tennis tournaments during 2001-2016, we demonstrate the reasonableness of the results obtained. We also perform sensitivity analysis for the effect of increasing irregularity in the pairwise win probability matrix on three traditional performance measures. Finally, we consider strategic shirking behavior, and show how our opponent choice design can eliminate or reduce such behavior, including in for some famous examples. In sum-mary, compared with the conventional design, the opponent choice design provides higher probabilities that the best player wins and also that the two best players meet, and reduces shirk-ing by both individual players and groups.

Location Analysis to Popularize Alternative Fuel Vehicles
Joint Session

Session Chair
Yudai Honma, The University of Tokyo, Meguro-Ku, Japan.

Session Chair
Ibrahim Capar, Bowling Green State University, Bowling Green, OH

1 **Considering Capacity in Designing Electrical Vehicle Chargers Network**
Ibrahim Capar[1], Ozgur M. Araz[2], Ismail Capar[3], [1]Bowling Green State University, Bowling Green, OH, [2]University of Nebraska–Lincoln, Lincoln, NE, [3]Texas A&M University, College Station, TX, Contact: icapar@bgsu.edu
Electrical vehicles (EVs) have a critical role in the future of sustainable transportation systems. In this paper, we present a network design framework to improve the infrastructure for EVs with quality of service constraints taken into considerations. We present a novel charging station location model with capacity allocation. The model maximizes the flow captured and minimizes the average service time for drivers. The model formulation allows assessing capacity and quality of service trade-offs and support service network design decisions. Operational insights are derived and presented for reflecting EV drivers' expectations. We demonstrate an application of the developed solution approach on real road network and evaluate the performance based on both computational efficiency and solution quality.

2 **Exact Solution Algorithms of Continuous P-median and P-center Problems of Manhattan Distance**
Thomas Byrne[1], Atsuo Suzuki[2], Mihiro Sasaki[2], [1]University of Strathclyde, Glasgow, United Kingdom; [2]Nanzan University, Nagoya, Japan. Contact: tom.byrne@strath.ac.uk
We propose algorithms to obtain the exact solutions of continuous p-Median and continuous p-Center problem of Manhattan distance. They are combinatorial problems and as far as we know, no practical algorithm to obtain the exact solution has been proposed. To overcome the difficulty, we propose Big Triangle and Small Triangle (BTST) and

Big Rectangle and Small Rectangle (BRSR) algorithms for both problems and obtain the exact solutions. We obtain a tight lower bound of the objective function in a triangle or rectangle which is essential for the BTST and BRSR algorithms by geometrical consideration. We show the effectiveness of the algorithms using the lower bound by the computational experiments.

3 Location-Routing Problem for Emergency Refueling Station Deployment to Support Alternative Fuel Vehicles Evacuation

Denissa Sari Darmawi Purba[1], Simon Balisi[2], Eleftheria Kontou[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Champaign, IL, [3]University of Illinois at Urbana-Champaign, Urbana, Contact: dpurba2@illinois.edu

Alternative fuel vehicles may pose challenges to evacuation planning due to their short driving range and sparse refueling infrastructure on transportation networks. Deployment and strategic siting of emergency refueling stations are needed to support the evacuation of alternative fuel vehicles to reach a shelter. This study proposes a location-routing problem with hop constraints that optimize the placement of emergency refueling stations of each alternative fuel type to support their evacuation routing. We develop a bender-decomposition method with a transformed network to solve the location problem and a matheuristic branch-and-price method to design evacuation routes that minimize travel and refueling time and satisfy the hop constraints of each vehicle type. We perform preliminary numerical experiments on the Sioux Falls network.

4 Locational Analysis of In-motion Wireless Power Transfer System for Long-distance Trips by Electric Vehicles

Yudai Honma, Daisuke Hasegawa, Katsuhiro Hata, Takashi Oguchi, The University of Tokyo, Tokyo, Japan. Contact: yudai@iis.u-tokyo.ac.jp

The popularization of electric vehicles (EVs) is limited by their driving range and long charging times. To address this, in-motion wireless power transfer systems (WPTSs) are currently attracting attention as a new system. In-motion WPTSs have coils embedded under the road to transfer power from the WPTSs to EVs while driving. However, the main drawback of WPTSs is its large investment, especially in supporting the long-distance trips of EVs on expressways. Therefore, this paper proposes a new mixed-integer programming model (MIP) to determine the optimal location of WPTSs for maximized total feasible flow demand. By focusing on long-distance trips on expressways, we proposed the first flow-capturing model for WPTS locations that can solve for the distance of WPTS installed as continuous variables, and solve problems based on real-scale data using a general MIP solver.

Community Engagement and Diversity, Equity and Inclusion in OR/analytics

Joint Session

Session Chair

Michael P. Johnson, University of Massachusetts Boston, Boston, MA

1 Vulnerable to Interconnected! Redefining Community Engaged Decision Making for Wicked Problems

Sajani Kandel[1], Namesh Killemsetty[2], [1]University of Massachusetts Boston, Boston, MA, [2]O.P. Jindal School of Government and Public Policy, Sonipat, New Delhi, India.

Value-focused thinking (VFT) is a widely used analytical approach to identify and structure the preferences of multiple stakeholders in a complex decision-making context. With its roots in decision sciences, VFT has been applied to understand decision making in large organizations involving professionals who are experts in the area. We argue that VFT has immense potential outside traditional domain in providing a unique perspective of marginalized communities to create community-valued/ centric decision opportunities. The paper uses two cases of VFT research application,1) housing preferences of slum communities in Odisha, India, and 2) climate change adaptation strategies in predominately black neighborhood in Boston,US, to elaborate the principal characteristics and methodological consdideration of VFT application in a non-traditional context.

2 Agent-based Model of Police Funding Tradeoffs Through the Lens of Legitimacy and Hardship

Jack Mitcham, University of Massachusetts Boston, Boston, MA, Contact: jack.mitcham001@umb.edu

There are mixed results in the literature when examining the impact of police spending and social welfare spending on crime rates. Here, we use an agent-based model to explore the impacts of the tradeoff between police spending and social welfare spending on crime in an attempt to explain

those mixed results and to provide guidance for policymakers who are implementing these funding decisions. We find that by including hardship of the people and their view of police legitimacy, the impact of increasing police spending has diminishing returns on the crime rate and under certain circumstances can lead to an increase in crime.

3 Using Analytics to Create Equity Throughout the Supply Chain

Kendra C. Taylor, KEYFFICIENCIES, Inc., Atlanta, GA, Contact: kendra@keyfficiencies.com

When we consider equity in business, we tend to consider it within a single company or institution. What if we expanded the view to include laborers experiencing harsh treatment and conditions to provide products and services that support the full supply chain. We will explore how companies are expanding Equity while tackling labor trafficking in their supply chain.

4 Bridging the Digital Divide: Role of Digital Platforms and Policy Framework

Roohid Ahmed Syed[1], Shivendu Shivendu[2], [1]University of South Florida, Tampa, FL, [2]University of South Florida, Tampa, FL, Contact: roohidahmed@usf.edu

Digital divide is a global phenomenon that gained much attention during the recent COVID-19 pandemic. Extent theoretical research has studied the impact of market regulation and subsidies to Internet Service Providers on broadband adoption. In this paper, we study two levels of digital divide: access divide and use divide. We model the heterogeneity of consumers along two dimensions: marginal valuation for broadband speed and digital literacy. Using game theoretic approach, we study the conditions for optimality for two types of subsidies: broadband subsidy and digital literacy training subsidy. The subsidies are provided by a social welfare maximizing social planner. We also consider a monopolist platform whose profits depend on the level of use divide and analyze the impact of platform's incentives on social planner's optimal subsidy strategy.

Emerging Topics in Behavioral Operations Management

General Session

Session Chair

Swanand Kulkarni, Atlanta, GA

Session Chair

Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA

1 Startup Fundraising and Equity Split: Do the Number of Investors and Contract Form Matter?

Evgeny Kagan[1], Kyle Hyndman[2], Anyan Qi[3], [1]Johns Hopkins Carey Business School, Washington, [2]University of Texas at Dallas, Richardson, TX, [3]The University of Texas at Dallas, Richardson, TX, Contact: axq140430@utdallas.edu

We study equity division between an entrepreneur and one or more potential investors. The investor(s) and the entrepreneur negotiate how much equity (ownership) in the startup the investor(s) should receive in exchange for their investment. The value of that equity is uncertain at the time of the negotiations. We examine how the allocation of startup equity between the entrepreneur and the investors is affected by the following: (1) the number of investors, (2) the outside option of the entrepreneur, and (3) whether investors receive downside protection via ``Preferred Stock'', as is sometimes done in practice.

2 Algorithm Reliance Under Pressure: The Effect of Customer Load on Service Workers

Clare Snyder[1], Stephen Leider[2], Samantha Meyer Keppler[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: claresny@umich.edu

Augmented (human + algorithm) intelligence can increase customer service efficiency and quality, allowing companies to increase service scale�if customer-facing workers use the algorithms. Service operations and algorithm reliance literature present conflicting evidence about how workers will rely on algorithms in the service setting. With a laboratory experiment, we show that workers' algorithm reliance is low, but that it increases with customer load. This effect grows over time as the high customer load creates more opportunities for feedback about the algorithm. With a second study, we show that learning interventions can further encourage algorithm reliance. Our results contribute to theory at the intersection of service operations and algorithm reliance and have practical implications about the algorithm-augmented service model.

3 When Less is More: Operations and Incentives of an On-demand Medical Crowdsourcing Platform

Jingxuan Geng[1], Guangwen (Crystal) Kong[2], Marco Shaojun Qin[1], [1]Temple University, Philadelphia, PA,

[2]Temple University, Wynnewood, PA, Contact: jingxuan.geng@temple.edu

We study how the pricing and non-pricing operational tools can be used to effectively balance supply and demand on a medical crowdsourcing platform. Specifically, we derive theoretical models and find that the pricing alone does not always yield optimal alignment between inquiries and answers. However, a platform can address it by capping the number of opinions in each inquiry (i.e., the control limit). Together with the optimal price, control limit allows the platform to charge higher and avoid doctors' over-participation. It also helps to retain high-quality doctors on the platforms. Interestingly, the platform's profit increases with patients' delay sensitivity (i.e., a patient prefers medical opinions that arrive earlier), and the effect of control limit substitutes the effect of delay sensitivity. We empirically test our predictions and get consistent results.

4 Spatial Information Sharing on On-demand Service Platforms: A Behavioral Examination

Swanand Kulkarni[1], Basak Kalkanci[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: swanandkulkarni@gatech.edu

Through a game-theoretic model and lab experiments, we examine how mechanisms to share demand-supply mismatch information spatially affect a platform's matching efficiency. We compare surge information sharing (where all drivers learn about a surge, common practice today) with full (where drivers learn about the demand conditions in all zones) and local information sharing (where only nearby drivers learn about a surge). Experimentally, with full or local information sharing, the platform achieves comparable matching efficiency to surge despite being dominated in theory and serves more customers than predicted. Thus, sharing demand-supply mismatch either fully or in a personalized manner can alleviate coordination problems on platforms.

Pharmaceutical Supply Chain Management: Drug Shortage and Drug Quality

General Session

Session Chair

Parshuram Hotkar, Indian School of Business, Hyderabad, India.

Session Chair

Hanu Tyagi, University of Minnesota, Minneapolis, MN

1 Mitigating the US Drug Shortages: Policy Interventions and Quality Reward

Sergey Naumov, In Joon Noh, Hui Zhao, Smeal College of Business, The Pennsylvania State University, University Park, PA, Contact: huz10@psu.edu

Using a two-stage system dynamics model, we capture essential features of the pharmaceutical market and supply chain related to drug shortages in the US and evaluate a number of existing and ongoing government interventions (such as quality reward) to improve supply chain resilience and mitigate drug shortages.

2 The Impacts of a Non-profit Organization on Drug Shortages

Junghee Lee[1], Hyoduk Shin[2], Daewon Sun[1], Jennifer K. Ryan[3], [1]University of Notre Dame, Notre Dame, IN, [2]UC-San Diego, La Jolla, CA, [3]University of Nebraska–Lincoln, Lincoln, NE, Contact: jlee93@nd.edu

The ongoing drugs shortages critically threaten public health. To mitigate the drug shortages, philanthropies and hospital systems founded a non-profit organization that "better" sources drugs. We investigate how the advent of the non-profit entity reshapes the competition and impacts the performance of each entity in a pharmaceutical drug supply chain.

3 Generic Drugs, Manufacturing Location, and Drug Safety

John V. Gray[1], In Joon Noh[2], George Ball[3], [1]Fisher College of Business, The Ohio State University, Columbus, OH, [2]Smeal College of Business, Penn State University, State College, PA, [3]Operations and Decision Technologies, Kelley School of Business, Indiana University, Bloomington, IN, Contact: gray.402@osu.edu

Generic drugs now represent nearly 90% of drugs dispensed in the United States. Consumers, doctors, and pharmacists generally assume that generics are interchangeable, allowing organizations that buy generic drugs to often focus mostly on the price. Partially because of this pricing pressure, generic drugs are increasingly made in lower-cost locations, such as India. In this study, we examine whether the location of manufacture relates to generic drug safety.

4 Impact of Expedited Approvals on Drug Shortages

Parshuram Hotkar[1], Diwakar Gupta[2], [1]Indian School of Business, Hyderabad, India; [2]University of Texas, Austin, TX, Contact: parshuram_hotkar@isb.edu

Many critical drugs, especially sterile injectable drugs, experience frequent shortages, and these shortages exact significant financial and human toll. In 2016, the US congress passed the Cures Act to expedite the review process and approvals of medical products. Through an empirical study, we investigate the impact of expedited approvals on the competition and drug shortages.

Session Chair

Li Ding, NULL, Atlanta, GA

1 Customers' Multi-homing in Ride-hailing: Evidence from a Structural Model

Sandeep Chitla[1], Maxime Cohen[2], Srikanth Jagabathula[1], Dmitry Mitrofanov[3], [1]NYU Stern School of Business, New York, NY, [2]McGill University, Montreal, QC, Canada; [3]Boston College, Chestnut Hill, MA

Using a large panel dataset with repeated choices of riders for both Uber and Lyft, we estimate a structural "consider-then-choose" model to better understand the trade-offs faced by riders. We find that riders' choices are not fully explained by operational factors such as price and waiting time, indicating that riders view the platforms as differentiated services and not as commodities. We also find that the multi-homing behavior of riders is only observed for a small fraction of the rides.

2 Trips for Tips? The Impact of Tips on Drivers' Relocation Decisions

Li Ding[1], Seyedmorteza Emadi[2], Basak Kalkanci[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, Contact: lding60@gatech.edu

Using a large-scale and granular taxi trip dataset, we analyze the role of passenger tips in drivers' relocation decision-making process using structure estimation. Inspired by different tip information sharing practices adopted in platform companies (e.g., real-time or delayed information sharing), we conduct counterfactual analysis to examine how tip information sharing policies affect drivers' income and platform efficiency.

3 The Impacts of Algorithmic Work Assignment on Fairness Perceptions and Productivity: Evidence from Field Experiments

Bing Bai[1], Hengchen Dai[2], Dennis Zhang[3], [1]Washington University-St Louis, Saint Louis, MO, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]Washington University in St Louis, ST LOUIS, MO, Contact: hengchen.dai@anderson.ucla.edu

The growing concern that algorithms may reproduce or even magnify the inequality historically exhibited by humans calls for research on how people perceive the fairness of algorithmic decisions (vs. human-based decision-making) and consequently, adjust their work motivation. We study how algorithmic (vs. human-based) task assignment processes change workers' fairness perceptions and productivity. In two field experiments with Alibaba where warehouse picking workers received tasks either from an algorithm or a human, the algorithmic assignment process was perceived as fairer and yielded productivity gains, despite that the two processes used the same underlying rule to allocate tasks. We showed via online experiments that people in the U.S. also viewed algorithmic task assignment as fairer.

4 Analysis of Automated Grocery Stores on Consumption Choices

Zhe Zhang[1], Xiaofeng Liu[2], [1]University of California-San Diego, San Diego, CA, [2]UC San Diego, La Jolla, CA, Contact: z9zhang@ucsd.edu

Unlike traditional physical grocery stores, autonomous stores, such as Amazon Go, don't have cashiers or check-out stations. With the advanced AI technology, consumers can walk in, pick out what they need, and then just walk out to complete a purchase trip in an autonomous store. In this paper, we try to understand the effects of autonomous stores on consumer purchase and traditional stores performance. We analyze the consumer purchase from the perspectives of purchase trips, product categories, and traditional stores. The paper could provide helpful insights for the retailers who would like to adopt autonomous stores or other new technology in the future.

Emerging Topics on Service Platform
General Session

Session Chair
Vahideh Manshadi, Yale University, New Haven, CT

Session Chair
Daniela Saban, Stanford University, Aachen

1 **Behavior-aware Queueing: When Strategic Customers Meet Strategic Servers**
Yueyang Zhong[1], Raga Gopalakrishnan[2], Amy R. Ward[1], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]Smith School of Business at Queen's University, Kingston, ON, Canada. Contact: yzhong0@chicagobooth.edu
Service system design is often informed by queueing theory. Traditional queueing theory assumes that servers work at constant speeds. While this is reasonable in computer science and manufacturing contexts, servers in service systems are people, and, in contrast to machines, both systemic and monetary incentives created by design decisions impact their work speeds. We use asymptotic analysis to study how server work speed is affected by managerial decisions concerning (i) how many servers to staff and how much to pay them, and (ii) whether and when to turn away customers, in the context of a finite-buffer many-server queue in which the work speeds emerge as the solution to a noncooperative game. In addition, we characterize the "price of anarchy" by comparing the performance under the equilibrium with that under the optimal solution to the centralized optimization problem.

2 **Matchmaking Strategies for Maximizing Player Engagement in Video Games**
Mingliu Chen, Xiao Lei, Adam Elmachtoub, Columbia University, New York, NY
We propose a general framework to analyze the dynamic matching problem in online video games, aiming to maximize player engagement. Players have different skill levels, which affect the outcomes of matches, and the win-loss record influences their willingness to remain engaged. We fully characterize the optimal matching policy on a stylized model where there are two skill levels, and players churn only when they experience a losing streak. The optimal policy always matches as many low-skilled players who are not at risk of churning to high-skilled players who are one loss away from churning. Compared to the industry status quo that matches players with the same skill level together, we prove the benefit of optimizing the matchmaking system grows linearly with the number of skill levels. Our framework can also handle the addition of AI bots and pay-to-win system.

3 **Platform Fulfillment: Antitrust and Upstream Market Power**
Amandeep Singh[1], Jiding Zhang[2], Senthil Veeraraghavan[3], [1]University of Washington, Seattle, WA, [2]New York University Shanghai, Shanghai, China; [3]University of Pennsylvania, Philadelphia, PA, Contact: amdeep@uw.edu
Fulfillment by Platform (FBP) has been widely adopted by many e-commerce sellers. Despite providing better service to customers, platforms have come under regulatory scrutiny. We demonstrate that the adoption of fulfillment services offered by platforms improves consumer welfare but also affects competition among the sellers in the upstream markets. We use data from a leading online retailing marketplace to estimate the welfare effects of downstream fulfillment on upstream supply echelons. We find that the adoption of fulfillment by platform affects upstream market competition, measured by the Herfindahl-Hirschman Index, which is attributable to the higher cost of service. In particular, smaller merchants, with lower margins, are forced to increase their prices more to remain profitable with FBP, leading to a price disadvantage compared to bigger merchants.

4 **Dynamic Matching with Competition over Resources**

1 **Identifying Linked AI Repositories on Github: A Graph Self Supervised Learning Approach**
Ben Lazarine[1], Sagar Samtani[2], [1]Indiana University, Bloomington, IN, [2]Indiana University, Bloomington, Contact: belazar@iu.edu

Artificial Intelligence (AI) has seen a rapid acceleration in its use and development in recent years for safety-critical systems like production business systems, transportation, and medicine. A critical factor that has enabled this acceleration has been the AI development community's adoption of open-source software (OSS) practices. While OSS platforms, particularly GitHub, have helped accelerate AI development, they also lead to the accelerated spread of security issues. Therefore, this research aims to predict linkages between open-source AI tools on GitHub through a novel self-supervised deep learning-based graph embedding approach to help identify unknown influential vulnerable open-source AI packages for mitigation.

2 Identifying Major Human Behaviors Impacting Depression Using Sensor Signal Data: A Multiview-based Attention Approach

Aijia Yuan, Indiana University, Bloomington, IN, Contact: yuana@iu.edu

Mental health has become a leading cause of disability worldwide, and depression is one of the most common and serious mental illnesses affecting millions of people. In addition, student has been identified as one of the most vulnerable populations to depression. Although many universities provide counseling services to monitor students' mental health status, traditional approaches usually involve interviews and self-reports that require massive human labors and expenses. Therefore, we choose sensor signal data as an alternative to assess students' mental health conditions more objectively, ubiquitously, and cost-effectively. For this study, in addition to depression detection, we aim to identify the human behaviors associated with depression by developing a novel deep learning-based attention mechanism.

3 An Interaction Analysis of Targeting Across Multi-platforms in the Consumer Purchase Funnel

Ran (Alan) Zhang[1], Shivendu Shivendu[2], Daniel Zantedeschi[3], [1]Texas Tech University, Lubbock, TX, [2]University of South Florida, Tampa, FL, [3]University of South Florida, Tampa, TX, Contact: ran.alan.zhang@ttu.edu

We advance an empirical strategy aiming at measuring synergistic effects of online platforms for targeted advertising along the consumer-purchasing funnel. Gauging interaction effects between activities on different platforms is challenging, due to the presence of the "activity biases" where the most active users end up being targeted more frequently. We use a combination of matching strategy for multiple treatments and the control function approach mitigating the potential endogeneity issue. We find that targeting across platforms is positively associated with the ultimate conversion for consumers at the lower funnel, but there is no synergistic effect for the upper funnel consumers. Our finding points to the presence of complementarities between social media and traditional platforms along the purchasing funnel.

4 Price Discrimination in Crowdfunding

Weijia You[1], Xiahua Wei[2], [1]Beijing Forestry University, Iowa City, [2]University of Washington, Bothell, WA

In crowdfunding, fundraisers employ multiple marking strategies to attract backers to raise more funds, among which coupon is becoming popular while the impact is unclear yet. This study aims to fill in the gap. Based on the project-level panel data from a leading crowdfunding platform, we find that coupon positively contributes to the funds raised for the campaigns of most of the campaigns but not those in the categories of donation and publication. Regarding the coupon strategies, for the campaigns in the category of technology and design, there is a U shape relationship between the types of the coupons distributed and funds raised. We also find that coupons with higher minimum requirements, lower discounts, and in the early stage of the campaign can hurt the fundraising. These findings provide managerial implications for the fundraiser and the platform.

Sustainability in Agricultural and Food Supply Chains

General Session

Session Chair

Andre Du Pin Calmon, Scheller College of Business, Georgia Institute of Technology, Atlanta, GA

Session Chair

Philippe Blaettchen, Bayes Business School (formerly Cass), City University of London, London, United Kingdom.

1 Optimal Pricing Policies for Precision Agriculture Technologies

Heng Chen[1], Ying Zhang[2], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]Clemson University, Clemson, SC, Contact: heng@unl.edu

Precision agriculture can improve the efficiency of agricultural operations through reduced inputs and improved yields. Agricultural technology providers have used outcome-based pricing to promote the application of precision agriculture. In this paper, we explore the implications of outcome-based pricing on the adoption rate of precision agriculture and the benefits to farmers and technology providers. We build a two-period game model to study a provider's optimal pricing decisions, considering that the provider may learn in the second period through the experience in the first.

2 Traceability Technology Adoption in Supply Chain Networks

Philippe Blaettchen[1], Andre Du Pin Calmon[2], Georgina Hall[3], [1]Bayes Business School (formerly Cass), City University of London, London, United Kingdom; [2]Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, [3]INSEAD, Fontainebleau, France. Contact: philippe.blaettchen@city.ac.uk

Modern traceability technologies promise to make food supply chains safer and more transparent. However, benefits depend on supply chain-wide technology adoption. Hence, traceability initiatives need to subsidize some early adopters within a network of supply chains. We address the problem of identifying the most cost-effective set of firms to target for technology to diffuse broadly. While the problem is hard even to approximate, we introduce an LP algorithm that identifies exact solutions in polynomial time under some assumptions on the network structure. We establish that supply chain networks in practice tend to follow these assumptions. We then use our algorithm to derive key managerial insights into targeting based on structural properties, validating approaches taken by initiatives in practice. Finally, we derive heuristics for lower and upper bounds.

3 On the Management of Premade Foods

Jae-Hyuck Park[1], Erica Plambeck[2], Dan Andrei Iancu[2], [1]The Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]Stanford University, Stanford, CA, Contact: jaehyuck@ust.hk

We examine a grocery retailer's management of a premade food product whose goal is to maximize a weighted sum of direct profit and customer welfare. Considering the deterioration, the retailer chooses the shelf life, whether to issue items in FIFO or LIFO, and whether to use a timestamp. With timestamps, customers decide whether to purchase based on each item's age; without timestamps, they decide based on the average quality of purchased items. First, we find that LIFO outperforms FIFO when shelf life and issuance are jointly optimized. Second, our analysis suggests that the retailer should timestamp items only if customers have heterogeneous preferences and the disposal cost is sufficiently low or the retailer cares substantially about customer welfare. Lastly, we show how a mandate to donate unsold food can harm shoppers and reduce the quantity and quality of donated items.

4 Informal Cross-Border Trade in Africa: Operations, Policy, and Opportunities

Michael Lim[1], Jimin Park[2], Karthik Murali[3], [1]Seoul National University, Seoul, NA, Korea, Republic of; [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Oregon State University, Corvallis, OR

We seek to develop insights to understand the informal cross-border trade (ICBT) value chain and offer policy recommendations to successfully integrate it into the formal economy. Using a game-theoretic model, we analyze the operations and key market dynamics of ICBT, and examine implications of three representative UN policy directives. We apply our model to a case study based on Uganda's agricultural exports over an 11 year horizon to obtain insights on the efficacy of these policies and the tradeoffs that must be considered.

1 Spatial Price Integration in Commodity Markets with Capacitated Transportation Networks

Ian Yihang Zhu[1], Timothy C. Y. Chan[1], John R. Birge[2], Michael Pavlin[3], [1]University of Toronto, Toronto, ON, Canada; [2]University of Chicago, Chicago, IL, [3]Wilfrid Laurier University, Waterloo, ON, Canada.

Spatial price integration is extensively studied in commodity markets as a means of examining the degree of integration between regions of a geographically diverse market. Many commodity markets are supported by stable and well-defined transportation networks. In this paper, we analyze the relationship between the spatiotemporal distribution of prices and the features of the underlying transportation network. We characterize this relationship and show that price integration is strongly influenced by the characteristics of the network, especially when there are capacity constraints on links in the network. Our results are summarized using a price decomposition that explicitly isolates the influences of market forces (supply and demand), transportation costs, and capacity constraints among a set of equilibrium prices. We use these theoretical insights to develop a unique discrete optimization methodology to capture spatiotemporal price variations indicative of underlying network bottlenecks. We apply the methodology to gasoline prices in the southeastern United States, where the methodology effectively characterizes the price effects of a series of well-documented network and supply chain disruptions, providing important implications for operations and supply chain management.

2 Improving Drinking Water Access and Equity in Rural Sub-Saharan Africa

Chengcheng Zhai, Kurt Bretthauer, Alfonso Pedraza-Martinez, Kelley school of Business, Bloomington, IN

In 2020, 771 million people lacked basic drinking water access (UNICEF and WHO 2021). Building new water projects such as hand-pumps and small piped systems is the primary operational response by many non-governmental organizations (NGO) to bring people their first access to clean water in the rural areas of developing countries. Our research studies where to optimally build new water projects. To close the loop between practice and research, we collaborate with a local NGO and an international NGO working in rural Sub-Saharan Africa and conduct field research in Ethiopia. We first develop a decentralized water project location optimization model based on the current practice of a decentralized decision-making and project management system in the field and an equal per-beneficiary budget structure. We further identify that we can leverage groundwater distribution characteristics to improve water access equity. Groundwater, as a natural resource, is unevenly distributed within each community and across different communities, which leads to a naturally inequitable drinking water access. We propose three new models to improve both water access and access equity: a minimax model, an equitable budget structure, and a centralized model that leverages the existing community involvement. Through numerical studies, we compare the model solutions and generate recommendations for NGOs. Lastly, motivated by the current armed conflict in Ethiopia, we develop a stochastic model to study how to improve drinking water access while mitigating the negative impact of water project supply shocks. Our work studies a previously over- looked problem of drinking water access in rural areas of developing countries. It also provides a scalable methodology and managerial insights to NGOs building new water projects by combining large geo-coded data sets and field data.

Management of Service Systems

General Session

Session Chair

Wei Liu, University of North Carolina at Chapel Hill, Chapel Hill, NC

1 Joint Admission and Service Rate Control of an Unobservable Queue

Wei Liu, University of North Carolina at Chapel Hill, Chapel Hill, NC

Managers of call centers and healthcare centers need to decide the right number of customers to admit and the right value of service rate to use in the queueing system. We call this the joint admission and service rate control problem and study it in an unobservable single server queueing system. We focus on a general reward structure where the system earns an award from serving a customer under a general queueing system. Considering the general reward structure under a general queueing system is highly relevant for the system manager to do admission control in the industry like call center and healthcare. We show that when the server cost is less than or equal to the server value, we should admit all the customers, otherwise, we should not operate the queueing system. This policy would help the customer behave in a socially optimal way with self-regulation.

2 The Effects of Information Granularity on Abandonment and System Performance in Observable Priority Queues

Philipp Afeche[1], Junqi Hu[2], Rouba Ibrahim[3], Vahid Sarhangian[1], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, TORONTO, ON, Canada; [3]University College London, London, United Kingdom. Contact: junqijh.hu@utoronto.ca

Motivated by empirical studies of the abandonment behavior of customers in service systems, we propose new priority queueing models with time-varying arrivals and state-dependent abandonment depending on the granularity of state information available to the customers. We investigate the performance under three levels of information granularity (no, partial, and full information) by exploiting a fluid model of the system. For each information level, we establish the existence, uniqueness, and stability of an equilibrium. Then, we compare the equilibria under the three information designs and provide insights on the effects of information granularity on queue length and abandonment rate.

3 Value of Return Time Windows when Selling Experience Goods to Heterogeneously Informed Consumers

Punya Chatterjee[1], Aydin Alptekinoglu[2], Nicholas C. Petruzzi[3], [1]Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, University Park, PA, [3]University of Wisconsin-Madison, Madison, WI, Contact: pxc85@psu.edu

We study a profit-maximizing retailer's optimal return policy when selling an experience good to a market of heterogeneously informed consumers. The retailer offers either a return time window at full price (and full refund in the event of a return) or no returns at a price discount or both. We focus on the effect of learning through consumption in the consumers' return behavior and the attendant return policy decisions by the retailer. We find that salvage value of returns is a crucial factor in whether the retailer's optimal return policy would employ return windows and if it offers consumers a choice between a return window at full price and no-return at a discounted price.

Optimization Society's Award Session

Award Session

Session Chair

Alper Atamturk, IEOR, UC Berkeley, Berkeley, CA

Session Chair

Andy Sun, MIT, Cambridge, MA

1 Khachiyan Prize - Solving QCQPs

Daniel Bienstock, Columbia University, New York, NY

QCQPs (quadratically constrained quadratic programs) are becoming increasingly prevalent, arising in multiple engineering domains. A prime example is provided by the ACOPF problem, which models the operation of an electric power network under steady state -- ACOPF instances can be quite large and quite intricate and also display highly nonlinear behavior, in the sense that slightly infeasible solutions can also prove visibly superoptimal. The current state-of-the-art for QCQPs relies on two complementary and distinct techniques, one for proving bounds through relaxations (spatial branch-and-bound) and another for computing good feasible "local" solutions (nonlinear solvers). While both techniques, in particular NLP, can be successful, both can be challenged by large, complex instances.A project that I have been interested in for some time focuses on developing a generic technique, based on linear integer programming, for addressing both upper and lower bounds, with quality guarantees, and with good opportunistic performance. In this talk we will discuss our current efforts. This is joint work with current and former students: Mark Zuckerberg, Gonzalo Munoz and Matias Villagra.

2 Khachiyan Prize - Improved Data-driven Decision-making via Optimization: Models, Algorithms, and Applications

David B. Shmoys, Cornell University, Ithaca, NY

Khachiyan's paper on LP stands as a landmark achievement in the history of optimization, with impact far beyond its theoretical implications. In this talk, I will give a personal perspective on the interplay between theory & practice in optimization research, and how this integration has led to the best work in each, with ever greater challenges in this data-rich world. Modeling decision-making settings, developing effective algorithms, & addressing real-world problems are intertwined elements: I will touch upon work that exemplifies these aspects, using problem structure in the analysis of algorithmic efficiency & effectiveness, with applications in the sharing economy, congressional districting, & even Covid-19 mitigation.

3 Farkas Prize - An Accelerated Coordinate Gradient Descent Algorithm for Non-Separable Composite Optimization

Beck Amir, Tel Aviv University, Tel Aviv, Israel.

We define a monotone accelerated coordinate gradient descent-type method for problems consisting of minimizing f+g, where f is quadratic and g is prox-tractable nonsmooth and non-separable. The algorithm utilizes the forward-backward envelope that constitutes an exact smooth reformulation of f+g. We prove the algorithm achieves a convergence rate of O(1/k^1.5) in terms of the original objective function, improving current coordinate descent-type algorithms. In addition, we describe an adaptive variant of the algorithm that backtracks the spectral information and coordinate Lipschitz constants of the problem. We examine our algorithms on various settings, including two-dimensional total-variation-based image inpainting problems.

Distributionally Robust Learning and Optimization - II

General Session

Session Chair

Hamed Rahimian, Clemson University, Clemson, SC

Session Chair

Harsha Gangammanavar, Southern Methodist University, Dallas, TX

1 Contextual Expected-Value-Constrained Stochastic Programming

Hamed Rahimian, Clemson University, Clemson, SC, Contact: hrahimi@clemson.edu

Unlike classical stochastic programming models that often describe uncertain parameters independent of side information, we study a contextual expected-value-constrained stochastic programming formulation that incorporates features. We propose a tractable and fully data-driven approximation model that relies on weighted sums of random variables, and we present finite-sample and asymptotic feasibility and optimality guarantees of the data-driven optimal solution. We illustrate our findings on real and synthetic data.

2 Robust Markov Decision Processes with Data-Driven, Distance-based Ambiguity Sets

Siva Ramani, Archis Ghate, University of Washington, Seattle, WA

We consider MDPs where the true state-transition probabilities are unknown. We assume that they belong to certain ambiguity sets, and pick actions that maximize the worst-case expected total discounted reward over all transition probabilities from these sets. In our setup, the ambiguity set for the whole problem is a Cartesian product of ambiguity sets. Specifically, it includes all pmfs within a certain distance from an empirical transition pmf. We show that the optimal values of the robust MDPs converge to the optimal value of the true MDP, as the sample-size tends to infinity. A rate of convergence result is also derived. We also establish that the robust optimal value provides a lower bound on the value of the robust optimal policy in the true MDP, with a high probability. These results rely on two sufficient conditions that several commonly used distances satisfy.

3 Robust Contextual Portfolio Optimization with Gaussian Mixture Models

Grani Adiwena Hanasusanto[1], Yijie Wang[1], Chin Pang Ho[2], [1]The University of Texas at Austin, Austin, TX, [2]Imperial College London, London, United Kingdom.

We consider the portfolio optimization problem with contextual information that is available to better quantify and predict the uncertain returns of assets. Motivated by the regime modeling techniques for the finance market, we consider the setting where both the uncertain returns and the contextual information follow a Gaussian Mixture distribution. This problem is shown to be equivalent to a nominal portfolio optimization problem where the means and the covariance matrix are adjusted by the contextual information. We then apply robust optimization and propose the robust contextual portfolio optimization problem, which reduces the sensitivity of model parameters used in the Gaussian Mixture model. Finally, we conduct a numerical experiment in the US equity markets and demonstrate the advantage of the proposed method against other benchmark methods.

4 Sequential Sampling-based Methods for Distributionally Robust Optimization

Harsha Gangammanavar, Southern Methodist University, Dallas, TX

Predominant approaches to solving distributionally robust optimization problems are based on reformulation to equivalent convex programs. These reformulations are specific to the ambiguity set descriptions. We present an alternative approach that involves constructing ambiguity sets in a data-driven manner. Such ambiguity sets result in statistical approximations of the worst-case expectation function. This flash talk presents a sketch of a sampling-based algorithm design for two-stage distributionally robust optimization (DRO).

Algorithms for Assortment Optimization
General Session

Session Chair
Omar El Housni, Cornell Tech, New York, NY

Session Chair
Bradley Sturt, University of Illinois at Chicago, Chicago, IL

1 Joint Assortment Optimization and Customization Under a Mixture of Multinomial Logit Models: On the Value of Personalized Assortments

Omar El Housni, Huseyin Topaloglu, Cornell Tech, New York, NY, Contact: oe46@cornell.edu

We consider a joint customization and assortment optimization problem under a mixture of MNL models. A firm faces customers of different types, each making a choice according to a different MNL model. In the first stage, the firm picks an assortment of products to carry subject to a cardinality constraint. In the second stage, a customer of a certain type arrives into the system. Observing the type of this customer, the firm customizes the assortment that it carries by, possibly, dropping products from the assortment. We study the complexity of this problem, present tight bounds on the value of customization and design a novel algorithm that gives $\Omega(1/\log m)$-approximation to the problem, where m is the number of customer types. The problem has obvious connections to assortment optimization under a mixture of MNL models, which can only admit a $O(1/m)$-approximation.

2 Dynamic Pricing for a Large Inventory of Substitutable Goods

Vineet Goyal[1], Garud N. Iyengar[1], Rajan Udwani[2], [1]Columbia University, New York, NY, [2]UC Berkeley, Berkeley, CA

We consider a dynamic pricing problem for a large inventory of substitutable products over a finite planning horizon. When every good in stock must have a feasible price i.e., one cannot show only a subset of available goods, previous results do not apply. By defining and characterizing a novel property of choice models namely, chain convex decomposability, we give near-optimal pricing algorithm for MNL and (1-1.e) approximate pricing algorithm for general random utility choice models.

3 The Value of Robust Assortment Optimization Under Ranking-based Choice Models

Bradley Sturt, University of Illinois at Chicago, Chicago, IL

The ranking-based choice model is a popular model in revenue management for predicting demand for a firm's products based on the assortment of products that the firm offers to their customers. Because this model has a huge number of parameters, many different ranking-based choice models can be consistent with the historical sales data generated by a firm's past assortments. Motivated by the use of ranking-based choice models in assortment planning, we consider the following *identification question*: Is it possible to identify an assortment with an expected revenue that is strictly greater than the expected revenues of the firm's past assortments under all ranking-based choice models that are consistent with the firm's historical sales data? In this talk, we present the first answers to the identification question by using robust optimization.

4 Approximation Schemes for Joint Assortment and Pricing Problems with Opaque Products

Yukai Huang[1], Jacob Feldman[2], Xingxing Chen[3], [1]Olin Business School, St. Louis, MO, [2]Olin Business School, Saint Louis, MO, [3]University of Richmond, Richmond, VA, Contact: yukaihuang@wustl.edu

We study a dynamic joint assortment and pricing problem, wherein each product can either be offered as a traditional "transparent" product or as part of a group of products offered together as a single "opaque" product. Opaque product is a collection of products that customers are promised to receive one of them upon the retailer's choice. In each period, depending on the current inventory level, the decision-maker must decide a subset of transparent products and their price, as long as the price, make-up, and delivered item for opaque products.
We first consider a simplified version in that only the opaque product is offered. Our LP-based fluid approximation yield a 1-1/e approximation scheme. Next, we add back in the possibility to offer transparent products alongside an opaque product. In this more general setting, we provide a simple and elegant 1/3 approximation scheme.

1 **Adjusted Portfolio Selection Models Reflecting the Macroeconomic Variables**

Jihye Yang, Seongmoon Kim, Yonsei University, Seoul, Korea, Republic of. Contact: jihyeyang89@gmail.com

This study suggests improved investment strategy based on Markowitz's portfolio selection model reflecting the macroeconomic variables of our interest: Inflation rate and Money supply. We propose portfolio selection models reflecting the macroeconomic indicators respectively. First, the portfolio selection models actively adjust the total proportion of capital invested in risky assets conservatively or aggressively on the rebalancing date depending on the macroeconomic factors respectively. Secondly, the models actively adjust the proportion of capital invested in each risky asset depending on the macroeconomic variables' sensitivity of each stock. We empirically evaluate the performance of the proposed models in 12 different stock markets.

2 **Performance of Active Portfolio Managers when the Benchmark is Not Observed**

Luis Chavez-Bedoya, ESAN University, Lima, Peru. Contact: lchavezbedoya@esan.edu.pe

In the framework of active portfolio management, we propose a methodology to evaluate the performance of active portfolio managers when the benchmark portfolio cannot be either observed or determined by the agent performing the analysis. This suggested methodology assesses performance with respect to a combination of funds that minimizes residual risk; and, it is well-suited for evaluating the performance of pension-fund managers in defined-contribution pension systems, especially those operating in Latin America. We also provide numerical results when our methodology is applied to appraise the historical performance of the pension fund administrators of the Peruvian Private Pension System.

3 **The Economics of Litigation Finance**

Sandro Lera[1,2], Robert Mahari[3,4], Moris Simon Strub[5], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Southern University of Science and Technology, Shenzhen, China; [3]Massachusetts Institute of Technology, Cambridge, MA, [4]Harvard Law School, Cambridge, MA, [5]Southern University of Science and Technology, Shenzhen, China. Contact: rmahari@mit.edu

We study the economics of litigation with a particular focus on litigation finance. Based on a data set of 489,383 U.S. civil lawsuits, we present stylized empirical facts about lawsuits at the trial phase. Grounded in these insights, we build a base model for a lawsuit and a model extension that includes litigation finance. Using these models, we arrive at three main insights. First, compared to law firms, litigation funders prefer high-risk litigation, which can enable access to justice but also challenges the legal system by increasing the number of lawsuits. Second, litigation finance disproportionately benefits small law firms and plaintiffs in non-contingency arrangements. Third, the presence of litigation finance increases the amount spent on litigation and these costs are carried by the funder alone as cost sharing between funders and law firms is sub-optimal.

1 **Multi-objective Decision Making Framework for Smart Municipal Solid Waste Management**

Seyed Omid Hashemi Amiri, George Mason University, Fairfax, VA, Contact: ohashem@gmu.edu

Due to the explosion of waste generation rate and acceleration of environmental degradation worldwide, waste management turns into one of the critical urban services and a great deal of attention has been devoted to municipal solid waste issues. To address the main sustainability issues (e.g., circular economy, environmental problems, adverse social impacts) and measure the influence of modern technologies on municipal solid waste system, this research aims to introduce a new smart municipal solid waste framework.
In this study, a multi-objective stochastic programming model is developed to improve the resiliency of the system against high priority or emergency demands and reduce the environmental impacts while providing financial advantages to the waste system and society.

2 **Classification Machine Learning Methods Applied to Predict Sea Level Variations**

Kassandra Hernandez, Aaron Hoskins, Fresno, CA, Contact: hernandezkassandra@mail.fresnostate.edu

The goal of this study was to apply the classification methods to solve the problem of predicting sea level variations. The specific variables used in the classification model were sea-level, sea-level-risk, wave height, wave risk, tide height, tide risk, erosion, erosion risk, waves, and tide. The classification methods used were the decision trees, random forests, and k nearest neighbor. The results demonstrate a statistically significant difference in the performance of each algorithm applied to the sea level data utilized.

3 The Federal Emergency Management Agency'S National Exercise Division: Improving National Resilience and Readiness Through Data-informed Management

Tiffany Wimenta, FEMA - National Exercise Division, Washington DC, DC, Contact: tiffany.wimenta@fema.dhs.gov

Federal Emergency Management Agency's (FEMA) National Exercise Division (NED) is committed to advancing and improving the efficiency of business practices to meet the emerging threats our Nation faces. To do so, the NED has leveraged data-informed decision making to guide policy implementation, business processes, and human capital planning. We will share best practices NED used to integrate data science into its operational culture and make actionable recommendations for using data analytics in other organizations. Specifically, we'll explore types of data science and analytical capabilities that organizations can use to allocate resources and support strategic decision making.

4 Modelling Ripple Effect Propagation and Global Supply Chain Workforce Productivity Impacts

Xavier Brusset[1], Morteza Davari[1], Aseem Kinra[2], Davide La Torre[1], [1]SKEMA Business School, Paris, France; [2]Bremen University, Bremen, Germany. Contact: xavier.brusset@free.fr

Disruptions in ports, plants and warehouses have generated ripple effects impacting supply networks. The spread of the pandemic explains the ripple effect by reducing the workers' participation to production.

Our model of the spatio-temporal dynamics of the propagation of pandemics on supply networks contributes to ripple effect visualization and quantification by combining the flow of goods and materials through a supply chain with an epidemiological model. The model enables what-if analyses to be performed to simulate the impact on the workforce and production in each node. We present useful tools for managers and scholars. Results from this research will mitigate the impact and the spread of a pandemic in a particular region and on the ability of a supply network to overcome the ripple effect.

A stylised case study of a supply chain illustrates the ripple effect.

Optimization under Uncertainty: Applications in Healthcare

General Session

Session Chair

Hrayer Aprahamian, Texas A&M University, College Station, TX

Session Chair

Hadi El-Amine, George Mason University, Fairfax, VA

1 An Optimization-based Framework for Problems with Time-dependent Uncertainty, with Application to Infectious Disease Screening

Marwan Shams Eddin[1], Hadi El-Amine[2], Hrayer Aprahamian[3], [1]George Mason University, Manassas, VA, [2]George Mason University, Fairfax, VA, [3]Texas A&M University, College Station, TX, Contact: mshamsed@gmu.edu

We consider a setting in which a decision-maker has partial information on the variation of system parameters over a finite time horizon. The decision-maker would like to determine optimal points in time to make a minimal number of decision adjustments due to operational constraints. We provide a novel mathematical framework that determines robust solutions. We then present refinements to significantly reduce computational time. Our case study on large-scale population screening demonstrates that the proposed framework can lead to significant reductions in costs and misclassification errors.

2 A Two-stage Stochastic Formulation for Targeted Mass Screening with Uncertain Symptomatic Cases

Jiayi Lin[1], Hrayer Aprahamian[2], George Golovko[3], [1]Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, [3]The University of Texas Medical Branch, Galveston, TX, Contact: jiayilin@tamu.edu

Mass screening is an essential tool that arises in a number of important settings (e.g., infectious outbreaks). Under limited budget, testing facilities need to allocate a portion of the budget to target sub-populations (proactive screening) while reserving the remaining budget to screen future symptomatic cases (reactive screening). We study this problem and formulate it as a two-stage stochastic program with endogenous uncertainty. By analyzing the resulting model, we provide two solution approaches: (i) a re-parameterization-based scheme and (ii) a linearization-based scheme. Our COVID-19 case study reveals substantial benefits over conventional approaches, highlighting the importance of data-driven policies.

3 Optimizing Stochastic Systems via Finite Approximation with an Application to Equitable Capacity Sizing in Transplant Waiting Lists

Shukai Li, Sanjay Mehrotra, Northwestern University, Evanston, IL, Contact: shukaili2024@u.northwestern.edu

We study capacity sizing in multiple transplant waiting lists to maximize fairness and meanwhile enforce a series of quality-of-service constraints. We consider the system with a possibly limited scale due to organ shortage as well as possible service-line abandonment (i.e., patients may die while calling for organ donations). Specifically, we model each waiting list as a queueing system in which a patient abandons if her patience time elapses before her transplant service is accomplished. Patients' inter-arrival time, service time, and patience time are independent and follow general distributions. We propose a finite approximation method to evaluate the system performance as an alternative to asymptotic analyses that rely on a large market assumption. We compute the optimal capacity level at each waiting list by solving a mixed-integer program.

4 Optimizing the Pre-positioning and Transportation of Medical Emergency Supplies Under the Uncertainty of Epidemic Breakouts

Zeyu Liu[1], Jia Shu[2], Anahita Khojandi[1], Xueping Li[1], [1]University of Tennessee, Knoxville, TN, [2]Southeast University, Nanjing, China. Contact: zeyu.liu@utk.edu

The Covid-19 pandemic has inflicted tremendous economic losses to countries around the world. To alleviate the disastrous impacts of epidemic breakouts, it is vital to set up relief systems with emergency medical supplies. However, due to the uncertainty in epidemic breakouts, optimizing the pre-positioning of supplies before the outbreak, as well as the transportation of supplies during the outbreak, faces great challenges. In this study, we utilize a novel sequential decision-making framework to optimize the inventory management of emergency supplies, considering resource distribution and stochastic demand in a long horizon. To solve the model efficiently, we implement a decomposition algorithm that provides significant computational advantages. Further, we draw insights and provide suggestions to practitioners via a case study using real-world data.

1 Full-low Evaluation Methods for Bound and Linearly Constrained Problems

oumaima Sohab, Lehigh University, BETHLEHEM, PA, Contact: ous219@lehigh.edu

Full-low evaluation methods are a class of DFO methods that considers two types of iterations. The first type is expensive in function evaluations (Full-Eval) but exhibits good performance in the smooth, non-noisy case. The second type is cheaper (Low-Eval), and more appropriate in the presence of noise or non-smoothness. Motivated by its performance in the unconstrained case, we extend this framework to the bound and linearly constrained case by making use of approximate tangent cones identified by nearby active constraints. The instance we consider for the Full-Eval step is a line-search where the step is a projection of the BFGS step on the approximate tangent cone and the Low-Eval step is a direct-search based on probabilistic feasible descent. We analyze the convergence and complexity of the resulting method for these particular iteration instances.

2 Linewalker: Line Search for Black Box Derivative Free Optimization and Surrogate Model Construction

Dimitri Papageorgiou[1], Jan Kronqvist[2], Krishnan Kumaran[3], [1]ExxonMobil Research & Engineering, Annandale, NJ, [2]KTH Royal Institute of Technology, Stockholm, Sweden; [3]Accenture, Raritan, NJ

We present a simple, but effective sampling method for learning the extrema of a discrete approximation of a multi-dimensional function along a one-dimensional line segment of interest. The method does not rely on derivative information and the function to be learned can be a "black box" function that must be queried via simulation or other means. We assume that the underlying function being approximated is noise-free and smooth. However, the algorithm can still be effective when the underlying function is non-differentiable and possibly discontinuous. Numerous examples are shown to illustrate the algorithm's competitiveness and potential superiority relative to state-of-the-art methods like NOMAD and Bayesian optimization.

3 Branch-and-Model: A Derivative-free Global Optimization Algorithm

Kaiwen Ma[1], Luis Miguel Rios[2], Atharv Bhosekar[3], Nikolaos Sahinidis[4], Sreekanth Rajagopalan[5], [1]Carnegie Mellon University, Pittsburgh, PA, [2]End-to-End Analytics, Lima, Peru; [3]GAMS Development Corporation, New York, NY, [4]Georgia Institute of Technology, Atlanta, GA, [5]The Dow Chemical Company, Lake Jackson, TX, Contact: kaiwenm@andrew.cmu.edu

Derivative-free optimization (DFO) is an important class of optimization algorithms that solve problems based on objective and function evaluations. DFO methods have enormous practical potential to address problems where derivatives are unavailable, unreliable, or only available at a significant cost. In this work, we present a novel derivative-free global algorithm *Branch-and-Model (BAM).* The BAM algorithm utilizes a flexible partition scheme and model-based search techniques, which exploit the local trend and speed up the convergence in solution refinement. The BAM algorithm is guaranteed to converge to the globally optimal function value under mild assumptions. Extensive computational experiments over 500 publicly open-source test problems show that BAM outperforms state-of-the-art DFO algorithms, especially for higher-dimension problems.

4 Derivative-Free Optimization of a Rapid-Cycling Synchrotron

Jeffrey Eldred[1], Jeffrey Larson[2], Misha Padidar[3], Eric Stern[1], Stefan Wild[4], [1]Fermi National Accelerator Laboratory, Batavia, IL, [2]Argonne National Laboratory, Argonne, IL, [3]Cornell University, Ithaca, NY, [4]Argonne National Laboratory, Lemont, IL

We develop and solve a constrained optimization model to identify an integrable optics rapid-cycling synchrotron lattice design that performs well in several capacities. Our model encodes the design criteria into 78 linear and nonlinear constraints, as well as a single nonsmooth objective, where the objective and some constraints are defined from the output of Synergia, an accelerator simulator. We detail the difficulties of optimizing within the 32-dimensional, simulation-constrained decision space and establish that the space is nonempty. We use a derivative-free manifold sampling algorithm to account for structured nondifferentiability in the objective function. Our numerical results quantify the dependence of solutions on constraint parameters and the effect of the form of objective function.

Recent Advances in Nonlinear and Stochastic Optimization

General Session

Session Chair

Baoyu Zhou, Lehigh University, Bethlehem, PA

Session Chair

Albert Solomon Berahas, University of Michigan, Ann Arbor, MI

1 Recent Progress in Stochastic and Deterministic Derivative-free Nonsmooth Optimization

Luis Nunes Vicente, Lehigh University, Bethlehem, PA

We focus on the minimization of a nonsmooth black-box function, without assuming access to (generalized) derivatives and without knowledge of function nonsmoothness.
In the deterministic case, we propose a trust-region model that is the sum of a max-linear term with a quadratic one. Our trust-region methods enjoy the same global convergence of directional methods, provided the vectors for the max-linear term are densely generated. The numerical results show that our approach is efficient and robust.
In the stochastic case, we use tail bounds to define a tailored probabilistic condition for function estimation that eases the theoretical analysis of both direct-search and trust-region methods. Our condition is posed on the estimate of the difference between the function at current and potential iterates.
Joint work with F. Rinaldi, G. Liuzzi, S. Lucidi, and D. Zeffiro.

2 Worst-case Complexity of Trace with Inexact Subproblem Solutions for Nonconvex Smooth Optimization

Qi Wang[1], Frank E. Curtis[2], [1]Lehigh University, Bethlehem, PA, [2]lehigh university, Bethlehem, PA, Contact: qiw420@lehigh.edu

An algorithm for solving nonconvex smooth optimization problems is proposed, analyzed, and tested. The algorithm is an extension of the Trust Region Algorithm with Contractions and Expansions (TRACE) [Math.~Prog.~162(1):132, 2017]. The extension allows inexact subproblem solutions, in favor of solving large-scale problems. The algorithm maintains the optimal iteration complexity of $\mathcal{O}(\epsilon^{-3/2})$ for attaining an ϵ-approximate first-order stationary point and improves the worst-case complexity of Hessian-vector products as compared to the original TRACE. Numerical experiments show the benefits of allowing inexact subproblem solutions and that the algorithm compares favorably to a state-of-the-art technique.

3 An Outer Nonlinear Programming Approach for Constrained Derivative-free Optimization

Melody Qiming Xuan, Jorge Nocedal, Northwestern University, Evanston, IL, Contact: qxuan@u.northwestern.edu

Interpolation-based optimization methods have been extensively studied for unconstrained derivative-free optimization due to their robustness and efficiency in terms of function evaluations. Yet extending these methods to general constrained optimization is not straightforward and such approach has received limited attention. To provide insights into the design of constrained derivative-free optimization solvers, we study DFO problems with analytically available constraints. We extend IBO methods and refer to such approach as OuterDFO as it requires an outer solver to compute the next iterate. We argue that this seemingly expensive approach can be quite efficient if the objective is much more expensive to evaluate than the constraints and if the number of variables is small. We provide such evidence in this work and demonstrate the difficulties of this approach.

1 Riemannian Optimization for Projection Robust Optimal Transport

Shiqian Ma, University of California - Davis, Davis, CA

The optimal transport problem is known to suffer the curse of dimensionality. One way to mitigate this is to project the sampled data from the high dimensional probability distribution onto a lower dimensional subspace, and then compute the optimal transport between the projected data. However, this requires to solve a max-min problem over the Stiefel manifold, which is very challenging in practice. In this talk, we propose a Riemannian block coordinate descent (RBCD) method to solve this problem. We analyze the complexity of arithmetic operations for RBCD to obtain an eps-stationary point, and show that it significantly improves the corresponding complexity of existing methods. Numerical results on both synthetic and real datasets demonstrate that our method is more efficient than existing methods, especially when the number of sampled data is very large.

2 Scalable Nonconvex Min-max Optimization and Applications in Fair Machine Learning

Meisam Razaviyayn, Dmitrii Ostrovskii, Andrew Lowy, University of Southern California, Los Angeles, CA

Min-max optimization problems have been extensively studied in the convex-concave regime. In the nonconvex regime, on the other hand, most problems cannot be solved to any reasonable notion of stationarity. In this talk, we present different classes of smooth nonconvex min-max problems that can be solved efficiently up to first-order stationarity of its Moreau envelope. We propose efficient algorithms for finding (first-order) stationary solutions to nonconvex min-max problems classes when the inner maximization problem is concave or when the diameter of the constraint set for the inner maximization problem is “small”. We also discuss the validity of our assumptions in various applications and evaluate the performance of our algorithms on different applications including training adversarially robust neural networks and fair machine learning.

3 What is a Good Metric to Study Generalization of Minimax Learners?

Sarath Pattathil, Massachusetts Institute of Technology, Cambridge, MA

A fundamental question for minimax problems remains elusive: What is a good metric to study generalization of minimax learners? We aim to answer this question by first showing that primal risk, a universal metric to study generalization in minimization problems, fails in simple minimax problems. Another popular metric, the primal-dual risk, also fails to characterize the generalization behavior for minimax problems with nonconvexity, due to non-existence of saddle points. We thus propose a new metric to study generalization of minimax learners: the primal gap, to circumvent these issues. Next, we derive generalization bounds for the primal gap in nonconvex-concave settings. Finally, we leverage this new metric to compare the generalization behavior of two popular algorithms - gradient descent-ascent (GDA) and gradient descent-max (GDMax) in minimax optimization.

4 A Decomposition Algorithm for Two-stage Stochastic Programs with Nonconvex Recourse

YING Cui, University of Minnesota, Minneapolis, MN

We consider a decomposition method for solving a class of nonconvex two-stage stochastic programs, where both the objective and constraints of the second-stage problem are nonlinearly parameterized by the first-stage variable. Due to the failure of the Clarke regularity of the nonconvex recourse function, classical decomposition approaches such as Benders decomposition and Lagrangian-based algorithms cannot be directly generalized to solve such models. By exploring an implicitly structure of the recourse function, we introduce a novel decomposition framework based on the partial Moreau envelope. The algorithm successively generates convex quadratic approximations of the recourse function based on the solutions of the second-stage subproblems and adds them to the master problem. Convergence under both fixed scenarios and interior samplings is established.

Lot Sizing Problems

General Session

Session Chair

Hugh Richard Medal, 1</sup

1 Lower Bound on Size of Branch-and-bound Trees for Solving Lot-sizing Problem

Santanu Subhas Dey[1], Prachi Shah[2], [1]ISyE Georgia Tech, Atlanta, GA, [2]ISyE, Georgia Tech, Atlanta, GA, Contact: prachi.shah@gatech.edu

We show that there exists a family of instances of the lot-sizing problem, such that any branch-and-bound tree that solves them requires an exponential number of nodes, even in the case when the branchings are performed on general split disjunctions. This result is of interest since there exists dynamic programming algorithms that solve lotsizing in polynomial-time. To the best of our knowledge, this is the first study that shows that dynamic programming can be exponentially faster than general branch-and-bound.

2 Stochastic Lot-sizing with Substitution and Service Level Constraints

Jim Luedtke[1], Narges Sereshti[2], Merve Bodur[3], [1]University of Wisconsin-Madison, Madison, WI, [2]HEC Montreal, Montreal, QC, Canada; [3]University of Toronto, Toronto, ON, Canada. Contact: jim.luedtke@wisc.edu

We consider a multi-stage stochastic lot-sizing problem with service level constraints and product substitution. A firm has multiple products and when meeting demand has the option to meet demand from substitutable products at a cost. Considering the uncertainty in future demands, the firm wishes to make ordering decisions in every period such that the probability that all demands can be met in the next period is at least a given target. We propose a rolling horizon policy in which a two-stage joint chance-constrained stochastic program is solved to make decisions in each time period. We demonstrate how to effectively solve this formulation, and compare the resulting policy to policies based on deterministic approximations. We also demonstrate the value of product substitution in this model.

3 Algorithms for a Two-level Multi-item Lot-sizing Problem with All-units Quantity Discounts

Hugh Medal[1], Samuel Affar[2], [1]University of Tennessee, Knoxville, TN, [2]University of Tennessee, Knoxville, Knoxville, TN

We study a two-level multi-item lot-sizing problem with all-units quantity discounts and an inventory capacity constraint. To enable orders of larger quantities, inventory of each item can be held at the supplier for a limited amount of time. The goal is to find an order plan that minimizes the total purchasing cost over the planning horizon. Other side constraints include minimum shipment quantities, minimum inventory levels, and minimum order quantities. We test an extended mixed-integer programming formulation using a piecewise linear function to model quantity discounts. We also test a Lagrangian relaxation approach along with speedups.

4 The Effects of Variable Demand Rate on Supplier Selection and Product Pricing

Gianni A. Di Carlo[1], Jose A. Ventura[2], [1]The Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, University Park, PA, Contact: gad5170@psu.

edu

We study a supplier selection and lot-sizing problem in a two-stage supply chain composed of a set of potential suppliers and a single buyer/retailer trading one product. The suppliers manufacture the product with negligible differences among them. The market demand at the buyer's stage is price-sensitive, and suppliers have finite production rates. Unlike other papers, we evaluate the supply chain by varying the demand function, whose input is the item's price. We examine the results of a mixed integer nonlinear programming model considering two different demand functions, the standard linear demand function, and the Logit demand function. By the end, we establish which of these two functions represents the real-life demand.

Mechanism and Market Design for Emerging Mobility Systems

General Session

Session Chair

Qi Luo, Clemson University, Clemson, SC

Session Chair

Xiaotong Sun, The Hong Kong University of Science and Technology (Guangzhou), Hong Kong, China.

1 Market and Mechanism Designs for Creating an Adaptable City

Cynthia Chen, University of Washington, Seattle, WA

Our society relies on maximizing efficiency. But COVID-19 has revealed vulnerabilities of systems designed for maximum efficiency. This has added stress to our society: what options do people, businesses and public agencies (e.g., transit) have in this evolving process of perturbation? As we anticipate that human society will face more challenges in the future, it is now time to think about creating adaptable cities that can adapt in this evolving process of perturbation. Using an urban system comprising urban space, small businesses, human behaviors, and transit as an example, this talk will focus on the roles of mechanism and market design for emerging mobility systems in creating an adaptable city. Future research directions are discussed.

2 An Equitable and Stable Two-sided Matching Problem: An Application to a Two-sided Crowd-shipping Market

Hui Shen, University of Illinois at Chicago, Chicago, IL, Contact: hshen23@uic.edu

This study proposes a matching mechanism that not only considers two sides' preferences equally, but also achieves a stable matching that no pair prefer each other to their current partners. It is the equitable and stable matching mechanism (ESMM). Egalitarian, side equality, and pair equality costs are created as equity metrics. Small, medium, and large scales of experiments are conducted to investigate its solution properties. Besides, we apply it to a designed crowdshipping (CS) market, and compare the performance of ESMM and traditional system optimization matching mechanism (SOMM) under five objectives. As a result, ESMM achieves good equity metrics. Although the matching rate by ESMM is lower than that by SOMM, it remains over 75% in experiments. And ESMM shows similar effects to SOMM on maximizing senders' benefits and social welfare in the designed CS market.

3 Robust and Resilient Equilibrium Routing Mechanism for Traffic Congestion Mitigation Built upon Correlated Equilibrium and Distributed Optimization

Yuqiang Ning, Lili Du, University of Florida, Gainesville, FL, Contact: y.ning@ufl.edu

This study develops a correlated equilibrium routing mechanism (CeRM) to alleviate traffic congestion, which drives a group of vehicles' route choices to a systematically optimal traffic condition while still satisfying individuals' selfish nature. A distributed Augmented Lagrangian algorithm (D-AL) is developed to efficiently solve the CeRM, taking advantage of the on-board computation resources of individual vehicles. Considering random communication failures, we proved the convergence robustness of the D-AL and developed the convergence rate upper bound as a function of the communication failure probability. To improve the solution algorithm's resilience in the computation performance, we further designed and proved an acceleration scheme aided D-AL (aD-AL) to expedite the convergence rate under the high likelihood of communication failures.

4 Does Equilibrium Remain a Relevant Paradigm for Modeling Connected and Automated Mobility?

Minghui Wu[1], Yafeng Yin[1], Jerome Lynch[2], [1]University of Michigan, Ann Arbor, MI, [2]Duke University, Durham, NC,

Contact: minghuiw@umich.edu
In the connected and automated mobility era, commuters (connected drivers or automated vehicles) will possess strong computation capability and their travel decisions can be algorithmic and strategic. We investigate the day-to-day travel choice evolution of such strategic commuters who are capable of long-term planning and computation. We model the process as a mean field game and examine the mean field equilibrium to derive the evolution pattern. The proposed model is general and can be applied to modeling various choices including route or departure time. Under mild assumptions, we prove the existence and uniqueness of the day-to-day equilibrium traffic evolution pattern as well as its convergence to stationarity. The physical interpretation of the stationary solution is discussed and connected to Wardropian equilibrium.

1 Fleet Composition Optimization with Truckload and Less-than-truckload Shipping Options

Yue Wang[1], Joseph Geunes[1], Xiaofeng Nie[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: yuewang92@tamu.edu
We study a fleet composition problem with stochastic and bounded, periodic demand, which must be fulfilled via a combination of internal truckload (TL) capacity and external less-than-truckload (LTL) shipments. Internal capacity costs include a fixed ownership cost per truck and a fixed dispatch cost per truck trip, while LTL costs are incurred per unit shipped. We characterize the expected shipping cost per period as a function of internal fleet size for both homogeneous and heterogeneous fleets. For certain demand distributions, we explore the properties of the optimal fleet size, and the corresponding expected quantities shipped via TL and LTL, respectively.

2 An Integrated Learning and Progressive Hedging Method for Stochastic Network Design Problem

Fatemeh Sarayloo[1], Teodor Gabriel Crainic[2], Walter Rei[3], [1]Purdue University, West Lafayette, IN, [2]Université du Québec à Montréal, Montréal, QC, Canada; [3]University of Quebec-Montreal, Saint-Lambert, QC, Canada.
In this talk, we address Multicommodity Capacitated Fixed-charge Network Design problem with uncertain demands, formulated as a two-stage stochastic program. We rely on the progressive hedging algorithm where the scenarios are defined using scenario grouped. We propose an efficient matheuristic which we refer to as integrated learning and progressive hedging (ILPH). The proposed method takes advantage of a specialized learning-based matheuristic that is able to quickly produce high-quality solutions to multi-scenario subproblems. Furthermore, we propose a novel reference point definition, at each aggregation step of the PH algorithm, which leverages subproblem information regarding promising design variables. Extensive computational experiments show the interest of the proposed approach in terms of computation time and solution quality.

3 Drayage Operation with Charging Planning Using Diesel and Battery Electronic Heavy-duty Trucks

Siyuan Yao[1], Maged M. Dessouky[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: siyuanya@usc.edu

We study a drayage operation problem minimizing truck operating costs and emissions with a mixed fleet of diesel trucks and Battery Electronic Heavy-Duty Trucks (BEHDTs). There has been a long history of Greenhouse Gas (GHG) emission regulations in California. Battery Electronic Heavy-Duty Trucks (BEHDTs) are gradually introduced into drayage operations as a substitute for traditional diesel trucks to reduce GHG emissions. BEHDTs have range limits due to the current battery technology, making it essential to consider charging during truck routing planning.

4 Charging Network Design and Allocation of Shared Micro-scale Mobility Under Range and Equity Constraints

Amir Sadeghi, Demetra Protogyrou, Leila Hajibabai, North Carolina State University, Raleigh, NC, Contact: asadegh3@ncsu.edu

This study focuses on micro-scale mobility systems that offer short-range ride options and first-/last-mile solutions. In this research, we investigate the contributing factors that support the adoption of shared rideable robots to facilitate transportation in diverse neighborhoods and evaluate their socio-economic impacts. A mathematical model is developed that accounts for decisions of business operators along with their interactions with users. The numerical results confirm the quality of the solutions.

Logistics Operations for Infrastructure Network Restoration

General Session

Session Chair

Bahar Cavdar, Texas A&M University, College Station, TX

1 The Flood Mitigation Problem in a Road Network

Vahid Eghbal Akhlaghi[1], Ann Melissa Campbell[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Iowa, Iowa City, IA, Contact: vahid-eghbalakhlaghi@uiowa.edu

Floods can deteriorate and block transport systems, leading to loss of access to healthcare facilities. To mitigate these consequences, it is crucial to determine which improvements to a city's transportation infrastructure can improve access to emergency service facilities. This presentation addresses a pre-disaster planning problem that identifies the best road segments in a transportation network to strengthen to enable travel from population centers to healthcare facilities after a flood event. We examine an objective to minimize the residents' travel times subject to the available budget and facility capacity restrictions.

2 Restoration of Infrastructure Networks with Precedence Relationship Under Incomplete Information

Subhojit Biswas, Bahar Cavdar, Joseph Geunes, Texas A&M University, College Station, TX, Contact: subhojit.biswas@tamu.edu

A rise in the frequency and magnitude of natural disruptions (e.g., earthquakes, snowstorms, hurricanes) has increasingly and negatively impacted power infrastructure networks globally. Power network restoration following such events requires deploying restoration crews under limited information about the state of the network. Although we may know that a given set of network nodes lacks power, we may not have information on whether the equipment at each such node is faulty and requires repair. Given a set of nodes without power, as well as a probability that each such node requires repair, we seek a node visit sequence that minimizes the weighted expected customer downtime in the network. We formulate this problem as an MDP and, because of the problem's complexity, propose an approximate dynamic programming heuristic solution approach.

3 Framework to Support Infrastructure Upgrades for Decarbonization of US Freight Rail

Adrian Hernandez[1], Max Ng[1], Pablo Luis Durango-Cohen[1], Hani S. Mahmassani[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: adrianhernandez2025@u.northwestern.edu

The decarbonization of the US transportation sector presents a considerable challenge for the freight railroads, whose operations are extremely energy intensive and networks span tens of thousands of track-miles. We present a hierarchical framework to address the network deployment and sizing of the refueling infrastructure required by alternative fuel propulsion technologies. This framework is applied to two railroad networks, an Eastern and a Western US railroad, for a series of scenarios. The results are analyzed with respect to cost of deployment and emissions reductions potentials.

4 Repair Crew Routing for Infrastructure Network Restoration

Bahar Cavdar[1], Qie He[2], Feng Qiu[3], [1]Texas A&M University, College Station, TX, [2]Amazon, Santa Clara, CA, [3]Argonne National Laboratory, Lemont, IL, Contact: bcavdar@tamu.

edu

We study a repair crew routing problem to restore a disrupted power network where technical crew travels to a number of sites to repair damaged equipment with minimum total service disruption time. We call this problem the Power Restoration Traveling Repairman Problem (PRTRP). The main challenge in this problem is that the service disruption time in a location depends on the interaction of the routing sequence with both networks, i.e., the road network and the power grid. To solve the problem, we develop an exact method based on bi-directional dynamic programming. We then improve the method by reducing the search space with solution upper and lower bounds, and threshold rules derived from the precedence relations in the power network. We also propose efficient heuristic variants of the method. We present computational results and compare our method with benchmark heuristics.

1 Catch Me if You Can! The Economic Analysis of Geofencing

Xiangjing Chen[1], Ian Ho[2], Shengjun Mao[3], [1]Arizona State University, Tempe, AZ, [2]Pennsylvania State University, State College, PA, [3]The University of Hong Kong, Hong Kong, Hong Kong. Contact: xchen328@asu.edu

Geofencing enables a firm to set a virtual fencing zone surrounding its store and entice consumers to visit it via advertising. We investigate how consumer awareness affects geofencing using a game-theoretic model. Specifically, we start by comparing geofencing and traditional advertising in various awareness conditions and obtain the optimal fencing radius and price. We show three benefits of geofencing, including market expansion, profit-margin increment, and cost savings. To further improve efficiency, we propose a novel strategy that allows the firm to choose the point of interest flexibly (i.e., no longer restricted to its store). The analyses confirm that flexible geofencing is particularly useful when consumer awareness is correlated with the distance to the store. Our findings provide advertisers with executable actions to improve advertising efficiency.

2 Pandemic in the Gaming Ecosystem: How Covid-19 Changed the Interplay Between Gaming and Live Streaming

Sung Hyun Kwon[1], Il-Horn Hann[2], [1]University of Maryland, College Park, MD, [2]University of Maryland, College Park, MD

The Covid-19 outbreak has necessitated individual behavioral changes, including social distancing. For the gaming population in Korea, this meant a significant reduction of visits to PC Cafes. We investigate how this change affected the interplay between the two central parts of the video game ecosystem: gaming and live game streaming. Live game streaming is essentially user generated content produced and consumed independently by gamers that earned a central role in the ecosystem. Using data from Korean PC Cafés and Twitch, we measure the temporal nature of the network effect and spillover within and across platforms. Our results indicate a mutually beneficial network effect between the two platforms. We also estimate the change in the size of network effects due to the exogenous shock from the pandemic and show that network effects across the platforms are not constant.

3 Goal-reward Schemes for On-demand Learning: A Field Experiment

Jaeung Sim[1], Dongwon Lee[2], Yeolib Kim[3], Jiye Baek[4], [1]KAIST College of Business, Seoul, Korea, Republic of; [2]HKUST, Kowloon, Hong Kong; [3]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of; [4]Korea University, Seoul, Korea, Republic of.

The on-demand nature of online learning is tied to less student feedback, less face-to-face communication, and social isolation. Thus, learners are left to fend for themselves for various learning activities in an asynchronous online environment. This study proposes that goal-reward schemes allow online learners to regulate their learning time for on-demand learning. Specifically, we focus on two novel dimensions of goal design: 1) learner autonomy and 2) sub-goal granularity. We test the effectiveness of such design factors by conducting a randomized field experiment on an online education platform. We find that for the partial-autonomy condition, we observe an inverted U-shaped relationship between sub-goal granularity and its effectiveness. Notably, we observe a positive impact on non-incentivized learning behaviors only from the full-autonomy condition.

On the Robustness of Second-Price Auctions in Prior-Independent Mechanism Design

Jerry Anunrojwong, Columbia University, Columbia, NY

The seller wants to sell an item to n buyers such that the buyers' valuation distribution is from a given class (i.i.d., mixtures of i.i.d., affiliated and exchangeable, exchangeable, and all distributions) and the seller minimizes worst-case regret. We derive in quasi closed form the minimax values and the associated optimal mechanism. We show that the first three classes admit the same minimax regret, decreasing in n, while the last two have the same minimax regret equal to that of the case n = 1. Across all settings, the optimal mechanisms are second-price auctions with random reserve.

The Gittins Policy is Nearly Optimal in the M/G/k under Extremely General Conditions

Ziv Scully, Isaac Grosof, Carnegie Mellon University, Pittsburgh, PA

Scheduling to minimize mean response time in the preemptive M/G/1 is a classic problem. Its solution, the Gittins policy, works for unknown job sizes, known job sizes (where Gittins reduces to SRPT), and a range of partial information settings. However, minimizing mean response time in multiserver systems, such as the M/G/k, is a much more difficult problem. We give the first analysis bounding Gittins's performance in the M/G/k, showing that it achieves mean response time close to that of Gittins in a resource-pooled M/G/1. Our bound implies that Gittins is heavy-traffic optimal in the M/G/k.

Small Shadows of Lattice Polytopes

Alexander Black, UC Davis, Davis, CA

The diameter of a d-dimensional lattice polytope contained in [0,k]^(n) is well known to be at most dk due to work of Kleinschmidt and Onn. However, the question of finding a pivot rule for the simplex method that is guaranteed to trace a path on the surface of a polytope satisfying that bound or even a bound in polynomial in d and k remains open. We prove many partial results in this direction including finding a pivot rule that a satisfies a bound of dnk||A||_{\infty}, where A is an integral constraint matrix for the polytope.

The Probability Mass Function of the Kaplan-Meier Product-Limit Estimator

Yuxin Qin, William and Mary, Williamsburg, VA

Kaplan and Meier's 1958 paper developed a nonparametric estimator of the survivor function from a right-censored data set. Determining the size of the support of the estimator as a function of the sample size provides a challenging exercise for students in an advanced course in mathematical statistics. We devise two algorithms for calculating the support size and calculate the associated probability mass function for small sample sizes and particular probability distributions for the failure and censoring times.

The Non-Markovian Nature of Nested Logit Choice

Selena Li, University of California, Berkeley, Santa Barbara, CA

Discrete choice models are widely used to model how customers choose between substitutable goods. We study the relation between two well studied choice models, Nested Logit (NL) and Markov. Both models generalize the Multinomial Logit model and admit tractable algorithms for assortment optimization. Past evidence indicates that NL may be well approximated by, or be a case of, Markov. We show that generally, NL cannot be represented by Markov. Further, we describe a family of instances of NL with choice probabilities that cannot be approximated to within a constant error by any Markov model.

1 A Model for Servicizing Operations

Yinshi Agnes Gao[1], Saurabh Bansal[2], V Daniel R Guide[1], [1]Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, State College, PA, Contact: yzg115@psu.edu

The study focuses on a servicizing OEM who provides a product to customers on lease, remanufactures the product at the end of the lease, and then re-leases the product. We discuss properties of lease parameters, cost and profit implications for the OEM.

2 The Impact of Work Hours on Performance of Gig Workers in Online Retail

Reeju Guha[1], Daniel S. Corsten[2], [1]IE Business School, Madrid, Spain; [2]IE Business School, Madrid, Spain. Contact: reejuguha@student.ie.edu

Companies operating under gig-contractor models have shifted towards offering full-time jobs to meet the demand-supply gap and ensure better productivity through longer work availability. However, several online platforms still operate in the gig-contractor model, where demand surges can be met only if gig workers work longer durations. This, however, raises the issue of adverse effects of longer work hours on performance. We argue that *voluntary* longer work availability resulting from schedule flexibility ameliorates the negative effects of longer workhours. Using panel data from an online grocery retailer, we observe that longer workhours improves productivity, and service quality. We further find that experience of performing similar tasks can moderate the effect of work hours on performance, after controlling for worker and task-specific characteristics.

3 A Survey of Reinforcement Learning Tools in Ride-hailing Platforms

Yudi Huang[1], Sebastien Martin[2], [1]Northwestern university, Kellogg School of Management, Evanston, IL, [2]Northwestern University, Kellogg school of management, Cambridge, MA, Contact: yudi.huang@kellogg.northwestern.edu

Ride-hailing markets rely heavily on the efficiency of operational decisions. Over the past few years, RL-based tools have been proven to be powerful approaches to get outperforming policies in the industry. In this talk, we will give a brief overview of the motivations under a variant of RL frameworks. We will also present some seminal works and discuss the most prominent open questions in the RL application in the ride-hailing markets.

Recent Advancement of Stochastic Modeling for Service Systems
General Session

Session Chair
Yue Hu, Columbia University, New York, NY

1 Steady-state Performance Approximations of Many-server Queueing Networks

Anton Braverman, Northwestern University, Evanston, IL, Contact: anton.braverman@kellogg.northwestern.edu

Motivated by the need for decision support tools for workload prediction and capacity planning in hospitals under the COVID-19 pandemic, we consider a queueing network consisting of two many-server stations, which models the flow of patients between medical/surgical and intensive care unit wards. We approximate the steady-state customer count using the stationary distribution of the associated diffusion model, which can be computed efficiently and be used as a real-time decision support tool.

2 Modeling and Analysis of Queues with Strategic Agents

Yueyang Zhong[1], Raga Gopalakrishnan[2], Amy R. Ward[1], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]Smith School of Business at Queen's University, Kingston, ON, Canada.

Service system design is often informed by queueing theory, which traditionally assumes that customers and servers work at constant speeds. However, when customers and servers are people, design decisions influence their behavior. First, we focus on the impact of only strategic servers using a game-theoretic model, where servers' (state-independent) choice of work speed depends on managerial decisions regarding (i) how many servers to staff and how much to pay them, and (ii) whether and when to turn away customers. We then highlight the challenges of extending our model to also incorporate strategic customers' joining decisions (and then the manager's decision (ii) above might instead become, e.g., how much to charge customers for service) and analyzing joint equilibria. We conclude with an open discussion on modeling state-dependent work speed choices by the servers.

3 Observation-driven Abandonment in Congested Systems

Costis Maglaras[1], Ran Snitkovsky[2], Assaf Zeevi[3], John J. Yao[4], [1]Columbia Business School, New York, NY, [2]Tel Aviv University, Tel Aviv - Jaffa, Israel; [3]Columbia University, New York, NY, [4]University of Miami, Coral Gables, FL

We introduce a queueing model of a congested service system in which delay-sensitive customers make abandonment decisions; Customers naively estimate their remaining waiting time based on their queue position and on service-time realizations they observe, and abandon when the estimate exceeds their patience threshold. These abandonment decisions are coupled via common service-time observations, and lead to abandonment 'waves' triggered by long service times. We study this phenomena with the aid of a suitable fluid model, corresponding to the limit of a scaled queueing process. We reveal some surprising results about the scaled process, particularly, that abandonment waves result in a queue length negligibly smaller than the system scale.

4 Dynamic Load Balancing in Parallel Queueing Networks

Timothy Chan, Jangwon Park, Vahid Sarhangian, University of Toronto, Toronto, ON, Canada. Contact: jangwon.park@mail.utoronto.ca

Motivated by the problem of guiding interfacility patient transfers in a hospital network, we study dynamic load balancing in a network of parallel queues. We investigate policies for transferring customers between queues at discrete points in time by analyzing an associated fluid control problem and characterizing the structure of its optimal solution. Our results provide insights for design of guidelines for transferring patients in a hospital network, aimed at mitigating imbalances in congestion between hospitals and reducing the adverse effects of high congestion.

(Stochastic) First-order Methods for Convex and Nonconvex Problems in Machine Learning

General Session

Session Chair

Digvijay Boob, Southern Methodist University, Dallas, TX

1 On the Projection Complexities of Convex Optimization

Yuyuan Ouyang[1], Jimmy Zhang[2], [1]Clemson University, Clemson, SC, [2]Georgia Institute of Technology, Atlanta, GA, Contact: yuyuano@clemson.edu

We study the projection complexity of first-order methods for solving convex optimization problems. Our problem of interest is to minimize a convex function over a feasible set on which we can perform projection operations. We assume that the objective function is either nonsmooth or differentiable with Holder gradients. Matching lower and upper complexities on the number of projections are presented.

2 Approximation Approaches for the Cardinality Minimization Problem

Miju Ahn, Southern Methodist University, Dallas, TX

We study a cardinality minimization problem (CMP) which penalizes the number of violations of soft constraints by the indicator function. Our approach reformulates the discrete CMP as continuous problems; we present an equivalent formulation of mathematical program with complementarity constraints and an approximate difference of convex program. The alternative formulations' stationary solutions are investigated, emphasizing the recovery of the local solutions of the CMP. The results of our numerical study demonstrate the effectiveness of our method for enforcing soft conditions on several suitable applications.

3 Level Constrained First-order Methods for Function Constrained Optimization

Digvijay Boob[1], Qi Deng[2], Guanghui Lan[3], [1]Southern Methodist University, Dallas, TX, [2]Shanghai University of Finance and Economics, Shanghai, China; [3]ISyE Ga Tech, Atlanta, GA, Contact: dboob@smu.edu

In this talk, we present a new level constrained proximal gradient method for composite nonconvex function constrained optimization. The algorithm converts the original problem into a sequence of convex subproblems. By carefully increasing this constraint level parameter, we provide a simple solution to overcome a challenge in bounding the Lagrangian multipliers, and show that the algorithm asymptotically converges to a stationary point. Finally, we develop a simple, proximal gradient descent type analysis, showing that the complexity bound of this new algorithm is comparable to gradient descent for unconstrained setting which is new in the literature. Our algorithms can be extended to stochastic, finite-sum and structured nonconvex cases. Our complexity results match with proximal gradient method for unconstrained problems.

4 **A Randomized Block Coordinate Prima-dual Method for Large-scale Saddle Point Problems**

Erfan Yazdandoost Hamedani[1], Afrooz Jalilzadeh[2], Necdet Serhat Aybat[3], [1]University of Arizona, Tucson, AZ, [2]The University of Arizona, Tucson, AZ, [3]Penn State University, State College, PA

In this talk, we consider a stochastic convex-concave saddle point problem with high-dimensional decision variables that arises in various machine learning problems, e.g., robust classification, kernel matrix learning, and generative adversarial network. To contend with the challenges in computing gradients, we employ a stochastic block-coordinate primal-dual scheme in which randomly selected primal and dual blocks of variables are updated using sample partial gradients at each iteration. We investigate the convergence of the proposed under different blocking strategies and provide the corresponding complexity results. Finally, for both single and increasing sample size scenarios, almost sure convergence of the iterate sequence to a saddle point is shown.

Data-driven decisions and applications

General Session

Session Chair

Jackie W. Baek, MIT, Cambridge, MA

1 **Fairness and Efficiency in Covid-19 Lockdowns: Intervening in Network Games when Local Public Goods Have Unequal Impact**

Hamsa Sridhar Bastani[1], Tsai-Hsuan Chung[1], Kenneth Moon[2], [1]Wharton School, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, Contact: angelchung841025@gmail.com

The economic costs and health benefits of lockdowns during COVID-19 pandemic were disparately borne by disadvantaged communities. Our matching-based analyses have found that, when low-income counties implement lockdown policies, they blunt new case rates by more than for high-income counties, but at the expense of significantly diminished work hours not suffered by high-income counties. However, we also find that in low-income areas, locked down residents seek to lessen the economic impact by significantly increasing economic activity in neighboring counties without locked down. Overall, we find evidence of economic spillover effects between localities based on socioeconomic status. This work empirically assess the unequal impacts of lockdown policies on networks of neighborhoods and design policies which incorporate these findings and fairness metrics.

2 **Exploration Optimization for Dynamic Assortment Personalization Under Linear Preferences**

Sajad Modaresi[1], Fernando Bernstein[2], Denis Saure[3], [1]UNC Chapel Hill, Kenan-Flagler Business School, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]University of Chile, Santiago, Chile.

We study efficient real-time data collection approaches for an online retailer that dynamically personalizes assortments based on customers' attributes. We study the structure of efficient exploration in this setting, prove a performance lower bound, and propose efficient learning policies. We test the performance using a dataset from a large Chilean retailer.

3 **Improving TB Treatment Adherence Using Targeted Behavioral Interventions**

Jackie W. Baek, MIT, Cambridge, MA

Lack of adherence to treatment protocols is a major barrier to eliminating the global disease burden of tuberculosis (TB). We partner with a platform operating in Kenya that requires patients to verify their treatment adherence daily. The platform can reach out to a subset of patients each day to encourage them to comply with their treatment. Using observational data from this platform, we derive a simple policy that decides which patients to reach out to, and we show that this policy significantly increases the effect of each outreach. Our work demonstrates the huge potential gain from targeting interventions through learning personalized patient behaviors.

4 **Fast Rates for Contextual Linear Optimization**

Yichun Hu[1], Nathan Kallus[1], Xiaojie Mao[2], [1]Cornell University, New York, NY, [2]Tsinghua University, Beijing, China. Contact: yh767@cornell.edu

Incorporating side observations in decision making can reduce uncertainty and boost performance, but it also requires we tackle a potentially complex predictive relationship. While one may use off-the-shelf machine learning methods to separately learn a predictive model and plug it in, a variety of recent methods instead integrate estimation and optimization by fitting the model to directly optimize downstream decision performance. Surprisingly, in the case of contextual linear optimization, we show that the naive plug-in approach actually achieves regret convergence rates that are significantly faster than methods that directly optimize downstream decision performance. While there are other pros and cons to consider as we discuss and illustrate numerically, our results highlight a nuanced landscape for the enterprise to integrate estimation and optimization.

1 Design and Analysis of Finite Element Simulations

Shaowu Yuchi, Roshan V. Joseph, C F Jeff Wu, ISyE Georgia Tech, Atlanta, GA

Numerical accuracy of Finite Element Analysis depends on the number of finite elements used in discretization of the space, which can be varied using mesh size. We develop a method to optimally find the mesh sizes for each simulation and satisfy same time constraints as a single/double mesh size experiment.

2 Ensemble Active Learning by Contextual Bandits for AI Training in Manufacturing

Yingyan Zeng[1], Xiaoyu Chen[2], Ran Jin[3], [1]Virginia Tech, Blacksburg, VA, [2]University of Louisville, Louisville, KY, [3]Virginia Tech, Blacksburg, VA

It is challenging but important to save annotation efforts in streaming data acquisition to maintain data quality for supervised learning base learners. We propose an ensemble active learning method to actively acquire samples for annotation by contextual bandits, which will enforce the exploration-exploitation balance and improve the AI modeling performance.

3 Tensor-based Temporal Control for Partially Observed High-dimensional Streaming Data

Zihan Zhang, Shancong Mou, Kamran Paynabar, Jianjun Shi, ISyE Georgia Tech, Atlanta, GA

In advanced manufacturing processes, high-dimensional (HD) streaming data (e.g., sequential images or videos) are commonly used to provide online measurements of product quality. Though numerous research has been done for monitoring and anomaly detection of HD streaming data, little research is conducted to perform feedback control based on HD streaming data to improve product quality, especially in the presence of incomplete responses. To address this challenge, this work proposes a novel partially observed tensor-based automatic control (poTAC) method for missing HD streaming data, which consists of two stages: offline training and online control. In the offline training stage, we propose a one-step method integrating parameter estimation of the system model and missing value imputation for the response data, which (i) improves the accuracy of parameter estimation, and (ii) maintains a stable and superior imputation performance in a wider range of the rank or missing ratio for the data to be completed, compared to the existing data completion method. In the online control stage, the new partial observation is imputed by balancing its low-rank information and the one-step-ahead prediction result based on the control action from the last time step. Furthermore, we conduct two sets of simulations and a case study of the semiconductor photolithography process to validate the superiority of the proposed framework.

4 A Supervised Tensor Dimension Reduction-Based Prognostic Model for Applications with Incomplete Imaging Data

Chengyu Zhou, North Carolina State University, Raleigh, NC

Most image-based prognostic models have two common limitations. First, they require degradation images to be complete. Second, they usually employ an unsupervised dimension reduction method. To address these challenges, this article develops a supervised tensor dimension reduction-based prognostic model. The model first proposes a supervised dimension reduction method for tensor data. It uses historical TTFs to guide the detection of a tensor subspace to extract low-dimensional features. Next, the extracted features are used to construct a prognostic model based on (log)-location-scale regression. An optimization algorithm is proposed for parameter estimation and closed-form solutions are derived under certain distributions. Simulated data and a real-world data set are used to validate the performance of the proposed model.

Interpretability and Explainability via Human Behavior and Performance Modeling
General Session

Session Chair
Xiaoyu Chen, 1</sup

1 **Explaining Machine Learning Predictions to Human Decision Makers**
Xiaomei Wang, University of Louisville, Louisville, KY, Contact: xiaomei.wang@louisville.edu
There is increasing interest in applying machine learning (ML) techniques on supporting challenging decisions in complex situations such as manufacturing and healthcare. Generally, ML models can be developed for any domain wherever there is data. However, it is a long way to go before the models positively impact a real-world decision. Because of the black box nature of most ML models, even system developers are incapable of fully tracking and manipulating how models learn and generate results, which creates many problems for human-centered computing. To realize the promised benefits of ML on decision making, the following questions need to be considered while designing, implementing, and using ML-based decision support tools: What needs to be explained? What can be explained? What most effectively support users' judgments?

2 **VLP: A Visual Language Processing Modeling Framework via an Attention-on-attention Mechanism**
Xiaoyu Chen[1], Ran Jin[2], [1]University of Louisville, Louisville, KY, [2]Virginia Tech, Blacksburg, VA, Contact: xiaoyu.chen@louisville.edu
Quantitatively understanding human visual searching process in interactive and intelligent systems will not only advance the knowledge preservation of human expertise, but also enhance the AI modeling performance by imitating the human visual searching process. A general visual language processing (VLP) modeling framework is proposed to provide computational attention on visual attention (AonA) based on eye movements. Specifically, VLP defines the transition of fixations (i.e., visual attention) as a visual sentence; it then correlates the visual sentence with the visual searching decision by identifying the significant words in the visual sentence (i.e., computational attention). This VLP modeling framework is expected to explain visual searching decisions via AonA even for counter-intuitive scenarios when cognitive threats bias human decision making.

3 **Models and Algorithms for Demand Response Under Bounded Rationality in Residential Electricity Distribution**
Guanxiang Yun[1], Qipeng Phil Zheng[1], Lihui Bai[2], [1]University of Central Florida, Orlando, FL, [2]University of Louisville, Louisville, KY, Contact: lihui.bai@louisville.edu
Instead of choosing the optimal electricity consumption profile, which are often prescribed by traditional game theory or optimization models, in reality electricity consumers tend to simply pick solutions that are acceptable in terms of cost or convenience. This paper proposes Boundedly Rational User Equilibrium models to study residential electricity consumption in a smart grid. Particularly, we study a new time-of-day pricing framework to reduce the system peak in residential electricity usage while considering consumers' boundedly rational behaviors. Several best- and worst- case scenarios are formulated as bi-level optimization models, for which theoretical results on hidden convexity are obtained. Lagrangian dual methods are developed and are shown to outperform other solution methods through extensive numerical experiments.

4 **Influence Network Design via Multi-level Optimization Considering Boundedly Rational User Behaviours in Social Media Networks**
Qipeng Phil Zheng[1], Guanxiang Yun[1], Vladimir Boginski[1], Eduardo Pasiliao[2], [1]University of Central Florida, Orlando, FL, [2]Air Force Research Laboratory, Eglin AFB, FL
Social media networks have been playing an increasingly vital role for both socialization and information dissemination. To build the optimal network structure to influence the whole, this paper studies mathematical models to simulate the users' behaviors interacting with others in the information provider's network. Linear threshold propagation model is used to determine the re-posting actions, Boundedly Rational User Equilibrium (BRUE) models are used to determine the following or unfollowing actions. Hence, the topology of the network changes and depends on the information provider's plan to post various kinds of information. A three-level optimization model is proposed to maximize total number of connections. Exact algorithms are used to solve a small-scale synthetic network to demonstrate the efficacy of the models.

Chaoyue Zhao, University of Washington at Seattle, Stillwater, OK

1 **Stochos: An Opportunistic Maintenance Scheduling Approach Under Uncertainty for Offshore Wind Farms**
Petros Papadopoulos, Rutgers University, Piscattaway, NJ
Operations and Maintenance (O&M) constitute a major contributor to offshore wind's cost of energy. Offshore wind turbines typically have high capacities, are installed in remote locations, and operate under harsh environmental conditions. In addition, the decision-making process of O&M scheduling typically involves multiple sources of uncertainty, including offshore weather parameters, site accessibility constraints, electricity prices, and turbine degradation. In response, we propose a holistic maintenance optimization model, which is centered around the idea of seizing cost-optimal "maintenance opportunities" whenever they arise, while considering the aforementioned sources of uncertainty. Tested on real-world data from the U.S. North Atlantic region, significant margins of improvements, across several O&M metrics, are realized.

2 **Model-informed Generative Adversarial Network (MI-GAN) for Optimal Power Flow (OPF) Problem**
Yuxuan Li[1], Chaoyue Zhao[2], Chenang Liu[1], [1]Oklahoma State University, Stillwater, OK, [2]University of Washington, Seattle, WA, Contact: chenang.liu@okstate.edu
The optimal power flow (OPF) problem remains challenging due to variability, intermittency, and unpredictability of renewable energy brought to power system. The capability of existing optimization approaches is insufficient when the problem scale is large. Hence, this work proposed a novel model-informed GAN (MI-GAN) method to handle the OPF problem, which can ensure optimality, flexibility, and efficiency by a proposed new model-informed generator with a developed recursively iterative algorithm. The numerical experiments using the IEEE test systems showed this method is very promising.

3 **Distributionally Robust Multi-Stage Virtual PowerPlant Scheduling**
William Yang[1], Chaoyue Zhao[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA, Contact: wtyang15@uw.edu
The Virtual Power Plant (VPP) is a portfolio of heterogeneous distributed energy resources (DER) that can participate in the wholesale energy market. Scheduling VPPs is challenging since dynamic scheduling decisions for various components are required to respond to system uncertainties. We present a multi-stage distributionally robust optimization (MSDRO) approach that utilizes the dynamic influx of information to aid real-time scheduling decisions. The MSDRO produces a risk-averse but not overly-conservative scheduling strategy to cope with uncertainty from renewable energy and customer demand, under unreliable distributional information. To solve our model efficiently, a dynamic programming algorithm is developed. Numerical experiments show our approach outperforms a traditional stochastic model when imperfect distributional information is used.

4 **Optimization Layer Embedded Deep Neural Network for Optimal Power Flow Problem**
Yang Chen[1], Byungkwon Park[2], Kai Sun[3], Zhenping Guo[4], Xiaowen Su[4], [1]Oak Ridge National Laboratory, Oak Ridge, TN, [2]Oak Ridge National Laboratory, Oak Ridge, TN, [3]University of Tennessee at Knoxville, Knoxville, TN, [4]University of Tennessee at Knoxville, Knoxville, TN
AC optimal power flow problem (AC-OPF) is an essential, and yet challenging power system operation problem due to its nonlinearity. In this work, we construct and train deep neural network for predicting main decisions directly for AC-OPF including real/reactive power, voltage magnitude, voltage angle. In order to reduce violation on equality/inequality constraints, very recent developed implicit layer (optimization layer) is adopted to output predictions while satisfying the constraints. The proposed deep learning model has been tested in several IEEE standard bus systems using public benchmark dataset. The results has demonstrated the effectiveness of proposed method.

1 Functional Directed Graphical Models and Applications in Root-cause Analysis and Diagnosis

Kamran Paynabar[1], Ana Maria Estrada Gomez[2], [1]ISyE Georgia Tech, Atlanta, GA, [2]Purdue, West Lafayette, IN, Contact: kamran.paynabar@isye.gatech.edu

Directed graphical models aim to represent the probabilistic relationships between variables in a system. Learning a directed graphical model from data includes parameter learning and structure learning. Nowadays, in many applications, the variables are infinite-dimensional signals that need to be treated as functional random variables. This presentation proposes a novel method to learn directed graphical models in the functional setting. When the structure of the graph is known, function-to-function linear regression is used to estimate the parameters of the graph. When the goal is to learn the structure, a penalized least square loss function with a group LASSO penalty, for variable selection, and an L2 penalty, to handle group selection of nodes, is defined. Through simulations and a case study, the advantage of the proposed method is proven.

2 Robust Experimental Designs for Model Calibration

Arvind Krishna, Northwestern University, Evanston, IL

A computer model can be used for predicting an output only after specifying the values of some unknown physical constants known as calibration parameters. These parameters can be estimated by conducting physical experiments. This paper presents an approach to optimally design such an experiment. The problem of optimally designing a physical experiment, using a computer model, is similar to the problem of non-linear optimal design. However, the problem is more challenging because of the possibility of model discrepancy. Therefore, we propose an optimal design approach that is robust to potential model discrepancies. We show that our designs are better than the commonly used physical experimental designs that do not make use of the information contained in the computer model and other nonlinear optimal designs that ignore potential model discrepancies.

3 Complex Geometries in Additive Manufacturing: A New Solution for Lattice Structure Modeling and Monitoring

Bianca Maria Colosimo, Marco Grasso, Politecnico di Milano, Milan, Italy.

The production of novel types of complex shapes is nowadays enabled by new manufacturing paradigms such as additive manufacturing, also known as 3D printing. The continuous increase of shape complexity imposes new challenges in terms of inspection, product qualification and process monitoring methodologies. The paper presents an innovative solution for modeling the deviation between the nominal geometry (the originating 3D model) and the real geometry (measured via x-ray computed tomography) by converting 3D deviation maps into 1D deviation profiles enabling the use of a profile monitoring scheme for local defect detection. The feasibility and potential of this method are demonstrated focusing on a novel category of complex shapes known as lattice structures, or metamaterials.

Solving Large-scale Power System Optimization Problems

General Session

Session Chair

Feng Qiu, Argonne National Laboratory, Lemont, IL

1 Power Grid Restoration Optimization Considering Decision Maker's Risk Tolerance on Parameter Uncertainty

Gino J. Lim[1], Behnam Sabzi[2], Jian Shi[1], Saeedeh Abbasi[3], Masoud Barati[4], [1]University of Houston, Houston, TX, [2]University of Houston, Houston, TX, [3]University of Houston, HOUSTON, TX, [4]Univesity of Pittsburgh, Pittsburgh, PA, Contact: ginolim@uh.edu

This paper presents two optimization models and introduces the concept of degree of conservativeness providing the decision-makers the flexibility of customizing the restoration plan according to the planner's risk tolerance (i.e., risk-averse or risk-prone) on unknown status of transmission lines. First, a mixed-integer programming (MIP) model (GPP) is formulated under the assumption that all parameters are known. Second, the uncertainty of transmission line status is considered through a worst-case robust optimization (RCP). The degree of conservativeness concept is discussed and the proposed models are tested and analyzed with three IEEE case studies of 14, 39 and 118- bus test systems.

2 A Joint Chance-Constrained Game Framework for Coordinating Active Distribution Networks in Energy and Reserve Market

Yifu Ding, University of Oxford

Active distribution networks (ADNs) incorporate distributed energy resources (DERs) and flexible loads, which can provide energy services such as reserves for the upstream utility. In the energy and reserve market, ADN as an independent entity can proactively adjust their bids and compete with each other. However, due to the uncertainty of renewable power sources and demands, their service provision is not firmly secured. In this work, we design a joint chance-constrained (JCC) game theory framework considering the net load uncertainty and network constraints to coordinate ADNs in the energy and reserve market. The optimized Bonferroni approximation is employed to solve the JCC problem so that both the reserve quantity and provision failure rate regulations can be optimized.

3 Parallel Power System Restoration

Sangho Shim[1], Sunil Chopra[2], Feng Qiu[3], [1]Robert Morris University, MoonTwp, PA, [2]Northwestern University, Evanston, IL, [3]Argonne National Laboratory, Lemont, IL, Contact: shim@rmu.edu

Power system restoration is an essential activity for grid resilience, where grid operators restart generators, re-establish transmission paths, and restore loads after a blackout event. The core decisions in restoration planning are to partition the grid into a few sub-networks, each of which has an initial power source for black-start (called sectionalization problem), and then restart the generators and pick up the loads in each network (called generator startup sequencing problem or GSS) in a parallel fashion, aiming to restore electric service in shortest time. Due to the significant complexity of each problem, the sectionalization and GSS problems are usually solved separately, resulting in a sub-optimal solution. In this work, we develop models and computational methods to solve the two problems simultaneously.

4 A Polyhedral Study on Fuel-Constrained Unit Commitment

Ming Zhao, University of Delaware, Newark, DE

The electricity production of a thermal generator is often constrained by the available fuel supply. These fuel constraints impose a maximum bound on the energy output over multiple time periods. Fuel constraints are increasingly important in electricity markets, due to two main reasons. First, as more natural gas-fired generators join the deregulated market, there is often competition for natural gas supply from other sectors (e.g., residential and manufacturing heating). Second, as more environmental and emission regulations are being placed on fossil fuel-fired generators, fuel supply is becoming more limited. However, there are few studies that consider the fuel constraints in the unit commitment problem from the perspective of computational analysis. To address the challenge faced by an independent power producer with a limited fuel supply, we study a fuel-constrained self-scheduling unit commitment (FSUC) problem where the production decisions are coupled across multiple time periods. We provide a complexity analysis of the FSUC problem and conduct a comprehensive polyhedral study by deriving strong valid inequalities. We demonstrate the effectiveness of our proposed inequalities as cutting planes in solving various multistage stochastic FSUC problems.

Optimization Models in Electric Power and Transportation Systems

General Session

Session Chair

Miguel F. Anjos, University of Edinburgh, Edinburgh, United Kingdom.

1 The Value of Long-duration Energy Storage and Its Interaction with a Zero-emissions Electricity Grid

Patricia Hidalgo-Gonzalez, [1</sup]

Long-duration energy storage (LDES) is a key resource in enabling zero-emissions electricity grids. Using the SWITCH capacity expansion model with high temporal and geographical resolutions, we model a zero-emissions Western Interconnect to understand how the value of LDES changes under different scenarios. We find that a) LDES is most valuable in majority wind-powered regions and regions with diminishing hydropower generation, b) the seasonal operation of storage becomes cost-effective if storage capital costs fall below 5 $/kWh, and c) mandating the installation of enough LDES would reduce electricity price surges by over 70%. Our results provide policy makers with a broad understanding of the need for LDES and impacts of storage mandates.

2 **A Multinational Carbon-Credit Market Integrating Distinct National Carbon Allowance Strategies**

Miguel F. Anjos[1], Felipe A. Feijoo[2], Sriram Sankaranarayanan[3], [1]University of Edinburgh, Edinburgh, United Kingdom; [2]Pontificia Universidad Católica de Valparaíso, Valparaiso, Chile; [3]IIM Ahmedabad, Ahmedabad, India. Contact: anjos@stanfordalumni.org

We propose a multinational carbon-credit (CC) market allowing countries to procure CCs and allocate them to their electricity producers via national strategies that may include taxes on emissions or subsidies for fossil fuel-based production. We compare the cases of producers accessing the market directly versus through their government. Rrecent mathematical optimization methods are used to compute the relevant market outcomes. Using historical data and 2050 EIA projections for the USA, we confirm that acting as intermediaries, countries can adjust their production and mitigate the impacts of high CC prices. We evaluate the impact of imposing renewable portfolio standards on the government versus on the producer, and observe that while output remains similar, the cash flows are favorable for producers if they are responsible for meeting the standards.

3 **Heuristic Methods for Finding Optimal Evcharging Station Placement**

Steven Lamontagne[1], Emma Frejinger[2], Margarida Carvalho[3], Miguel F. Anjos[4], Bernard Gendron[5], [1]Université de Montréal, Montréal, QC, Canada; [2]Universite de Montreal, Montreal, QC, Canada; [3]University of Montreal & CIRRELT, Montreal, QC, Canada; [4]University of Edinburgh, Edinburgh, United Kingdom; [5]Universite de Montreal (DIRO), Montreal, QC, Canada. Contact: steven.lamontagne@umontreal.ca

Effective placement of public charging infrastructure can increase the number of electric vehicles (EVs), as highlighted by the importance of recharging access in the existing literature. We consider the problem of selecting which stations to open and the number of outlets to install over a multi-period time span, with the objective to maximise EV adoption. The demand of users is estimated via a random utility maximisation model, examining if the charging infrastructure is sufficient to allow for recharging. Under the assumption that the stations have no capacity limits, we propose a maximum covering formulation of the problem. However, the maximum covering formulation is intractable for larger instances, necessitating the use of heuristics. Various heuristic methods are proposed and compared for solving this model.

4 **ADMM-based Unit and Time Decomposition for Price Arbitrage by Cooperative Price-Maker Electricity Storage Units**

Miguel F. Anjos[1], James R. Cruise[2], Albert Solà Vilalta[1], [1]University of Edinburgh, Edinburgh, United Kingdom; [2]Heriot-Watt University, Edinburgh, United Kingdom. Contact: albert.sola@ed.ac.uk

We propose a solution method for the optimal control of multiple price-maker electric energy storage units that cooperate to maximize their total profit from price arbitrage. The proposed method can tackle the nonlinearity introduced by the price-maker assumption. The main novelty is the combination of a decomposition by unit and a decomposition in time. The decomposition by unit is based on the Alternating Direction Method of Multipliers (ADMM) and breaks the problem into several one-unit subproblems. Every subproblem is solved using an efficient algorithm for one-unit problems from the literature that exploits an on the fly decomposition in time. This results in a time decomposition for the whole solution method. Our numerical experiments show very promising performance in terms of accuracy and computational time.

Emerging Energy Technologies

General Session

Session Chair

Alexandra M. Newman, Colorado School of Mines, Golden, CO

1 **Estimating the Value of Concentrating Solar Power with Ancillary Services**

Karoline M. Hood, Colorado School of Mines, Golden, CO, Contact: khood@mines.edu

Extant studies on the economic value of concentrating solar power focus on metrics such as levelized cost of energy, which fails to adequately consider dispatchability. We employ an existing mixed-integer program to capture the nuances of plant operations and employ a price-taker approach in the wake of recent technological advancements. Economic value estimates arise not only from the value from energy services and storage, but also from the provision of spinning reserves. We use historical market price data, and demand for spinning reserves, in the case studies we present.

2 Characterizing the Relatedness of Offshore and Onshore Wind Using Patent Analysis

Yiwen Wang, Anna Goldstein, Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA, Contact: yiwwang@umass.edu

As a promising technology for efficient clean power generation, offshore wind energy remains more costly than onshore wind energy due to less learning experience accumulated. This research aims at answering to what degree offshore wind technology is an offshoot of onshore wind technology and to what degree it is novel. We quantify the relatedness between offshore and onshore wind technologies by investigating their patenting activities.

3 Real-time Dispatch Optimization for Concentrating Solar Power with Thermal Energy Storage

Alexander Zolan[1], John Cox[2], William Hamilton[3], Alexandra M. Newman[2], Michael J. Wagner[4], [1]National Renewable Energy Laboratory, Austin, TX, [2]Colorado School of Mines, Golden, CO, [3]National Renewable Energy Laboratory, Wheat Ridge, CO, [4]National Renewable Energy Laboratory, Golden, CO, Contact: alexander.zolan@nrel.gov

Concentrating solar power (CSP) plants, especially those using a central receiver configuration and paired with thermal energy storage, present a promising path towards utility-scale dispatchable renewable energy. However, the variable nature of the solar resource and the conservatism with which the receiver is operated prevent perfect control over the receiver outlet temperature. To support operator decisions in a real-time setting, we develop a revenue-maximizing non-convex mixed-integer, quadratically-constrained program which determines a dispatch schedule with 5-minute time fidelity and considers temperature-dependent power cycle efficiency. We present exact and inexact techniques to improve problem tractability that include a hybrid nonlinear and linear formulation. Our results demonstrate usability for decision support in a real-time setting.

4 High Temporal Resolution Capacity Expansion Planning for Power System Decarbonization

Todd Levin, Argonne National Laboratory, Lemont, IL, Contact: tlevin@anl.gov

In order to ensure that mixed-integer capacity expansion problems are computationally tractable a representative subset of hours in each day and/or days in each year are typically selected. As wind, solar and storage technologies become more prevalent it will be more important to consider intra-hour resource availability and inter-hour state of charge management with high fidelity. We present analyses of the impacts of consider 1) 5-minute dispatch intervals and 2) an increasing number of representative days in a capacity expansion problem of an ERCOT-like system. We find that both these parameters impact the least-cost investment plan; specifically considering 5-minute dispatch resolution increases investment in battery storage capacity.

1 The Value of Returning Donors for Online Matching on Nonprofit Crowdfunding Platforms

Vahideh Manshadi[1], David Simchi-Levi[2], Sabrina Chen Wen Zhai[2], [1]Yale University, New Haven, CT, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: zhai@mit.edu

Motivated by philanthropic crowdfunding platforms like DonorsChoose, we study an online matching problem where sequentially arriving donors must be matched to a fixed set of projects requiring funding. Empirical studies have shown that (i) donors have heterogeneous preferences over the projects, and (ii) many return to make more than one donation. Facing such donors, the platform's aim is to match each donor to one of their preferred projects so as to maximize the total donation without over-funding any projects and without knowing the arrival pattern. We show that a simple and return-agnostic algorithm achieves a performance guarantee that improves with the number of returning donors without differentiating between the original and return donors. We also establish upper bounds on the performance of any algorithm to shed further light on the value of returning traffic.

2 Performative Power

Moritz Hardt[1], Meena Jagadeesan[2], Celestine Mendler-Dünner[1], [1]Max Planck Institute for Intelligent Systems,

Tübingen, Germany; [2]UC Berkeley, Berkeley, CA, Contact: mjagadeesan@berkeley.edu

We introduce the notion of *performative power*, which measures the ability of a firm operating an algorithmic system, such as a digital content recommendation platform, to steer a population. We relate performative power to the economic theory of market power. Traditional economic concepts are well known to struggle with identifying anti-competitive patterns in digital platforms--a core challenge is the difficulty of defining the market, its participants, products, and prices. Performative power sidesteps the problem of market definition by focusing on a directly observable statistical measure instead. High performative power enables a platform to profit from *steering* participant behavior, whereas low performative power ensures that *learning* from historical data is close to optimal.

3 Designing Policies for Allocating Housing to Persons Experiencing Homelessness

Bill Tang[1], Cagil Kocyigit[2], Phebe Vayanos[1], [1]University of Southern California, Los Angeles, CA, [2]University of Luxembourg, Luxembourg, Luxembourg. Contact: yongpeng@usc.edu

We study the problem of allocating scarce housing resources of different types to individuals experiencing homelessness based on their observed covariates. Our goal is to leverage administrative data collected in deployment to design an online policy that maximizes mean outcomes while satisfying budget requirements. We propose a policy in which an individual receives the resource maximizing the difference between their mean treatment outcomes and the resource bid price, or roughly the opportunity cost of using a resource. Our approach has nice asymptotic guarantees and is easily interpretable.

4 Fairer Algorithms for Sortition

Bailey Flanigan, Carnegie Mellon University, Pittsburgh, PA, Contact: bflaniga@andrew.cmu.edu

Citizens' assemblies are a method of policymaking where randomly selected citizens, rather than elected representatives, make policy decisions. Citizens' assemblies are increasingly popular worldwide, being administered by more than 40 organizations in over 25 countries. Our line of work on citizens' assemblies considers their fairness, transparency, manipulability, and more. In this talk, I will discuss our paper *Fair algorithms for citizens' assemblies*, in which we present a sampling algorithm that gives all volunteers a maximally fair chance at being chosen for the assembly, while also ensuring approximate demographic representation. This algorithm uses ideas from fair division and optimization to make significant improvements in fairness over the previous state-of-the-art. It has now been deployed by major groups of assembly organizers worldwide.

Emerging Topics in Sustainable Operations

General Session

Session Chair

Somya Singhvi, USC Marshall School of Business, Los Angeles, CA

1 Understanding the Drivers of Service Quality in the Context of Cloud Kitchens - Empirical Evidence from India

Maya Ganesh[1], DEBJIT ROY[2], [1]Indian Institute of Management Ahmedabad, Ahmedabad, India; [2]Indian Institute of Management Ahmedabad, Ahmedabad, India. Contact: mayag@iima.ac.in

Cloud-kitchen model has seen a steep increase in its presence in the last few years. The goal of quality standardisation becomes challenging when freshly cooked food is the product. The cloud kitchen model has added complexities, as the food prepared travels longer distances compared to a traditional dine-out model where it travels from the restaurant kitchen to the restaurant table. Insights related to aspects of service quality valued by customers will aid managers to improve customer experience. In the context of a large Indian cloud-kitchen company, we use order level data in two cities for a period of six months to determine the factors that drive food and delivery quality. Further, we classify the drivers of service quality into material, operational and personnel aspects and examine the relationship between quality-of-service experience and reordering behavior.

2 Enhancing Digital Road Networks for Better Operations in Developing Countries

Valentijn Stienen, Tilburg University, Tilburg, Netherlands.

Data scarcity in developing countries often significantly complicates the use of analytics to address development challenges. One of the most fundamental data structures needed in operations management is digitized road data; a poorly digitized road network significantly reduces our ability to optimize, for instance, trade of micro-enterprises (SDG 8) and placement of hospitals (SDG 3). Here, we introduce a method that accurately extends and combines large, existing road network representations, for regions with sparse geospatial data. Our method significantly improved the digital road network for smallholder farmers in Indonesia, and, in a case study of optimized geospatial accessibility to healthcare in Timor-Leste, it improved the detection of people located in the vicinity of a hospital.

3 Designing Payment Models for the Poor

Bhavani Shanker Uppari[1], Sasa Zorc[2], [1]Singapore Management University, Singapore, Singapore; [2]University of Virginia, Darden School of Business, Charlottesville, VA, Contact: bhavaniu@smu.edu.sg

Some life-improving technologies for the poor are unaffordable to them, as their limited liquidity puts the purchase costs out of reach. Thus, business models have emerged where the consumers pay a fraction of the price upfront to acquire the technology and make a series of payments for continued access, at the end of which the ownership of the technology may be gained by the consumers. This offers flexibility to sometimes pay low/no amounts (alleviating cash constraints), and at the same time, disciplines consumers by remotely turning off the technology when they lag behind on payments (reducing default risk). Using the optimal contracting approach, we investigate the payment mechanisms that balance flexibility, discipline, and ownership incentives. Several implementable features that improve both the firm's profits and the consumers' welfare emerge from our analysis.

Operations Research Methods in Wildfire Response and Mitigation Planning

General Session

Session Chair

Brittany Segundo, TAMU, College Station, TX

1 Predicting Demand for Wildfire Suppression Resources

Yasser Zeinali[1], Ilbin Lee[1], Mostafa Rezaei[2], [1]University of Alberta, Edmonton, AB, Canada; [2]ESCP Business School, Paris, France. Contact: yzeinali@ualberta.ca

From 2011 to 2021, there were an average of 62,425 wildfires annually, and an average of 7.47 million acres were impacted each year in the U.S. The Forest Service spends about $2 billion per year on suppression, and statistics show that this cost is growing. Wildfire management agencies are under intense pressure to devise an effective resource allocation strategy to fight the fires. Forest fire centers dispatch firefighters, air tankers, helicopters, and other equipment to suppress the wildfires. We develop models to predict demand for these resources in the coming days, allowing managers to make better resource allocation decisions.

2 Risk-averse Stochastic Programming Model for Wildfire Fuel Treatment Planning

Lina M. Villa Zapata, Texas A&M University, College Station, TX, Contact: lina.villa@tamu.edu

Every few months fire managers must consider fuel treatment options to minimize wildfire risk under limited budgets and uncertain weather conditions. In this work, we devised a two-stage risk-averse stochastic programming model for multiperiod fuel treatment planning in grassland regions. We model this problem using a rolling horizon framework to capture dynamic data uncertainties in vegetation growth, weather, and wildfire risk. We apply this model to a case study based on data for west Texas.

3 Multistage Stochastic Programming Approaches to Escaped Wildfire Response Planning

Brittany Segundo[1], Lewis Ntaimo[2], [1]The National Academies of Sciences, Engineering, and Medicine, Washington, DC, [2]Texas A&M University, College Station, TX

In this work we allocate resources to an escaped wildfire already in the extended attack phase. Because the time until containment is unknown, we approximate multistage stochastic decision-making using a rolling horizon framework. The aim of this program is to contain the wildfire through the construction of discrete firelines. We incorporate endogenous uncertainty by modeling the interaction between constructed firelines and growing firefronts. Parameters are gathered from forecasted and actual wind data and simulated fire behavior in eastern Texas.

Recent Developments of Online Optimization in RM

General Session

Session Chair

Jiashuo Jiang, New York Uniersity, New York, NY

Session Chair
Zikun Ye, 1</sup

1 Optimal Algorithm for Minimizing Compositions of Convex Functions and Random Functions and Its Applications in Network Revenue Management

Zikun Ye[1], Xin Chen[1], Niao He[2], Yifan Hu[1], [1]University of Illinois at Urbana Champaign, Urbana, IL, [2]ETH Zürich, Zürich, Switzerland. Contact: zikunye2@illinois.edu

We solve network revenue management problems under booking limit control, which can be formulated as nonconvex stochastic optimization problems. The objective function is a composition of convex function and random function (booking limit truncated by random demand). We proposed an online algorithm Mirror Stochastic Gradient Descent to obtain an approximate global optimal solution with provable optimal sample and gradient complexities. Furthermore, we show the superior performance of the booking limit control policy in both passenger and complicated air-cargo network revenue management problems with extensive numerical experiments.

2 Online Learning for Dual Index Policies in Dual Sourcing Systems

Jingwen Tang[1], Cong Shi[2], Boxiao Chen[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Illinois, Chicago, IL, Contact: tjingwen@umich.edu

We consider a periodic review dual sourcing inventory system. Even with complete information on the demand distribution, it is well known that the optimal inventory replenishment policy is complex and state-dependent. We consider a class of heuristic policies called the dual-index policy. When the demand distribution is unknown, we develop a nonparametric online learning algorithm that learns the demand distribution using historical data and converges to the optimal dual-index policy. Our algorithm integrates stochastic bandits and sample average approximation techniques in an innovative way, and it admits a cumulative regret bound of $O(\sqrt{T}(\log T)^{2})$, which matches the regret lower bound for any feasible learning algorithms up to a logarithmic factor. We explicitly prove that the underlying Markov chain is ergodic and converges to its steady state exponentially fast via coupling arguments. Our work provides practitioners an easy-to-implement and provably-good online decision support for managing a dual sourcing inventory system.

3 Limiting Actions over Time in the Prophet Inequality

Sebastian Perez Salazar[1], Mohit Singh[2], Alejandro Toriello[2], [1]Rice University, Houston, TX, [2]ISyE Georgia Tech, Atlanta, GA, Contact: swps3@gatech.edu

Consider the setting where a seller is selling one item to buyers. The seller offers a price, and if the buyer's valuation is higher than the offered price, then the item is sold to the corresponding buyer. Changing the price too frequently could be considered unfair in many settings. The literature has studied two extremes: fixed price and fully adaptive pricing. This work examines the middle situation where we allow restricted adaptivity by offering at most k prices over the time horizon. Using the framework of the iid prophet problem, we present asymptotic results in k and results for small values of k. From a technical standpoint, we use a linear program formulation to show the guarantees of our approach.

4 Online Resource Allocation with Samples

Negin Golrezaei[1], Patrick Jaillet[2], Zijie Zhou[3], [1]Massachusetts Institute of Technology, Lexington, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: zhou19981107@gmail.com

The problem of online allocation of scarce resources is one of the most important problems faced by governments, hospitals, e-commerce, etc. We study the problem where we have uncertainty about demand and the reward of each type of demand for resources. The lack of knowledge about agents' rewards is inspired by the problem of allocating new resources with unknown effectiveness/value. We assume that we can test the market before the allocation period starts. We study how to exploit the sample information under adversarial arrival processes. We present an asymptotically optimal algorithm that achieves $1-\Theta(1/\sqrt{m})$ competitive ratio, where m is the number of resources, and show that it is tight. We further demonstrate the efficacy of our proposed algorithm using a dataset that contains the number of COVID-19 related hospitalized patients across different age groups.

1 Joint Placement, Delivery Promise and Fulfillment in Online Retail

Yicheng Bai[1], Huseyin Topaloglu[2], Paat Rusmevichientong[3], [1]Cornell Tech, New York, NY, [2]Cornell Tech, New York, NY, [3]USC Marshall School of Business, Los Angeles, CA

We consider placement, delivery promise and fulfillment decisions faced by an online retailer. We have a set of products with given numbers of units to be placed at different fulfillment centers with capacity constraints. Once we make the placement decisions, we face random demand for the products from different demand regions. In response to each demand, we need to pick a delivery promise to offer, which determines the probability that the demand converts into sale, as well as choose a fulfillment center to use to serve the demand. Our goal is to decide where to place the units to maximize the total expected profit from the sales over a finite selling horizon. We give a general approximation framework for this joint placement, delivery promise and fulfillment problem and provide a 1/(4+�) performance guarantee for any �>0.

2 Joint Assortment and Inventory Planning Under Markov Chain Choice Model

Omar El Housni[1], Omar Mouchtaki[2], Guillermo Gallego[3], Vineet Goyal[2], Salal Humair[4], Sangjo Kim[5], Ali Sadighian[6], Jingchen Wu[7], [1]Cornell Tech, New York, NY, [2]Columbia University, New York, NY, [3]Hong Kong University of Science and Technology, Hong Kong, China; [4]Amazon, Inc., Sammamish, WA, [5]SUFE, Shanghai, China; [6]Uber, New York, NY, [7]Amazon, Seattle, WA

We study a joint assortment and inventory optimization problem faced by an online retailer who needs to decide on both the assortment and the inventories of a set of N substitutable products before the start of a selling season of length T to maximize the expected profit. We model dynamic stock-out based substitution by proposing a Markov Chain choice model and present a near-optimal algorithm for the problem achieving a O(√(NT)) regret with respect to an LP upper bound. Our algorithm balances between expected revenue and inventory costs by identifying a subset of products that can pool demand without significantly cannibalizing the revenue in the presence of dynamic substitution. We conduct computational experiments that show that our algorithm empirically outperforms natural approaches both on synthetic and realistic instances.

3 Demand Estimation Under Uncertain Consideration Sets

Srikanth Jagabathula[1], Dmitry Mitrofanov[2], Gustavo J. Vulcano[3], [1]NYU Stern School of Business, New York, NY, [2]Boston College, Chestnut Hill, MA, [3]Universidad Torcuato di Tella, Ciudad Autónoma Buenos Aires, Argentina.

Consider-then-Choose (CTC) models have gained significant popularity recently within operations. But, in practice, we do not observe consideration sets, making it difficult to estimate these models.
This raises the following question: when firms only collect transaction data, do CTC models offer any predictive advantage over the classic choice models? In this work, we study a general class of CTC models. We propose techniques to estimate these models efficiently and compare them against the classic approach which ignores consideration sets. We find that CTC models outperform classic models when there is noise in the offer set information and the noise is asymmetric across the training and test offer sets, but otherwise offer no particular predictive advantage . We demonstrate the benefits of using the CTC models in real-world retail and online platform settings.

4 Pricing Multiple Products and Competition Analysis Under the Threshold Utility Model

Guillermo Gallego[1], Zhuodong Tang[1], Ruxian Wang[2], [1]Hong Kong University of Science and Technology, Hong Kong, China; [2]Johns Hopkins University, Carey Business School, Kensington, MD, Contact: ztangai@connect.ust.hk

We consider pricing and competition problems arising from the threshold utility model (TUM). Under the TUM, consumers purchase all products whose net utility exceeds a non-negative threshold selected to maximize the expected consumer surplus subject to a bound on the number of products purchased in expectation. For the monopolistic problem, we identify conditions under which the multi-product price optimization can be efficiently solved. We also show the joint concavity of revenue function with respect to market shares holds. In the oligopolistic setting, we establish the existence of a Nash equilibrium under multiple-product price competition. We further analyze the competition in market shares and show the existence and uniqueness of Nash equilibrium under which fewer consumers are served. The key results hold even when product’s utility is non-linear in the price.

Advances in Revenue Management

General Session

Session Chair

Tarek Abdallah, Northwestern University, Kellogg School of Management, Chicago, IL

1 Disclosing Low Product Availability: An Online Retailer's Strategy for Mitigating Stockout Risk

Dmitry Mitrofanov[1], Benjamin Knight[2], [1]Boston College, Chestnut Hill, MA, [2]Instacart, San Francisco, CA

In this paper, we investigate how sharing information regarding the low availability of certain items can influence customers' purchase decisions.

In a field experiment, we exogenously share low item availability information with a random subset taken for a sample of more than 840K customers using Instacart. We find evidence that customers are 25% less likely to purchase low availability items when item availability information is disclosed. In addition, we show that low product availability disclosure leads to higher customer satisfaction and positively affects the platform's fundamentals in the context of our field experiment. More specifically, our results indicate that this innovative and cost-free approach leads to a 5.33% increase in revenue per customer and a 4.9% increase in order frequency over the long term.

2 Assortment Optimization with Multi-item Basket Purchase Under the Multivariate MNL Model

Chengyi Lyu[1], Stefanus Jasin[2], Sajjad Najafi[3], Huanan Zhang[1], [1]University of Colorado Boulder, Boulder, CO, [2]University of Michigan, Ann Arbor, [3]HEC Paris, VERSAILLES, France. Contact: chengyi.lyu@colorado.edu

Assortment selection is one of the most important decisions faced by retailers. Most existing papers in the literature assume that customers select at most one item out of the offered assortment. While this is valid in some cases, it contradicts practical observations in many shopping experiences, both in online and brick-and-mortar retail, where customers may buy a basket of products instead of a single item. In this paper, we incorporate customers' multi-item purchase behavior into the assortment optimization problem. We consider both uncapacitated and capacitated assortment problems under the so-called Multivariate MNL (MVMNL) model, which is one of the most popular multivariate choice models used in the marketing and empirical literature.

3 Additional Luggage Pricing Without Price Variation

Ruijiu Mao, National University of Singapore, Singapore, Singapore.

We study the additional luggage pricing problem in airlines, where the historical unit price remains the same for a long time. The lack of price variation presents a major challenge in identifying the demand pattern, which is the basis of the pricing problem. In this work, we utilize the variation in usage to reveal the demand pattern in the absence of price variation. Specifically, we formulate a discrete-continuous choice model which captures the heterogeneity of both the usage sensitivity and the price sensitivity. Based on the analysis of the choice model, an MLE framework is applied to calibrate the parameters. We also present an application to validate the effectiveness of the framework and demonstrate our pricing strategy.

4 Estimating Demand with Unobserved No-purchases on Revenue-managed Data

Anran Li[1], Kalyan Talluri[2], Müge Tekin[3], [1]The Chinese University of Hong Kong (CUHK), Hong Kong, Hong Kong; [2]Imperial College Business School, London, United Kingdom; [3]Erasmus University Rotterdam, Rotterdam, Netherlands.

This paper investigates the joint estimation of the consumer arrival rate and choice model parameters when ``no-purchasers” are not observable. Estimating demand even with the simplest discrete-choice model such as the MNL becomes challenging. Some previous approaches have proposed using market-share to pin down the parameter; however, market-share data are difficult to obtain in practice. Another complication is the sales are ``revenue-managed”, that is, optimized nearly continuously by analysts and algorithms. In this paper we propose a two-step GMM based robust method when the firm cannot observe no-purchases, has no market-share information, and the data has been revenue-managed.

Sunday, 11AM–12:15 PM

Complexity of Neural Networks

General Session

Session Chair

Christoph Hertrich, London School of Economics, United Kingdom.

1 **New Structural Results in Linear Threshold Neural Networks**

Sammy Khalife, Johns Hopkins University, Baltimore, MD, Contact: khalife.sammy@jhu.edu

In this talk I will present new results on neural networks with linear threshold activation functions. The class of functions that are representable by such neural networks can be fully characterized, and
two hidden layers are necessary and sufficient to represent any function in the class. This is a surprising result in the light of recent exact representability investigations for neural networks using other popular activation functions like rectified linear units. I will discuss precise bounds on the sizes of the neural network, and I present an algorithm to solve the empirical risk minimization (ERM) problem to global optimality for these neural networks with a fixed architecture. The algorithm's running time is polynomial in the size of the data sample, if the input dimension and the size of the network architecture are considered fixed constants.

2 **Training Fully Connected Neural Networks is R-complete**

Daniel Bertschinger[1], Christoph Hertrich[2], Paul Jungeblut[3], Tillmann Miltzow[4], Simon Weber[1], [1]ETH Zurich, Zurich, Switzerland; [2]London School of Economics, London, United Kingdom; [3]Karlsruhe Institute of Technology, Karlsruhe, Germany; [4]Utrecht University, Utrecht, Netherlands. Contact: c.hertrich@lse.ac.uk

We consider the algorithmic problem of finding the optimal weights and biases for a two-layer fully connected neural network to fit a given set of data points. This problem is known as empirical risk minimization in the machine learning community. We show that the problem is R-complete. This complexity class is widely believed to be a strict superset of NP. It can be defined as the set of algorithmic problems that are polynomial-time equivalent to finding real roots of a polynomial with integer coefficients. Our results hold even for very simple architectures, showing that they are already difficult to train. The result offers an explanation (though far from a complete understanding) on why only gradient descent is widely successful in training neural networks in practice. We generalize a recent result by Abrahamsen, Kleist and Miltzow [NeurIPS 2021].

3 **The Hidden Convex Optimization Landscape of Deep Neural Networks**

Tolga Ergen, Stanford University, Stanford, CA, Contact: ergen@stanford.edu

Since deep neural network training problems are inherently non-convex, their recent dramatic success largely relies on non-convex optimization heuristics. Therefore, understanding the reasons behind the success of these highly complex non-convex architectures remains an open problem. To this end, we introduce exact convex formulations of ReLU network training problems and prove that shallow networks can be globally trained via convex programs with polynomial time complexity. Our results provide an equivalent characterization of neural networks as sparse locally linear models. We also discuss extensions to convolutional networks, batch normalization, and deeper architectures. Finally, we present numerical simulations illustrating the efficiency and effectiveness of our convex training approach over standard local search heuristics such as SGD.

Power Systems Expansion Planning

General Session

Session Chair

Joaquim Dias Garcia, PSR, Brazil.

Session Chair

Tiago Coutinho Carneiro de Andrade, PSR-inc

1 **An Integrated Progressive Hedging and Benders Decomposition with Multiple Master Method to Solve the Brazilian Generation Expansion Problem**

Alessandro Soares[1], Alexandre Street[2], Tiago Coutinho Carneiro de Andrade[3], Joaquim Masset Lacombe Dias Garcia[3], [1]PSR, Rio de Janeiro, Brazil; [2]University of Rio de Janeiro (PUC-Rio), Rio de Janeiro, Brazil; [3]PSR, Rio de Janeiro, Brazil. Contact: alessandro@psr-inc.com

This talk exploits the decomposition structure of the generation expansion planning problem with an integrated modified Benders Decomposition (BD) and Progressive Hedging (PH) approach. We represent the multistage stochastic nature of the optimal hydrothermal operational policy through co-optimized linear decision rules for individual reservoirs. Therefore, we ensure investment decisions compatible with a nonanticipative (implementable) operational policy. To solve the large-scale optimization problem, we propose an improved BD with multiple instances of the master problem, strengthened by primal cuts and new Benders cuts generated by each master's trial solution. Additionally, our new approach allows using

PH penalization terms for accelerating the convergence of the method. We present real data from the Brazilian power system as a case study.

2 Climate-aware Generation and Transmission Expansion Planning: A Three-stage Robust Optimization Approach

Alexandre Moreira[1], David Pozo[2], Alexandre Street[3], Enzo E. Sauma[4], Goran Strbac[5], [1]Lawrence Berkeley National Laboratory, Berkeley, CA, [2]Skolkovo Institute of Science and Technology, Moscow, Russian Federation; [3]University of Rio de Janeiro (PUC-Rio), Rio de Janeiro, Brazil; [4]Pontificia Universidad Catolica de Chile, Santiago, Chile; [5]Imperial College London, London, United Kingdom. Contact: alexandremoreirads@gmail.com

We propose a three-stage robust generation and transmission expansion planning model considering generation profiles of renewable energy sources (RES) affected by different long-term climate states. Essentially, we extend the broadly utilized two-stage modeling approach to properly consider partial information of climate states with conditional short-term scenarios of RES output and outages. The proposed model is formulated as a five-level optimization problem. Within this multi- level structure, the optimal investment plan considers a more realistic decision setting, where system operators adapt RES forecasts based on the observed climate conditions before planning the operational schedule. To solve the problem, a variant of the nested column-and-constraint-generation algorithm is proposed with global-optimality guarantee in a finite number of steps.

3 Flexible Network Expansion with N-1 Security Constraints

Tiago Coutinho Carneiro de Andrade, Bruno Bernhardt, Joaquim Garcia, PSR-inc, Rio de Janeiro, Brazil. Contact: tiago.andrade@psr-inc.com

We propose a power system expansion with a flexible network and solved by Benders decomposition. The first stage is the investment problem modeled as an integer problem. The second stage is an operations problem modeled as multistage stochastic programming and solved by stochastic dual dynamic programming (SDDP). We consider equipment investments to gain flexibility in the network as flow controllers controlling the circuit susceptances, phase shifters, and battery using typical days. Moreover, it considers N-1 security constraints with efficient computation of the line outage distribution factor (LODF) matrixes and lazy constraints for circuit capacities. We test the proposed approach using real-world data.

1 Learning to be Proficient? A Structural Model of User Dynamic Engagement in e-Health Interventions

Tongxin Zhou[1], Yingfei Wang[2], Lu (Lucy) Yan[3], Yong Tan[2], [1]Arizona State University, Tempe, AZ, [2]University of Washington, Seattle, WA, [3]Indiana University, Bloomington, IN

User attrition has been a major challenge confronted by eHealth interventions. In this study, we aim to examine how individuals dynamically engage in eHealth interventions to shed light on users' continued participation. In the participation process, users' intervention perceptions play an important role in affecting their subsequent participation decisions. To capture the updates in individuals' intervention perceptions and the associated behavior dynamics, we establish a hierarchical Bayesian learning framework to structurally characterize individuals' decision-making processes. Through analysis of a 4-month dataset collected for users' intervention participation in an online weight-loss platform, our study provides empirical evidence for individuals' learning behaviors in online health management.

2 Tweet in Unison? Examining Content Coordination and Social Media Engagement During Disasters

Eunae Yoo[1], Changseung Yoo[2], Alfonso J. Pedraza-Martinez[1], [1]Indiana University, Bloomington, IN, [2]McGill University, Montreal, QC, Canada. Contact: yooeun@iu.edu

Many disaster relief organizations (DROs) post social media content via multiple accounts within a single platform. Each account represents a distinct operational entity and is managed independently. A natural question is whether this strategy is more effective vs. a strategy where accounts under the same DRO produce content in unison. Our study answers this question by examining how engagement is affected by the agreement of content creation decisions across a DRO's accounts. Using Twitter data collected in partnership with the Canadian Red Cross, we show that engagement experiences a negative spillover effect when accounts under the same DRO make identical content creation decisions. Our findings provide actionable guidelines for DROs' internal coordination of content production in order to better deliver information to those that need it during disasters.

3 The Ownership Economy: How Stock Rewards Shape Consumer Spending

Ziyi Cao[1], Tingting Nian[2], Arun Sundararajan[3], [1]University of California, Irvine, Irvine, CA, [2]University of California, Irvine, CA, [3]New York University, New York, NY, Contact: zcao6@uci.edu

Behavioral theories pose loyalty programs such as cash rewards trigger reciprocity and affect towards the brand. It has been well documented that loyalty programs can promote good customer relationships and customer retention, yet little has been done in understanding the effect of stock rewards. We leverage transaction-level data from a FinTech company and investigate the impact of stock rewards on consumer spending. We find users increase spending by 23.3% after receiving stock rewards and the effect does not vanish until three months later. The effectiveness of stock rewards is documented as 503%, greater than 32% of cash rewards, revealing possible motivating effects besides monetary benefit, which can be explained by the sense of ownership. Our research is among the first to study the impact of stock reward on individual investors' consumption tendencies.

4 You Say, Firm Says: An Empirical Study on Online Employer Brand and Firm Performance

Lorin Hitt[1], Fujie Jin[2], Bowen Lou[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Kelley School of Business, Indiana University, Bloomington, IN, [3]University of Connecticut, Storrs, CT, Contact: jinf@indiana.edu

We use a large-scale multiyear dataset to examine how various digital communication channels jointly provide signals of the quality of a firm as an employer, build up its online employer brand, and affect firm market value.

Recent Advances in using ML for Supply Chain and Revenue Management

General Session

Session Chair

Divya Singhvi, 1</sup

1 Inventory Management in Omnichannel Supply Chains

Pavithra Harsha[1], Ali Koc[2], Chandra Narayanaswami[1], Brian Quanz[3], Mahesh Ramakrishna[1], Dhruv Shah[1], Shivaram Subramanian[1], [1]IBM Research, Yorktown Heights, NY, [2]IBM TJ Watson Research Center, Yorktown Heights, NY, [3]IBM, Yorktown Heights, NY, Contact: pharsha@us.ibm.com

We study the multi-period inventory replenishment problem for an omnichannel retailer that aims to optimally position inventory across its warehouses and stores to meet its uncertain omnichannel demand that includes walk-ins at stores as well as online demand that can be fulfilled from any location. We present a robust optimization-based heuristic and discuss different variations to solve this problem. Using real-data from a retailer, we perform network-based simulations and compare the impact of this and other typical heuristics on various KPIs of interest.

2 Deep Policy Iteration with Integer Programming for Inventory Management

Brian Quanz[1], Pavithra Harsha[2], Ashish Jagmohan[3], Jayant Kalagnanam[3], Divya Singhvi[4], [1]IBM, Yorktown Heights, NY, [2]IBM Research, Pleasantville, NY, [3]IBM Research, Yorktown Heights, NY, [4]New York University, New York, NY, Contact: blquanz@us.ibm.com

Reinforcement learning has led to considerable break-throughs in diverse areas such as robotics, games and many others, but its application in complex real-world decision making problems remains limited. Many problems in OM are characterized by large action spaces and stochastic system dynamics, providing a challenge for existing RL methods that rely on enumeration techniques to solve per step action problems. To resolve these issues, we develop Programmable Actor Reinforcement Learning (PARL), a policy iteration method that uses techniques from integer programming and sample average approximation. We demonstrate its effectiveness on a variety of multi-echelon inventory management settings.

3 Improving Product Availability to Reduce Customer Attrition in Clothing Rental Subscriptions

Lennart Baardman, Xuening Wang, University of Michigan, Ann Arbor, MI, Contact: baardman@umich.edu

Customer attrition is a serious challenge for subscription services. Often, customers leave the service within the first few months of signing up. Using data from a clothing rental service, we create a machine learning method to understand why customers leave. One major issue is the lack of variety in clothing styles, which is partially caused by products being unavailable. We develop an optimization algorithm that controls inventory by managing which products are displayed to the customer in order to maximize product availability while minimizing the risk of customers not receiving their products.

4 Safe: A Supervised Approach for Feature Engineering

Tamar Cohen-Hillel[1], Georgia Perakis[2], Ioannis Spantidakis[3], Leann Thayaparan[4], [1]UBC Sauder School of Business, Vancouver, BC, Canada; [2]Massachusetts Institute of Technology, Belmont, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, [4]Massachusetts Institute of Technology, Somerville, MA, Contact: georgiap@mit.edu

In the age of data availability, being able to analyze high-dimensional data is crucial for decision-making. Nevertheless, accounting for a large number of features can introduce several challenges and dimensionality reduction techniques are necessary to improve both the speed of the machine learning algorithm as well as its accuracy. To address this concern, in this research we develop a new dimensionality reduction algorithm called Supervised Approach for Feature Engineering (SAFE). Our proposed approach identifies a projection that best explains, not the variance in features, but how well those features are correlated with the dependent variable, facilitating any future supervised machine learning algorithms.

Decision Making under Information Acquisition

General Session

Session Chair

Renyuan Xu, University of Oxford, Oxford, United Kingdom.

1 Recover Utility of Rational Inattentive Agent and Applications on Robo-advising

Hao Xing, Zeyu Zhu, Boston University, Boston, MA, Contact: haoxing@bu.edu

We consider a rational inattentive agent who acquires costly signal to make decisions. By observing agent's actions, we formulate an inverse reinforcement learning problem to recover agent's utility. We propose an efficient numeric algorithm and prove its convergence. The framework is applied to robo-advising problems to recover investors' utilities by observing their investment strategies.

2 Parallel Search for Information in Continuous Time

Wenpin Tang, Columbia University

We consider the problem of a decision-maker searching for information on multiple alternatives when information is learned on all alternatives simultaneously. The decision-maker has a running cost of searching for information, and has to decide when to stop searching for information and choose one alternative. The expected payoff of each alternative evolves as a diffusion process when information is being learned. After establishing the well-posedness of the equation, we show that the optimal boundary where search is stopped (free boundary) is star-shaped, and present an asymptotic characterization of the value function and the free boundary. We show that the distance between the free boundary and each point on the diagonal is logarithmic in the number of alternatives.

3 The Cost of Regret

Luhao Zhang, The University of Texas at Austin, Austin, TX

We study a learning decision-making problem over an infinite horizon. In this problem, the decision-maker (DM) can choose between two products, a well-known product A anda new product B, where the return of product A is deterministic (fully observable) while the return of the new product B, denoted as ⍰ {l, h}, is unknown to the DM. We consider a framework where the DM can make an initial decision after learning for some time and change her mind later on at a cost. This is formulated as a sequential decision-making problem in two periods. In the first period (up to a stopping time picked by the DM), the DM collects information and learns about the return of the unknown product B. At stopping time ⍰, the DM makes an initial choice between product A and product B, and the DM is able to continue observing the return signals of product B and has one opportunity to change to the alternative at a cost.

4 Independent and Decentralized Learning in Markov Potential Games

Manxi Wu, Cornell University, ORIE, Ithaca, NY

We propose a multi-agent reinforcement learning dynamics, and analyze its convergence property in infinite-horizon discounted Markov potential games. We focus on the independent and decentralized setting, where players do not know the game model and cannot coordinate. In each stage, players update their estimate of a perturbed Q-function at a fast timescale, and update their policies using a smoothed optimal one-stage deviation strategy at a slow timescale. We prove that our learning dynamics converge to a stationary Nash equilibrium in Markov potential games with probability 1.

1 Optimal Decisions for the Innovative Enterprise Considering Brand Goodwill and Consumers' Quality Expectation
Xiaoya Han[1], Huichen Zhang[1], Xin Liu[2], [1]University of Shanghai for Science and Technology, Shanghai, China; [2]Elon University, Elon, NC, Contact: xliu3@elon.edu
This study investigates product pricing and quality strategies by considering the brand goodwill of the innovative enterprise and the consumers' quality expectation. pricing. Under the framework of the Bertrand game, we analyze the competitive pricing problem of the innovative enterprise. We also extend the competition problem under consideration of information asymmetry and the Stackelberg game framework.

3 Fast Rescheduling Method for Semiconductor Assembly Lines with Reentrance and Constrained Time Windows
Yutong Su[1], Bala Krishnan[2], Husam Daoud[3], Nital Patel[3], Feng Ju[4], [1]Arizona State University, Tempe, AZ, [2]Intel, Bangalore, India; [3]Intel, Chandler, AZ, [4]Arizona State University, Tempe, AZ, Contact: yutongs1@asu.edu
In semiconductor manufacturing, a master schedule over several weeks' time horizon is typically created to optimize production. However, machine failures may cause the master schedule to be infeasible by violating the time window constraint or suboptimal due to delays. In this work, considering the reentrant structure and time window constraint, we develop a decentralized approach based on a series of mixed-integer programming models to adjust the master schedule. The experiment results show that the proposed method can respond to machine failures much faster than the master scheduler and heuristic-based methods.

4 The Price of Friction in Multi-channel Retail: Insights for Retail Operations Managers
Aneesh Banerjee[1], Sabrina Gottschalk[1], Joerg Ries[2], [1]City University London, London, United Kingdom; [2]City University London, London, United Kingdom. Contact: aneesh.banerjee@city.ac.uk
Manufacturers use multiple sales channels: own physical and online stores, as well as third party physical and online stores. In such an environment, manufacturers can control channel characteristics such as experience and friction, only on some channels. However, as these channel characteristics and prices influence consumers' purchase decisions as well as the profitability of the channel, the development of a multichannel strategy requires understanding consumers' channel choices as well as the operational implications of the fulfilment process. Using a choice-based conjoint experimental design we study how customers' utility is affected by price, friction and experience. We offer important new insights about consumer switching behaviour between channels and implications for operations managers to optimize their channel fulfilment process.

5 Overconfidence in Context: The Moderating Role of Demand Distributions in the Newsvendor Problem
Dahai Cai[1], Sam Kirshner[2], MENG WU[1], Lushuang Yang[1], [1]Sichuan University, Chengdu, China; [2]UNSW Business School, Sydney, Australia. Contact: s.kirshner@unsw.edu.au
This talk explores how demand can moderate the influences of overconfidence in decision-making in the newsvendor problem. We posit that an individual's overconfidence depends on their cognitive load, which increases with greater demand ranges. Accordingly, we hypothesize that a wider demand range will lead to a more substantial pull-to-center effect due to greater reliance on overconfident estimates of the demand distribution. We test and find support for our hypothesis in two experimental studies.

6 The Visible Hand: Name-based Rationing System for Mitigating Strategic-purchasing and Panic-buying
Jiuh-Biing Sheu[1], Vivi Kuo[2], [1]National Taiwan University, Da An Qu, Taiwan; [2]National Taiwan University, Taipei, Taiwan.
This paper presents a conceptual model to investigating the causal relationship between supply chain resilience and its causes under government deployed a name-based rationing

system (NBRS) amid Covid-19 outbreaks. Grounded upon resource dependency theory and supply chain disruption risk management strategies, one of the distinctive features of the proposed model is that a name-based rationing system (NBRS) is treated as a moderator on the effect of retailer strategic purchasing and consumer panic buying on supply chain resilience.

7 When Do Human Decision Makers Beat Computerized Support? - A Field Experiment in Retailing

Anna-Lena Sachs[1], Michael Becker-Peth[2], Stefan Minner[3], Ulrich Thonemann[4], [1]Lancaster University, Lancaster, United Kingdom; [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]Technical University of Munich, München, Germany; [4]Universitat zu Koln, Köln, Germany. Contact: a.sachs@lancaster.ac.uk

Retail managers face the challenging task of placing orders for perishable products. Central tools can support them by providing model-based order quantities, but if local managers have additional market information, it might be beneficial to decentralize decisions. However, human decision makers are prone to biases. To assess the benefit of decision support, we conducted a field experiment at a European retail chain. We randomly assigned stores to four groups and provided different levels of support. We find that decision makers are prone to the pull-to-center bias, but the bias is reduced for store managers receiving model-based order quantities. Store managers can outperform the central system in terms of total cost by incorporating local information, but higher levels of decision support can hinder the implementation of local information.

8 What Drives Your Customer Nuts? Predicting Complaints in Semiconductor Order Fulfillment

Patrick Moder, Kai Hoberg, Kühne Logistics University gGmbH, Hamburg, Germany. Contact: patrick.moder@the-klu.org

Late or insufficient order fulfilment creates the risk of bad publicity, customer churn and lost sales. In a semiconductor B2B setting, we predict customer complaints when shipped orders deviate from the initial commitment. We apply machine learning models to approximate the complaint prediction problem and find that extreme gradient boosted trees perform best for the imbalanced target variable on hand. We show that sampling approaches only contribute limited performance improvements, study the impact of cutoff selection on absolute prediction outcomes, and investigate the importance of input features using SHAP values.

Nudging to Improve Decision-making in Operations

General Session

Session Chair

Karen L. Donohue, University of Minnesota, Minneapolis, MN

Session Chair

Yeonjoo Lee, Minneapolis, MN

1 Nudging Green but Slow Shipping Choices in Online Retail

Yeonjoo Lee, Karen L. Donohue, University of Minnesota, Minneapolis, MN, Contact: yjlee@umn.edu

While fast delivery helps retailers to stay competitive, it often leads to worse environmental outcomes. We study how to nudge online retail customers to voluntarily choose slower but greener delivery in two logistical contexts: no-rush and consolidated shipping. Drawing from current practice and research on nudging sustainable behavior, we develop a theory on what types of information will be most effective in which context and why. Through a series of experiments, we find that the effectiveness of information strategies varies by logistical context. In particular, green signaling is critical for no-rush shipping but less useful for consolidated shipping. Also, process information is most effective for consolidated shipping, while outcome information is most effective for no-rush shipping. Effects can be explained by the reduction of psychological barriers.

2 Nudging Patient Choice by Messaging

Jiayi Liu[1], Diwas S. KC[2], [1]Emory University, Atlanta, [2]Emory University, Atlanta, GA

Patient no-show has been a chronic problem in outpatient clinics. In this study, we use text-based nudges to reduce no-shows. Through a field experiment in the clinic, we find that certain message framing designed to make future wait time salient has greatly boosted patient attendance.

3 Improving Customer Compatibility with Tradeoff Transparency

Ryan Buell, MoonSoo Choi, Harvard Business School, Boston, MA, Contact: rbuell@hbs.edu

Through a large-scale field experiment with customers considering opening a credit card with a nationwide retail bank, we investigate how providing transparency into an offering's tradeoffs affects subsequent rates of customer acquisition and engagement. We find tradeoff transparency to have an insignificant effect on acquisition rates, but customers who were shown each offering's tradeoffs selected different products than those who were not. Moreover, prospective customers who experienced transparency and subsequently chose to open an account went on to exhibit higher quality service relationships over time. Monthly spending was 9.9% higher and cancellation rates were 20.5% lower among those who experienced tradeoff transparency. Providing tradeoff transparency may be an effective strategy for informing customer choices, leading to better outcomes.

4 Automation or Collaboration? Machine Learning vs Integrated Demand Planning Methods

Rebekah Brau[1], John Aloysius[2], Enno Siemsen[3], [1]Brigham Young University, Provo, UT, [2]University of Arkansas, Fayetteville, AR, [3]University of Wisconsin-Madison, Madison, WI, Contact: bbrau@byu.edu

Our research compares integrated forecasts (human judgment and algorithms) with machine learning forecasts absent of human input. We use a laboratory experiment in combination with a field study involving over five million product-store forecasts to compare two integrated methods: interactive learning (IL) and human-guided learning (HGL) with unsupervised machine learning. The two integrated methods represent supervised learning; they allow the algorithm to make use of human judgment to train the model using iterative linear weighting of human judgment and model predictions. Our studies demonstrate that human judgment benefits demand planning processes as the two learning methods are more accurate than machine learning without human input.

The Advancement of Machine Learning and Data-driven Decision Making

General Session

Session Chair

Xuan Bi, University of Minnesota, Minneapolis, MN

1 Offline Reinforcement Learning with Instrumental Variables in Confounded Markov Decision Processes

Zhengling Qi, The George Washington University, Washington D.C., MD

We study offline reinforcement learning (RL) in the confounded Markov decision processes (MDPs). Due to the lack of online interaction with the environment, offline RL is facing the following two significant challenges: (i) the agent may be confounded by the unobserved state variables; (ii) the offline data collected a prior does not provide sufficient coverage for the environment. To tackle the above challenges, with the aid of instrumental variables, we propose various policy optimization algorithms with the finite-sample regret guarantee for finding an optimal in-class policy under mild data coverage assumptions. Our extensive theoretical investigations and one numerical study motivated by kidney transplantation demonstrate the promising performance of the proposed algorithms.

2 Economic Impact of New Category Recommendations: Evidence from Randomized Field Experiments

Meizi Zhou[1], Ravi Bapna[2], Gediminas Adomavicius[2], Jonathan Hershaff[3], [1]Boston University, Boston, MA, [2]University of Minnesota, Minneapolis, MN, [3]University of Michigan, Ann Arbor, MI

New category introduction is an intensive-margin-oriented strategy. There is a lack of studies explicitly designed to guide users to unexplored product categories, and evaluating the real-world causal economic impact of category expansion. Thus, we design and evaluate new category introduction approaches and their economic impact using ML-based recommendation techniques and field experiments. We firstly show the impact of recommending a new category on consumers' purchase behaviors. Furthermore, providing multiple choices further amplifies the impact. We show that ML-based personalization techniques utilizing granular information about users' online activities can help locate the most relevant categories for individual customers. Critically and finally, we show the causal economic impact of new category recommendations in a real-world setting.

3 Heterogeneous Task Segmentation & Acquisition Tree: Learning Multidimensional Wisdom of Crowd on Crowdsourcing Marketplace

Junyu Cao[1], Yan Leng[2], [1]The University of Texas at Austin, Provo, [2]University of Texas at Austin, Austin, TX, Contact:

yan.leng@mccombs.utexas.edu

Crowdsourcing platforms have emerged as a practical paradigm for enabling the wisdom of crowd. This study formulates a new data acquisition problem to learn worker skills and heterogeneous task skill requirements. We propose an interpretable tree-based adaptive data acquisition algorithm to predict top workers. The proposed algorithm allows for two practical considerations: (1) the transient nature of workers may naturally lead to a transductive setting; (2) workers in the exploration period subject to availability constraint. We adaptively segment tasks based on skill requirement similarity and then learn a transductive bandit policy for each task segment. We evaluate the algorithm on the real-world Yoloka data for two transductive settings, and improves both for more than 50% in the task completion accuracy than state-of-the-art benchmarks.

4 Fix the Issue! A Contextual Bandit Approach for Open Source Software Feedback Triage

Zisu Wang, University of Arizona, Tucson, AZ, Contact: zisuwang@email.arizona.edu

The continuous development and eventual success of open source software (OSS) hinge on the timely resolution of community feedback (i.e., feedback triage). However, feedback triage has become an increasingly challenging task due to the informational richness of community feedback, rapid growth of contributor base, and inherent uncertainty of contributor skills. In this study, we propose a contextual bandit approach to automatically identify appropriate contributors for feedback triage. Our approach employs a fine-tuned deep learning language model to understand community feedback, and then adaptively learn contributors' skills through their past contribution history. Utilizing a novel dataset from GitHub, we demonstrate our approach's utility in generating interpretable findings and giving superior contributor recommendations over existing benchmarks.

Advances in New Product Development

General Session

Session Chair

Janne Kettunen, George Washington University, Washington

1 Product Development by Startups: A Behavioral Investigation

Sinan Erzurumlu[1], karthik ramachandran[2], Sreekumar R. Bhaskaran[3], [1]Babson College, Babson Park, MA, [2]Georgia Tech, Atlanta, GA, [3]Southern Methodist University, Dallas, TX, Contact: serzurumlu@babson.edu

Entrepreneurial decision makers make several operational decisions that are crucial for their startups as they continue to develop their product and search for product-market fit. They decide whether to persevere or not after failed attempts; whether to take a life-line in the form of external funding; and whether to cash-out by salvaging assets such as remaining endowments. Theory suggests that an optimal stopping framework would be useful as a decision-support tool. But there has been no behavioral test of such models. In this research, we explore these decisions with a behavioral study. We examine how decisions may be influenced by behavioral factors. We develop theoretical insights that would be helpful in supporting entrepreneurs and providing a decision framework that would account for their behavioral tendencies.

2 Prototyping in New Product Development

Gaoyu Xie[1], Janne Kettunen[2], [1]George Washington University School of Business, DC, [2]George Washington University, Washington

We adapt the binomial option pricing model to investigate (i) conditions when it is optimal to develop a prototype and (ii) what is the optimal timing to develop a prototype. The analysis is conducted under uncertainty in the outcomes of product development efforts when the decision-makers (DMs) maximize their mean-variance utility. We show that prototyping is highly beneficial when both the development uncertainty and the DMs' risk aversion are at the medium level. Furthermore, we prove that there exists a boundary in terms of the initial revenue estimate above which prototyping is optimal for DMs. The model and the derived results can be useful for DMs to support the optimal use of prototyping.

3 One Size Does Not Fit All: Strengths and Weaknesses of the Agile Approach

Evgeny Kagan[1], Tobias Lieberum[2], Sebastian Schiffels[3], [1]Johns Hopkins Carey Business School, Washington, DC, [2]Technical University of Munich, München, Germany; [3]Lancaster University, Leipzig, Germany. Contact: ekagan@jhu.edu

Agile project management techniques, such as iterative sprints and granting workers task autonomy, have become commonplace in many organizations. We experimentally examine how these techniques affect performance in two innovation settings. Our results suggest that the effects of

Agile on performance are not uniform and depend on the innovation setting and on the performance measure. Agile improves average performance in the product development setting but lowers average performance in the business model innovation setting. In both settings, Agile techniques lead to more incremental (less radical) strategies, which narrows performance variance.

4 Choice Bracketing in New Product Development

Matthias Seifert[1], Janne Kettunen[2], Gaoyu Xie[3], [1]IE Business School - IE University, Madrid, Spain; [2]George Washington University, Washington, [3]The George Washington University, Washington, DC, Contact: matthias.seifert@ie.edu

We study the effect of narrow and broad bracketing on decision behaviour in product development. Previous research has suggested that decision errors result from myopic behaviour when decision-makers overly focus on a single alternative (narrow bracketing) instead of assessing all available alternatives concurrently (broad bracketing). We conducted laboratory experiments (N=384) using a 2x2x3 factorial design, where we varied (i) the modes of task information (aggregated vs segregated), (ii) product evaluation (simultaneous vs sequential), and (iii) the target threshold for profit to be reached (high vs low vs zero target). Contrary to past research, we find decision performance to be systematically superior under narrowly bracketed tasks. That is, subjects earned higher profits when product alternatives were assessed sequentially and with less information.

Human, Machines, and Algorithms Session 2

General Session

Session Chair

Kyuhan Lee, 1</sup

1 Is Transparency the Best Policy? Impact of (im) plausible AI Transparency on Human Adoption of AI for Fake News Detection

Kyuhan Lee[1], Jihae Suh[2], Jinsoo Park[3], [1]Arizona State University, Tempe, AZ, [2]Seoul National University of Science and Technology, Seoul, Korea, Republic of; [3]Seoul National University, Seoul, Korea, Republic of. Contact: klee264@asu.edu

The growing application of AI, especially in fake news moderation, raises an important quandary for humans to understand its working mechanism. While, recently, there has been a burst of research in this vein due to the hype of AI transparency, generally, no agreement has been made among previous studies regarding its impact on humans' AI attitudes. To fill the research gap, we propose a new, unexplored dimension, plausibility, of AI transparency. Based on this, we investigate the heterogeneous effects of AI transparency on users' attitudes towards AI for fake news detection. Additionally, we take account of AI reliability as a factor moderating the impact of plausible (and implausible) AI transparency on users' AI attitudes. Our study paves the way for future studies in theorizing the human-AI interaction and suggests practical implications regarding the use of AI.

2 Bias Mitigation in AI

Reihane Boghrati[1], Amir Sepehri[2], Jonah Berger[3], [1]Arizona State University, Tempe, AZ, [2]ESSEC, Paris, France; [3]University of PA- Wharton, Philadelphia, PA

Minority groups often need to overcome invisible barriers to achieve higher professional goals. This phenomenon which is referred to as glass ceiling, is mostly studied in organization settings but could also extend to other contexts. We demonstrate that while organizations try to be equality conscious and even use machine learning to avoid human biases, male entrepreneurs are prequalified for higher loan amounts compared to female entrepreneurs. Machine learning methods can improve prediction accuracy, and sometimes reduce human errors, but we show that they often carry over biases against unprivileged groups (e.g., women) and can even intensify such biases. Our findings demonstrate the glass ceiling phenomena in a novel setting, provide a comprehensive framework for quantifying bias, and outline a series of steps and approaches researchers can use to mitigate bias.

3 Learning from the Data: Startup Success Prediction Using Graph Neural Networks

Yuanxia Li, Sudha Ram, University of Arizona, Tucson, AZ

Startup success prediction has important implications for investors, who spend a lot of effort trying to identify the promising startups, but still suffer from expensive errors. Human intelligence has its advantages, but falls short on learning from large amounts of information, which we believe is important for startup success prediction. In this study, we develop a Graph Neural Network (GNN) model that learns to predict startup success using a very large dataset.

4 **Credit Risk Modeling Without Sensitive Features: An Adversarial Deep Learning Model for Fairness and Profit**

Xiyang Hu[1], Yan Huang[2], Beibei Li[1], Tian Lu[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Tepper School of Business, Carnegie Mellon University, Pittsburgh, PA, [3]Arizona State University, Tempe, AZ, Contact: xiyanghu@cmu.edu

We propose an adversarial deep learning model for credit risk modeling, which can make use of sophisticated ML model's ability to triangulate, i.e. infer the sensitive group affiliation by using only permissible features, which is often deemed "troublesome" in the fair machine learning research, in a positive way to increase both borrower welfare and lender profits while improving fairness. We train and test our model on a dataset from a real-world microloan company. Our proposed model performs well on increasing borrowers' welfare and lenders' profits and improving the fairness in the allocation of financial resources. It significantly outperforms regular deep neural networks and the currently most popular credit risk model XGBoost. Our framework is ready to be customized for other microloan firms, and can be easily adapted to many other decision making scenarios.

Amazon Last Mile Science

General Session

Session Chair

Liron Yedidsion, Amazon, Redmond, WA

1 **Capacity and Coincidence Aware Package Assignment**

Chinmoy Mohapatra[1], Rohit Malshe[1], Jin Ye[2], LIRON Yedidsion[3], Dipal Gupta[1], [1]Amazon, Seattle, WA, [2]Amazon, Kirkland, WA, [3]Amazon.com Inc, Seattle, WA, Contact: cmohapat@amazon.com

Package delivery "coincidence" is a key metric in last mile logistics where a higher coincidence improves utilization of on-road resources. Last mile capacities are often planned in terms of package counts alone. We propose algorithmic and computational approaches to model capacities in terms of both package counts and on-road delivery times that enhance in-station and on-road resource utilization, and package delivery density.

2 **Alternating Direction Method of Multipliers (ADMM) for Centralized Labor Planning**

Mahdieh Allahviranloo[1], Gah-Yi Ban[2], Rohit Malshe[3], [1]City College New York, CUNY, New York, NY, [2]Robert H. Smith Business School, University of Maryland, Maryland, MD, [3]Amazon LLC, Seattle, WA

Sub-organizations within a large organization often deviate from centralized planning objectives, leading to bottlenecks and additional costs. In order to minimize costs and produce a consensus amongst the participating agents, consensus planning methods such as the alternating direction method of multipliers (ADMM) may be useful. In this paper, we talk about how ADMM can be used for planning labor in a large organization such as Amazon.

3 **Newsvendor Approach Capacity Planing at Amazon**

Liron Yedidsion[1], Rohit Malshe[2], Chinmoy Mohapatra[3], Abhilasha Katariya[4], Tolga Cezik[5], Tamar Cohen-Hillel[6], [1]Amazon, Redmond, WA, [2]Amazon, Bellevue, WA, [3]Amazon, Arlington, TX, [4]Amazon, Issaquah, WA, [5]Amazon.com, Seattle, WA, [6]UBC Sauder School of Business, Vancouver, BC, Canada. Contact: lirony@amazon.com

Labor planning is done well in advance of realizing the actual workload. A Newsvendor approach solution is shown in this work, demonstrating how to minimize handling costs. We may have more than one lever to tackle underage or overage. Hence, we would like to use them in an escalating manner up to their respective capacities. Unlike the classic Newsvendor model, with multiple overage and underage options and costs, the target percentile is not constant and may shift significantly depending on the distribution.

1 **Split Liver Transplantation: An Analytical Decision Support Model**

Yanhan (Savannah) Tang[1], Alan Scheller-Wolf[1], Sridhar R. Tayur[1], Emily R. Perito[2], John P. Roberts[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of California, San Francisco, CA, [3]University of California, San Francisco, CA

Split liver transplantation (SLT) can save two lives using one liver. SLT may also improve equity by giving smaller candidates (e.g. children) increased access. We evaluate different ways of splitting and allocating livers within a multi-queue fluid system incorporating donor-recipient size matching, patients' dynamic health conditions, fairness, and endogenous patient acceptance decisions. Leveraging a novel decomposition result, we find the exact optimal matching. Numerical results, utilizing data from OPTN, show that increased utilization of SLT can improve both efficiency and fairness.

2 **Dropping Standardized Testing for Admissions Trades off Information and Access**

Faidra Monachou[1], Nikhil Garg[1], Hannah Li[2], [1]Harvard University, Cambridge, MA, [2]MIT, Menlo Park, CA

We study the role of information and access in capacity-constrained selection problems with fairness concerns. We develop a theoretical framework with testable implications that formalizes the trade-off between the (potentially positive) informational role of a feature and its (negative) exclusionary nature when members of different social groups have unequal access to this feature. Our framework finds a natural application to recent policy debates on dropping standardized testing in college admissions. Our primary takeaway is that the decision to drop a feature (such as test scores) cannot be made without the joint context of the information provided by other features and how the requirement affects the applicant pool composition. Dropping a feature may exacerbate disparities by decreasing the amount of information available for each applicant, especially those from non-traditional backgrounds. However, in the presence of access barriers to a feature, the interaction between the informational environment and the effect of access barriers on the applicant pool size becomes highly complex. In this case, we provide a threshold characterization regarding when removing a feature improves both academic merit and diversity. Finally, using application and transcript data from UT Austin, we illustrate that there exist practical settings where dropping standardized testing improves or worsens all metrics.

3 **Sequential Fair Allocation: Achieving the Optimal Envy-Efficiency Tradeoff Curve**

Sean Sinclair, Siddhartha Banerjee, Christina Lee Yu, Cornell University, Ithaca, NY

We tackle a problem established from a partnership with the Food Bank of the Southern Tier in optimizing their mobile food-pantry operations. We model it as an online resource allocation problem under demand uncertainty, where individuals arrive over T rounds, with each round having a random number of individuals characterized by their type. We provide an exact characterization of the achievable (envy, efficiency) pairs in this model, showing that any algorithm achieving low envy must suffer from poor efficiency, and vice-versa. Moreover, we complement this exact characterization with a simple algorithm capable of achieving any desired point along the trade-off curve.

1 **How to Effectively Teach Collaborative Filtering and AI Recommendation Systems Algorithms to MBA Students?**
Abraham Seidmann, Boston University, Newton, MA
Recommender systems have been introduced to help users navigate large sets of feasible alternatives. They usually lead to improved marketing, or decision making in general. However, teaching the internal logic of these systems turned out to be rather challenging. In this talk, we introduce the 3rdFriday Collaborative Filtering (Movie Recommendation) system simulation. It allows students to interactively fine tune some of the 'choice logic' parameters and functions, and by doing so - to reenforce their learning by doing. Experience have shown that students gain important technical insights by using our tool.

2 **An Interactive Spreadsheet Model for Teaching Classification Using Logistic Regression**
Vahid Roshanaei, University of Toronto, Toronto, ON, Canada.
We present an interactive spreadsheet model to teach essential concepts in binary classification using the Logistic Regression (LR) model. This spreadsheet reinforces concepts like probabilities, likelihoods, and the usage of likelihoods to optimize the LR model's parameters. Students will learn how to dynamically convert probabilities into classification using the Decision Boundary (DB), impact classification outcomes by varying DBs, and determine the classification accuracy based on various performance measures. These performance measures are depicted and dynamically adjusted when the DB changes. We also reiterate the usage of these measures in the context of cross-validation and imbalanced data sets. We provide a case study that implements LR with multiple predictors. We discuss pedagogical aspects of this spreadsheet.

3 **A Hands-on, White-box Approach to Decision Tree Teaching**
Gerhard Trippen, University of Toronto, Rotman School of Management, Toronto, ON, Canada.
Using Decision Trees, we demonstrate our teaching approach to ML Algorithms through a variety of different tools allowing the students a deeper understanding of the subject. Accompanied by a visual example, notes introduce the basics. A handout with a toy example enables us to do the calculations easily by hand to practice the more technical steps. We write Python code using scikit-learn to construct a decision tree for a larger data set. The decision tree is then visualized. Students can easily modify the code to tune hyperparameters. Individual assignments test the students' understanding through conceptual and calculated questions, and applied group project assignments requires the students to run the algorithms on larger data sets.

Collaborative Routing and Planning of Aerial and Other Vehicles

General Session

Session Chair

Fanruiqi Zeng, GEORGIA TECH, Atlanta

1 Cost and Emissions Tradeoff of Integrated Drone Delivery Systems

Juan Zhang, University of Wisconsin–Eau Claire, Eau Claire, WV

This research examines the tradeoffs between delivery costs and lifecycle greenhouse gas emissions of an integrated drone delivery system. We consider multi-stop truck delivery routes, along with two types of drone delivery strategies: drone-only delivery where drones travel out-and-back from a depot to make each delivery, and truck-drone delivery where a truck and drone, in tandem, make parallel deliveries with the drone launched and recovered by the truck as the truck completes a multi-stop route. Continuous approximation models are developed to analyze optimal operations with a range of vehicle operating characteristics, delivery environments, and drone energy consumptions. Results show the tradeoffs of cost and emissions are determined by the relative values of the ratio of vehicle operating cost rate to vehicle emissions rate for the drone and truck.

2 Last-mile Drone and Truck Delivery Energy Comparisons

Taner Cokyasar, Argonne National Laboratory

One important concern is the energy efficiency of direct delivery drones compared to conventional delivery trucks at a regional systems level. In this study, we develop and apply methods to quantify the regional energy impacts of drone delivery, then we assess these impacts and compare them to the impacts of truck delivery. To study this problem, we develop an optimization model that determines an optimal set of fulfillment centers (FCs) with variable service capacities that allow drones to make direct e-commerce deliveries. We also develop another optimization model to account for the energy consumption of diesel trucks (DTs) and battery electric vehicles (BEVs). We test the models using validated simulation data for the Chicago metropolitan area to quantify the energy implications of these three delivery modes.

3 Drone Routing Problem Model for Lastmile Delivery Using the Public Transportation Capacity as Moving Charging Stations

Amir Hossein Moadab[1], Fatemeh Farajzadeh[2], Omid Fatahi Valilai[3], [1]Washington State University, Pullman, WA, [2]Worcester Polytechnic Institute, WORCESTER, MA, [3]Jacobs University Bremen, Bremen, Germany. Contact: Amirhossein.moadab@wsu.edu

This paper considers a last-mile delivery system in which a set of drones are operated in coordination with public transportation system to deliver a set of orders to customer locations. A mathematical model based on VRP is extended to solve this problem. A real-world case inspired by Bremen 2025 transportation paradigm is also developed to validate the mathematical formulation. Results show that the sequence of visiting customers and public transport stations highly impacts the remaining charge and efficiency of drone tour planning. Also, using public transport vehicles, which enables drones to charge their battery or to approach customers, can reduce the number of drones required for satisfying the demands in a service area. The results show that there are high potentials to save energy for drone-enabled last-mile delivery by using the public transportation network.

4 Risk-aware UAV-UGV Rendezvous with Chance-constrained Markov Decision Process

Guangyao Shi[1], Nare Karapetyan[2], Ahmad Bilal Asghar[2], Jean-Paul Reddinger[3], James Dotterweich[3], James Humann[3], Pratap Tokekar[4], [1]University of Maryland, College Park, MD, [2]University of Maryland, College Park, MD, [3]DEVCOM Army Research Laboratory, College Park, MD, [4]University of Maryland, College Park, MD, Contact: sgyhit@gmail.com

We study a chance-constrained variant of the cooperative aerial-ground vehicle routing problem, in which a UAV with limited battery capacity and a UGV that can also act as a mobile recharging station need to jointly accomplish a mission. Due to the limited battery capacity of the UAV, two vehicles sometimes have to deviate from their task to rendezvous and recharge the UAV. We address the challenge of stochastic energy consumption of the UAV. We are interested in finding the optimal policy that decides when and where to rendezvous such that the expected travel time of the UAV is minimized and the probability of running out of charge is less than tolerance. We formulate this problem as a Chance Constrained Markov Decision Process. The problem is solved by Linnear Programming. We demonstrate the effectiveness of our formulation in a surveillance mission.

JWM - Room 209

Operations Management for Advanced Air Mobility

General Session

Session Chair

Syed Arbab Mohd Shihab, Kent State University, Ames, IA

1 **A Cloud-based Low Altitude Surveillance System for Advanced Air Mobility Operations: Cost-benefit Analysis for the State of Ohio**

Esrat Dulia, Kent State University, Kent, OH

Advanced Air Mobility (AAM) will enable emerging aircraft to operate efficiently in lower altitude airspace in the near future. To detect and track AAM traffic, a Low Altitude Surveillance Information Clearinghouse (LASIC) can serve a vital role as a cloud-based data collection, monitoring, and distribution center, where AAM operators handling different AAM use cases — passenger and cargo transportation, medical delivery etc. — will subscribe to receive relevant AAM traffic data to plan their operations. In this work, we present a framework for the LASIC of Ohio and perform a cost-benefit analysis. The insights gained justify investment in this infrastructure, showing that LASIC will generate revenues from subscriptions for investors and benefit AAM operators and policymakers.

2 **Deepdispatch a Deep Reinforcement Learning-based Vehicle Dispatch Algorithm for Advanced Air Mobility**

Elaheh Sabziyan Varnousfaderani, Kent State University, Kent, OH, Contact: elahe.sabziyan70@gmail.com

Advanced Air Mobility (AAM) is envisioned to use short-range electric aircraft to transport passengers between vertiports. For realizing AAM, new aircraft dispatch models are needed to 1) take into account the unique operational aspects and constraints of AAM and 2) ensure the commercial viability of AAM operations. We address this need by developing a deep reinforcement learning-based dispatch algorithm with a centralized approach to learn the optimal dispatch policy that maximizes operational profit. Real-world datasets of dynamic passenger demand and electricity prices in California have been used to evaluate the performance of the algorithm. The results are expected to show that the algorithm can learn the optimal dispatch policy and outperform our previously developed optimization-based algorithm.

3 **Bird Movement Prediction Using LSTM-RNn to Prevent Bird Strikes with Low Altitude Aircraft**

Syed Arbab Mohd Shihab, Kent State University, Kent, OH, Contact: sshihab@kent.edu

The lower altitudes of the National Airspace System are soon expected to see an increasing number of Advanced Air Mobility aircraft for various operations such as package delivery and passenger transportation. Since most bird strikes with aircraft occur in the low altitude (below 400 feet), minimizing the bird strike risk needs to be considered during flight planning to ensure safe collision-free aircraft operations. To address this problem, a Long Short Term Memory-Recurrent Neural Network (LSTM-RNN) model has been developed for predicting bird movement. A real-world data set of sparrows' movement has been used to evaluate the algorithm. The results suggest that the LSTM-RNN algorithm can provide bird movement forecast with relatively high accuracy.

4 **A Study of Social Equity Strategies in Advanced Air Mobility Development from Industry to Academia**

Christopher J. Johnson[1], Amber Woodburn McNair[2], [1]Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH, Contact: johnson.8067@osu.edu

Advanced Air Mobility (AAM) has the potential to contribute environmental and social benefits within the transportation sector, yet it is not clear how the industry's organizations articulate and understand social equity and social integration. This study implements an online questionnaire to identify trends of convergence and divergence in approaches to social equity and integration. The survey is disseminated to workforce participants in corporate, government, and academic settings, at both junior and senior levels. The results of the study contextualize perceptions of equity strategies and offer insight into how equity ranks against other relevant organizational priorities.

Reinforcement Learning in Operations Management

General Session

Session Chair

Zhengyuan Zhou, Stern School of Business, New York University, New York, NY

Session Chair

Boxiao (Beryl) Chen, University of Illinois-Chicago, Chicago, IL

1 **Cooperative Multi-player Bandit Optimization**

Ilai Bistritz, Stanford University, Stanford, CA, Contact: bistritz@stanford.edu

Consider N cooperative players that want to learn the action profile that maximizes their sum of rewards. At every turn, each player chooses an action and receives a reward that is an unknown function of all the players' actions. The players cannot observe the actions or rewards of others, and can only get partial information by communicating with their neighbors. We design a distributed learning algorithm that overcomes the informational bias players have towards maximizing the rewards of nearby players they got more information about. We prove that even if players always take actions based only on a small random subset of the rewards, our algorithm converges with probability 1 to the set of stationary points of (projected) gradient ascent on the sum of rewards function. For a concave sum of rewards, we also prove regret bounds for a game with T turns.

2 **Policy Learning with Adaptively Collected Data**

Ruohan Zhan[1], Zhimei Ren[2], Susan Athey[1], Zhengyuan Zhou[3], [1]Stanford University, Stanford, CA, [2]Chicago University, Chicago, IL, [3]Stern School of Business, New York University, New York, NY, Contact: rhzhan@stanford.edu

Learning optimal policies from historical data enables the gains from personalization in a wide variety of applications. The growing policy learning literature focuses on a setting where the treatment assignment policy does not adapt to the data. However, adaptive data collection is becoming more common in practice due to its abilities to improve inferential efficiency and evolve operations to improve performance over time (e.g. contextual bandits). In this talk, we address the challenge of learning the optimal policy with adaptively collected data. We propose an algorithm based on generalized augmented inverse propensity weighted estimators and establish its finite-sample regret bound. We further complement this regret upper bound with a lower bound, which characterizes the fundamental difficulty of policy learning with adaptive data.

3 **Regret Bounds of Cooperative Thompson Sampling**

Yan Chen, Duke University, Durham, NC, Contact: yan.chen@duke.edu

We consider the cooperative RL problem where n agents cooperatively learn to make decisions by sharing data with each other. Existing works in this area have empirically shown that Thompson sampling algorithms provide an attractive alternative for inducing cooperation. But no regret bound is known on any such algorithms. We fill this gap by considering two cases. We first study the finite-horizon episodic regret setting, where each agent samples from the joint posterior at the beginning of each episode. We then show a $\tilde{O}(HS\sqrt{\frac{AT}{n}})$ per-agent regret, where H is the horizon of the episode, S is the number of states, A is the number of actions, T is the number of episodes and n is the number of agents. The per-agent regret decreases at a rate of $O(\frac{1}{\sqrt{n}})$. This regret bound further improves to $\tilde{O}(H\sqrt{\frac{SAT}{n}})$

4 **Optimal No-regret Learning in Repeated First-price Auctions**

Zhengyuan Zhou, Stern School of Business, New York University

First-price auctions have very recently swept the online advertising industry, replacing second-price auctions as the predominant auction mechanism on many platforms for display ads bidding. This shift has brought forth important challenges for a bidder: how should one bid in a first-price auction, where unlike in second-price auctions, it is no longer optimal to bid one's private value truthfully and hard to know the others' bidding behaviors? In this paper, we take an online learning angle and address the fundamental problem of learning to bid in repeated first-price auctions. We discuss our recent work in leveraging the special structures of the first-price auctions to design minimax optimal no-regret bidding algorithms.

Causal Inference and Data-driven Decision Making

General Session

Session Chair

Zhengling Qi, The George Washington University, Potomac, MD

1 **Fairness-oriented Learning for Optimal Individualized Treatment Rules**

Lan Wang, University of Miami, Key Biscayne, FL

A notable drawback of the standard approach to optimal individualized treatment rule (ITR) estimation is that the estimated optimal ITR may be suboptimal or even detrimental to certain disadvantaged subpopulations. Motivated by the importance of incorporating an appropriate fairness constraint in optimal decision making (e.g., assign treatment with protection to those with shorter survival time), we propose a new framework that aims to estimate an optimal ITR to maximize the average value with the guarantee that its tail performance exceeds a prespecified threshold. The optimal fairness-oriented ITR corresponds to a solution of a nonconvex optimization problem. Furthermore, we extend the proposed method to dynamic optimal ITRs. (Joint work by Ethan Fang, Zhaoran Wang and Lan Wang)

2 Distribution-Invariant Differential Privacy

Xuan Bi, Xiaotong Shen, University of Minnesota, Minneapolis, MN

Differential privacy is becoming one gold standard for protecting the privacy of publicly shared data. It has been widely used in social science, public health, information technology, and the U.S. decennial census. Nevertheless, to guarantee differential privacy, existing methods may unavoidably alter the conclusion of the original data analysis, as privatization often changes the sample distribution. This phenomenon is known as the trade-off between privacy protection and statistical accuracy. In this work, we mitigate this trade-off by developing a distribution-invariant privatization method to reconcile both high statistical accuracy and strict differential privacy. As a result, any downstream statistical or machine learning task yields essentially the same conclusion as if one used the original data. Superior performance is shown on three benchmarks.

3 A Proximal Temporal Consistency Learning Approach for Infinite Horizon Dynamic Treatment Regimes

Ruoqing Zhu, University of Illinois Urbana Champaign, Champaign, IL, Contact: rqzhu@illinois.edu

Many mHealth applications involve a large number of intervention options and under an infinite time horizon setting where the number of decision stages diverges to infinity. In addition, temporary medication shortages may cause optimal treatments to be unavailable, while it is unclear what alternatives can be used. We propose a Proximal Temporal consistency Learning (pT-Learning) framework to estimate an optimal regime that is adaptively adjusted between deterministic and stochastic sparse policy models. The resulting minimax estimator avoids the double sampling issue in the existing algorithms. It can be further simplified and can easily incorporate off-policy data without mismatched distribution corrections. We study the theoretical properties of the sparse policy and establish finite-sample bounds on the excess risk and performance error.

4 Demystifying (Deep) Reinforcement Learning with Optimism and Pessimism

Zhaoran Wang, Northwestern University, Evanston, IL

Coupled with powerful function approximators such as deep neural networks, reinforcement learning (RL) achieves tremendous empirical successes. However, its theoretical understandings lag behind. In particular, it remains unclear how to provably attain the optimal policy with a finite regret or sample complexity. In this talk, we will present the two sides of the same coin, which demonstrates an intriguing duality between optimism and pessimism.
- In the online setting, we aim to learn the optimal policy by actively interacting with the environment. To strike a balance between exploration and exploitation, we propose an optimistic least-squares value iteration algorithm, which achieves a \sqrt{T} regret in the presence of linear, kernel, and neural function approximators.
- In the offline setting, we aim to learn the optimal policy based on a dataset collected a priori. Due to a lack of active interactions with the environment, we suffer from the insufficient coverage of the dataset. To maximally exploit the dataset, we propose a pessimistic least-squares value iteration algorithm, which achieves a minimax-optimal sample complexity.

1 Conjecturing-Based Discovery of Patterns in Data

Paul Brooks[1], David Edwards[1], Craig E. Larson[1], Nico Van Cleemput[2], [1]Virginia Commonwealth University, Richmond, VA, [2]Virginia Commonwealth University, Ghent, Belgium.

We propose the use of a conjecturing machine that generates feature relationships in the form of bounds involving nonlinear terms for numerical features and boolean expressions for categorical features. The proposed Conjecturing framework recovers known nonlinear and boolean relationships among features from data. In both settings, true underlying relationships are revealed. The framework is applied to patient-level data regarding COVID-19 outcomes to suggest possible risk factors that are confirmed in medical literature.

2 Learning Product Rankings Robust to Fake Users

Negin Golrezaei[1], Vahideh Manshadi[2], Shreyas Sekar[3], Jon Schneider[4], [1]Massachusetts Institute of Technology, Lexington, MA, [2]Yale School of Management, New Haven, CT, [3]University of Toronto, Toronto, ON, Canada; [4]Google Research, New York, NY

In many online platforms, customers' decisions are influenced by product rankings. This incentivizes sellers to artificially inflate their position by employing fake users. Motivated by such fraudulent behavior, we study the problem of learning product rankings when a platform faces a mixture of real and fake users who are indistinguishable from each other. We show that many popular learning algorithms are sub-optimal under manipulation. To overcome this, we develop efficient learning algorithms that converge to the optimal ranking, while being robust to the aforementioned fraudulent behavior. Our results indicate that platforms can effectively combat fraud even when they are oblivious to the number and identity of the fake users.

3 Generalized Regret Analysis of Thompson Sampling using Fractional Posteriors

Prateek Jaiswal, Debdeep Pati, Anirban Bhattacharya, Bani Mallick, Texas A&M University, College Station, TX

Thompson sampling (TS) is one of the most popular and earliest algorithms to solve stochastic multi-armed bandit problems. We consider a variant of TS, named ⍰-TS, where we use a fractional or ⍰-posterior (⍰ (0,1)) instead of the standard posterior distribution. For ⍰-TS we compute near-optimal problem-dependent and problem-independent frequentist regret bounds for general prior and reward distributions (with bounded support). Our key contribution is to deliver the near-optimal frequentist regret bounds under a very mild regularity condition on the prior distribution that only requires the prior to place positive mass in an appropriate Rényi neighborhood of the true reward distribution. Moreover, our analysis does not require additional structural properties such as closed-form posteriors or conjugate priors.

4 Improving Human Decision-Making with Machine Learning

Hamsa Bastani[1], Osbert Sinchaisri[1], Park Sinchaisri[2], [1]University of Pennsylvania, Philadelphia, PA, [2]University of California, Berkeley, Berkeley, CA

Focusing on sequential decision-making, we design a novel machine learning algorithm that is capable of extracting "best practices" from trace data and conveying its insights to humans in the form of interpretable "tips". Our algorithm selects the tip that best bridges the gap between the actions taken by humans and those taken by the optimal policy. We evaluate our approach through a series of randomized controlled experiments where participants manage a virtual kitchen. Our experiments show that the tips generated by our algorithm can significantly improve human performance relative to intuitive baselines. In addition, we discuss a number of empirical insights that can help inform the design of algorithms intended for human-AI interfaces.

1 Device-Cloud Collaborative Learning for Recommendation Personalization

Jiangchao Yao, Shanghai Jiao Tong University, Shanghai, China. Contact: Sunarker@sjtu.edu.cn

With the rapid development of storage and computing power on mobile devices, it becomes critical and popular to deploy models on devices to save onerous communication latencies and to capture real-time features. We are among the first attempts to study the Device-Cloud Collaborative Learning (DCCL) framework. Specifically, in DCCL, a novel MetaPatch learning approach on the device side can efficiently achieve "thousands of people with thousands of models" given a centralized cloud model. Then, with billions of updated personalized device models, we propose a "model-over-models" distillation algorithm, namely MoMoDistill, to update the centralized cloud model. Our extensive experiments over a range of datasets with different settings demonstrate the effectiveness of such collaboration, especially its superiority to model long-tailed users.

2 Whole Page Optimization on Amazon Search Page

Wenyang Liu, 1</sup

The Amazon Search page is the primary gateway for customers to search, refine, and explore the large collection of content that Amazon offers. There are various components and content types on the Search page, such as lists of products and widgets of different types (e.g., video, recommendation, and navigation). How to best optimize and display those components holistically remains challenging, especially when accounting for each customer's shopping journey. This talk gives an overview of how Amazon Search tackles this whole page optimization problem, leveraging multi-arm bandits, multi-variate testing, deep learning, and reinforcement learning.

3 Modeling for Data Heterogeneity in Page Layout Optimization for E-commerce

Pratik Lahiri, Amazon, Seattle, WA

The search page of an e-commerce website enables customers to find and discover products with ease and confidence by addressing durable customer needs. Determining the optimal layout for the search results page promotes ease and confidence of shopping for customers at various stages of their shopping journey. The preferred page layout may differ by device, shopping category, and customer profile. In this talk, we will share our learning on how we tackle this problem by modeling the various sub-populations in our data and balancing bias-variance tradeoffs.

1 Wind Turbine Faults Detection and Diagnosis on a Novel Network-based Deep Recurrence Analysis

Bo Peng[1], Cheng-Bang Chen[2], [1]University of Miami, Miami, FL, [2]University of Miami, Miami, FL, Contact: bxp547@miami.edu

Wind energy is a vital energy source for the power grid. Robust maintenance of wind turbines (WTs) to avoid unexpected breakdowns is prominent to ensure energy resilience. Due to the chaotic weather, the wear of WTs is highly dynamic. It remains a challenge to identify WT faults from the sensory data accurately. This research proposed a novel framework, utilizing the subtle recurrence characteristics of WT, to tackle this issue. We first develop a heterogeneous recurrence network (HRN) to capture the sophisticated dynamics from the sensory data. Then, we established a deep neural network to diagnose WT faults from the corresponding HRN. The experimental study shows that our proposed framework outperforms the current state-of-art methods.

2 Robust Interpretation for Covid-19 Diagnosis Using Vision Transformer

Chen Zhou[1], Soundar Kumara[2], [1]Pennsylvania State University, State College, PA, [2]Pennsylvania State University, University Park, PA, Contact: cbz5148@psu.edu

This work presents a novel mask-based training method for Vision This work presents a novel mask-based training method for Vision Transformer (ViT) on chest X-ray classification. While ViT uses an extra trainable token to capture the global information of image patch tokens, we believe it misses the rich local information contained in the patch tokens. In this work, we investigate how these token features can be leveraged to improve the ViT performance by introducing the lung masks as supervision. Our method is straightforward: we calculate the loss of patch token embeddings and the ground truth masks and aggregate it to the original classification loss, e.g., we pose a strong regularization on the loss function and force the model to pay attention to the interesting areas. We show the proposed method can consistently and robustly improve the ViT performance on chest X-ray data.

3 Deep Thermal Fusion Network Methodology for Surface Deformation Detection in Additive Manufacturing

Christian Zamiela[1], Linkan Bian[2], [1]Mississippi State University, Mississippi State, MS, [2]Mississippi State University, Mississippi State University, MS, Contact: cez39@msstate.edu

The objective is to develop a data fusion network methodology for deformation detection using multi-sensor thermal data. A core problem with additive manufacturing (AM) is abnormalities that commonly occur due to rapid changes in the thermal gradient. Different non-destructive in-situ thermal sensors monitor the build process but are limited by small temperature ranges and sensor field of view of the fabrication process. Various sensors are employed to mitigate problems with lost thermal gradient information, but it brings forth challenges with combining data. We develop a deep thermal fusion methodology that fills the gap in combining multiple sensors and characterizing surface deformation. Rapid thermal gradient formation and identification of deformation is a key step toward using thermal gradient data and machine learning to improve quality control in AM.

4 Clustering of Multi-channel Sequential Data Using Advanced Heterogeneous Recurrence Analysis

Cheng-Bang Chen, University of Miami, Miami, FL, Contact: cxc1920@miami.edu

Recurrence is a core property of dynamic systems. Literature indicates that Recurrence Analysis (RA) is an effective tool for characterizing complex systems. However, the conventional RA treats the recurrences homogeneously, which raises issues in clustering similar recurrence patterns in diverse states. This research presents a novel approach utilizing advanced heterogeneous recurrence analysis (HRA) to cluster multi-channel sequential data to resolve the issues. We first leverage the state-space to delineate the transitions of multi-channel sequential data. Then, we characterize the subtle dynamic characteristics of each instance with the proposed HRA. Finally, the instances are clustered through the weighted dynamic characteristics. Experimental results show that our methods can effectively cluster the multi-channel sequential data.

Sequential Decision-making in Healthcare

General Session

Session Chair

Sadjad Anzabi Zadeh, University of Iowa, Coralville, IA

1 Personalized Breast Cancer Treatment Decision Modeling Considering Patient Preferences

Ahla Ko[1], Shengfan Zhang[1], Raha Akhavan-Tabatabaei[2], Juan David Bolivar[3], [1]University of Arkansas, Fayetteville, AR, [2]Sabanci University, Istanbul, Turkey; [3]Uber, Bogota, Colombia. Contact: ahlako@uark.edu

Health-related quality of life has been an important indicator to the continuation and maintenance treatments. While patients often choose an aggressive therapy with reduced recurrence and mortality disregarding potential late toxicity and complication, they may experience long-term adverse effects or chronic conditions that negatively affect their quality of life. In breast cancer treatment, there are numerous treatment modalities with different side effects, which vary by patient age, cancer type, and cancer stage. We develop a dynamic decision model for the personalized optimal breast cancer treatment that consider not only the improved survival of the patient but also a quantitative measure of personal preferences. The effect of delayed treatment has also been investigated to maximize the quality of life in the case of initial cancer stage or older patients.

2 An Algorithm to Determine Treatment Timing in Mobile Health: Design and Evaluation

Xiang Meng, Harvard University, Cambridge, MA

HeartSteps V2 and V3 are micro-randomized trials (MRTs) that aim to increase physical activity in individuals with stage 1 hypertension. When sedentary, participants were repeatedly randomized to receive either an anti-sedentary message or not five minutes. The sampling algorithm in the MRT has two goals: 1. deliver an average of 1.5 messages and 2. produce randomization probabilities that are uniform over a user's sedentary times. We evaluate the algorithm by asking: 1. Does it meet the target of 1.5 interventions per day? 2. Is the randomization probability uniform enough? The sampling algorithm does well in general. Analysis of mean and median shows it achieves the goal of 1.5 interventions per day and its average KL divergence outperforms that of a common baseline algorithm.

3 Optimal Dosing of Warfarin Using Policy Gradient Methods

Sadjad Anzabi Zadeh[1], Nick Street[2], Barrett Thomas[2], [1]University of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, IA

Warfarin is a widely used anticoagulant with high variability in patient response and narrow therapeutic range. We showed in our previous work how Deep Q-learning can be utilized to produce effective dosing protocols. To produce a more interpretable and explainable dosing protocol for warfarin, in this work, we present our results on how policy gradient algorithms can be used in this context.

4 Test-retest and Quarantining Policies: A POMDP Approach

Zack Zhu, Steven Shechter, Woonghee Tim Huh, University of British Columbia, Vancouver, BC, Canada. Contact:

ziqian.zhu@sauder.ubc.ca
Motivated by recent debates on Covid quarantining policies, we model test-retest and quarantining policies as a partially observable Markov decision process. Costs include testing, quarantining, and spreading the virus, while the state of Covid (truly "positive" or "negative") is partially observable. Daily decisions involve whether to test and/or quarantine. We derive structural results of the optimal cost function and optimal testing/quarantining policy under different modelling assumptions. We discuss how individuals, workplaces, and governments may differ in their preferred policies.

Machine Learning Applications Involving Data with Complex Structure

General Session

Session Chair

Chen Kan, University of Texas at Arlington, Arlington, TX

1 **Bridging Vacuum Ultraviolet Spectra and Chemical Compound Structures with Machine Learning**

Yujing Yang[1], Kevin A. Schug[1], Victoria C. P. Chen[1], Chen Kan[2], [1]The University of Texas at Arlington, Arlington, TX, [2]University of Texas-Arlington, Arlington, TX, Contact: yxy9663@mavs.uta.edu

Vacuum ultraviolet (VUV) spectra are closely related to chemical compound structures and have been increasingly used for compound identification and differentiation. It is of great interest to predict the VUV spectrum from a given compound or determine the compound structure from the VUV spectrum. Achieving this using conventional regression methods, nevertheless, is hindered due to the data complexity. This study develops a new representation learning framework to fill the gap, which 1) extracts features from compound structures using a graph-based approach; 2) depicts the morphology of VUV spectra with shapelets learning; and 3) connects graph features with shapelets with a convolutional neural network. The framework is evaluated with Aromatic and Olefin compounds and their VUV spectra. Results have demonstrated the effectiveness of the developed framework.

2 **Lasso Based State Transition Modeling with Interactions in Adaptive Interdisciplinary Pain Management**

Amith Viswanatha[1], Victoria C. P. Chen[2], Jay Michael Rosenberger[1], [1]University of Texas-Arlington, Arlington, TX, [2]The University of Texas at Arlington, Arlington, TX, Contact: amith.viswanatha@mavs.uta.edu

The UT Southwestern Medical Center has an interdisciplinary chronic pain management program modeled as a two-stage adaptive treatment decision problem. In an adaptive setting, the causal treatment estimates are biased due to time-varying confounding and Inverse Probability of Treatment Weighting (IPTW) is one technique to address this issue. In this study, we address the challenge of modeling state-treatment interactions that are critical to enable personalized treatment for individual patients. It is important for the modeling method to identify the causal features and interactions. A LASSO based method named HierNet is combined with IPTW to build models that enable feature selection and modeling of interaction effects in the presence of time-varying confounding. The proposed approach is studied using a simulated case study structured on the Medical Center data.

3 **Classification for Predicting Recidivism in Criminal Justice**

Shirish Rao[1], Khan Md Ariful Haque[2], Bahar Nasirian[3], Victoria C. P. Chen[3], [1]EDP Renewables North America, Houston, TX, [2]Washington State University, Pullman, WA, [3]The University of Texas at Arlington, Arlington, TX, Contact: khanmdariful.haque@wsu.edu

In criminal justice, recidivism refers to individuals that are perpetual repeat offenders. These individuals are a small set of criminals that are costly to the policing system. An ability to predict recidivism would enable law enforcement to develop strategies that break the cycle of recidivism. In the Summer of 2021, the National Institute of Justice posted a Recidivism Forecasting Challenge. Two years of data from the State of Georgia and two performance metrics, Brier score and fair and accurate, are used. The data involved a mix of both qualitative and quantitative input variables with potentially complex relationships with the probability of recidivism. In this talk, a new classification model is presented to address this data challenge.

1 Forecasting Financial Risk Using Generalized Quantile Random Forests

Robert James[1], Jessica Wai Yin Leung[2], [1]University of Sydney, Sydney, Australia; [2]Monash University, Melbourne, Australia. Contact: r.james@sydney.edu.au

This paper studies various approaches to forecast Value-at-Risk and Expected Shortfall using Generalized Random Forests. The method naturally allows for a large set of economic and financial covariates to interact non-linearly to predict financial risk. We discuss the steps associated with implementing our approach and document the forecasting performance during periods of relatively low volatility and during periods of financial distress. Finally, we outline which covariates are the most important for financial risk forecasting.

2 Sparse Frequency Severity Model Estimation and Its Applications to the Insurance Industry

Jessica Wai Yin Leung[1], Dmytro Matsypura[2], [1]Monash University, Melbourne, Australia; [2]The University of Sydney, Sydney, Australia.

We study the problem of sparse model estimation in the context of the frequency severity model. Using Fenchel duality, we present a mixed integer approach with an outer approximation algorithm to estimate the sparse frequency severity model. A preliminary comparative study shows that the performance of our method is comparable to other state-of-the-art methods within a reasonable time frame.

3 An Online Convex Optimization-based Framework for Convex Bilevel Optimization

Lingqing Shen[1], Nam Ho-Nguyen[2], Fatma Kilinc-Karzan[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Sydney, Sydney, Australia.

We propose a new framework for solving convex bilevel optimization, where one optimizes a convex objective over the optimal solutions of another convex optimization problem. We develop two online convex optimization (OCO) algorithms, one which works under minimal convexity assumptions, and the other equipped to exploit structural information on the objective function, including smoothness, lack of first-order smoothness, and strong convexity. We then adapt the OCO algorithms to convex bilevel optimization, leading to rates of convergence in terms of both inner and outer objective functions simultaneously. We illustrate the numerical efficacy of our algorithms on standard linear inverse problems and a large-scale text classification problem.

4 Presenter

Bradley Rava[1,2], [1]University of Sydney Business School, Sydney, Australia; [2]University of Sydney, Sydney, Australia. Contact: bradley.rava@sydney.edu.au

We study fairness in classification, where one wishes to make automated decisions for people from different protected groups. When individuals are classified, the decision errors can be unfairly concentrated in certain protected groups. We develop a fairness-adjusted selective inference (FASI) framework and data-driven algorithms that achieve statistical parity in the sense that the false selection rate (FSR) is controlled and equalized among protected groups. The FASI algorithm operates by converting the outputs from black-box classifiers to R-values, which are intuitively appealing and easy to compute. Selection rules based on R-values are provably valid for FSR control, and avoid disparate impacts on protected groups. The effectiveness of FASI is demonstrated through both simulated and real data.

1 Matrix Auto-regressive Model with Vector Time-series Covariates

Hu Sun, University of Michigan, Ann Arborg, MI

In this talk, we propose a novel model to forecast a spatio-temporal process based on historical matrix-valued time-series and auxiliary vector-valued time-series data. In our model, a future matrix is jointly predicted by the historical data under a partially linear auto-regressive framework. The high-dimensional matrix-valued coefficients are assumed to possess low intrinsic dimensions and are related with the observed matrices in a bilinear form. The vector-valued time-series predictors, typically of low intrinsic dimensions, are involved through a set of matrix basis functions. Model estimation is discussed and validated with various simulation studies. A real data application on forecasting the spatio-temporal process of a geophysics dataset is presented. Extensions of the model to a semi-parametric setting is also discussed.

2 Operationalizing Responsible AI in Large-scale Organizations

Kinjal Basu, LinkedIn Corporation, Austin, TX

Most large-scale organizations face challenges while scaling their infrastructure to support multiple teams across multiple product domains. Due to the differences in the products, the broad use of Responsible AI techniques is a serious challenge. From different definitions of "fairness" to very different measurement and mitigation solutions, it is tough to build a generalized scalable system to measure and mitigate the unintended consequences of AI models. In this talk, we'll showcase how we can operationalize Responsible AI in large-scale organizations.

3 Detecting Power Outage status in Online News Archives using NLP

Seungho Woo[1], Roshanak Nateghi[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, Lafayette, IN

In the United States, numerous numbers of counties or cities struggle with the power outage. How do we identify which region needs to reform the transmission network? We focus on the regional online news which stores historical power outage event news. A large unstructured amount of news textual big data needs to be filtered and processed by data mining techniques. The historical power outage event information such as date, location, reported time, outage duration, affected residents, and damages were extracted by the Natural Language Processing technique. In this paper, automatic text extraction was performed in online news sources to detect the power outage events and visualize the information.

4 Statistical Inference for Low Rank Matrix Regression with Adaptively Collected Data

Qiyu Han, Yichen Zhang, Wei Sun, Purdue University, West Lafayette, IN, Contact: han541@purdue.edu

Low-rank matrix recovery through matrix regression has been widely studied in the last decades. The statistical inference of the estimation based on offline data is also explored in recent years. In this article, we conduct the statistical inference of the low-rank estimator that can be obtained in a fully online fashion. In particular, we use the adaptively collected data to construct an estimator, where such construction involves the de-biasing of the typical low-rank estimator. This de-biasing procedure uses the samples adaptively collected through the online decision-making under the linear contextual bandit framework with the reward given by the trace regression model.

5 A Unified Complexity Metric for Nonconvex Matrix Completion and Matrix Sensing in the Rank-one Case

Haixiang Zhang[1], Baturalp Yalcin[2], Javad Lavaei[2], Somayeh Sojoudi[3], [1]UC Berkeley, Fremont, CA, [2]University of California, Berkeley, Berkeley, CA, [3]University of California, Berkeley, El Cerrito, CA

We develop a new complexity metric for an important class of low-rank matrix optimization problems, where the metric aims to quantify the complexity of th nonconvex optimization landscape and the success of local search methods. The existing literature has focused on two complexity measures, namely the RIP constant and the sampling rate in terms of the incoherence. The proposed complexity metric has the potential to unify these two notions and applies to a much larger class of problems. We illustrate the usefulness of the new complexity metric from three aspects, and we establish theoretical results to provid conditions on the existence of spurious solutions in terms of the proposed complexity metric.

6 A Generalized Formulation for Group Selection via ADMM

Chengyu Ke[1], Sunyoung Shin[2], Yifei Lou[2], Miju Ahn[3], [1]Southern Methodist University, Dallas, TX, [2]The University of Texas at Dallas, Richardson, TX, [3]Southern Methodist University, Dallas, TX, Contact: cke@smu.edu

This paper studies a statistical learning model where the model coefficients have a pre-determined non-overlapping group sparsity structure. We analyze the directional stationary solution of the proposed formulation, obtaining a sufficient condition for the stationary solution to achieve optimality and establishing a bound of the distance from the solution to a reference point that is related to the ground-truth from a probabilistic interpretation. Also, we develop an efficient algorithm that adopts an alternating direction method of multiplier (ADMM), showing that the iterates converge to a directional stationary solution under certain conditions.

7 Carbon Sequestration for Sustainable Urban Environments

Levente Klein, IBM, Yorktown Heights, NY

Nature-based carbon sequestration is one of the most straightforward ways to sequester and to store carbon from the atmosphere. Urban forests hold the promise of optimized carbon storage and temperature reduction in cities. Remote sensing imagery in combination with image processing techniques can identify individual tree location and their sizes, classify trees based on their species, and track tree health. While standard machine learning models like Random Forest and Support Vector Machine can achieve accuracy of 80% in separating trees from other land cover classes, additional deep learning models using noisy labeled data can further improve tree identification maps. We demonstrate such an approach by quantifying the carbon sequestration and urban heat island mitigation for New York City and Dallas.

8 FinRL-Meta: Open-Source Financial Reinforcement Learning

Xiao-Yang Liu, Columbia University, New York City, NY, Contact: xl2427@columbia.edu

FinRL is the first open-source framework to demonstrate the great potential of financial reinforcement learning. It has evolved into an ecosystem, FinRL-Meta, which is a playground for financial reinforcement learning. We believe FinRL-Meta will reshape our financial lives and our open-source community will make sure it's for the better.

9 The Implementation Path of Search Engine Optimization Driven by Double Factors: Taking Brand Keyword Search as an Example

Zuguo Cai, Lili Fan, Southwest Jiaotong University, Chengdu, China. Contact: caizuguo@yeah.net

This article constructs a ranking model for different types of search result lists containing the same sellers, examines the impact of search engine ranking results on sellers' revenue and consumer welfare. Then we explore the mechanism of whether the implementation of search engine optimization affects the ranking equilibrium. Moreover the motivations and effects of SEO implementation are analyzed, so as to provide management enlightenment and policy recommendations for improving the retrieval efficiency and welfare of consumers. The research finds that from brand keywords without SEO, only the sorting of sponsored search result lists is in line with consumers' search willingness, while the ranking of organic search result lists is inverse to consumers' search willingness.

10 Atomic Clique: A Novel Network Model to Analyze Comorbidity Progression

Parisa Sahraeian, Zhuqi Miao, Yajun Lu, Baski Balasundaram, Oklahoma State University, Stillwater, OK

Detection of comorbidity progression is an invaluable decision aid and a prominent challenge in healthcare research and practice. Comorbidity progression can be modeled as temporal disease networks (TDNs). The objective of this study is to detect comorbidity progression patterns among TDNs. In this regard, a new network model, Atomic Clique, and an associated optimization problem, Maximum Atomic Clique problem, were proposed. To deal with the large-scale instances, two main approaches, extended formulation for the maximum atomic clique problem and reduction from the maximum atomic clique problem to the maximum clique problem were developed.

Safety and Robustness in Machine Learning

General Session

Session Chair

Brendon Anderson, University of California-Berkeley, Oakland, CA

Session Chair

Sam Pfrommer, 1</sup

Session Chair

Somayeh Sojoudi, University of California, Berkeley, El Cerrito, CA

1 Learning Under Robustness Constraints

Luiz F. O. Chamon[1], Alex Robey[2], George J. Pappas[2], Hamed Hassani[3], Alejandro Ribeiro[2], [1]University of California, Berkeley, Berkeley, CA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA

While adversarial training methods has been shown to mitigate the fragility of deep learning models to input perturbations, they are increasingly application-dependent, heuristic in nature, and suffer from trade-offs between nominal performance and robustness. Moreover, the problem of finding worst-case perturbations is non-convex and underparameterized, engendering a non-favorable optimization landscape. Thus, there is a gap between the theory and practice of adversarial training, particularly as to when and why it works. In this talk, we take a constrained learning approach to these questions leveraging semi-infinite optimization and non-convex duality to show that adversarial training is equivalent to a statistical problem over a perturbation distribution and develop a hybrid Langevin method to obtain state-of-the-art results on MNIST and CIFAR-10.

2 Safe Feedback Motion Planning with Learned Dynamics Models

Glen Chou, University of Michigan, Ann Arbor, MI, Contact: gchou@umich.edu

Trustworthy robots must be able to complete tasks safely and reliably. While traditional motion planners can achieve this if the robot's dynamics are carefully modeled a priori, these guarantees fall apart in unstructured settings, where robots need data to refine their models. Deep learning provides a means to obtain dynamics models from data, but blindly trusting these potentially unreliable models when planning can cause unsafe behavior. In this talk, I will present our work in determining where learned models can be trusted for reliable motion planning, and to what extent. Using this information and tools from contraction theory, we plan trajectories with the learned model that can be safely tracked on the true system, with provable guarantees. We show that our theory translates to empirical success in controlling a variety of high-dimensional, underactuated systems.

3 Revisiting Hilbert-Schmidt Information Bottleneck for Adversarial Robustness

Zifeng Wang, Northeastern University, Boston, MA, Contact: zifengwang@ece.neu.edu

We investigate the HSIC (Hilbert-Schmidt independence criterion) bottleneck as a regularizer (HBaR) for learning an adversarially robust deep neural network classifier. In addition to the usual cross-entropy loss, we add regularization terms for every intermediate layer to ensure that the latent representations retain useful information for output prediction while reducing redundant information. We show that the HSIC bottleneck enhances robustness to adversarial attacks both theoretically and experimentally. In particular, we prove that the HBaR reduces the sensitivity of the classifier to adversarial examples. Our experiments on benchmark datasets and architectures demonstrate that incorporating HBaR attains competitive natural accuracy and improves adversarial robustness, both with and without adversarial examples during training.

4 Certified Robustness via Locally Biased Randomized Smoothing

Brendon Anderson[1], Somayeh Sojoudi[2], [1]University of California, Berkeley, Oakland, CA, [2]University of California, Berkeley, El Cerrito, CA

Randomized smoothing remains one of the state-of-the-art methods for robustification with theoretical guarantees. We show that using uniform and unbiased smoothing measures, as is standard in the literature, relies on the underlying assumption that smooth decision boundaries yield good robustness, which manifests into a robustness-accuracy tradeoff. We generalize the smoothing framework to remove this assumption and learn a locally optimal robustification of the decision boundary based on training data, a method we term locally biased randomized smoothing. We prove nontrivial closed-form certified robust radii for the resulting model, avoiding Monte Carlo certifications as used by other smoothing methods. Experiments on synthetic, MNIST, and CIFAR-10 data show a notable increase in the certified radii and accuracy over conventional smoothing.

Meizi Zhou, University of Minnesota, Minneapolis

1 "I Want to Know More!": Measuring the Impact of Consumer Curiosity in Recommender System

Pan Li, Alexander Tuzhilin, New York University, New York, NY, Contact: pli2@stern.nyu.edu

Curiosity constitutes an important factor in consumer decision-making in marketing applications. However, it has yet to be systematically studied in recommender systems. In this paper, based on the information gap theory, we present a measurement framework to quantify the level of curiosity triggered by each product, and we conduct a lab experiment to demonstrate its validity. We then propose a curiosity-aware recommendation framework by incorporating the curiosity levels into the utility function. Offline experiments show that our model significantly outperforms state-of-the-art relevance-oriented baselines, illustrating the importance of modeling curiosity in recommendations. We also conduct a large-scale online experiment at Alibaba, where our model significantly outperforms the latest production system by 25% across multiple business metrics.

2 Operation Dumbo Drop: To Airdrop or Not to Airdrop for Initial Coin Offering Success?

Jian Li[1], Xiang Wan[2], Kenny Cheng[2], Xi Zhao[1], [1]Xi'an Jiaotong University, Xi'an, China; [2]University of Florida, Gainesville, FL, Contact: xiang.wan@ufl.edu

To investigate the efficacy of token airdrop for Initial Coin Offerings (ICOs) success, we implement a regression discontinuity design by leveraging the quasi-randomization of a blockchain project's promotional airdrop campaign on the Ethereum platform. We find that the promotional airdrop leads to a 2.3 times increase of the potential investors' ICO investment probability. We further find that the airdrop is more effective in increasing the investment probability for individuals whose personality traits are dissimilar to the blockchain project than those similar to the project. Our study contributes to the literature of ICOs and provides important and useful managerial implications to blockchain companies.

3 Advertising as Information for Ranking E-commerce Search Listings

Xi Xiong[1], Navdeep Sahni[2], Joonhyuk Yang[3], Harikesh Nair[4], [1]JD.com american technologies copro, MOUNTAIN VIEW, CA, [2]Stanford University, Stanford, CA, [3]University of Notre Dame, Notre Dame, IN, [4]Stanford University, Stanford, CA, Contact: xiongxi9@gmail.com

Search engines and e-commerce platforms have substantial difficulty exposing new products to their users on account of an information problem: new products typically do not have user-engagement that enables platforms to reliably assess product quality. This paper evaluates the role of advertising in providing information to the platform regarding new product quality so as to solve this ''cold-start'' problem and engineer higher quality organic listings. Using a large-scale experiment implemented at JD.com---a large e-commerce platform in China---we show that using ad propensity information for ranking new products benefits both the platform and consumers, in the short run. Our findings showcase a new channel by which advertising can potentially improve user experience, through incorporating information to predict the quality of new products

1 Mapping Feedback Mechanisms Contributing to Dental Caries in Adolescents

Fatemeh Sadjadpour[1], Niyousha Hosseinichimeh[2], Bhavna Pahel[3], Sara Metcalf[4], [1]Virginia polytechnic institute and state university, Blacksburg, VA, [2]Virginia polytechnic institute and state university, Falls Church, VA, [3]University of North Carolina, Chapel Hill, NC, [4]The State University of New York at Buffalo, Buffalo, NY, Contact: fsadjadpour@vt.edu

Dental caries is the most prevalent chronic disease among adolescents in the United States. Our objective in this research is to study factors contributing to dental caries among adolescents to hypothesize & map the causal reciprocal relationships among the multilevel factors that influence disparities in dental caries among adolescents. The methods that we use are focused literature review & a system dynamic approach for developing feedback mechanisms underlying dental caries through Causal loop diagramming. The results of this study have identified individual, family & community-level factors & their feedback loops contributing to dental caries experience in adolescents. Conclusions: our findings lead to a better understanding of the factors that shape disparities in dental caries experience of adolescents & testing interventions to reduce them.

2 Machine Learning-based Sleep Quality Prediction with Body Signal Data

Hyojeong Kang, Juheon Kwak, Wonkeun Jo, Dongil Kim, Chungnam National University, Daejeon, Korea, Republic of.

Good sleep quality is important to maintain health. In this paper, we predicted sleep quality using body signal data collected from wearable devices with machine learning methods. The body signal data were preprocessed by time series analyzation techniques such as power spectrum density and Neurokit, etc. Then we constructed four machine learning models to predict sleep quality, random forest, support vector machine, multi-layer perceptron, and k-nearest neighbor. In addition, we employed the long short-term memory to improve the prediction performance for multivariate time series data. The experimental results showed that the performance of the proposed method was satisfactory in terms of accuracy.

3 Artificial Intelligence-based Analytics for Impacts of Covid-19 and Online Learning on College Students' Mental Health

Mostafa Rezapour, Scott Elmshaeuser, Wake Forest university, Winston Salem, NC, Contact: rezapom@wfu.edu

In this presentation, we discuss how the COVID-19 pandemic and online learning impact college students' emotional wellbeing. To do this we use several machine learning and statistical models to analyze data collected by the Faculty of Public Administration at the University of Ljubljana, Slovenia in conjunction with an international consortium of universities, other higher education institutions and students'

associations. Our results indicate that learning modality (face-to-face, online synchronous, online asynchronous, etc.) is the main predictor of students' emotional wellbeing, followed by financial security. Factors such as satisfaction with their university's and government's handling of the pandemic are also important predictors.

4 A New Approach for Automating Patient Prioritization in Emergency Department Using Machine Learning Algorithms

Mahsa Khosravi[1], Sigurdur Olafsson[1], Gül E. Kremer[2], [1]Iowa State University, Ames, IA, [2]University of Dayton, Dayton, OH, Contact: mahsak@iastate.edu

Triage decisions are critical to emergency department performance, and existing decision support is usually based on the Emergency Severity Index, which may lead to long wait times. This work analyses a unique data set capturing the judgment of physicians for patient prioritization and addresses the question of if machine learning (ML) can be utilized to automate patient ranking in the emergency department. A classification problem of pair-wise comparisons is constructed and used to train a predictive model with logistics regression, decision trees and tree ensembles. Results show that correct comparisons are predicted with over 90% accuracy, validating the use of ML for the ranking prediction specially when incorporating domain-knowledge.

Operational Effectiveness for Contested Environments

General Session

Session Chair

Brian J. Lunday, Air Force Institute of Technology, Beavercreek, OH

1 Utilization of Offshore Support Vessel Deployment for Contested Logistics Fulfillment

Gary Lazzaro, United States Naval Academy, Annapolis, MD

We investigate distributing the deployment of offshore support vessels (OSVs) for the replenishment of logistics in contested locations. The Joint Chiefs of Staff predict that additional resources will be need to supplement the Military Sealift Command in order to resupply units in areas of contention. We utilize an unclassified test scenario across 30 locations the Indo-Pacific region, and a database of 1,700 commercial OSV worldwide. We categorize OSV into similar types of vessels for military logistics use. We formulate a time-based simulation that creates a feasible schedule for OSV to resupply deployed units over a 45-day period. Our goal is to minimize the time required for replenishments to occur. The model determines the effectiveness of OSVs and answers questions such as the time required to fulfill resupply, the type and number of OSVs required to meet unit demand.

2 A Mathematical Model and Solution Method for the Temporal Network Vulnerability Problem

Carson Long[1], Brian J. Lunday[2], Phillip R. Jenkins[3], Kenneth Hopkinson[1], [1]Air Force Institute of Technology, WPAFB, OH, [2]Air Force Institute of Technology, Beavercreek, OH, [3]Air Force Institute of Technology, Wright-Patterson Air Force Base, OH

Transportation of material over ground distribution networks is subject to both man-made and natural disruptions. This research sets forth a multi-objective bilevel linear program to identify, quantify, and characterize network vulnerabilities for a defender solving a multi-objective material routing problem, given an adversary conducting a limited number of arc-specific, spatiotemporal attacks. Examining an instance comprised of real-world network topology, this research examines the efficiency of a customized genetic algorithm to search the upper-level decision space and identify high quality solutions, subject to alternative assumptions about the defender's relative priorities over its multiple objective functions.

3 Satellite Constellation Design Through a String of Pearls Approach Based on Design of Experiments and Regression Modeling

Nathaniel Choo, Darryl Ahner, Air Force Institute of Technology, Wright Patterson AFB, OH

A method for selecting a satellite constellation is developed that provides continuous coverage to points of interest on the Earth's surface. The satellite constellation is designed by applying a String of Pearls approach to a single repeating ground track of a circular orbit. A Design of Experiments approach is used in conjunction with simulation and regression modeling to relate orbital parameters meeting repeating ground track orbit conditions to a coverage metric. The coverage metric is used to evaluate the coverage a single satellite provides to the points of interest. The regression model is then used to select the orbit that optimizes the coverage metric. The String of Pearls further enhances this coverage by placing satellites in orbit that start coverage as the preceding satellite coverage ends.

4 Routing Semi-autonomous Assets with Hierarchal Relationships Utilizing Clustering a Heuristic

Stephen Donnel[1], Brian J. Lunday[2], Nicholas Tyler Boardman[3], [1]Air Force Institute of Technology, WPAFB, OH, [2]Air Force Institute of Technology, Beavercreek, OH, [3]Air Force Institute of Technology, Bellbrook, OH

Setting aside assumptions of communication dominance, Mosaic Warfare leverages `tiles' of assets via distributed, decentralized command and control. This study develops a hierarchal clustering heuristic to implement this decision-centric framework to routing command and control, sensor, and strike assets (e.g., aircraft) to service point demands at fixed locations in R^2 space while maintaining required hierarchal relationships. System performance metrics inspired by the Price of Anarchy indicate the relative efficiency of Mosaic Warfare compared to optimal solutions, over several combinations of scenarios, asset densities, and user-defined parameters for the solution procedure.

Parking Management and the Sharing Economy

Joint Session

Session Chair

Tara Radvand, University of Michigan

1 A Stochastic Model for Estimating Search Time for On-street Parking

Tara Radvand[1], Mojtaba Abdolmaleki[2], Yafeng Yin[2], [1]University of Michigan, ANN ARBOR, MI, [2]University of Michigan, Ann Arbor, MI, Contact: tararad@umich.edu

Estimation of parking search time plays a vital role in planning and managing on-street parking. Supplementing previous attempts, we develop a stochastic framework to model the parking search procedure considering the competition, occupancy rate, and traffic congestion in the area. The framework yields a unique equilibrium distribution of search time, validated by a simulation study. Furthermore, our model determines a threshold for occupancy rate beyond which substantial cruising-for-parking starts. This result can replace the widely adopted rule of thumb of the 85 percent occupancy rate for parking management.

2 Power Systems and Applied Probability: Electric Vehicles

Maria Vlasiou[1,2], Angelos Aveklouris[3], Bert Zwart[4], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]University of Twente, Enschede, Netherlands; [3]University of Chicago Booth School of Business, Chicago, IL, [4]CWI, Eindhoven, Netherlands. Contact: vlasiou@gatech.edu

We model a distribution grid used by electric vehicles as a resource-sharing network driven by greedy decentralized control rules. We develop bounds and asymptotic (measure-valued fluid and diffusion) approximations for the vector process of the total number of EVs and the number of not fully charged EVs and compare these with numerical outcomes. This leads to a set of dynamic equations that consider the stochastic behaviour of EVs and bounded voltage drops. The invariant point is unique and can be computed by solving a specific ACOPF problem, which admits an exact convex relaxation. We illustrate our findings with a case study using the SCE 47-bus network and several special cases that allow for explicit computations.

3 Electric Vehicles for Distribution System Load Pickup Under Stressed Conditions: A Network Equilibrium Approach

Zhaomiao Guo, Sina Baghali, University of Central Florida, Orlando, FL

We investigate the potential effects of electric vehicles (EVs) on reducing the load shedding in heavily loaded distribution systems (DSs). We propose a network equilibrium model that integrates market clearing in DSs and traffic flow balance in transportation systems. This model captures the decentralized interactions between key stakeholders in transportation and distribution networks as well as the spatial distribution of EV traffic in response to endogenously determined incentive signals. To mitigate the computational challenges brought by the non-convex network equilibrium model, we develop an equivalent convex reformulation with guaranteed global convergence. The proposed method could provide a fundamental tool for analyzing interdependent transportation and distribution networks coupled by charging facilities and EVs.

Optimization and Large-scale Policy in Healthcare

General Session

Session Chair

Hadi El-Amine, George Mason University, Fairfax, VA

1 The Impact of Early Large-scale Screening on the Evolution of Pandemics

Marwan Shams Eddin[1], Hadi El-Amine[1], Hrayer Aprahamian[2], [1]George Mason University, Fairfax, VA, [2]Texas A&M University, College Station, TX, Contact: helamine@gmu.edu

We study the problem of large-scale screening in the early stages of a pandemic. In this setting, resources such as testing kits, budget, and hospital beds are scarce, and early-stage testing has the potential to alter the dynamics of disease spread. Thus, devising optimal screening strategies that operate within these constraints is crucial to saving lives and reducing healthcare costs. To address the issue of limited testing capacity, we study two models that focus on either individual or group (pooled) testing, and we determine conditions under which each scheme is superior. We calibrate our models using data on the ongoing COVID pandemic and demonstrate the benefits of our proposed methods.

2 Personalized Immunosuppressive Therapies for Transplant Recipients

Naoru Koizumi[1], Hadi El-Amine[2], Meng-Hao Li[1], [1]George Mason University, Arlington, VA, [2]George Mason University, Fairfax, VA, Contact: nkoizumi@gmu.edu

Use of Machine learning (ML) has become increasingly popular in the medical field in the past decade. We developed and applied ML and optimization models to the national transplant registry data to examine the optimal combination of immunosuppressive drugs administered to the living and deceased kidney transplant recipients between January 2010 and November 2021. The transplant outcomes were evaluated using the 1-year graft failure rate, as well as the number of post-transplant malignancy and infection episodes, adjusting for various demographic and clinical risk factors. We explored conventional ML algorithms including logistic regression, random forest, and artificial neural network. We embed the resulting ML model in an optimization framework in which allows us to determine optimal treatments based on donor/recipient characteristics.

3 A Network-based Optimization Framework for the Allocation of Vaccines Across Populations with Heterogeneous Risk Profiles and Non-uniform Interactions

Su Li[1], Hrayer Aprahamian[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: dclisu@tamu.edu

The COVID1-9 pandemic has sparked substantial interest in identifying good performing vaccine distribution and allocation strategies. When vaccines are limited, a key question arises: Who should be prioritized for vaccination and when should they be vaccinated? We establish a network-based optimization framework that incorporates the population's heterogeneity in risk and non-uniformity in interactions. We formulate this problem as a mixed integer nonlinear program. By analyzing its structure, we construct a globally convergent scheme based on a reformulation linearization technique. To handle larger instances, we construct a greedy algorithm which we embed within a coordinate descent approach. Our results highlight the substantial benefits of vaccination strategies that are tailored to the specific risk and interaction profiles of the population.

4 The Optimal Testing Sequence Problem for Living Kidney Donor Workup

Joshua Nielsen[1], Hadi El-Amine[2], Monica Gentili[1], Naoru Koizumi[3], [1]University of Louisville, Louisville, KY, [2]George Mason University, Fairfax, VA, [3]George Mason University, Arlington, VA, Contact: joshua.nielsen@louisville.edu

Living kidney donors must undergo a workup process of several medical tests to assess their eligibility and suitability for transplantation. Hence, the donor evaluation process takes time and may result in more than 50% of donor candidates either becoming ineligible or droping out in the process. As a result, it often takes a long time for a patient to secure a donor who could complete the process and actually donate. In this context, we study the Optimal Testing Sequence Problem which, given donor candidate characteristics, aims to find a personalized optimal sequence of tests to minimize the total expected cost. We study both the cases where probabilities of test outcomes are treated as either being dependent or independent of the preceding test in the sequence.

Decision-making in Healthcare

General Session

Session Chair
Vishal Ahuja, Southern Methodist University, Dallas, TX

1 A Cost-effectiveness Analysis of Lethal Ovitrap for the Prevention of Dengue Fever

Yvonne Huijun Zhu[1], Joel Aik[2], Joel Goh[1], [1]National University of Singapore, Singapore, Singapore; [2]National Environment Agency, Singapore, Singapore. Contact: huijun96@u.nus.edu

We analyze the system-level cost-effectiveness of a network of lethal ovitraps for Dengue control. Benefits are modeled using an age-stratified multiple-infection epidemiological model and measured as reductions in disability-adjusted-life-years (DALYs). We estimate labor costs by modeling the workload needed for periodic maintenance of the traps via Traveling Salesmen Problems (TSPs).

2 Machine-learning Enhanced Hospital Workload Prediction and Resource Allocation

Tianchun Li[1], Jonathan Eugene Helm[2], Pengyi Shi[1], [1]Purdue University, West Lafayette, IN, [2]Indiana University, Bloomington, IN, Contact: li2657@purdue.edu

The COVID-19 pandemic has created new opportunities to develop and deploy high-impact analytics to combat severe resource shortages in a rapidly evolving environment, particularly staffing inadequacy. At the core of solving this problem is data-driven analytics and predictions to understand the patient workload and how to most efficiently allocate resources to all patients. We leverage a suite of analytics tools to develop an integrated, comprehensive solution to support workload prediction and nurse deployment decisions. Based on a close partnership with IU Health System, the largest health system in Indiana with 16 hospitals, we launched an academia-industry venture to implement and deploy our data-driven solution as a pilot in October 2021. A retrospective study estimates annual savings of over $300K using our tool.

3 The Allocation of Funds in Healthcare: Which Hospital to Support?

Lina D. Song[1], Soroush Saghafian[2], [1]University College London School of Management, London, United Kingdom; [2]Harvard Univeristy, Cambridge, MA, Contact: s.dahye@ucl.ac.uk

We examine policies to allocate funds among U.S., hospitals, in the context of two payment programs— Medicare DSH and the CAH—where one targets urban and the other rural hospitals. We analytically suggest optimal investment policies, such as investing in (substantially) rural and (slightly) lower-quality hospitals. We then calibrate our model to a dataset of over 300,000 patients and show that (a) investing more in DSHs or (b) reducing the total number of CAHs improves social welfare.

1 Calibrating the Transition Probabilities of Disease Progression Markov Chains with Aggregate Mortality Data

Hanie Eskandari, Jourdain Lamperski, University of Pittsburgh, Pittsburgh, PA

We consider the inverse problem of calibrating the transition probabilities of discrete-time Markov chain (DTMC) models of disease progression with aggregate mortality data. Existing work primarily considers tackling the problem with simulation techniques and has left open a number of interesting questions. In particular, it is not known under what conditions the transition probabilities of these models are identifiable. In this talk, we establish how many time periods of mortality data are needed to ensure that the transition probabilities are identifiable, and we present a method that is guaranteed to recover the parameters when they are identifiable. We also use our method to calibrate a colorectal cancer and an opioid use disorder model.

2 A Complex Agent-based Model of Opioid use Disorder

Mark S. Roberts[1], Mary Krauland[2], Hanie Eskandari[1], Amin Rahimian[1], Jourdain Lamperski[1], Antoine Douaihy[3], Kevin Kraemer[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, [4]University of Pittsburgh, Pittsburgh, PA

Opioid overdoses caused over 100,000 deaths last year and produced significant disability. Funding by the CDC, we have developed an agent-based simulation model that combines significant clinical detail in individual agents with a geospatially detailed representation of the population and characteristics surrounding individuals. We seek to construct a tool that can estimate the combined impact of multiple interventions for each of 3006 counties in the US. The model complexity, including multiple disease transition probabilities that vary by local characteristics has led to significant issues in calibration and validation, and computational complexities in the estimation of the impact of combinations of interventions in different counties. We present our methodologic solutions to these problems.

3 Minimizing Makespan Across Preloaded Machines

Clarence L. Worrell, Jourdain Lamperski, Lisa M. Maillart, University of Pittsburgh, Pittsburgh, PA, Contact: clw117@pitt.edu

Motivated by work balancing between pathology units in a multi-hospital setting, we consider minimizing makespan across preloaded, parallel machines when the system manager has a one-time, *a priori* opportunity to reassign any of the preloaded jobs to any of the other machines. Reassigned jobs are transported *en masse* in a fixed amount of time and must be returned to their original machine after they are processed. Processing times are deterministic, known prior to reassignment, and may be machine-specific. We develop a mixed-integer linear program to identify optimal reassignment policies, along with a list scheduling algorithm that we show achieves a 2-approximation guarantee when the machines are identical. A computational study shows that the algorithm often performs much better than this worst-case performance guarantee, even when the machines are not identical.

4 Modeling Social Contexts of Opioid Epidemics Using Aggregate Facebook Connectivity Data in a Large-scale Agent-based Model of the U.S.

Kushagra Tiwari[1], M.Amin Rahimian[1], Mary G Krauland[2], Mark S Roberts[2], David D Galloway[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: KUT20@pitt.edu

During the past two decades, the opioid epidemic has been a major cause of concern in the U.S. There has been an increasing recognition that its etiology is rooted in part in the social contexts that mediate substance use and access. Following a brief review of Spatial Point Pattern principles, we provide a detailed analysis of spatially clustered opioid overdose deaths (OOD) in the U.S. counties and their relationship with Facebook's social connectedness index (SCI). We will also discuss the use of SCI as a proxy to model social contexts of substance use (i.e., the effect of peer influence on opioid use initiation) in FRED (Framework for Reconstructing Epidemiological Dynamics) software developed at Pitt Public Health Dynamics Lab.

1 Automated VMAT Treatment Planning Using Sequential Convex Programming

Pinar Dursun, Linda Hong, Gourav Jhanwar, Jie Yang, Masoud Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY, Contact: dursungp@mskcc.org

Most current clinical systems for volumetric modulated arc therapy (VMAT) involve often time-consuming manual intervention by planners during the planning process. We propose an automated planning system for VMAT and integrate it with an FDA-approved treatment planning system. VMAT is a very challenging non-convex optimization problem and we solve it with a sequential convex programming (SCP) based direct aperture optimization algorithm. Tumor dose coverage is maximized first, and then dose to organs-at-risk is further minimized. Delivery efficiency is also considered by promoting aperture regularity and neighboring aperture similarity through convex objective functions. The performance of the system was tested on three different disease sites. The results show that the proposed system can automatically generate high quality and delivery efficient plans.

2 On the Value of a Multistage Approach for Radiation Therapy Planning

Doran Wood[1], Sila Cetinkaya[1], Harsha Gangammanavar[1], Weiguo Lu[2], Jing Wang[2], [1]Southern Methodist University, Dallas, TX, [2]UTSW Medical Center, Dallas, TX, Contact: doranw@smu.edu

We make a case in support of stochastic multistage radiation therapy planning formulations equipped with a generalized fractionation scheme which allow the beam intensity profile and prescription allocation to be optimized simultaneously. Updated patient CT scans revealing structural evolution between treatments represent realizations of a stochastic

process and a sequence of prostate cancer scans are used to generate numerical results. Performance evaluations reveal drastic improvements across the several metrics considered.

3 Optimal Tumor Resection Problem

Taghi Khaniyev[1], Kaan Cakiroglu[1], Asli Sena Bozkurt[1], Hanalioglu Sahin[2], [1]Bilkent University, Ankara, Turkey; [2]Hacettepe University, Ankara, Turkey. Contact: taghi.khaniyev@bilkent.edu.tr

Connectome is the representation of the structural connectivity (the physical wiring) of an organism's nervous system as a mathematical network. Given the connectome data of a human subject's brain where a number of regions are marked as "tumorous", our goal is to identify a maximal subset of contiguous tumorous regions whose removal will cause a limited disruption in the network's global efficiency. We formulate this problem as a network optimization problem, which is closely linked to the critical node/edge problem in the literature. The main challenge, after formulating the problem, is to solve real-life size problem instances with thousands of nodes for which we propose algorithmic approaches.

1 Unmasking Human Trafficking Risk in Commercial Sex Supply Chains with Machine Learning

Pia Ramchandani[1], Hamsa Bastani[1], Emily Wyatt[2], [1]Wharton, Philadelphia, PA, [2]TellFinder Alliance, Uncharted, Toronto, ON, Canada.

The covert nature of sex trafficking provides a significant barrier to generating large-scale, data-driven insights to inform law enforcement, policy and social work. We leverage massive deep web data (collected from leading commercial sex websites) in tandem with a novel machine learning framework to unmask suspicious recruitment-to-sales pathways, thereby providing a global network view of trafficking risk in commercial sex supply chains. This allows us to infer likely recruitment-to-sales trafficking routes of criminal entities, deceptive approaches used to recruit victims, and regional variations in recruitment vs. sales pressure. These insights can help law enforcement better coordinate efforts, and target local interventions.

2 Capping Mobile Data Access Creates Value for Bottom-of-the-Pyramid Consumers ‘Äì Experimental Evidence from a Mumbai Settlement

Alp Sungu, Kamalini Ramdas, London Business School, London, United Kingdom.

We find that addictive smartphone usage increases the information isolation of the poor, and we study an operational solution to this problem. We developed a usage-tracking app and deployed it in the poorest settlement in Mumbai, India. Our data reveals that users binge on digitally addictive apps early in a data plan and face subsequent data shortages. We find that during the late-plan data shortage period, participants are unable to access internet-enabled information. In a field experiment, we randomly assigned participants to standard (i.e., monthly) data plans or to the same plans, but with daily data caps. Capping data plans increases late-plan access to information and reduces social media checking. This has real-life implications. We find that random assignment to daily data caps increases the attendance of in-person health camps that we advertised over WhatsApp by a striking 27 percent. Many low-income smartphone users prefer the capped plans (especially those with low self-control and high FOMO), indicating that capped plans offer a viable policy prescription.

3 Fair Exploration via Axiomatic Bargaining

Jackie W. Baek, Vivek Farias, MIT, Cambridge, MA

Exploration is often necessary in online learning to maximize long-term reward, but it comes at the cost of short-term ‘regret’. We study how this cost of exploration is shared across multiple groups. For example, in a clinical trial setting, patients who are assigned a sub-optimal treatment are the ones who incur the cost of exploration, and groups can be defined as the race of patients. We introduce the ‘grouped’ bandit model, and we show that any regret-optimal policy results in the least fair outcome: the most disadvantaged group bears the entire cost of exploration. We formalize an axiomatic notion of fairness using the Nash bargaining solution, and we derive policies that are optimally fair and enjoy a small 'price of fairness'. We illustrate the relative merits of our algorithmic framework with a case study on contextual bandits for warfarin dosing.

1 A Blockchain-based Protocol to Elicit, Verify, and Reward Forecasts

Arthur Carvalho[1], Majid Karimi[2], [1]Miami University, Oxford, OH, [2]California State University San Marcos, San Marcos, CA, Contact: arthur.carvalho@miamioh.edu

We propose a blockchain-based protocol that enables Web 3.0 users to sell private data while ensuring privacy and transparency. Specifically, we focus on the case where a buyer is interested in a point or probabilistic forecast produced by a seller. This setting captures several realistic scenarios, from demand forecasting to predicting election results. Our proposed protocol relies on a smart contract to handle forecast elicitation, evaluation, and payments. Remarkably, by leveraging zero-knowledge proofs, that smart contract can achieve all the above without having access to the data (forecast). In other words, we provide formal guarantees that only the seller and the buyer have access to the forecast.

2 Exploiting Uncertainty in the NFL Draft

Yael Grushka-Cockayne[1], Jason R W Merrick[2], Cade Massey[3], Zach Drapkin[4], [1]Darden School of Business, Charlottesville, VA, [2]Virginia Commonwealth University, Richmond, VA, [3]University of Pennsylvania, Philadelphia, PA, [4]Wharton, Philadelphia, PA, Contact: grushkay@darden.virginia.edu

National Football League teams spend approximately $200m each year in player costs. One of the challenges in allocating that money is selecting players in the annual college draft. When making these selections teams utilize scout assessments of players' future performance. Using historical data from one NFL team over 12 years, we evaluate 64,139 forecasts from 90 scouts regarding 13,467 players. We use historical outcomes for mapping the categorical scout assessments into complete distributions. These distributions allow combining scout grade assessments while accounting for a prospect's uncertainty.

3 Combining Judgmental Forecasts with Base Rates to Improve Decision Making: A Data-driven Application to 20 Years of Drug Development Predictions

Asa Palley[1], Ville Satopaa[2], Charles Persinger[3], Yael Grushka-Cockayne[4], [1]Indiana University, Bloomington, IN, [2]INSEAD, Paris, France; [3]Eli Lilly & Company, Indianapolis, IN, [4]Darden School of Business, Charlottesville, VA

We propose a data-driven approach that leverages a simple behavioral model of belief updating in the context of a prior reference probability. The model allows for the possibility that experts either remain too close to or move too far away from this reference probability, and prescribes a context-specific degree of adjustment to counteract any such bias. We illustrate this approach by applying the method to expert forecasts of the probability of success in drug development. The experts are given a prior reference probability for the historical success rate of similar drugs in each phase of clinical trials and, after a group discussion, decide together on a probability prediction. The probability adjustments estimated by our model provide significant improvements in prediction accuracy, particularly within the costly Phase 3 trials.

4 Market Economies for Eliciting and Combining Judgemental Forecasts

Majid Karimi[1], Arthur Carvalho[2], [1]California State University San Marcos, San Marcos, CA, [2]Miami University, Oxford, OH

Judgemental forecasts are often combined to obtain a better predictive performance than individual forecasts. Researchers and practitioners often use statistical aggregation methods to find an optimal transformation of individual forecasts based on their statistical properties. Motivated by the recent advancements in the Wisdom of Crowds literature, we present market economies as an alternative for combining judgemental point forecasts. Unlike statistical aggregation methods, we argue that market economies present a practical solution for eliciting and aggregating a crowd's judgemental point forecasts. We provide a prescriptive analysis in an Inventory Planning and Control setting and illustrate the impact of our proposed market economies on inventory decisions.

4 Performance Evaluation Under Uncertainty Using Fuzzy Linear Physical Programming

Gazi Duman[1], Elif Kongar[2], Surendra M. Gupta[3], [1]University of New Haven, West Haven, CT, [2]Fairfield University, Fairfield, CT, [3]Department of Mechanical and Industrial Engineering,, Boston, MA

Continuous performance evaluations that utilize both qualitative and quantitative data play a significant role in sustaining efficient and effective business processes. The majority of these approaches use weighted evaluation criteria to introduce the relative importance of each weight into the problem environment. These weights are rarely generated by a data-driven process which might lead to misleading results. This study presents a linear physical programming-based performance evaluation approach that eliminates the subjectivity in weight assignment. A case study is provided demonstrating the applicability of the approach.

1 Fast or Slow? Competing on Publication Frequency

Lin Chen, Guillaume Roels, INSEAD, Fontainebleau, France.

For many information goods, longer publication cycles are more economical, but often result in less timely information. While the digitalization of publication processes makes shorter publication cycles more economically viable, not all firms choose to publish more frequently. In this paper, we build a game-theoretic model to determine how information providers should choose their publication cycles and prices under competition. We find that when the firms are *ex-ante* identical, they choose different publication cycles in equilibrium. While a reduction in the fixed cost of publication yields shorter publication cycles, it may also intensify the competitive dynamics, which lead firms to differentiate further. Our analysis also informs publishers to strategically leverage exclusive content and publication cycles to navigate a digital transformation.

2 Learning to Commit

Martino Banchio, Giacomo Mantegazza, Stanford University, Stanford, CA

Sellers generally benefit from the ability to credibly commit to a sequence of prices. In this work we ask whether online learning algorithms can earn such credibility. In a durable-good monopoly problem, we argue that reinforcement learning procedures need to be able to assess the value of reputation in order to sustain time-inconsistent policies, and we show how well-known design choices learn reputation effectively. We consider a monopolist learning to price an inventory of durable goods for patient, strategic, and heterogeneous consumers. Sustaining high prices guarantees maximal revenues, but it is irrational when facing only low-value consumers. We show that an algorithm with sufficiently long time-horizon learns to attribute the revenues earned early in the game to high prices in later periods, thus effectively learning to commit.

2 Is Your Machine Better than You? You May Never Know

Francis de Véricourt, Huseyin Gurkan, ESMT GmbH, Berlin, Germany. Contact: huseyin.gurkan@esmt.org

Artificial intelligence systems are increasingly demonstrating their capacity to make better predictions than human experts. Yet, recent studies suggest that professionals sometimes doubt the quality of these systems and overrule machine-based prescriptions. This paper explores the extent to which a decision maker (DM) supervising a machine can properly assess whether the machine produces better recommendations. To that end, we study a set-up, in which a machine performs repeated decision tasks under the DM's supervision. In this set-up, we characterize the evolution of the DM's belief and overruling decisions over time and the conditions under which learning failures occur. We also explore how mistrusting the machine affects our results.

New Advances in Procurement and Project Management

General Session

Session Chair

Vibhuti Dhingra, 1</sup

1 When Does Price-based Sourcing Hurt Performance?

Beverly Osborn[1], John Gray[2], [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH,

Contact: osborn.259@osu.edu
Excessively price-based decision-making in sourcing can contribute to subpar performance and lead to undervaluing risks and social and environmental issues. In this empirical study, we find evidence that excessively price-based sourcing is a widespread problem, and our setting allows us to infer a potential solution.

2 Developing Coalitions of Complimentary Growers and Investors to Mitigate Price and Yield Variability and Offset Risk

Miguel Peinado-Guerrero, Rene Villalobos, Rodrigo Ulloa, Arizona State University, Tempe, AZ
Matching the production of fresh fruits and vegetables to the market's demand is, in general, a complex problem. From the viewpoint of small and medium growers, what to plant and when to plant is important in the face of yield and price variability when it comes time to harvest. From the viewpoint of buyers, responsible for the procurement of product for specific markets, deciding how to aggregate sufficient amounts is the challenge. We propose the development of optimization models that automate these tasks. In particular, these models consider the complementarity of different growing regions, the stochasticity of prices and yields, and the risk tolerance of the growers along with the use of external investment to offset this risk. By considering these elements, optimal coalitions of growers can be determined to meet specific buyer requirements.

3 Behavioral Implications of Bilateral Relationships on Supply Chain Contracting

Alper Nakkas[1], Lei Hua[2], Kay-Yut Chen[3], Xianghua Wu[4], [1]University of Texas at Arlington, Arlington, TX, [2]University of Texas at Tyler, Tyler, TX, [3]University of Texas at Arlington, Mansfield, TX, [4]College of business, University of Texas At Arlington, ARLINGTON, TX, Contact: nakkas@uta.edu
This paper investigates the impact of bilateral relationships on procurement and competition incentives in a supply chain environment from a behavioral perspective. We focus on a two-retailer-two-supplier networked market where retailers negotiate supply procurement contracts with their potential suppliers. We first derive the theoretical benchmark, which is the bargaining equilibrium outcome as a function of network structure, and then conduct a laboratory experiment to confirm the results. Our experimental data suggests systematic deviations and reveal behavioral regularities on contracting behavior. We develop a new behavioral model, referred to as desperateness model, where a firm's unfavorable bargaining position inflicts additional distress to the firm and show that the behavioral model explains the experimental data well.

1 Competition and Collaboration on Fundraising for Short-term Disaster Response: The Impact on Earmarking and Performance

Arian Aflaki[1], Alfonso J. Pedraza-Martinez[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]Indiana University, Bloomington, IN
Problem definition: Most humanitarian organizations (HOs) allow donors to earmark their donations, i.e., designate their contributions to a specific purpose. Allowing earmarking may increase donations, however, it creates operational inefficiencies that undermine the impact of those donations. Extant literature has mainly studied earmarking and its operational consequences in the absence of funding competition. We examine how competition for funding impacts earmarking decisions, fundraising costs, and HO performance in short-term disaster response. We also analyze two collaborative fundraising models: (i) full collaboration, where HOs contact donors as a unit and donors cannot donate to specific HOs on the fundraiser, and (ii) partial collaboration, where HOs contact donors as a unit and donors choose among the contacting HOs. Methodology/results: We use game theory to model the interactions between multiple HOs and a market of donors and build a multinomial logit model for the donor choice problem. We find that competition for funding contributes to the prevalence of earmarked donations, increases fundraising costs, and hurts HO performance and utility. We show the two collaborative fundraising models can mitigate these issues depending on the availability of funding resources. When funding is abundant, full collaboration improves HO utility and reduces earmarking and fundraising costs. When

funding is scarce, partial collaboration reduces fundraising costs and improves performance and HO utility. When funding is intermediate, these two forms of collaboration do not necessarily benefit HOs. Managerial implications: We illustrate how funding availability drives earmarking and fundraising decisions as well as key performance metrics of different funding models during short-term disaster response. Using data from the 2010 Haiti earthquake, our numerical study indicates that partial collaboration benefits response to under-funded mega-disasters, while full collaboration suits well-funded disaster response. HOs competing for funds can use our insights to improve their response effectiveness.

2 Interpretable Models for the Automated Detection of Human Trafficking in Illicit Massage Businesses

Margaret Tobey[1], Ruoting Li[1], Osman Ozaltin[1], Maria Esther Mayorga[1], Sherrie Caltagirone[2], [1]North Carolina State University, Raleigh, NC, [2]Global Emancipation Network, Orlando, FL

Illicit massage businesses (IMBs) frequently profit illegally from the labor and sexual exploitation of victim workers. To detect human trafficking in this area, we combine data from multiple internet sources and train two interpretable prediction models, risk scores and optimal decision trees, that can identify human trafficking risk factors and asses a level of risk for each business. We focus our analysis on data from open sources in Texas and Florida including customer reviews and business data from Yelp.com, the U.S. Census, and GIS files such as truck stop, highway, and military base locations. The proposed multi-source data-based approach and interpretable models can be used by stakeholders at all levels to save time and resources, serve victim workers, and support well-informed regulatory efforts.

3 Analysis of Farm Equipment Sharing in Emerging Economies

Olufunke Adebola[1], Priyank Arora[2], Can Zhang[3], [1]Hello Tractor, Abuja, Nigeria; [2]University of South Carolina, Columbia, SC, [3]Duke University, Durham, NC

In recent years, there is a growing number of farm equipment sharing platforms in emerging economies that help connect smallholder farmers with tractor owners who are willing to fulfill farmers' requests for mechanization services. Due to the small farm sizes and low digital literacy in many rural areas of emerging economies, these platforms often rely on the so-called "booking agents" to collect demand from individual farmers and submit the aggregated demand on the platform (rather than having individual farmers submit their service requests). In this paper, we study how the presence of booking agents affects the platform's optimal pricing and wage decisions, and how various interventions (e.g., from local governments or donor agencies) that focus on enhancing the supply- and demand-side of such platforms affect the equilibrium outcomes, such as the total surplus earned by farmers. In terms of practical impact, our insights have inspired changes in Hello Tractor's practice of setting the payout ratio (wage over price) for booking agents.

4 Split Liver Transplantation: An Analytical Decision Support Model

Yanhan (Savannah) Tang[1], Alan Scheller-Wolf[1], Sridhar R. Tayur[1], Emily R. Perito[2], John P. Roberts[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of California, San Francisco, San Francisco, CA

Split liver transplantation (SLT) is a procedure that potentially saves two lives using one liver, increasing the total benefit derived from the limited number of donated livers available. SLT may also improve equity, by giving transplant candidates who are physically smaller (including children) increased access to liver transplants. However, SLT is rarely used in the US. To help quantify the benefits of increased SLT utilization and provide decision support tools, we introduce a deceased-donor liver allocation model with both efficiency and fairness objectives. We formulate our model as a multi-queue fluid system, incorporating the specifics of donor-recipient size matching and patients' dynamically changing health conditions. Leveraging a novel decomposition result, we find the exact optimal matching procedure, enabling us to benchmark the performance of different allocation policies against the theoretical optimal. Numerical results, utilizing data from UNOS, show that increased utilization of SLT can significantly increase total quality-adjusted life years, reduce patient deaths, and improve fairness among different patient groups.

5 Combating Excessive Overtime in Global Supply Chains

Chuanya Jiao[1], Anyan Qi[2], Jiayu Chen[3], [1]University of Science and Technology of China, Hefei, China; [2]The University of Texas at Dallas, Richardson, TX, [3]University of Calgary, Calgary, AB, Canada.

Workers in developing economies may be forced to work excessive overtime, which causes mental and physical issues and results in brand damage to the buyers if exposed in public. We develop a game-theoretic model of a dyadic supply chain and analyze the buyer's strategies to combat excessive overtime, including auditing and cross-training. We derive equilibrium outcomes and study the interaction of the strategies and their impact on the degree of excessive overtime and social welfare.

Five Starter Pieces: Quantum Information Science via Semi-definite Programs

Tutorial Session

Session Chair

Mabel Chou, National University of Singapore, SG, SG, Singapore.

1 **Five Starter Pieces: Quantum Information Science via Semi-definite Programs**

Sridhar R. Tayur[1], Vikesh Siddhu[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Colorado, Boulder, CO

As the title indicates, this manuscript presents a brief, self-contained introduction to five fundamental problems in Quantum Information Science (QIS) that are especially well-suited to be formulated as Semi-definite Programs (SDP). We have in mind two audiences. The primary audience comprises of Operations Research (and Computer Science) graduate students who have familiarity with SDPs, but have found it daunt-ing to become even minimally conversant with pre-requisites of QIS. The second au-dience consists of Physicists (and Electrical Engineers) already knowledgeable with modeling of QIS via SDP but interested in computational tools that are applicable more generally. For both audiences, we strive for rapid access to the unfamiliar mate-rial. For the first, we provide just enough required background material (from Quan-tum Mechanics, treated via matrices, and mapping them in Dirac notation) and simul-taneously for the second audience we recreate, computationally in Jupyter notebooks, known closed-form solutions. We hope you will enjoy this little manuscript and gain understanding of the marvelous connection between SDP and QIS by self-study, or as a short seminar course. Ultimately, we hope this disciplinary outreach will fuel ad-vances in QIS through their fruitful study via SDPs.

Driving Change in Service Operations Through Flexibility and Data Analytics

General Session

Session Chair

Kenneth Moon, University of Pennsylvania, Philadelphia, PA

1 **How Customers Process Good and Bad Waiting Experiences: Identifying Compensating Experiences in Service Networks Using Machine Learning**

Peiran Xu, Kenneth Moon, University of Pennsylvania, Philadelphia, PA, Contact: peiranxu@seas.upenn.edu

Despite pervasively waiting to acquire goods and services, customers typically find waiting painful. Nonetheless, consumers are surprisingly willing to wait in long queues for popular restaurants, movie premieres, and the releases of fashion lines. Moreover, underappreciated research shows that a reasonable time spent waiting can, at times, enhance customer satisfaction. Retail destinations, including shopping centers and amusement parks, bring together numerous storefronts and attractions resulting in mixtures of positive and negative waiting experiences. Using causal analysis and machine learning (graph neural networks), we investigate the combined effects of such mixed waiting experiences on customer choices and overall satisfaction and explore their implications for retail marketplace design and event-based promotions.

2 **Battery as a Service: Flexible Electric Vehicle Battery Leasing**

Lingling Shi[1], Bin Hu[2], [1]University of Texas-Dallas, Richardson, TX, [2]University of Texas at Dallas, Richardson, TX, Contact: lxs171930@utdallas.edu

Inspired by the electric vehicle (EV) startup NIO which adopts a Battery-as-a-Service (BaaS) model with a swappable battery design and experiments with flexible battery up/downgrading, we study a flexible EV battery lease program where customers lease batteries of their chosen capacities with the option to temporarily up/downgrade to batteries of different capacities during peak periods. Adopting a game-theoretical model, we find that the manufacturer may depend on acquiring additional batteries or reallocating customers' batteries to satisfy the peak up/downgrade needs, and that flexible battery leasing can lead to win-win outcomes (increased manufacturer profit and reduced customer total cost) compared with simple battery leasing. These findings inform EV manufacturers adopting the BaaS business model and highlight the value of flexible battery leasing.

3 **Preventing Healthcare Worker Burnout Using Better Big Data**

Kenneth Moon, University of Pennsylvania, Philadelphia, PA

On-the-job stress, turnover, and burnout are significantly disrupting the staffing and productivity of healthcare workers. Across the U.S. hospital system, physician turnover and the hours lost to burnout cost an estimated $4.6B annually, or approximately $7600 per physician, whereas nursing turnover is even more endemic. In collaboration with 3 intensive-care clinics (ICUs) operating within the University of Pennsylvania hospital system, we deploy wearable biometric sensors on the ICU nursing staff to identify episodes of high-stress workflows. Specialized forms of reinforcement learning are used to train algorithms that suggest real-time interventions in staffing.

4 It Takes Two to Make It Right: How Nurses' Response to Sepsis Alerts Impacts Physicians' Process Compliance

Zahra Mobini[1], Mehmet U.S. Ayvaci[2], Ozalp Ozer[3], [1]The University of Texas at Dallas, Jindal School of Management, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX, [3]Amazon, Richardson, TX, Contact: zahra.mobini@utdallas.edu

We empirically examine how a clinical team, consisting of the two roles of nurse and physician, provides care in compliance with evidence-based standards using a sepsis alert system. In particular, we study whether and when nurses' timely response to sepsis alerts (i.e., acknowledging the alert and notifying physicians within a designated time frame) impacts physicians' compliance with sepsis care standards (i.e., performing diagnostic or treatment actions within a designated time frame). Using data from a hospital system in the US, we find that nurses' timely response to alerts has a positive spillover effect on physicians' compliance, and this effect becomes stronger as workload increases and weaker as the number of false alerts increases.

Recent Developments in Retail Operations

General Session

Session Chair

Necati Ertekin, University of Minnesota, Minneapolis, MN

1 Pricing Behavior and Fake Reviews on Online Marketplace

Ziwei Zhu[1], Saravanan Kesavan[2], Bradley R. Staats[3], [1]Cornell University, Ithaca, NY, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: zz575@cornell.edu

Online marketplaces have suffered from review fraud for a long time. Proliferation of fake reviews is generally recognized as a disruption to online marketplaces which undermines their operational efficiency. However, we focus on economic impact of fake reviews and provide the empirical evidence that fake review is a good signal to online marketplace. Specifically, high historical level of fake reviews is accompanied with low pricing strategy of sellers while customer utility maintains the same level or even increases. It implicitly shows that sellers make efforts to promote products at the cost of their own benefits, which is beneficial to both online marketplace and customers.

2 The Value of Last-mile Delivery

Zhikun Lu[1], Ruomeng Cui[2], Tianshu Sun[3], [1]Emory University, Atlanta, GA, [2]Emory University, Decatur, GA, [3]University of Southern California, Los Angeles, CA

We study the value of last-mile delivery in retail. This problem is not only important to online retailers, such as Amazon and Alibaba, but also to traditional businesses under digital transformation. Despite its growing importance and popularity, little empirical research has been done. To investigate this issue, we collaborate with Alibaba's logistics subsidiary, Cainiao. Cainiao has established more than one hundred thousand last-mile stations for customer pick-up. In December 2020, Cainiao launched its home delivery service. We leverage this quasi-experiment to evaluate the economic impact brought by last-mile delivery. Our difference-in-differences analysis shows that the provision of last-mile delivery significantly increases the sales and customer spending at Taobao, the Alibaba's online retail platform.

3 Communication Versus Notification in Last Mile Delivery

Natalie Epstein[1], Santiago Gallino[2], Antonio Moreno[3], [1]Harvard Business School, Cambridge, MA, [2]University of Pennsylvania, Philadelphia, PA, [3]Harvard Business School, Boston, MA

We conduct an experiment with a last mile logistics company to study the effect of changing the channel (from a notification to a communication channel) through which they tell clients their package is on its way. We study measures of the process such as failed delivery rates, duration of the delivery and customers' ratings.

MSOM/Healthcare Flash Session
Flash Session

Session Chair
Maria R. Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL

Session Chair
Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI

1 How Cannabis Legalization Affects Hospital Operations

Max Yakovlev[1], Maria R. Ibanez[2], [1]Kellogg School of Management, Evanston, IL, [2]Kellogg School of Management at Northwestern University, Evanston, IL, Contact: maksim.yakovlev@kellogg.northwestern.edu

Since Colorado and Washington became the first US states to legalize recreational cannabis sales to the public in 2012, 18 states and Washington, D.C. have followed. Approximately half of Americans live in a jurisdiction with legalized recreational cannabis. In our work, we investigate the effect of RCL (recreational cannabis legalization) on hospital operational metrics.

2 Multi-channel Healthcare: Impact of Telemedicine Adoption on Clinic Patient Flow

Sokol Tushe[1], Hao Ding[2], Diwas S. KC[1], Suephy Chen[3], Howa Yeung[1], [1]Emory University, Atlanta, GA, [2]Emory University, Decatur, GA, [3]Duke University, Durham, NC

This paper studies a multi-channel healthcare system where physicians can diagnose patients and prescribe treatment remotely or in-person. We find that telemedicine adoption leads to higher patient complexity in the in-person channel, corresponding to a 20% increase in visit time and an 8.5% increase in required clinical resources. In addition, the adoption of telemedicine results in a higher throughput rate. However, we find a significant reduction in average wait time for in-person appointments (37.5%), and for medically necessary procedures (43%). We attribute the improved efficiency to early patient triage and a reduction of setup and switching costs.

3 Machine Learning Methods Applied to Cancer Treatment Planning

Jacqueline Jil Vallon[1], Wanqiao Xu[1], Neil Panjwani[1], Xi Ling[1], Sush Vij[1], Sandy Srinivas[1], John Leppert[1,2], Mark Buyyounouski[1], Mohsen Bayati[1], [1]Stanford University, Stanford, CA, [2]Veterans Affairs Palo Alto Health Care System, Palo Alto, CA, Contact: jjvallon@stanford.edu

Cancer treatment planning is complex, requiring the integration of many parts. Traditional analyses to guide cancer treatment decisions have several shortcomings: 1) Models often only incorporate covariates readily available in the EMR. However, texts such as biopsy reports include rich covariates used in clinical practice but missed in analyses because of their unstructured nature. 2) Advanced machine learning (ML) models trade off variance by injecting bias to increase estimation accuracy, potentially recommending decisions inconsistent with clinical intuition. We study these challenges by applying recent ML methods to prostate cancer treatment planning.

4 Data-driven Workforce Planning for Healthcare Organizations

Sandeep Rath[1], Kumar Rajaram[2], [1]University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, [2]University of California-Los Angeles, Los Angeles, CA, Contact: sandeep_rath@kenan-flagler.unc.edu

Due to a multitude of demographic factors, the US healthcare system will face an acute shortage of healthcare professionals. Utilizing data-driven approaches for workforce scheduling will be one way to reduce stress on hospital systems and healthcare professionals. We will look at an application of data-driven optimization models for scheduling and planning of healthcare professionals for chronic care and operating rooms. These implementations have helped reduce healthcare costs, improve patient health outcomes, and given employees with more stable and predictable schedules.

5 The Behavioral Drivers and Operational Impact of Discretion

RJ Niewoehner[1], Bradley R. Staats[2], Diwas S. KC[3], [1]Kelley School of Business, Indiana University, Bloom, IN, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Emory University, Atlanta, GA, Contact: rniewoeh@iu.edu

Recent operations research acknowledges that agents in our operational systems have discretion to make decisions. Modeling this behavior requires assumptions, but these assumptions may induce gaps between models and real-world observations. In the end, these decisions coalesce firm-level outputs, both for good and ill. Despite this, deliberate system design can transform problematic deviance into productive discretion. In this presentation, I detail three explorations of system design and the operational impact of human discretion.

6 **Can Hospital Advertising Benefit Emergency Patients?**

Tae Jung Yoon[1], TI Tongil Kim[2], Simon Kim[2], [1]KAIST College of Business, Seoul, Korea, Republic of; [2]University of Texas at Dallas, Richardson, TX, Contact: taejung.yoon@kaist.ac.kr

U.S. hospitals have substantially increased spending on advertising. As for emergency patients, a common belief is that advertising may not be effective for them choosing a hospital. However, using hospital discharge data and hospital television advertising data from Florida, we find that hospital advertising actually affects emergency patients' choice of hospitals and increases their travel distance to hospital. We also observe that a higher patient death rate is associated with a higher level of hospital advertising. We further discuss heterogeneous responses of patients and implications of hospital advertising to determine whether it can ultimately benefit emergency patients.

7 **A Data-driven Analytical Framework for the Opioid Prescription Epidemic**

Alireza Boloori[1], Soroush Saghafian[2], Stephen Traub[3], [1]University of Washington, Tacoma, Tacoma, WA, [2]Harvard Univeristy, Cambridge, MA, [3]Brown University, Providence, RI, Contact: aboloori@uw.edu

Opioid epidemic is attributed to the over-prescription of opioid painkillers. Medical guidelines have urged healthcare providers to lessen opioid prescriptions in their medical practices. This, however, could negatively affect those patients who suffer from acute or chronic pain symptoms. Utilizing commercial insurance claims and encounters data, we (1) analyze the trade-off between the side effects and potential benefits of using pain treatments, and (2) provide an analytical framework that helps physicians in prescribing these treatments.

8 **Conditional Approval Vs. Discount Schemes for New Medical Treatments**

Ozge Yapar[1], Stephen E. Chick[2], Noah Gans[3], [1]Indiana University, Kelley School of Business, Bloomington, IN, [2]INSEAD, Fontainebleau, France; [3]University of Pennsylvania, Philadelphia, PA, Contact: oyapar@iu.edu

Healthcare payers often make reimbursement decisions under uncertainty. A common view is that uncertainty about the health-economic value of a treatment can be mitigated either by reducing the price or by executing a conditional approval scheme (CA). Under a CA, a treatment's reimbursement is conditioned on whether data captured after the treatment has entered the market can verify its value. But the design of CAs has not received much attention. Using a game-theoretic model, we find that the price offered during a CA's period of post-market data collection can drastically affect equilibrium outcomes; and that, contrary to the common view, price and uncertainty reduction may not be substitutes.

9 **Patient Pods in the Emergency Department: A Comparison of Patient-physician Assignment Systems**

Robert J. Batt[1], Brian W. Patterson[2], [1]Wisconsin School of Business, UW-Madison, Madison, WI, [2]Wisconsin School of Business, UW-Madison, Madison, WI, Contact: bob.batt@wisc.edu

We compare the operational performance of two emergency department patient-physician assignment systems. One system is a physician-choice system in which the physician chooses what patient to serve next. The second system is a hybrid nurse-assignment-physician-choice system in which a nurse assigns the patient to an attending physician, but resident physicians may choose which patients to serve. Key measures of interest include wait time, length of stay, physician throughput, and physician multitasking level. We find evidence of physician free-riding under the physician-choice scheme.

10 **Digital Footprints: How Smartphone Location Data Can Track Health Behaviors and Other Phenomena**

Elisa Frances Long, UCLA Anderson School of Management, Los Angeles, CA

Smartphone geolocation data are increasingly used in social science to study human decision-making and behavioral phenomena. I will summarize three recent studies related to political partisanship, healthcare worker networks, and compliance with COVID social distancing orders.

11 **Should Small Online Retailers Pay for Keyword Recommendations?**

Qiuxia Chen, Bin Hu, Elena Katok, The University of Texas at Dallas, Richardson, TX, Contact: Qiuxia.Chen@utdallas.edu

Small online retailers depend heavily on keywords to generate demand. There are professional services offering paid keyword recommendations. Should all retailers pay for such recommendations? We show that they should not all pay for such recommendations because it leads to intense competition. We then show that intentionally degrading some recommended keywords may actually increase demand for recommendations and improve recommenders' profit.

CC - Room 141

Bayesian Learning under Strategic Interactions

General Session

Session Chair

Jussi Keppo, National University of Singapore, Singapore, Singapore.

Session Chair

Yanwei Jia, Columbia University, New York, NY

1 Learning to Lend Under Adverse Selection

Yifan Feng, Jussi Keppo, National University of Singapore, Singapore, Singapore.

We consider a dynamic pricing problem for a lender who repeatedly interacts with a borrower who has private information about his own default probability and strategically decides whether to accept the loan offers. We show that if the lender can commit to a simple markup policy, then asymptotically the information rent can be entirely offset by the benefit of learning. In addition, if the lender is sufficiently patient, she always lends the first loan at a low rate, which contrasts the implications of a static Akerlof-type model.

2 The Wisdom of Strategically Diverse Crowds

Yanwei Jia[1], Jussi Keppo[2], Ville Satopaa[3], [1]Columbia University, New York, NY, [2]National University of Singapore, Singapore, Singapore; [3]INSEAD, Paris, France.

In this work, we consider the wisdom of the crowd and analyze predictions that are affected endogenously by the crowd composition. In particular, the individuals are assumed to have external motives, represented by different degrees of strategic complementarity (herding) or substitutability (anti-herding). We characterize the equilibrium behavior and prove that a weakly anti-herding crowd induces the best performance and that higher uncertainty about the crowd's strategic types reduces the individuals' accuracy. In crowds with two strategy types, the simple average judgment of a homogeneous crowd is always preferred to that of a diverse crowd. As an alternative, we propose a clustering-based procedure that identifies subgroups and leverages their different strategic motives with weighted averaging.

3 Can Echo Chambers Reduce Polarization?

James Siderius[1], Mohamed Mostagir[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]University of Michigan, Ann Arbor, MI, Contact: jpsiderius@gmail.com

We build a model of how users join communities on social media. Agents enter with pre-existing beliefs and interests, and decide to join a subset of communities most aligned with them; in doing so, their future beliefs evolve with the sentiment of the community. At the center of our model is the observation that several communities that peddle misinformation and extremism are echo chambers: they mostly consist of users who share similar ideologies repeating the same information to each other. We show that aggressive policies intended to limit the harm of echo chambers (e.g., through censorship) can lead to a higher adoption of misinformation and extreme ideas. We fully characterize the set of optimal interventions in both the short term and long term. Finally, we demonstrate our main ideas empirically using data from various quarantined and banned communities on Reddit.

4 Diversified Learning from Multiple Biased Sources

Xinyuan Zhang[1], Michael Jong Kim[2], Jussi Keppo[3], [1]Sauder School of Business, University of British Columbia, Vancouver, BC, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]National University of Singapore, Singapore, Singapore. Contact: xinyuan.zhang@sauder.ubc.ca

We consider a decision-maker (DM) who can acquire signals from multiple biased information sources to learn about a hidden state prior to making his decision. Unbiased signals are also available, but the acquisition cost is high. The DM dynamically chooses how to allocate a fixed budget across different sources to balance the trade-off between estimation error and acquisition cost. The problem is motivated by financial and healthcare applications where forecasting and decisions must be based on combining data from different biased sources. We formulate the problem as a Markov decision process and propose a Bayesian network model for the information structure. We solve the associated dynamic programming equations and characterize the optimal policy, which seeks to always diversify over different sources based on the posterior belief. We also run numerical experiments.

Platform and Marketplace Operations: Perspectives and New Directions

General Session

Session Chair
Omar Besbes, Columbia University, New York, NY

Session Chair
Yuri Fonseca, New York, NY

Session Chair
Ilan Lobel, New York University, New York, NY

1 Pricing Control and Regulation in Online Service Platforms

Gerard P. Cachon[1], Tolga Dizdarer[2], Gerry Tsoukalas[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Wharton, Philadelphia, PA, [3]Boston University, Boston, MA, Contact: gerryt@bu.edu

Motivated by Uber's recent decentralized driver-pricing practice in California we investigate how a platform with large supply should set its fares when service providers are heterogeneous in costs. We use a stylized model to compare two prevalent methods in practice: platform-pricing, where the platform sets the prices for all servers, and server pricing, where prices are defined by the competitive equilibrium of server decisions. We, then, compare these methods to an optimal contract.

2 Design of Resale Platforms and the Urban-rural Income Gap in India

Ilan Morgenstern[1], Daniela Saban[1], Divya Singhvi[2], Somya Singhvi[3], [1]Stanford University, Stanford, CA, [2]New York University, New York, NY, [3]USC Marshall School of Business, Los Angeles, CA, Contact: ilanmor@stanford.edu

We collaborate with a large online marketplace in India, which is focused on reselling. In this platform, users browse for products and share information about these to their contacts attempting to sell these products, from which users generate earnings. We analyze data from this marketplace and observe significant differences in earnings for users from rural vs. urban areas. To understand the relationships between the different factors that interplay in the platform that may be driving this observation, we develop an analytical model of a resale platform. Then, we calibrate the parameters of the model using granular orders data from our collaborator and, finally, we propose interventions to improve rural users' outcomes.

3 Improving Dispute Resolution in Two-sided Platforms: The Case of Review Blackmail

Yiangos Papanastasiou, University of California Berkeley, Berkeley, CA

This paper investigates the relative merits of different dispute resolution mechanisms in two-sided platforms, in the context of disputes involving malicious reviews and blackmail.

4 Pricing and Downstream Competition in Services Marketplaces

Omar Besbes[1], Yuri Fonseca[1], Ilan Lobel[2], Fanyin Zheng[1], [1]Columbia University, New York, NY, [2]New York University, New York, NY, Contact: yfonseca23@gsb.columbia.edu

We study demand estimation and pricing policies in two-sided marketplaces that operate in two stages. In the first stage, service providers purchase leads for opportunities/customers from an assortment provided by the platform. In the second stage, customers select a provider from those who applied. A match occurs if and only if both consumers and suppliers agree. We develop a model that accounts for providers being strategic about congestion in the second phase. Based on data from a large service marketplace, we show empirically that such strategic behavior is key and ignoring it leads to overestimation of the demand elasticity. We show how one may correct for it through the structural model we propose, and validate the model with a field experiment.

Logistics and Capacity Planning
General Session

Session Chair
Manoj Vanajakumari, 1</sup

1 E-commerce Order Fulfillment with Limited Time Window

Quan Zhou, Mehmet Gumus, Sentao Miao, McGill University, Montreal, QC, Canada. Contact: quan.zhou3@mail.mcgill.ca

E-commerce companies have seen significantly higher fulfillment expenditures and worsened logistics issues, and the COVID-19 pandemic has exacerbated the situation. We study the optimal fulfillment decision in a multi-warehouse-multi-location problem with increasing marginal fulfillment costs, unlimited inventory, and multi-period fulfillment time window. We show that an optimal fulfillment strategy for the problem follows a warehouse-wise state-dependent threshold policy. Purposely delay of some fulfillment is

valuable when demands are unlikely to exceed the threshold. Most of the benefits can be gained by incorporating a short-period fulfillment window.

2 Supply Chain Planning with Hybrid Cross-docks and Uncertain Demand

Haoying Sun[1], Manoj Vanajakumari[2], Chelliah Sriskandarajah[3], [1]University of Kentucky, Lexington, KY, [2]University of North Carolina Wilmington, Wilmington, NC, [3]Texas A&M University, College Station, TX, Contact: manojuv@uncw.edu

Our research is inspired by the subcontracting problem at a major oil field services company in North America. The company's supply chain consists of suppliers bringing raw materials Free Trade Zone (FTZ). FTZ serves as the stock consolidation point for the region. The company then breaks-bulk and ship materials to various plants using subcontractors (3PLs). Subcontractors charge by the weight of the shipping unit. The goal is to minimize the total inbound and outbound transportation costs and the total inventory management costs. The demand at each plant is stochastic. We derive theoretical solutions and performs robust optimization.

3 Covid-19 and Its Impacts on Hospital Operational Performance Measures

Yu Wang[1], David Cho[2], Allison Witman[1], [1]The University of North Carolina Wilmington, Wilmington, NC, [2]California State University, Fullerton, Fullerton, CA

Using data reported by the State of California Office of Statewide Health Planning and the U.S. Department of Health & Human Services, this research first empirically investigates how performance measures such as patient average length of stay are affected by COVID-19 for over 300 hospitals in California. A stylized model is then formulated to analyze operational strategies hospitals can adopt to manage capacity when facing overwhelming demand.

4 Congestion Dissipation in Global Supply Chain from Port Disruption

Ming Hu, Chaoyu Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: cyu.zhang@rotman.utoronto.ca

The pandemic era has experienced a significant amount of port congestion. Such congestion at one port spreads to another, leading to shipping delays and driving up costs for shippers. We build a fluid model to study how a disruption at a port would impact the disrupted port itself in one country and its counterpart port in another country. We fully characterize the transient dynamics such as backlogs of goods and ships during the whole recovery process. Then we identify a whipsaw (whiplash) effect that one port (two ports) will (take turns to) be hit with backlogs of ships over time as container ships sequentially visit the two ports during the recovery process.

Emerging Topics in Sustainable and Socially Responsible Operations

General Session

Session Chair

Hang Ren, George Mason University, Fairfax, VA

1 Impact of Social Learning on Consumer Subsidies and Supplier Capacity for Green Technology Adoption

Hang Ren[1], Tingliang Huang[2], Georgia Perakis[3], [1]George Mason University, Fairfax, VA, [2]Carroll School of Management, Boston College, Newton, MA, [3]Massachusetts Institute of Technology, Belmont, MA, Contact: hren5@gmu.edu

To incentivize consumer adoption of green-tech products (e.g., electric vehicles and solar roofs), governments typically offer consumers subsidies through rebates and tax credits. Apart from subsidies, customers' adoption decisions are usually also influenced by the word-of-mouth information about product quality from earlier adopters. In this paper, we analyze the impact of such social learning on the government's optimal subsidy design, considering a supplier's capacity decision. We find that social learning may reduce social welfare by dis-incentivizing the supplier's capacity investment and diluting the demand base with weak-preference customers. As a result, the government may decrease (increase) the subsidy level offered to earlier (later) adopters, resulting in an increasing subsidy path.

2 Drivers and Implications of Combined Investment in Renewables and Energy Storage in the Residential Sector

Na Rea Cho[1], Youngsoo Kim[1], Karthik Murali[2], Mesut Yavuz[1], [1]University of Alabama, Tuscaloosa, AL, [2]Oregon State University, Corvallis, OR, Contact: ncho3@crimson.ua.edu

We consider a grid-connected household's problem of determining the optimal capacities of solar and energy storage technologies to minimize its electricity costs when faced with time-of-use electricity prices and sellback credits. We identify the impact of household and market characteristics, as well as electricity pricing and technology subsidy policies on the levels of investment in these two technologies. We supplement our analytical results with a case study of two U.S. cities and identify policy guidelines pertaining to the role of electricity pricing and technology subsidization on the uptake of these technologies and the ensuing implications for residential customers, the environment, and reliability of the grid.

3 From Curtailed Renewable Energy to Green Hydrogen: Infrastructure Planning for Hydrogen Fuel-cell Vehicles

Long He[1], Nan Ke[2], Wei Qi[3], Hongcai Zhang[4], [1]George Washington University, Washington, DC, [2]National University of Singapore, Singapore, Singapore; [3]McGill University, Montreal, QC, Canada; [4]University of Macau, Macau, Macao. Contact: longhe@gwu.edu

In this paper, we study how to promote hydrogen fuel-cell vehicles (HFVs) adoption by deploying HFV infrastructure and utilizing renewable sources. We formulate a planning model that integrates transportation and power grid networks. Our model jointly determines the locations and capacities of hydrogen refueling stations (HRSs) and hydrogen plants, as well as power generation, electricity transmission and grid upgrade. Applying our model to the case of Sichuan, a province in China with abundant hydropower resources and a vast amount of hydropower curtailment, we discuss how the HFV infrastructure should be deployed to reach different levels of HFV adoption target. We also develop insights into the effectiveness of promoting HFVs in reducing hydropower curtailment and the benefit of grid modeling through numerical experiments.

4 On the Complementarity Between Servicizing and Remanufacturing: Economic and Environmental Implications

Xichen Sun[1], Tharanga Rajapakshe[2], Rogelio Oliva[1], [1]Texas A&M University, College Station, TX, [2]University of Florida, Gainesville, FL, Contact: xsun@mays.tamu.edu

The recent shift in customer demand from product ownership to more economically attractive alternatives has motivated manufacturers to offer servicizing - a business strategy that sells a product's functionality as a service. Using a stylized model, this study investigates the complementarity between servicizing and remanufacturing in terms of firms' economic and environmental performance. We show that under certain conditions, adopting servicizing may contract the remanufactured product market, harm the environment, or both.

Supply Chain Practice and Empirics
Contributed Session

Session Chair
Brian Petrus, Westminster College, New Wilmington, PA

1 Redesigning Consumer Goods Supply Chains: Too Late, too Expensive?

Miguel Suarez, SKEMA Business School, Paris, France. Contact: miguel.suarez@skema.edu

One of the main lessons of the COVID-19 pandemic is the urgent need to design smarter, stronger and more diverse supply chains. Whilst there is a plethora of academic frameworks about different types of supply chain strategies, a lack of empirical approaches about how to redesign a supply chain in a structured way is evident. Especially in the case of consumer goods supply chains, choice of an optimal supply chain strategy has been the object of mainstream research: They are to be lean on the supply side, agile on the demand side and on top of everything robust, too, as disruptions often decide between financial success and bankruptcy. However and in spite of high stakes related with the right choice and timely implementation of supply chain strategy, this paper shows that consumer goods companies need too long to redesign their supply chains and points out the reasons for that.

2 The More Flexible the Better? Impacts of Manufacturing Flexibility on Supply Chain Responsiveness and Variability

Karolay Yepes Buitrago, Betzabé Rodríguez, University of Puerto RIco, Mayaguez, PR, Contact: karolay.yepes@upr.edu

Supply chain flexibility has been considered a strategic capability for industries since it allows the chain to adapt to market needs. Still, flexibility could add unwanted variability. In this regard, how flexible a manufacturer needs to be? This study seeks to answer this question using a simulation approach to compare different flexible and non-flexible scenarios at the manufacturer level and evaluate the impact on responsiveness and variability in the supply chain. Lot size variation and machine capabilities are considered drivers of flexibility. A case inspired by the pharmaceutical industry is studied. The analysis provides managerial insights to determine the needed trade-off to achieve a viable flexibilization scheme without compromising process stability.

3 Pandemic and Global Supply Chain Exploration

Brian Petrus[1], Christie Nelson[2], Benjamin Nelson[2], [1]Westminster College, New Wilmington, PA, [2]Rutgers University, Princeton, NJ, Contact: petrusba@westminster.edu

We investigated global supply chain challenges and the path to normalization. We evaluated three scenarios: (i) global outbreak of Covid-19; (ii) uneven reopening and pandemic related recovery efforts; and (iii) Russian invasion of Ukraine. We examined the impact on consumer, industrial, and commodity sectors. We performed data-driven analysis of certain key factors, such as the availability of semiconductors.

Stochastic Mixed Integer Programming and Applications

General Session

Session Chair

Haoxiang Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China.

Session Chair

Cheng Guo, Clemson University, New York, NY

1 Incorporating Dantzig-Wolfe Decomposition into Branch-and-Cut by Cutting Planes

Rui Chen[1], Oktay Gunluk[2], Andrea Lodi[1], [1]Cornell Tech, New York, NY, [2]Cornell University, Ithaca, NY, Contact: rui.chen@cornell.edu

Dantzig-Wolfe (DW) decomposition is a well-known technique in mixed integer programming (MIP) for decomposing and convexifying constraints to obtain potentially strong dual bounds. We investigate Fenchel cuts that are derivable from DW decomposition and show that they can provide equally strong bounds as DW decomposition. These cuts in the primal space can be incorporated into a standard branch-and-cut algorithm to utilize the dual information obtained from DW decomposition. We test our approach on MIP problems where DW decomposition can efficiently provide strong dual bounds. Numerical results show that the proposed cuts are helpful for accelerating the solution of such problems under the branch-and-cut framework without the sophistication of implementing branch-and-price.

2 Stochastic Operations of Transmission Power Systems: Challenges and Benefits

Dahye Han[1], Mathieu Tanneau[1], Pascal Van Hentenryck[2], [1]Georgia Tech, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA

The growing penetration of renewable generation and distributed energy resources has led to increased operational uncertainty for transmission system operators. In that context, the talk discusses the value of stochastic optimization in the various stages of power systems operations. From day-ahead to real-time operations, the computational challenges and practical benefits of stochastic unit commitment and economic dispatch formulations are discussed. Numerical results are presented on real-life systems in the US and France.

3 Robust Optimization with Continuous Decision Dependent Uncertainty

Haoxiang Yang[1], Hongfan Chen[2], Andy Sun[3], [1]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]The Chinese University of Hong Kong, Hong Kong, China; [3]MIT, Catonsville, MD, Contact: yanghaoxiang@cuhk.edu.cn

We consider a robust optimization problem with continuous decision-dependent uncertainty (RO-CDDU). RO-CDDU has two main features: an uncertainty set with linear dependence on continuous decision variables and a convex piecewise linear objective function. We prove that RO-CDDU is NP-hard in general. To address the computational challenges, we reformulate RO-CDDU to an equivalent mixed-integer nonlinear program with a decomposable structure. Such an MINLP model can be further transformed into a mixed-integer linear program by enumerating the extreme points of the uncertainty set. We propose an alternating direction algorithm and a column generation algorithm to iteratively solve the MILP formulation. We conduct numerical studies of RO-CDDU on a demand response management problem in electricity markets and demonstrate promising computational performance.

Robust, Interpretable, and Fair Machine Learning

General Session

Session Chair
Phebe Vayanos, University of Southern California, Los Angeles, CA

Session Chair
sina Aghaei, USC, Los Angeles, CA

1 Strong Optimal Classification Trees

sina Aghaei, Andres Gomez, Phebe Vayanos, University of Southern California, Los Angeles, CA, Contact: saghaei@usc.edu

Decision trees are among the most popular and interpretable ML models. We consider the problem of learning optimal binary classification trees. Literature on the topic has burgeoned in recent years, motivated by the empirical suboptimality of heuristic approaches and the tremendous improvements in mixed- integer optimization (MIO) technology. Yet, existing MIO-based approaches from the literature rely on weak formulations, resulting in slow convergence and large optimality gaps. To fill this gap, we propose a flow-based MIO formulation which can accommodate side constraints to enable the design of interpretable and fair decision trees. We show that our formulation has a stronger linear optimization relaxation than existing methods.

2 Fair Optimization

Qing Ye, Weijun Xie, Virginia Tech, Blacksburg, VA, Contact: yqing1@vt.edu

This paper studies decision-making problems in presence of the group unfairness issues via an optimization lens. We introduce several fair optimization models and develop efficient algorithms to generate fair and efficient decisions. We apply the framework to a range of fair decision-making problems, including medical resource allocation and political redistricting.

3 Multistage Robust Classification with Fairness Constraints

Zhuangzhuang Jia[1], Grani Adiwena Hanasusanto[2], [1]The University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, Contact: zj2869@austin.utexas.edu

In this talk, we study the multistage fair classification problem where fairness is explicitly incorporated as a constraint in the training process. We use techniques from distributionally robust optimization to enhance the out-of-sample performance. More specifically, an ambiguity set centered around the empirical distribution via Wasserstein metric is employed to model the uncertainty. We get a conservative approximation for the worst-case equal opportunity unfairness measure. We show that our approximation is equivalent to a mixed-integer optimization problem that can be solved using off-the-shelf optimization solvers. We demonstrate that our model mitigates unfairness with a negligible drop in predictive accuracy on both synthetic and real datasets.

4 Odtlearn: A Python Package for Learning Optimal Decision Trees

Patrick Vossler[1], Sina Aghaei[2], Nathan Justin[2], Nathanael Jo[2], Phebe Vayanos[2], Andres Gomez[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: pvossler@usc.edu

We present the ODTlearn Python package for learning optimal classification trees via mixed-integer programming. The package provides classifiers for several settings including binary classification with fairness constraints, binary classification under adversarial perturbations to data features, and personalized treatment assignment. We provide a standardized API that can directly interact with the well-established scikit-learn API, making it easy to use with existing data analysis pipelines. In addition to the high-level API, the package provides access to the fitted binary tree and includes customizable visualization methods for each classifier. The ODTlearn source code is available under a permissive open-source license.

Data Driven Distributionally Robust Optimization
General Session

Session Chair
Kartikey Sharma, [1]</sup

1 Residuals-based Distributionally Robust Optimization with Covariate Information

Guzin Bayraksan[1], Rohit Kannan[2], Jim R. Luedtke[3], [1]The Ohio State University, Columbus, OH, [2]Los Alamos National Laboratory, Los Alamos, NM, [3]University of Wisconsin-Madison, Madison, WI, Contact: bayraksan.1@osu.edu

We consider data-driven approaches that integrate a machine learning prediction model within distributionally robust optimization (DRO), given limited joint observations of uncertain parameters and covariates. The approach uses residuals of the prediction/regression model to create a nominal distribution. We investigate asymptotic and finite-sample properties using Wasserstein, sample robust, and phi-divergence-based ambiguity sets within our DRO formulations, and explore cross-validation approaches for sizing these ambiguity sets. Numerical experiments validate our theoretical results, study the effectiveness of our approaches for sizing ambiguity sets, and illustrate the benefits of our DRO formulations in the limited data regime.

2 Fast Robust Classifiers for Data Streams

Kartikey Sharma, 1</sup

In this paper, we consider classification problems with streaming data that can be modeled by a time series for each class. Current methods for data streams require substantial re-computation after new observations. We develop a method that requires minimal effort to capture new information. For this, we extend the concept of Minimax Probability Machine (MPM) towards classifying data streams, and develop two algorithms: (i) The Adaptable Robust Classifier (AdRC), efficiently re-solves the MPM problem at every time step using updated moments. (ii) The Adjustable Robust Classifier (AjRC), adversarially learns the time series models and provides decision rules to adjust the classifier to new observations. Both methods are robust against the uncertainty inherent in time series. The performance of both of these methods is probed with numerical experiments.

3 Sequential Domain Adaptation by Synthesizing Distributionally Robust Experts

Bahar Taskesen, EPFL, Frankfurt am Main

Least squares estimators, when trained on a few target domain samples, may predict poorly. Supervised domain adaptation aims to improve the predictive accuracy by exploiting additional labeled training samples from a source distribution that is close to the target distribution. Given available data, we investigate novel strategies to synthesize a family of least squares estimator experts that are robust with regard to moment conditions. When these moment conditions are specified using Kullback-Leibler or Wasserstein-type divergences, we can find the robust estimators using convex optimization. We use the Bernstein online aggregation algorithm on the proposed family of robust experts to generate predictions for the sequential stream of target test samples.

4 Targeted Robustness in Minimizing Extreme Risks with Limited Data

Anand Deo, Karthyek Murthy, Singapore University of Technology and Design, Singapore, Singapore. Contact: karthyek_murthy@sutd.edu.sg

We introduce a new approach for robustifying objectives involving risk measures such as CVaR against the error introduced by "plugging-in" a model estimated from data. Differing from the conventional approach of hedging against the worst-possible element from an ambiguity set, the proposed estimator seeks to automatically cancel the bias introduced despite not knowing the nature of the error committed in the estimation step. This debiasing exercise is shown to lead to consistent decisions with exponentially fewer data samples than required by sample-average approximation. These findings add to the growing body of evidence on the effectiveness of targeted form of robustness towards tackling major challenges in "estimate, then-optimize" paradigm while optimizing under uncertainty.

Theory, Algorithms, and Applications of Multistage Optimization I

General Session

Session Chair

Shixuan Zhang, Georgia Institute of Technology, Atlanta, GA

Session Chair

Andy Sun, MIT, Catonsville, MD

1 Data-driven Multistage Distributionally Robust Optimization

Rui Gao, University of Texas at Austin, Austin, TX, Contact: rui.gao@mccombs.utexas.edu

We consider multistage distributionally robust optimization with nested distance. Due to the non-convexity of the uncertainty set, the resulting multistage distributionally robust problem is notoriously difficult to solve. Despite this challenge, we develop an equivalent dynamic programming reformulation. Our contributions are three-fold: (1) Modeling-wise, the dynamic programming reformulation unifies two different formulations for distributionally robust multistage problems. (2) Computation-wise, we identify conditions under which the robust Bellman recursion can be solved via tractable convex programs. (3) Algorithm-wise, we develop a stochastic dual dynamic programming algorithm and demonstrate its superior out-of-sample performance.

2 A Long-term Generation Expansion Planning Considering Emission Quotas Under Multiple Uncertainties

Anil Kaya[1], Steffen Rebennack[2], [1]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany; [2]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany. Contact: anil.kaya@kit.edu

We introduce a long-term stochastic power generation expansion model, considering multiple uncertainties. Our aim is to minimize the total cost including investment and expected operational costs during the planning horizon. Model is defined as a two-stage stochastic mixed-integer linear program which is solved by Benders decomposition algorithm. The master problem is a deterministic problem that computes investment and retirement decisions whereas the sub-problem is a multi-stage stochastic linear optimization problem that determines operational decisions under multiple uncertainties with emission constraints. The sub-problem is solved by a stochastic dual dynamic programming. Results are coupled with an agent-based electricity market simulation (AMIRIS). We present a case study for the German power system to illustrate the efficiency of our approach.

3 Multistage Stochastic Programs with a Random Number of Stages: Applications in Hurricane Relief Logistics Planning

Murwan Siddig[1], Yongjia Song[2], [1]RWTH Aachen University, Aachen, Germany; [2]Clemson University, Clemson, SC, Contact: yongjis@clemson.edu

We consider a logistics planning problem of prepositioning relief items in preparation for an impending hurricane landfall. This problem is modeled as a multiperiod network flow problem where the objective is to minimize the logistics cost of operating the network and the penalty for unsatisfied demand. We assume that the demand for relief items can be derived from the hurricane's predicted intensity and landfall location, which evolves according to a Markov chain. We consider a multistage stochastic programming model with a random number of stages and benchmark its performance with other approximation policies such as the static and rolling-horizon two-stage stochastic programming approaches. Our numerical results provide key insight into the value of multistage stochastic programming in disaster relief logistics planning.

4 Decentralized Gossip-based Stochastic Bilevel Optimization over Communication Networks

Xuezhou Zhang, Princeton University, Princeton, NJ, Contact: zhangxz1123@gmail.com

This work studies the setting of distributed bilevel optimization over a network where agents can only communicate with neighbors, with examples from multi-task, multi-agent learning and federated learning. We propose a gossip-based distributed bilevel learning algorithm that allows networked agents to solve both the inner and outer optimization problems in a single timescale and share information via network propagation. We show that our algorithm enjoys the $\cO(\frac{1}{K \epsilon^2})$ per-agent sample complexity for general nonconvex bilevel optimization, achieving a speedup that scales linearly with the network size. The sample complexities are optimal in both ϵ and K. We evaluate our algorithm on the tasks of hyperparameter tuning and decentralized reinforcement learning, and show that our algorithm achieves superior efficiency.

Theory and Applications of Global Optimization

General Session

Session Chair

Emily Speakman, University of Colorado Denver, Denver, CO

1 New Results in the Global Minimization of Molecular Potential Energy Functions

Anatoliy Kuznetsov[1], Nikolaos Sahinidis[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: akuznetsov3@gatech.edu

In this work, we introduce novel convexification techniques for minimization problems involving the Lennard-Jones potential, a common component of molecular potential energy functions. Additionally, we present optimality-based bounds on the inter-particle distances in Lennard-Jones clusters. In order to construct these bounds, we extend a known geometric argument by incorporating upper bounds on the global minima. We present an open-source implementation of these results, and demonstrate their impact using the Lennard-Jones cluster structure prediction problem as a benchmark with the global optimization solver BARON. Finally, we discuss extensions of our results to other molecular potential energy functions.

2 Optimal Recursive McCormick Linearizations for Multilinear Programs (MLP)

Arvind Raghunathan[1], Carlos Cardonha[2], David Bergman[3], Carlos Nohra[1], [1]Mitsubishi Electric Research Laboratories, Cambridge, MA, [2]University of Connecticut, Storrs, CT, [3]University of Connecticut, Waltham, Contact: raghunathan@merl.com

We consider development of strong Linear Programming (LP) relaxations of MultiLinear Programs (MLPs) or linearization of MLP. The LP relaxations are derived using Factorable Programming techniques introduced in the 1970s and implemented in state-of-the-art global optimization solvers. In this talk, we present two fundamental innovations to this linearization approach. First, we present a method for identifying the linearization that yields the smallest size LP relaxation for a given MLP. Second, we present a method for identifying the linearization that yields the best bound for a given LP size. Our results on a collection of benchmarks indicate that our formulation can find smaller linearizations (up to 30% reduction in number of variables) and tighter relaxations (30% reduction in the root-node optimality gaps).

3 A Novel Algorithm for Constructing Tight Quadratic Underestimators for Global Optimization

William Strahl[1], Arvind Raghunathan[2], Nikolaos Sahinidis[3], Chrysanthos E. Gounaris[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Mitsubishi Electric Research Laboratories, Cambridge, MA, [3]Georgia Institute of Technology, Atlanta, GA, Contact: wstrahl@andrew.cmu.edu

Global optimization algorithms extensively utilize polyhedral outer approximations of convex relaxations to compute lower bounds. Noting recent improvements in algorithms for solving quadratically constrained quadratic programming problems, we introduce quadratic non-linearity into outer approximation methods at the prospect of computing tighter bounds. We present an algorithm to construct quadratic outer approximators for twice differentiable convex functions and non-convex difference of convex functions. Using function and optimization problem examples extracted from global optimization benchmark libraries, we demonstrate the quality of the quadratic underestimators and evaluate the root-node lower bounds they provide.

4 Using Volume to Compare Polyhedral Relaxations: What Has Been Done so Far?

Emily Speakman, University of Colorado Denver, Denver, CO, Contact: emily.speakman@ucdenver.edu

Volume has been used in the literature as a measure to compare alternative relaxations in the context of mixed-integer linear and nonlinear optimization. Here, we consider various results obtained for polyhedral relaxations and discuss techniques to extend and generalize these results. We will present ongoing work in this area and identify possible directions for further research.

Network and Graph Optimization

Contributed Session

Session Chair

Hamish Thorburn, Lancaster University, Lancaster, United Kingdom.

1 Multi-visitor Trip Planning with Activity Reservations in Crowded Destinations

Joris Slootweg, CWI, Amsterdam, Netherlands. Contact: joris.slootweg@cwi.nl

In our study we plan leisure trips in congested areas for visitors with heterogeneous preferences and with reservations for activities. We develop an algorithm that through a combination of customization and coordination can improve average user satisfaction considerably. Numerical experimentation and a case study show that our algorithm outperforms the classical First-Come-First-Served reservation policy both in terms of user happiness, and in terms of fairness among visitors. Moreover, our results show that our algorithm leads to good solutions compared to optimal for small-sized instances. Finally, the computational effort with regard to number of visitors is bounded by the capacity and the number of events, while the increase in computation time for the number of attractions is bounded by the average number of activities that fit into a trip.

2 Graph Reduction and Row Generation Schemes for Finding Maximum Independent Set

Dongwoo Kang, Hong Seo Ryoo, Korea University, Seoul, Korea, Republic of. Contact: towarmer@korea.ac.kr

An Independent set in a graph is a set of vertices that are pairwise not adjacent. The maximum independent set (henceforth, MIS) problem is an optimization problem to find the largest independent set in a graph, which is well-known to be NP-complete. For finding an MIS of a large and dense graph, we develop a graph reduction/simplification scheme that corresponds to row generation in a corresponding optimization problem based on edge information and optimality criteria. More specifically, we reduce the original graph into a weighted graph of disjoint independent sets, each of which represents a key relation with regard to maximum cardinality. This allows one to find an MIS in a graph on smaller-size, weighted graphs obtained from the original one. We demonstrated the efficacy and efficiency of our new results with benchmark and randomly generated graphs.

3 Staff Allocation in Multicommodity Processing Facilities Using Network Design Models

Hamish Thorburn, Anna-Lena Sachs, Jamie Fairbrother, John Boylan, Lancaster University, Lancaster, United Kingdom. Contact: h.thorburn@lancaster.ac.uk

Many facilities involve sequential processing of different materials. Often these materials need to pass through different work areas to be processed. Adequate staff levels in these facilities is essential, as delays upstream affect processing downstream. Furthermore, it is beneficial to shift managers to minimise staff allocated (to reduce costs) and beneficial to workers to minimise shift changes (for convenience). We use a network design model to set appropriate staff levels, and apply this model to a mail centre. We solve this model using a mixed-integer programming formulation, minimising both total staff allocated and number of changes in a shift. The two objectives are balanced by minimising a weighted linear combination of the objectives, with weights set to prioritise one objective over the other. Our results improve on those used in practice on both objectives.

The Power of Adaptivity in Learning and Decision-making

General Session

Session Chair

Rohan Ghuge, University of Michigan, Ann Arbor, MI

1 A Sharp Memory-regret Trade-off for Multi-pass Streaming Bandits

Arpit Agarwal[1], Sanjeev Khanna[2], Prathamesh Patil[2], [1]Columbia University, New York, NY, [2]University of Pennsylvania, Philadelphia, PA, Contact: arpit.agarwal@columbia.edu

The stochastic K-armed bandit problem has been studied extensively due to its wide-ranging applications such as online advertising, clinical trials etc. Motivated by applications where the number of arms can be massive, we consider a streaming setting where the arms are presented in a stream and the algorithm uses limited memory to process these arms. We establish tight upper and lower bounds on the trade-off between memory and regret when B passes over the stream are allowed, for any B≥1. Our results uncover a surprising *sharp transition phenomenon*: O(1) memory is sufficient to achieve \tilde{?}(T^{1/2+1/(2^{B+2}-2)}) regret in B passes, and increasing the memory to any quantity that is o(K) has almost no impact on further reducing this regret.

2 The Pandora's Box Problem with Sequential Inspections

Ali Aouad[1], Jingwei Ji[2], Yaron Shaposhnik[3], [1]London Business School, London, United Kingdom; [2]USC, Los Angeles, NY, [3]University of Rochester, Rochester, NY, Contact: yaron.shaposhnik@gmail.com

The Pandora's box problem is a core model in economic theory that captures an agent's (Pandora's) search for the best alternative (box). We study an important generalization of the problem where the agent can either fully open boxes for a certain fee to reveal their exact values or partially open them at a reduced cost. This introduces a new tradeoff between information acquisition and cost efficiency. We employ an array of techniques in stochastic optimization to provide a comprehensive analysis of this model and show that intuitive threshold-based policies that extend the Pandora's box optimal solution provide very effective solutions.

3 Instance-optimal PAC Algorithms for Contextual Bandits

Zhaoqi Li, University of Washington, Seattle, WA, Contact: zli9@uw.edu

In the stochastic contextual bandit setting, regret-minimizing algorithms have been extensively researched, but their instance-minimizing best-arm identification counterparts remain seldom studied. In this work, we focus on the stochastic bandit problem in the PAC setting: given a policy class, the goal of the learner is to return a policy whose expected reward is approximately that of the optimal policy with high probability. We characterize the first instance-dependent PAC sample complexity of contextual bandits, and provide matching upper and lower bounds. We show that no algorithm can be both minimax-optimal for regret minimization and instance-dependent PAC for best-arm identification. Our main result is a new instance-optimal and computationally efficient algorithm that relies on a polynomial number of calls to a cost-sensitive classification oracle.

4 Batched Dueling Bandits

Arpit Agarwal[1], Rohan Ghuge[2], Viswanath Nagarajan[2], [1]Columbia University, New York, NY, [2]University of Michigan, Ann Arbor, MI

The K-armed dueling bandit problem, where the feedback is in the form of noisy pairwise comparisons, has been widely studied. Previous works have only focused on the sequential setting where the policy adapts after every comparison. However, in many applications such as search ranking and recommendation systems, it is preferable to perform comparisons in a limited number of *parallel batches*. We study the *batched K-armed dueling bandit* problem under two standard settings: (i) existence of a Condorcet winner, and (ii) strong stochastic transitivity and stochastic triangle inequality. For both settings, we obtain algorithms with a smooth trade-off between the number of batches and regret. Our regret bounds match the best known sequential regret bounds (up to poly-logarithmic factors), using only a logarithmic number of batches.

1 Strategies for Non-myopic Bayesian Optimization

Darian Nwankwo, Cornell University, Ithaca, NY

Several strategies for myopic Bayesian optimization have been proposed where the immediate reward is maximized. Myopia isn't inherently bad; rather than under-weighting future consequences, we ignore them altogether. Non-myopic Bayesian optimization aims to resolve these issues by using "lookahead" algorithms that maximize a reward over a finite horizon. In this work, we provide a novel formulation for constructing non-myopic heuristics using well-tested myopic heuristics as building blocks. Our formulation creates a family of non-myopic acquisition functions that is highly parametric; the choice of "base acquisition function" and horizon creates this familial space.

2 Robust Matrix Completion with Heavy-tailed Noise

Bingyan Wang, Princeton University, NJ

We study how to estimate an underlying low-rank matrix given a set of highly incomplete entries with heavy-tailed noise. Toward this end, we adopt Huber loss which is robust against large errors when the parameter is carefully designed to balance the Huberization biases and robustness. Then, we propose an efficient nonconvex algorithm via a low-rank matrix factorization with gradient decent with robust spectral initialization. We prove that under bounded second moment condition on the error distribution, the Euclidean error of the iterates generated by the algorithm decrease geometrically fast until achieving a minimax-optimal estimation error, which has the same order as the sub-Gaussian case.

3 Random-key Optimization - Problem Independent Solvers for Combinatorial Optimization

Mauricio G. C. Resende[1], Martin Schuetz[2], Kyle Brubaker[3], Helmut Katzgraber[4], [1]Amazon.com, Inc., Bellevue, WA, [2]AWS, New York, NY, [3]AWS, San Diego, CA, [4]AWS, Seattle, WA

A random key is a randomly-generated real number in the interval (0,1]. A vector of random keys X is a vector of N random keys. A solution to a combinatorial optimization problem can be encoded as a vector of random keys. Given X, a decoder is a deterministic algorithm that takes X as input and outputs a solution to the optimization problem. As an example, consider the decoder that sorts the keys in X and outputs the indices of the sorted vector of random keys. Any solution represented as a permutation (e.g., TSP) can be recovered with this decoder. A Random-Key Optimizer (RKO), which operates in the space of the random keys and uses a decoder to evaluate solutions, is problem independent. Given an RKO one needs only to implement a decoder to apply the algorithm to a specific problem. An example of an RKO is the Random-Key GA of Bean (1994). In this talk we present other examples of RKOs.

4 Exploration of Power Demand Spatial Patterns Using Unsupervised Learning

Alfredo Oneto[1], Paolo Gabrielli[1], Giovanni Sansavini[2], Filippo Tettamanti[1], Blazhe Gjorgiev[1], [1]ETH Zurich, Zurich, Switzerland; [2]ETH Zurich, Zurich, Switzerland. Contact: aalfredo@ethz.ch

"Distribution grid data is crucial to assess the ability of the distribution grids to accept new loads and distributed sources in the light of the energy transition. However, getting reliable distribution grid data remains a challenge. Consequently, many researchers use generic data sets. Unsupervised learning has been identified as a promising approach to tackle this problem because it does not require prior knowledge of the power grids. This work proposes a novel method that identifies supply zones for power demand, which are used to derive country-wide distribution grid models using state-of-the-art routing schemes."

5 Towards Robust Cyber Vulnerability Management

Soumyadeep Hore, Ankit Shah, University of South Florida, Tampa, FL, Contact: soumyadeep@usf.edu

Vulnerability management is a critical task performed by Cyber Security Operations Centers (CSOC), which consists of vulnerability prioritization and mitigation. Researchers have explored triage methods by modeling the vulnerability selection for mitigation as a deterministic optimization problem. However, the vulnerability arrival and mitigation processes are highly stochastic due to the uncertainty in both the number and type of arrivals, as well as the time required to mitigate them. Hence, it is critical to model uncertainty in optimizing vulnerability management at a CSOC. In this talk, we present novel modeling and solution approaches for solving this problem under uncertainty.

6 Performance Enhancement Program Framework for Convex Smooth Optimization

Yunheng Jiang, Clemson University, Clemson, SC

We derived new parameters by studying the Performance Enhancement Program framework for convex smooth optimization.

7 Explaining Adverse Actions in Credit Decisions Using Shapley Decomposition

Vijayan N. Nair[1], Tianshu Feng[2,1], Linwei Hu[1], Zhanyang Zhang[1], Jie Chen[3], Agus Sudjianto[1], [1]Wells Fargo, Charlotte, NC, [2]George Mason University, Fairfax, VA, [3]Wells Fargo, San Francisco, CA, Contact: tfeng@gmu.edu

When a financial institution declines an application for credit, an adverse action (AA) occurs. The applicant is then entitled to an explanation for the negative decision. This work focuses on credit decisions based on predictive models for the probability of default and proposes a methodology for AA explanation. The problem involves identifying the important predictors responsible for the negative decision. In this work, we consider models with low-order interactions and develop an intuitive approach based on first principles. We show how the methodology generalizes to the well-known Shapely decomposition and the concept of Baseline Shapley (B-Shap). Compared with other Shapley techniques for the local explanation of machine learning outputs, B-Shap is more computationally tractable. An illustrative case study is used to demonstrate the usefulness of the method.

1 Risk-adjustable Chance Constrained Programs with Right-hand Side Uncertainty Using Wasserstein Metric

Yiling Zhang, University of Minnesota, Minneapolis, MN, Contact: yiling@umn.edu

In this presentation, we will talk about distributionally robust chance constraints with random right-hand side (RHS) under Wasserstein ambiguity. The risk tolerance of the chance constraints, instead of being predetermined, is treated as a decision variable, and the objective trades off the risk and the cost of other variables. For discrete distributions, based on efficient points, the problem is formulated as mixed-integer programs where binary variables are used for determining optimal risk tolerance. For continuous distributions, the problem is formulated as mixed conic programs which can be enhanced by valid inequalities via utilizing submodularity. We specify the solution approaches for a demand response problem where chance constraints are used to ensure the probability of consuming renewable energy efficiently.

2 Eliminating Waste in Cadaveric Organ Allocation

Peng Shi, Junxiong Yin, University of Southern California, Los Angeles, CA, Contact: junxiong.yin@marshall.usc.edu

There is a shortage in the supply of cadaveric organs in most countries, but many successfully procured and medically tenable organs are being discarded. Many reforms have been or are currently being implemented to address the wastage problem. However, we show that waste will still be a problem as long as the allocation mechanism continues to prioritize patients by their waiting times, which incentivizes patients to reject organs of reasonable quality now to wait for better offers in the future. Through analyzing a theoretical model, we show the necessary and sufficient conditions to eliminating waste and highlight that eliminating waste may inevitably hurt certain patients' welfare.

3 A Decomposition Framework for Solving Gas Network Expansion Optimization

Yijiang Li[1], Santanu Subhas Dey[1], Nikolaos Sahinidis[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: yijiangli@gatech.edu

Gas networks are used to transport natural gas which is an important resource for both residential and industrial customers in the United States. A few types of gas network problems have been studied and the physical properties of the networks generally lead to challenging nonlinear and non-convex optimization tasks. In this paper, we propose a decomposition framework and study the expansion of gas networks. In particular, we focus on the so-called design from scratch problem and utilize a two-stage procedure that involves a convex reformulation of the original problem. We conduct extensive experiments on a benchmark network to validate the performance of our approach.

4 An Extended Formulation of the Uncapacitated Facility Location Problem and Its Polyhedra

Ishwar Murthy, Indian Institute of Management Bangalore, Bangalore, India. Contact: ishwar@iimb.ac.in

We present and extended formulation of the Single Source Uncapacitated Facility Location Problem that incorporates cardinality of the customer set assigned to facility. In this formulation, potential facility location variables as well as variables describing assignment of customers to facilities are disaggregated into n possible cardinalities. We first show that all non-trivial facets of the polytope can be described by 0-1 coefficients for variables representing assignment of customers to facilities. This greatly simplifies the identification of such facets. We next present all structures of these non-trivial facet inequalities, called p-Agent Cardinality Matching Inequalities. This then comprehensively describes the polytope.

5 Models and Algorithms for Stadium Seating Problem

Saharnaz Mehrani, Carlos Henrique Cardonha, David Bergman, University of Connecticut, Storrs, CT

We present models and algorithms for stadium-seating problems, which concern with seat-assignment of multiple small groups of people in a layout with seats aligned in consecutive rows, facing the same direction, with the goal to maximize people's utility. We present different evaluation metrics that consider different utility functions for the attendees. Under these evaluation metrics, we show the performance of our proposed optimization algorithms (exact and heuristic) on a set of randomly generated instances as well as on a real-world instance from a charity organization.

6 Faster Matchings via Learned Duals

Michael Dinitz[1], Sungjin Im[2], Thomas Lavastida[3], Benjamin Moseley[4], Sergei Vassilvitskii[5], [1]Johns Hopkins University, Baltimore, MD, [2]University of California, Merced, Florence, CA, [3]University of Texas at Dallas, Dallas, TX, [4]Carnegie Mellon University, Pittsburgh, PA, [5]Google, New York, NY

A recent line of research investigates how algorithms can be augmented with machine-learned predictions to overcome worst case bounds. This has revealed algorithmic insights into problems, with particular success in the design of online algorithms. We consider improving running times with predictions by combining the idea of machine-learned predictions with that of ``warm-starting" primal-dual algorithms for weighted bipartite matching. We identify and solve three key problems when using learned dual variables, yielding an efficient learning-augmented algorithm for weighted bipartite matching. We validate our theoretical findings through experiments on both real and synthetic data.

7 An Exact Method for the Capacitated Vehicle Routing Problem with Cross Docking

Albert Schrotenboer[1], Tom Van Woensel[2], David Lai[3], Jian Zhang[4], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Mb Eindhoven, Netherlands; [3]Eindhoven University of Technology, Amsterdam, Netherlands; [4]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: a.h.schrotenboer@tue.nl

Realizing that the depot is readily available location for the temporary storage of orders in practice, this paper presents several exact methods for solving the so-called vehicle routing problem with flexible cross docking options. We explicitly allow each order to either be crossdocked or to be transported without consolidation via the crossdock.

8 A Heuristic for a Multiple Depot Heterogeneous Autonomous Vehicle Routing Problem Considering Workload Balance

Jung Yun Bae[1], Abhishek Patil[2], Myoungkuk Park[2], [1]Michigan Technological University, Houghton, MI,

[2]Michigan Technological University, Houghton, MI, Contact: bae@mtu.edu
While the heterogeneity in multi-vehicle systems is challenging due to the heavy computational load increase on the algorithms, this research aims to develop a heuristic that provides good approximate solutions within a reasonable time. Given autonomous vehicles with different (average) running velocities and load capacities, the heuristic solves that vehicles depart from distinctive depots, visit all given targets and return to the depots while considering workload balancing. The problem is a generalization of the Traveling Salesperson Problem (TSP) and NP-hard. A hierarchy heuristic is proposed based on the primal-dual technique. The algorithm relaxes capacity constraints and solves a min-max multiple depot heterogeneous TSP. The jobs that violate capacity constraints are redistributed to the available vehicles from the relaxed solution.

1 Information Preferences of Individual Agents in Linear-quadratic-gaussian Network Games
Furkan Sezer[1], Ceyhun Eksin[2], [1]Texas A&M University-College Station, College Station, TX, [2]Texas A&M University, College Station, TX
We consider linear-quadratic-gaussian network games in which agents have quadratic payoffs that depend on their own and neighbors' actions, and an unknown payoff-relevant state. An information designer determines the fidelity of information revealed to the agents about the payoff state to maximize the social welfare. In this paper, we provide conditions based on the strength of the dependence of payoffs on neighbors' actions under which a rational agent is expected to benefit from optimal solution of full information disclosure. We find that all agents benefit from information disclosure for the star network structure when the game is symmetric and submodular or supermodular. We also identify that the central agent benefits more than a peripheral agent from full information disclosure unless the competition is strong and the number of peripheral agents is small enough.

2 Approximate Submodularity of Maximizing Anti-coordination in Network Games
Soham Das, Ceyhun Eksin, Texas A&M University, College Station, TX, Contact: soham.das@tamu.edu
We consider decentralized learning dynamics for agents in an anti-coordination network game. Agents' utilities playing their preferred actions decrease as more neighbors adopt it, potentially causing agents to select less desirable actions. We measure anti-coordination by the number of edges in the underlying graph that have at least one agent on either end not taking the preferred action on convergence. The MAC problem seeks to find an optimal set of agents to control so that the overall network disconnect is maximized. We show that MAC is approximately submodular in line networks, using which we motivate and derive a performance guarantee for a greedy agent selection algorithm. We further establish average submodularity of MAC for dense bipartite graphs. Finally, we show computationally the effectiveness of greedy strategies to solve MAC on general bipartite networks.

3 Optimal Information Provision for Strategic Hybrid Workers
Sohil Shah[1], Saurabh Amin[2], Patrick Jaillet[3], [1]MIT, Madison, WI, [2]MIT, Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: sshah95@mit.edu
We study a strategic planner (SP) who signals about an uncertain infectious risk parameter. Signals affect public belief over the parameter, and hybrid workers then choose where to work. The SP seeks certain outcomes for each realization of the uncertain parameter and maximizes the probability that agents choose such an outcome for the true parameter. If the set of outcomes is invariant to the risk parameter, we derive the optimal signalling mechanism and show that it partitions the parameter domain into at most two intervals with the signals generated by interval-specific distributions. We also solve for the optimal signalling mechanism using a linear program in a situation where the SP seeks to enforce progressively more stringent in-person work capacity limits as the risk parameter increases.

4 Attraction-based Congestion Pricing Method in Monopolistic and Monopolistic Competitive Markets
Li Qinxu[1,2], Sun Zhanbo[1,2], Zhu Baichuan[1,2], [1]Southwest Jiaotong University, Chengdu, China; [2]National Engineering Laboratory of Integrated Transportation Big Data Application Technology, Chengdu, China. Contact: chacylee@my.swjtu.edu.cn
A novel attraction-based pricing (ABP) scheme is proposed to manage traffic demand and alleviate negative traffic externalities. Under ABP, the attraction sites are charged for

causing congestion, and the tolls are (partially) transferred to travelers. The Stackelberg model are used to investigate the impacts. The lower-level in both cases is a route choice model that considers attraction sites' attractiveness and generalized travel cost. In a monopoly market, the upper-level maximizes the total profit of all attraction sites. In a monopolistic competitive market, the noncooperative game among attraction sites is described using variational inequality. The proposed scheme is validated using an illustrative network. Results show that *ABP* is effective in balancing traffic demand and reducing road congestion, without affecting the profits of the attraction sites.

Disjunctive Constraints and Cutting Planes

General Session

Session Chair

Bochuan Lyu, Rice University, Houston, TX

Session Chair

Illya V. Hicks, Rice University, Houston, TX

1 Deepest Cuts for Benders Decomposition

Mojtaba Hosseini[1], John G. Turner[2], [1]Tippie College of Business, University of Iowa, Iowa City, IA, [2]University of California - Irvine, Irvine, CA

Benders Decomposition (BD), is a prevalent method for tackling challenging large-scale problems that lie at the heart of operations research. The key element in effective implementation of BD is the derivation of Benders cuts. We introduce a novel unifying Benders cut selection technique based on a geometric interpretation of cut "depth". Leveraging the duality between separation and projection, we develop a Guided Projections Algorithm for producing deepest cuts while exploiting the combinatorial structure or decomposability of problem instances. Through a generalization, we also provide systematic ways of selecting the normalization coefficients in the Minimal Infeasible Subsystems method. As a proof of concept, we demonstrate that deepest cuts often reduce both runtime and number of Benders iterations, as compared to other cut selection strategies.

2 Modeling Combinatorial Disjunctive Constraints via Junction Trees

Bochuan Lyu[1], Illya V. Hicks[1], Joey Huchette[2], [1]Rice University, Houston, TX, [2]Google Research, Mountain View, CA, Contact: bl46@rice.edu

In this work, we study the independent-branching (IB) framework of combinatorial disjunctive constraints (CDCs) and identify a class of pairwise IB-representable CDCs: combinatorial disjunctive constraints admitting junction trees. For this class of constraints, the existence of junction trees can be recognized in polynomial time. We also present a polynomial-time heuristic algorithm for the minimum biclique cover problem on the associated conflict graphs to build small and strong MIP formulations. Additionally, we apply the heuristic to find smaller MIP formulations of generalized special ordered sets with fewer variables and constraints than the existing results.

3 A Combinatorial Disjunctive Constraint Approach to Optimal Footstep Planning

Raul Garcia, Rice University, Houston, TX, Contact: rg66@rice.edu

A central modeling primitive in mathematical optimization is the disjunctive constraint: any feasible solution must satisfy at least one of some finite collection of alternatives. One approach for constructing small, ideal formulations for these is the independent branching scheme, in which the disjunctive constraint is represented in terms of a series of simple choices. In this talk we apply the independent branching scheme framework in the context of footstep planning where each footstep is assigned to one of several polyhedral obstacle-free regions in the plane. Such a formulation requires a biclique cover of an associated graph, with smaller covers resulting in a smaller problem. While the minimal biclique cover problem is NP-complete, we apply a planar separator algorithm in a divide-and-conquer manner to obtain a biclique cover in polynomial time.

1 Performance Comparison of Hydrogen Fuel Cell Drones with Battery Drones for Truck-and-drones Last Mile Delivery System

Jayasurya Ragupathi, Purdue University, West Lafayette, IN, Contact: jragupat@purdue.edu

Hydrogen Fuel Cells are abundant and cleaner sources of energy. Hydrogen Fuel Cell Delivery Drones are much more efficient than battery drones because they have better endurance and payload capacity. This research focuses on comparing the performance of Hydrogen and Battery Delivery Drones for a truck-drone last mile delivery system. The last mile delivery system is modeled as a two-echelon vehicle routing problem with drones where multiple drones are launched from the truck to serve one or more customers. A Mixed Integer Programming model is formulated with an objective to minimize the total time of delivery of both trucks and drones for small/medium customer instances and heuristic algorithms are used to solve for large-size customer instances. A sensitivity analysis is conducted to show delivery time improvements of hydrogen drones over battery drones.

2 Nested Vehicle Routing Problem: Optimizing Drone-Truck Surveillance Operations

Fanruiqi Zeng, Georgia Institute of Technology, Atlanta, GA

We address the coordinated routing of a drone-truck pairing where the drone travels to multiple locations to perform specified observation tasks and rendezvous periodically with the truck to swap its batteries. We develop a MIQCP formulation with critical operational constraints, including drone battery capacity and synchronization of both vehicles during scheduled rendezvous. An enhancement of the MIQCP model is achieved by deriving the equivalent MILP formulation as well as leveraging lifting and Reformulation-Linearization techniques to strengthen the subtour elimination constraints of the drone. We propose an efficient neighborhood search (NS) heuristic. We envision that this framework will facilitate the planning and operations of combined drone-truck missions.

3 Crowd-based Intra-city Service Network Design

Ozgur Satici, Iman Dayarian, University of Alabama, Tuscaloosa, AL

We consider a crowd-based service network design for intra-city package delivery service in a stochastic environment. The network consists of courier company stores that can serve as sorting facilities, and inter-facility transport is performed by a set of contracted drivers and crowd-shippers that are augmented by third-party drivers employed on an as-needed basis. Taking the stochastic information for future demand and crowd-shipper availability, a two-stage stochastic model, based for minimizing the system cost on a rolling time horizon is formulated and solved using Bender's Decomposition. The first stage problem represents the allocation of the contracted drivers, then, in the second stage, available crowd-shippers and third-party drivers are integrated into the network, freeing some of the contracted drivers to be removed from the plan to decrease the cost.

4 Hybrid Truck-drone-robot Delivery Systems with Autonomous Repositioning and Docking Stations

Mohamed R. Salama[1], Sharan Srinivas[2], [1]Purdue University, West Lafayette, IN, [2]University of Missouri, Columbia, MO, Contact: salamam@purdue.edu

This research considers the problem of routing and coordinating multiple aerial drones and ground robots with a single truck for last-mile parcel delivery. Unlike previous works, a network of docking stations and autonomous repositioning of drones and robots are considered in route planning. An optimization model is formulated with the objective of minimizing the delivery completion time. Furthermore, heuristic approaches are developed to efficiently solve large instances. Different delivery settings are assessed to show the impact of autonomous repositioning and the benefit of employing a mothership vehicle (i.e., a truck that can carry drones and robots). The results demonstrate that substantial savings in delivery time can be achieved by operating the hybrid system and provide theoretical as well as practical insights on hybrid truck-drone-robot routing.

Advanced Modeling Techniques to Urban Rail Operations

General Session

Session Chair

Saeid Saidi, 1</sup

1 Estimating Rider Journey Variability Using Customer-facing WiFi Connection Data in Toronto, Canada

Willem Klumpenhouwer, Amer Shalaby, University of Toronto, Toronto, ON, Canada. Contact: willem.

klumpenhouwer@utoronto.ca
The goal of measuring public transit reliability performance is to effectively capture the entire journey experience of a rider and understand how this experience changes over time and space. Unfortunately, common measures and metrics used in practice often fall short by focusing on stop-level or vehicle-level reliability and fail to accurately reflect rider experience from origin to destination. Using data from recently introduced WiFi service in the Toronto subway system, we propose and calculate various trip-level performance measures and explore how they vary during disruptions, over the course of a day, and seasonally. These measures can help transit agencies target points of high variability within their system for improvement and to restore rider trust by demonstrating a strong understanding of rider experience.

2 The Effect of a Skip-stop Policy on The Train Frequency of a Mass Transit Line

Rodolphe Farrando[1,2], Nadir Farhi[3], Zoi Christoforou[3,4], Alain Urban[1], [1]RATP, PARIS, France; [2]Université Gustave Eiffel, Paris, France; [3]Université Gustave Eiffel, PARIS, France; [4]University of Patras, Patras, Greece. Contact: rodolphe.farrando@ratp.fr

Implementing a skip-stop policy on a metro line brings benefits to both operators and passengers. In this paper, we develop an algebraic Max-plus model that quantitatively compares train frequency on a line operated with and without a skip-stop policy. The model analytically yields three distinct phases for train frequency: free flow, capacity, and congestion. In addition, we provide and interpret analytical formulas that reveal the impact of the number of trains parity on train frequency. These formulas also allow us to calculate the gains induced by this policy. These gains come from the increase in commercial speed which, in our case, improves the capacity of the line. Finally, the gain function is piecewise linear and depends on the number of trains; we show the existence of an optimal number of trains for which the gain is maximal.

3 Integrated Agent-based Modeling for Dynamic Operations in Urban Rail Transit Systems

Bingyu Zhao[1], Yili Tang[2], [1]Vienna University of Technology, Vienna, Austria; [2]University of Regina, Regina, SK, Canada. Contact: yili.tang@uregina.ca

This study developed an agent-based simulation by integrating the data-driven optimization and passenger behavioral modeling to analyze the dynamic operations in urban rail transit systems. In the proposed simulation framework, an infrastructure environment is generated to establish the transit network characteristics including the platforms, links and transfers. Passengers' travel choices are then modelled within the network involving travel times, crowding costs and the queuing costs. Smartcard and schedule data are incorporated to evaluate the dynamic operations of the transit systems including travel patterns, in-vehicle crowdedness, operational capacity and on-platform queuing times. Results indicate the robustness, scalability and practicality of the integrated agent-based simulation to capture behavioral and operational dynamics.

1 Order Picking for Multi-entity Cooperation in Picking Warehouses

Jingwei Liu, Auburn University, Auburn, AL, Contact: jzl0196@auburn.edu

Motivated by the high flexibility of AMRs (autonomous mobile robots), we propose an order picking method for warehouses where multiple entities (pickers, transporters) with distinct tasks cooperate to fulfill orders. In our method, each picker moves to the assigned locations and picks the items from the racks. After picking an item, the picker will move to a hand-off location (could be the same as the picking location) to place the item on a transporter before picking the next item. Each transporter will take and transport multiple items to a depot to complete the order picking. A MILP model is formulated to generate routes for all entities. Also, a simulation testbed based on Simio is provided to test the performance and robustness of our method under different variabilities.

2 Congestion-aware Path Coordination Game with Markov Decision Process Dynamics

Sarah H.Q. Li, University of Washington, Seattle, WA, Contact: sarahli@uw.edu

To model competitive multi-agent stochastic path planning for heterogeneous players, we propose a novel atomic congestion game framework with Markov decision process (MDP) dynamics. Each player is equipped with a shared MDP state-action space, distinct transition dynamics, and cost functions coupled to the joint probability distribution. At the resulting Nash equilibrium, players avoid congested paths while optimally achieving individual objectives. For a subset of cost functions, finding the Nash equilibrium is equivalent to solving a potential optimization problem. We present an algorithm that extends single-agent MDP solutions to solve for the Nash equilibrium with linear complexity in the number of players. Our results are demonstrated in a warehouse setting where multiple robots autonomously deliver packages while avoiding collisions.

3 Dynamic Order Picking in a Stochastic Retail Store

Joyjit Bhowmick[1], Jennifer A. Pazour[2], Iman Dayarian[3], [1]Troy, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]University of Alabama, Tuscaloosa, AL

We propose new dynamic order picking policies to synchronize collaborative robots (cobots) with stochastically arriving in-store customers and dedicated pickers to fulfill online orders from retail stores. While emerging research has considered cobots in warehouses, where both cobots and pickers are controllable, we capture in-store customers' uncertain arrivals and behaviors. We modeled the problem as a Markov Decision Process and proposed multiple heuristic approaches to govern the item assignments and routing decisions for picking resources. Experiments show the potential to offset the high requirements for human picking resources while meeting high demands and commitments for curbside pickup and home delivery services.

4 Task Assignment and Route Planning in Robotic Warehousing

Cynthia Barnhart[1], Alexandre Jacquillat[2], Riley Lenaway[3], Alexandria Schmid[4], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT Sloan School of Management, Cambridge, MA, [3]MIT, Cambridge, MA, [4]MIT, Cambridge, MA, Contact: aschmid@mit.edu

We partner with a major online retailer to optimize two of the core questions in robotic warehousing: task assignment (which robot will pick up which shelf and drop it off at which station) and route planning (which robot travels through which path to avoid congestion). We develop an original integer optimization formulation using a time-space network representation of fulfillment center operations. To solve it, we propose a large-scale neighborhood search algorithm to break the problem down into smaller components, and re-optimize the solution iteratively while maintaining global feasibility. We develop machine learning models and domain-based heuristics to guide the search at each iteration. We demonstrate, via extensive computational experiments, the benefits of our model and algorithm as compared to baseline algorithms and realistic heuristics.

2 A Model of Livestream Selling with Online Influencers

Jing Hou[1], Houcai SHEN[1], Fasheng Xu[2], [1]Nanjing University, Nanjing, China; [2]Syracuse University, Syracuse, NY

This paper develops a model of livestream selling to investigate a firm's optimal livestream adoption strategy. First, livestream selling should only be adopted when the influencer can attract a considerable number of viewers and can accurately identify the product quality, but requires low price discounts from the firm. Second, the livestream adoption always increases the firm's quality investment level but may decrease the quality-price ratio and consequently lead to lower consumer surplus and even social welfare. Third, a lower endorsement reliability or a larger bargaining power of the influencer may benefit the firm. Lastly, as more consumers become sophisticated, it always hurts the product quality and the firm's profit, and may even lower consumer surplus, leading to a "lose-lose" outcome.

3 Game-based Pedagogy in Operations Management: Impact of Playing a Simulation Game and Providing Feedback on Students' Knowledge

Hossein Rikhtehgar Berenji[1], Hossein Najmi[2], [1]Pacific University, Forest Grove, OR, [2]University of Central Oklahoma, Edmond, OK

We use Revised Bloom's Taxonomy framework to measure students' knowledge of Operations Management using Soda Pop Game. Further, we investigate the impact of providing formative feedback (general and detailed feedback) as instructional support on students' performance. Our findings extend the understanding of learning, which results from participation in simulation games and designing game-based pedagogy.

4 Perils and Merits of Cross-channel Returns

Armagan Ozbilge[1], Elkafi Hassini[2], Mahmut Parlar[2],

[1]McMaster University, Hamilton, ON, Canada; [2]McMaster University, Hamilton, ON, Canada. Contact: ozbilgea@mcmaster.ca

We study the impact of cross-channel returns on a bricks-and-clicks dual-channel retailer's overall profit, individual channel-prices, and -demand under two scenarios: (1) exogenous returns, and (2) refund-dependent returns. Our study reveals a number of interesting results, for example, when channel substitutability is high (self- and cross-channel price-sensitive parameters are close), welcoming the returns of online purchases to the B&M store is likely to drive the channel price up, despite a drop in the B&M demand due to the cannibalization effect. The retailer should mind the channel substitutability, return handling costs, and self-channel returns before collecting online returns by her physical facility as cross-channel returns may undermine the overall profit. We are also able to verify that our main findings are fairly consistent under both scenarios.

Sample Complexity of Policy Learning for Inventory Control with Censored Demand

Xiaoyu Fan, Nanjing University, New York, NY

We study both single period and infinite horizon inventory models with offline learning under censored demand. The level of censoring in the data set impacts the learning quality of an offline algorithm. We specify sufficient conditions for the data set under which the optimal policy can be sufficiently learned. Sampling-based algorithms are proposed to circumvent downward biases caused by data censoring. We establish optimal upper bounds on the number of samples needed for the sampling-based solution to perform close to the true optimal solution under any accuracy level with high probability.

Constructing Branching Trees of Geostatistical Simulations

Juan Valencia, Universidad de Santiago de Chile, Santiago, Chile.

This paper proposes the use of multi-stage stochastic programming with recourse for optimised open-pit mine planning. The key innovations are, firstly, that a branching tree of geostatistical simulations is developed to take account of uncertainty in ore grades, and secondly, scenario reduction techniques are applied to keep the trees to a manageable size. Our example shows that different mine plans would be optimal for the downside case when the deposit turns out to be of lower grade than expected. Our approach moves toward adaptive mine planning rather than just producing a single mine plan.

The Way: "Safest" Way Out

Ilkim Bahar Güneri, Beyza Cekinel, Yagmur Lara Gorur, Kadir Can Kasan, Bilkent University, Ankara, Turkey.

In earthquake-prone cities, it is crucial to have a post-disaster plan to mitigate the effects of an earthquake and increase disaster responsiveness. This paper proposes a methodology to solve a bi-objective problem, finding the shortest and safest paths between two points in Istanbul, Fatih after an earthquake. Risk scores of arcs are found based on building attributes and earthquake-related parameters. Weighted sum scalarization is used to find Pareto optimal paths between two points in the network. This paper also presents two methods to make the methodology customizable to other places.

Information Diffusion, Influence, and Engagement on Social Media

General Session

Session Chair

Hanqi Wen, University of Michigan, Ann Arbor, MI

1 Charactering the Motifs of Different Rumor Topics in Weibo During a Public Health Crisis

Lifang Li[1], Ruiyao Xie[2], Haolin Wang[3], Qingpeng Zhang[4], [1]King's College Lodon, London, United Kingdom; [2]Xi'an Jiaotong University, Xi'an, China; [3]Chongqing Medical University, Chongqing, China; [4]City University of Hong Kong, HongKong, Hong Kong. Contact: lifangli2-c@my.cityu.edu.hk

The public health crisis was accompanied by an infodemic. However, rumours of different topics have some differences in nature. For example, some rumours meet people's needs for information, while some rumours cater to users' inherent cognition. Knowing the propagation process of rumours on different topics is the basis for learning the psychological needs of users and can also provide more specific strategies for the governance of rumours. This paper uses Weibo data to classify the rumours on Weibo into four types first; second, the communication network is constructed for each type of rumour and the unique Motif is analysed; third, use psychological theories to explain the rationale for the emergence of different types of motifs in the rumours. This study makes up for the lack of connections between existing rumour propagation theories and data-driven related research.

2 Disentangling SNS Privacy Paradox with the Negative Impression Management SNS-NIM Model

Guruprasad Y. Gadgil[1], Gayle Prybutok[2], Victor Prybutok[3], [1]University of Alaska Anchorage, Anchorage, AK, [2]University of North Texas, Denton, TX, [3]University of North Texas, Denton, TX, Contact: gygadgil@alaska.edu

The SNS-negative-impression-management-model is presented using the mixed approach in this (SNS-NIM) study. This model proposes new constructs for describing the relationships that impact negative impression behaviors on social media platforms. SNS selective disclosure awareness, SNS desired differential privacy awareness, and SNS stalking awareness are all antecedents of online SNS activities in this study. Factor analysis and PLS/SEM are used to analyze 399 useable samples and confirm that the SNS-NIM model creates resonant impressions in a negative mode in SNS contexts. As a result, this study explores and demonstrates how mediating behavioral links increase model complexity.

3 What Drives Engagement During a Large Connective Action on a Financial Social Media Forum - A Text Analytics Perspective

Adrija Majumdar, Shreya Pandey, Indranil Bose, Indian Institute of Management Ahmedabad, Ahmedabad, India.

In this paper, we analyze the mechanisms through which engagement is facilitated in a concerted financial online social movement. We observe the unfolding discussion on a social media forum and show how affective expressions and personal motivation frames lead to higher engagement in the connective action movement. Particularly, we study the impact of a) the personal frame of similarity in expression style b) the personal frame of negative financial sentiments, and c) the personal frame of informational relevance on the popularity of the content.

4 Dynamic Expansions of Social Followings with Lotteries and Give-aways

Hanqi Wen[1], Jingtong Zhao[2], Van-Anh Truong[3], Jie Song[4], [1]The University of Michigan, Ann Arbor, MI, [2]Renmin University of China, Beijing, China; [3]Columbia University, New York, NY, [4]Peking University, Beijing, China.

The problem of how to attract a robust following on social media is one of the most pressing for influencers. We study a practice common on popular social networking platforms of influencers' expanding their followings by running lotteries and giveaways, where a user reposts a particular blog and follows the influencer in order to join a lottery game. We are interested in how the lottery size and the seeding decisions will influence the final reward for such a campaign. We construct an information-diffusion model and show that the influenced population is first convex and then concave and increasing with the lottery size. And we also study the adaptive seeding problem by modeling it as a Markov Decision Process. We show several properties of the optimal policies. Furthermore, we provide managerial insights on both the lottery size and seeding decisions.

Stochastic Models, Epidemiology Simulation, Deep Learning, and Robust Stability

General Session

Session Chair

Chang-Han Rhee, Northwestern University, Chicago, IL

1 Conditional Uniformity and Hawkes Processes

Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

Classic results provide the distribution of a Hawkes process cluster's size through a connection to branching processes, but this is irrespective of time. Insight into the chronology of the cluster has been more elusive. Here, we employ a novel adaptation of the random time change theorem to establish an analog of the conditional uniformity property enjoyed by Poisson processes, yielding a decomposition with that is valuable both methodologically and practically.

2 Shift, Scale and Restart Smaller Models to Estimate Larger Ones: Agent-based Simulators in Epidemiology

Sandeep Juneja, Tata Institute of Fundamental Research, Mumbai, India.

In this talk we primarily focus on agent based simulators for modelling COVID-19 pandemic and dig deeper into the underlying probabilistic structure of an associated agent based simulator (ABS) to arrive at modifications that allow smaller models to give accurate statistics for larger models. We exploit the observations that in the initial disease spread phase, the starting infections behave like a branching process. Further, later once enough people have been infected, the infected population closely follows its mean field approximation. We build upon these insights to develop a shifted, scaled and restart version of the simulator that accurately evaluates the ABS's performance using a much smaller model while essentially eliminating the bias that otherwise arises from smaller models.

3 Eliminating Sharp Minima from SGD with Truncated Heavy-tailed Noise

Xingyu Wang, 1</sup

Recently, there have been discourses in machine learning literature that heavy-tailed noises in deep learning tasks enable SGDs to efficiently escape from sharp minima, which are known to lead to poor generalization. In this work, we show that by truncating the stochastic gradients in SGD under heavy-tailed noises, we can achieve a much stronger notion of the (almost) complete elimination of sharp local minima from the training trajectories of SGD. First, we establish an Eyring-Kramers type first exit time formula for truncated heavy-tailed SGD. Moreover, under appropriate structural conditions, we prove that the path-wise dynamics of truncated heavy-tailed SGD converge to a continuous-time Markov chain that never visits sharp minima. Our deep learning experiments confirm that truncated heavy-tailed SGD finds "flatter" minima with better generalization.

4 A New Approach to Robust Stability of Multiclass Queueing Networks

Feiyang Zhao[1], John Hasenbein[1], Itai Gurvich[2], [1]University of Texas-Austin, Austin, TX, [2]Northwestern University, Kellogg School of Management, Evanston,, IL, Contact: feiyang_zhao@utexas.edu

The focus of this research is on the robust stability of stochastic processing networks, under a wide class of control policies. A framework for robust stability is developed, in which the resources are given freedom to decide their own priority policy, under some general constraints. We offer a new approach for determining sufficient conditions for robust stability, which builds on, and makes connections to, suitable robust optimization problems, with the collection of priority policies as the uncertainty set. We also show how robust stability of a family of policies is inherited from the stability of some special policies, i.e., static-priority policies.

Model Uncertainty and Distributionally Robust Optimization

General Session

Session Chair

Henry Lam, 1</sup

Session Chair

Shengyi He, Columbia University, New York City, NY

1 On the Limits of Marginal Modeling of Utilities in Consumer Choice

Yanqiu Ruan[1], Xiaobo Li[2], Karthyek Murthy[1], Karthik Natarjan[1], [1]Singapore University of Technology and Design, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: yanqiu_ruan@mymail.sutd.edu.sg

Given data on choices made by consumers for different assortments, a key challenge is to develop tractable models that describe and predict consumer choice behavior. One such choice model is the marginal distribution model. In this paper, we develop an exact characterisation of the set of choice probabilities representable by the marginal distribution model. Allowing for alternatives to be grouped based on the marginal distribution of their utilities, we show (a) verifying consistency of choice probability data with this model is possible in polynomial time and (b) finding the closest fit reduces to solving a mixed integer convex program. Our results show that the marginal distribution model provides much better representational power as compared to multinomial logit and much better computational performance as compared to the random utility model.

2 Inf-convolution, Optimal Allocations, and Model Uncertainty for Tail Risk Measures

Fangda Liu[1], Tiantian Mao[2], Linxiao Wei[3], Ruodu Wang[1], [1]University of Waterloo, Waterloo, ON, Canada; [2]University of Science and Technology of China, Hefei, China; [3]Wuhan University of Technology, Wuhan, China. Contact: f27liu@uwaterloo.ca

We study the optimization of risk sharing for general tail risk measures. The inf-convolution of tail risk measures is shown to be a tail risk measure with an aggregated tail parameter, a phenomenon very similar to the cases of Value-at-Risk, the Expected Shortfall and the Range-Value-at-Risk. Optimal allocations are obtained in the settings of elliptical models and model uncertainty. In particular, several results are established for tail risk measures in the presence of model uncertainty, which may be of independent interest outside the framework of risk sharing. The technical conclusions are quite general without assuming any form of convexity of the tail risk measures. Our analysis generalizes in several directions the recent literature on quantile-based risk sharing.

3 Distributionally Robust Nonparametric Gaussian Regression

Xuhui Zhang, Stanford University, STANFORD, CA, Contact: xuhui.zhang@stanford.edu

We study a distributionally robust optimization formulation (i.e. a min-max game) for the problem of non-parametric Gaussian process regression. We choose the best mean-squared error predictor on an infinite-dimensional space against an adversary which chooses the worst-case model in a Wasserstein ball around an infinite-dimensional Gaussian model. The Wasserstein cost function is chosen to control features such as the amount of roughness on the sample paths that the adversary is allowed to inject. We show that the game has a well-defined value (i.e., strong duality holds in the sense that max-min = min-max) and existence of a unique Nash equilibrium which can be computed by a sequence of finite-dimensional approximations.

4 Higher-Order Expansion and Bartlett Correctability of Distributionally Robust Optimization

Shengyi He[1], Henry Lam[2], [1]Columbia University, New York City, NY, [2]Columbia University, New York, NY, Contact: sh3972@columbia.edu

: Distributionally robust optimization (DRO) is a worst-case framework for optimization under uncertainty that has gained recent popularity. In particular, DRO with an uncertainty set constructed as a divergence ball, when the ball size is suitably calibrated, has been shown to provide confidence intervals for nonparametric functionals and bears a duality with empirical likelihood (EL). In this talk, we show how refining this ball size can reduce higher-order coverage errors similar to the so-called Bartlett correction. Our correction, which applies to general von Mises functionals, is more general than the existing EL literature that only focuses on smooth function models or M-estimation. Our analysis relies on a general high-order expansion of DRO and Edgeworth expansion that also implies new insights including a higher-order self-normalizing property of DRO.

Recent Advances in Parallel-server Systems
General Session

Session Chair
Daniela Hurtado-Lange, William and Mary, Williamsburg, VA

1 Transportation Polytope and Its Applications in Two-sided Queues

Sushil Varma, Georgia Institute of Technology, Atlanta, GA

We first analyze the transportation polytope defined as the set of all assignments that divide the fluid supply to meet the fluid demand. We establish novel results on the connectivity of the so-called support graphs and the extreme points of the transportation polytope.
Futhermore, we use the above results to analyze parallel server systems with widespread applications in manufacturing, ride-hailing, call centers, etc. Heterogeneous customers arrive in the system. Only a subset of servers can serve any given customer type. Our contribution is three-fold. We characterize asymptotic delay for a given flexibility graph, design delay-optimal sparse flexibility graphs, and improve the performance of a given system by adding one extra edge. These results serve as a guidebook for designing and improving manufacturing and production systems.

2 Heavy Traffic Queue Length Distribution Without Resource Pooling in an Input-queued Switch

Prakirt Raj Jhunjhunwala, Georgia Institute of Technology, Atlanta, GA

Input-queued switch acts as a representative of SPNs that do not satisfy the so-called complete resource pooling (CRP) condition, and consequently exhibit a multidimensional state space collapse. Except in special cases, only mean queue lengths of such non-CRP systems have been obtained in the literature. In this paper, we develop the transform method to study the steady state distribution of non-CRP systems like Input-queued switch. The key challenge is in solving an implicit functional equation involving the Laplace transform of the heavy-traffic limiting distribution. We then consider the general nxn input-queued switch that has n^2 queues. Under a conjecture on uniqueness of the solution of the functional equation, we obtain an exact joint distribution of the heavy-traffic limiting queue-lengths in terms of a non-linear transformation of 2n iid exponentials.

3 Optimal Scheduling in the Multiserver-job Model Under Heavy Traffic

Isaac Grosof, Carnegie Mellon University, Pittsburgh, PA, Contact: igrosof@cmu.edu

Multiserver-job systems, where jobs require concurrent service at many servers, occur widely in practice. To minimize mean response time, we must balance the twin objectives of prioritizing small jobs and optimizing throughput.
In this presentation, we present the ServerFilling-SRPT scheduling policy, the first policy to minimize mean response time in the multiserver-job model, in the heavy traffic limit. Our results also generalize beyond the known size setting to the unknown or partially known size setting, using the ServerFilling-Gittins scheduling policy.

Case Studies from the International Statistical Engineering Association

General Session

Session Chair

Arman Sabbaghi, Purdue University, West Lafayette, IN

1 An Introduction to Statistical Engineering

Mark Vandeven, Colgate-Palmolive, Piscataway, NJ, Contact: mark_vandeven@colpal.com

The development of the theory and application of individual statistical and analytical methods has gotten the statistics profession far. However, there is a sense that "a lot of money has been left on the table." These lost opportunities point to the need to think more deeply about how to capture major opportunities by linking and integrating methods into an overall data-based approach to scientific inquiry.
The International Statistical Engineering Association recognizes this need and has devised a unified approach to problem solving which integrates multiple methods in a holistic, integrated framework.
In this session, we will first give an overview of ISEA with emphasis on what makes ISEA distinct from other professional organizations. This overview will touch on key guiding principles and will introduce the six phases of a typical Statistical Engineering project.

2 Testing the Prediction Profiler with Disallowed Combinations - A Statistical Engineering Case Study

Ryan Lekivetz, JMP, Cary, NC, Contact: Ryan.Lekivetz@jmp.com

The prediction profiler is an interactive display that allows a user to explore the relationships between multiple factors and responses. A common use case of the profiler is for exploring the predicted model from a designed experiment. Some experiments require constraining the design region as defined by a set of disallowed combinations that the profiler should obey when presenting a predicted model. While it may not be apparent that software testing can fit within the statistical engineering framework, testing the profiler with disallowed combinations required the creation of a team from across development and testing groups and touched upon each of the fundamental principles of statistical engineering.

3 Predictive Monitoring Using Machine Learning Algorithms and a Real-life Example on Schizophrenia

Leo C. E. Huberts, University of Amsterdam, Amsterdam, Netherlands.

Predictive process monitoring aims to produce early warnings of unwanted events. We consider the use of the machine learning method extreme gradient boosting as the forecasting model in predictive monitoring. A tuning algorithm is proposed as the signaling method to produce a required false alarm rate. We demonstrate the procedure using a unique data set on mental health in the Netherlands. The goal of this application is to support healthcare workers in identifying the risk of a mental health crisis in people diagnosed with schizophrenia. The procedure we outline offers promising results and a novel approach to predictive monitoring.

4 Statistical Engineering Synergies

Dennis Leber, NIST, Gaithersburg, MD, Contact: dennis.leber@nist.gov

As a young and growing professional organization, the International Statistical Engineering Association (ISEA) is working to solidify its identity. Central to this identity is the definition of the discipline of statistical engineering that is colloquially communicated as the art and science of solving complex problems that require data and data analysis. In this talk, we briefly review several INFORMS case studies, drawing contrasts and comparisons to the ISEA case studies presented separately in this session. Through this comparison, we reinforce ISEA's mission and the definition of statistical engineering while highlighting the potential synergies between INFORMS and ISEA.

Sunday, 12:30 PM–1:45 PM

Modeling Dynamic Network Systems from High Dimensional Data for Change Point Detection

General Session

Session Chair

Ana Maria Estrada Gomez, [1</sup]

1 Multiple Change Point Detection in Reduced Rank High Dimensional Vector Autoregressive Models

George Michailidis, U Florida, Gainesville, FL, Contact: gmichail@ufl.edu

We study the problem of detecting and locating change points in high-dimensional Vector Autoregressive (VAR) models, whose transition matrices exhibit low rank plus sparse structure. The detection is based on a two-step algorithm, wherein the first step, an exhaustive search for a candidate change point is employed for overlapping windows, and subsequently a backwards elimination procedure is used to screen out redundant candidates. The two-step strategy yields consistent estimates of the number and the locations of the change points. The effectiveness of the proposed algorithms and methodology is illustrated on both synthetic and two real data sets.

2 Estimation of High-dimensional Markov-switching VAR Models with an Approximate EM Algorithm

Xiudi Li[1], Ali Shojaie[2], Abolfazl Safikhani[3], [1]Harvard University, Boston, MA, [2]University of Washington, Seattle, WA, [3]George Mason University, Fairfax, VA

Regime shifts in high-dimensional time series arise naturally in many applications. This problem has received considerable attention in low-dimensional settings, with both Bayesian and frequentist methods developed for parameter estimation. The EM algorithm is a particularly popular strategy for parameter estimation in low-dimensional settings, although the statistical properties of the resulting estimates have not been well understood. Moreover, its extension to high-dimensional time series proved challenging. To overcome these challenges, we propose an approximate EM algorithm for Markov-switching VAR models that leads to efficient computation and facilitates the investigation of asymptotic properties of the resulting parameter estimates. We establish consistency of the proposed EM algorithm and investigate its performance in simulation studies.

3 Adaptive Sequential Change-point Detection for Hawkes Networks

Haoyun Wang[1], Yao Xie[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA

We present a new CUSUM procedure for sequential change-point detection in Hawkes networks using discrete events data. Hawkes networks have become a popular model in statistics and machine learning, primarily due to their capability in modeling irregularly observed data where the timing between events carries a lot of information. We propose an online recursive implementation of the CUSUM statistic for Hawkes processes, which is computationally and memory-efficient and can be decentralized for distributed computing. We prove theoretical properties of this new CUSUM procedure, then show the improved performance of this approach over existing methods via simulation studies and an application to population code change-detection in neuroengineering.

4 Graph Analytics-Based Vulnerability Assessment of World Trade Network

Mary E. Ogidigben[1], Dyutimoy N. Das[2], Amanda C. Jurado Guzman[3], Alfonso Mejia[3], Soundar Kumara[1], [1]Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, University Park, PA, [3]Pennsylvania State University, University Park, PA, Contact: meo5362@psu.edu

Current disruption due to the pandemic has brought out the importance of the resilience of supply chain networks. A network representation of the world trade network allows us to extract hidden information regarding climate shocks, economic causalities, and dependencies between countries. This allows us to explore the robustness of the network to determine the supply chain reaction/resilience to shocks to better understand vulnerabilities within the global supply chain. We study multi-layered trade networks, as well as nestedness and modularity to make inferences on the resilience characteristics of the global trade networks.

Sunday, 12:30 PM–1:45 PM

New Frontiers of Data Mining and Machine Learning in Manufacturing

General Session

Session Chair

Jia Liu, Auburn University

Session Chair

Wenmeng Tian, Mississippi State University, Mississippi State, MS

1 Imbalanced Data Classification via Generative Adversarial Network with Application to Anomaly Detection in Additive Manufacturing Process

jihoon Chung, Bo Shen, Zhenyu James Kong, Virginia Tech, Blacksburg, VA, Contact: jihoon7@vt.edu

For the quality assurance of the additive manufacturing (AM) process, classification models have been widely utilized to process anomaly detection. However, since abnormal process states rarely occur in the process, the number of training data from a normal state outweighs the number of abnormal states. It causes imbalanced training data. To overcome this training bias, it is valuable to generate effective artificial sample data for the abnormal process states to make a balanced training set. To achieve it, we propose a novel data augmentation method that is based on a generative adversarial network (GAN). Specifically, the method consists of three-player, namely, discriminator, generator, and classifier. The effectiveness of the proposed method is validated by both open-source data and real-world case studies in polymer and metal AM processes.

2 An Impulse Response Formulation for Small-sample Learning and Control of Additive Manufacturing Quality

Qiang Huang, University of Southern California, Los Angeles, CA, Contact: qiang.huang@usc.edu

Machine Learning for AM (ML4AM) is a viable strategy to enhance 3D printing performance. However, the amount of data required for model training and the lack of ability to infer AM process insights can be serious barriers for black-box learning methods. Due to the nature of low-volume fabrication of infinite product variety in AM, ML4AM also faces ``small data, big tasks” challenges to learn heterogeneous point cloud data and control the quality of new designs. To address these challenges, this work establishes an impulse response formulation of layer-wised AM processes to learn and predict printing quality.

3 Thermal History Data Anonymization for Cross-system Process-defect Modeling for Metal-based Additive Manufacturing

Durant Fullington[1], Linkan Bian[2], Wenmeng Tian[1], [1]Mississippi State University, Mississippi State, MS, [2]Mississippi State University, Mississippi State University, MS, Contact: tian@ise.msstate.edu

The research objective is to develop a secured data sharing mechanism for additive manufacturing (AM) process data that masks the printing path information while retaining quality control characteristics. A core problem in data aggregation from multiple AM users is the data privacy concern of sharing raw data, which usually contain confidential design information. The proposed adaptive design deidentification for AM (ADDAM) methodology integrates AM process knowledge with the k-anonymization method to mask the printing path information contained within the AM thermal history and synthesize a "surrogate" thermal image. A real-world case study based on the directed energy deposition (DED) process is used to validate the proposed method.

4 Allocating Robot/cobots to Production Systems Considering Both Productivity and Ergonomic Strain

Congfang Huang[1], Shiyu Zhou[2], [1]UW Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, Contact: chuang286@wisc.edu

The job allocation between human and robot resources can improve the performance of an assembly serial system in both productivity and ergonomics. Most of the recent research on job allocation in assembly systems focus on the job decomposition of an individual job or consider the productivity performance and the ergonomic factors separately. In this work, we formulate a well-defined human-robot collaborative assembly system and propose an optimization model for the job allocation problem between human, independent, and collaborative robots at the system task level. The objective function of our optimization model is unified integrated metrics of productive and ergonomic performance. Several simulated cases are designed based on the real-world scenarios and some rules and strategies are concluded from the optimization results.

Sunday, 12:30 PM–1:45 PM

Resource Adequacy and Resilience in Market Modeling

General Session

Session Chair

Yinong Sun, Johns Hopkins University, Lakewood, CO

1 Insights into Methodologies and Operational Details of Resource Adequacy Assessment

Yinong Sun[1,2], Bethany Frew[2], Sourabh Dalvi[2], Surya Dhulipala[2], [1]Johns Hopkins University, Lakewood, CO, [2]National Renewable Energy Laboratory, Golden, CO, Contact: ysun104@jhu.edu

In this study, we systematically explore how operational details impact resource adequacy (RA) assessments. The RA modeling dimensions include: the objective function and level of operational detail in the underlying model formulation; the quantity (look-ahead) and quality (accuracy) of data that is available for making operational decisions within models; and the physical configuration of PV with battery storage hybrid resources, whose charging cycles introduce complexity for how such resources can contribute to RA. We apply a spectrum of probabilistic RA tools and production cost modeling tools to a realistic test system based loosely on a future ERCOT system dominated by solar PV resources. Our results suggest that multi-stage probabilistic assessments may provide a more robust evaluation of RA by capturing a wider range of operational and system interactions.

2 The Impact of Wholesale Market Design on Long-run Resource Investment and Reliability

Jonghwan Kwon[1], Todd Levin[1], Audun Botterud[2], Zhi Zhou[3], [1]Argonne National Laboratory, LEMONT, IL, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Argonne National Laboratory, Argonne, IL, Contact: kwonj@anl.gov

Increasing penetrations of low or zero marginal cost generation may lead to declining wholesale energy prices and a corresponding decline in revenues for generators. As a result, resources may increasingly rely on revenues from other services, such as reserves or capacity, to ensure revenue sufficiency. This talk will discuss the impact of wholesale market designs on resource investment and system reliability. We will first introduce a market-based resource adequacy assessment framework that can analyze the system generation portfolio that results in a competitive market environment. The modeling framework is based on Stackelberg leader-follower games and is formulated as a bi-level optimization problem, which is then transformed into a mathematical program with equilibrium constraints. A case study of the ERCOT-like system will be discussed.

3 Extreme Events and Resource Adequacy for a Decarbonized Future

Aidan Tuohy[1], Jo Ann Rañola[2], [1]Electric Power Research Institute, Chicago, IL, [2]Electric Power Research Institute, Austin, TX

As the resource mix of the electric system changes to meet decarbonization targets, and with extreme weather such as widespread heat and cold events having particular impact in recent years, there is a need to revisit methods for resource adequacy. In an ongoing project, these issues are being examined in terms of new metrics and criteria to ensure adequacy, updated models and improvements in the software tools. A particular focus is on ensuring energy reliability and resilience towards extreme events, with methods under development to better identify the scenarios that must be included. Case studies examining these issues will be presented here, showing how stress testing can be incorporated into the broader picture of adequacy studies.

4 Resource Value Streams in an Adequacy-Aware Planning Framework

Gord Stephen, University of Washington, Seattle, WA

Traditional power system planning optimizations rely on planning reserve margin constraints and exogenously-specified resource capacity credits in order to enforce system adequacy requirements. While the shadow prices of such constraints can provide a rough approximation of capacity market price signals, the exogenous nature of the capacity accreditation process prevents a more detailed first-principles understanding of the economic value of a resource's adequacy contribution. This presentation introduces a novel adequacy construct for power system planning models and explores the deeper economic insights it can provide for understanding the fundamental value streams provided by resources with varying operational characteristics.

Sunday, 12:30 PM–1:45 PM

Optimizing Power Grid Resilience to Extreme Weather Events

General Session

Session Chair

Erhan Kutanoglu, University of Texas-Austin, Austin, TX

1 Budget Allocation for Power Grid Resilience: Hardening, Pre-event Preparation or Load Loss

Ashutosh Shukla, Erhan Kutanoglu, John Hasenbein, University of Texas-Austin, Austin, TX, Contact: ashutosh.shukla@utexas.edu

We present and analyze a three-stage stochastic optimization model that integrates outputs from a hydrological flooding model with an optimal power flow model for grid resilience decisions against storm-surge-induced flooding. The model coordinates the decisions made in multiple stages of the resilience management cycle and recommends an optimal allocation of the overall resilience investment budget across mitigation and preparedness measures. The model trades off such investments with the total value of load loss incurred due to the out-of-service components of the grid. We also present a case study for the Texas Gulf Coast region to demonstrate how the proposed model is used to address different kinds of grid resilience questions.

2 A Performance-constrained Stochastic Optimal Power Flow Model for Flood Resilience Planning

Brent Austgen[1], John Hasenbein[2], Erhan Kutanoglu[2], [1]The University of Texas at Austin, Austin, TX, [2]University of Texas-Austin, Austin, TX

We present a stochastic power flow model for informing flood mitigation decisions prior to an imminent hurricane. The model's objective is to minimize the number of mitigation resources required to satisfy a set of post-disaster grid performance constraints. We compare and contrast a few classes of performance constraints including deterministic, chance, and conditional value-at-risk constraints. Finally, we apply the model to a synthetic but representative grid of Texas subjected to realistic flooding scenarios based on Hurricane Harvey and discuss the results.

3 Equitable Optimization of Power Grid Resiliency

Baris Bilir, Erhan Kutanoglu, John J. Hasenbein, The University of Texas at Austin, Austin, TX

Extreme weather events result in devastating damages in the U.S. These low probability high impact events can cause widespread power outages and cost billions of dollars to society. Scientists predict that such events will be more frequent and more intense, and last longer with climate change. Therefore, resiliency of the power grid to extreme weather events is of increasing importance. In addition, there is evidence that underprivileged communities experience power outages more frequently and for longer periods of time than others. Hence, integrating equity into decisions regarding improving power grid resiliency is critical. In this study, we consider equitable resilience investment decisions and quantify its benefits with computational experiments using the synthetic Texas grid as a case study.

4 Capacity Expansion of Power Grid to Enhance the Resilience Against Extreme Weather

Berk Sahin[1], John Hasenbein[2], Erhan Kutanoglu[2], [1]University of Texas-Austin, Austin, TX, [2]University of Texas-Austin, Austin, TX, Contact: berk.sahin@utexas.edu

Grid operators should continuously expand the capacities of grid components to satisfy the growing demand. Due to the demand constraints and budget, it is not possible to make expansion investments simultaneously. A capacity expansion investment plan is needed to make reasonably ordered investment decisions. We propose a two-stage stochastic programming model to prioritize the capacity expansion decisions of the power grid considering resilience against extreme weather events. We consider expanding the capacities of power grid components such as generators, lines, substations, and switches. The model aims to minimize the load shed considering the extreme weather scenarios. We present numerical results on a synthetic version of the Texas grid considering the scenarios generated using historical extreme weather events.

1 Optimizing Collaborative Energy Storage Systems and Its Equity Outcomes
Ogechi Nwadiaru, University of Massachusetts, Massachusetts, MA
To support the delivery of an equitable and just transition it is imperative to study models of ownership that can promote adoption in a sustainable way. The aim of the study is to assess the benefits for co-operatively owned and operated storage systems. We hypothesize that there will be savings. The hypothesis is built on the flexibility offered by storage as a demand response asset, which can be used by residents in price-based demand response programs and equally provides consumers with increased autonomy and reduced cost.

2 Energy Resources' Effect on Energy Poverty
Erick C. Jones, University of Texas at Arlington, Arlington, TX, Contact: erick.jones@uta.edu
Energy is treated as an unlimited resource with no caps on demand and supply expected to keep up with whatever demand as increasing price encourages more expensive production. While on a macro scale this is largely accurate, rising energy prices illustrate an inefficient use of energy resources that disproportionately impacts the most vulnerable households. Certain energy resources are better at certain uses than others and rationing demand of more valuable energy resources for higher value uses can decrease energy costs disproportionately benefiting the most vulnerable.

3 Infrastructure Decision Preferences and the Influence of Social Justice Education
Charles Van-Hein Sackey[1], Destenie S. Nock[2], Christine Cao[1], Alexander Davis[1], Daniel Armanios[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Oxford University, London, United Kingdom. Contact: cvanhein@andrew.cmu.edu
The research question we explore in this paper is how does educating stakeholders in the energy sector about social justice change their preferences for equality and decision-making process in planning electricity systems. We use the maximize energy access (MEA) benefit-maximization model to generate maps of electricity system plans. Each map generated is based on a given value of equality. We then use these maps in a discrete choice experiment, in which participants' preferences for equality are estimated based on their choice of maps. Our work contributes to the literature by quantitatively determining the impact of education on equality preferences in an electricity system planning model.

4 Low-carbon Energy Transitions: A Systematic Approach to Quantifying Equity and Sustainability Trade-offs
Teagan Goforth[1], Destenie S. Nock[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: tgoforth@andrew.cmu.edu
Energy transitions require rapid changes to a nation's electricity generation mix, yet there is vast uncertainty about how these pathways will affect the nation's energy equity and sustainability goals. We develop a framework for analyzing the trade-offs between cost, sustainability, and equity under different decarbonization pathways. We accomplish this by coupling a least cost energy optimization model with a multi-criteria decision analysis model. Our initial results show that communities with high Black and high poverty populations are more likely to experience higher concentrations of pollutants until a mandate requires full deployment of renewable or low-carbon technologies.

5 Phasing Out Coal Power Plants Based on Cumulative Air Pollution Impact and Equity Objectives in Net Zero Energy System Transitions
Erin Mayfield, Dartmouth College, Hanover, NH
Transitioning to a net zero economy entails rapidly retiring coal capacity, a major source of both greenhouse gases and air pollution. To evaluate the coal phase-out, we optimize

for alternative climate policy goals as well as air pollution objectives related to the distribution of impacts on the basis of demographic, economic, and political factors. Phase-out strategies associated with policy objectives to minimize cumulative mortalities across the population are generally consistent with objectives to minimize impacts on vulnerable subpopulations, but differ from those that target specific environmental justice communities.

6 Impact of Building Climate Adaptation on Energy Burden Using a Coupled Weather-building Energy Model

Luis Ortiz, George Mason University, Fairfax, VA

As summers temperatures rise, so will the need for air conditioning as well as the economic burden associated with its use. Here, we estimate this burden, and strategies to reduce it, using a coupled weather-building energy model driven by present and end of century climate data and up-to-date urban morphology, with New York City as a case study. Results show that under a full adoption scenario, building adaptation strategies benefit low-income households the most, lowering energy burdens by up to 20% in the highest burden areas. p { line-height: 115%; margin-bottom: 0.1in; background: transparent }

7 Modeling for a Just and Reasonable Energy Future: Examining Pathways for Considering Social Equity in Power System in Distribution System Planning

Jasmine McAdams, University of California Berkeley, Berkeley, CA, Contact: jmcadams@berkeley.edu

Social equity has recently emerged as a key priority for decision-makers as they consider policies and investments to support a low-carbon energy future. Public utility commissions, in particular, have been mandated in a growing number of states to consider equity in their regulation of investor-owned utilities, thus having significant influence on aspects such as affordability, reliability and resilience of energy services and the modernization of the distribution grid. This presentation will explore how such considerations can be incorporated into distribution system planning.

8 An Equitable Transition to Clean Heating for Us Cold Climates

Parth Vaishnav, Claire J. McKenna, Shagun S. Parekh, University of Michigan, Ann Arbor, MI, Contact: parthtv@umich.edu

Electrifying residential space heating is a key decarbonization strategy, but it may raise energy bills for existing homes in cold regions. We gather data on household behavior and physical housing characteristics from 50 households, half of which have incomes below the regional median, and around 40% of which are energy-insecure, in Southeast Michigan. We integrate these data with physics-based energy models to estimate energy use and heating bills, and validate these models against empirically-observed energy use. We then test a suite of envelope upgrades along with air source heat pumps and expect to identify a package of strategies that reduce the bills for each home under dynamic utility pricing scenarios. We present building upgrade cost estimates. We juxtapose these data with data on income and housing values to assess the environmental justice implications.

1 Individual Fairness in Prophet Inequalities

Makis Arsenis[1], Robert Kleinberg[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, Contact: marsenis@cs.cornell.edu

Standard stopping rules for prophet inequality problems might treat individual candidates unfairly in a number of different ways. In this work we identify two types of individual fairness that might be desirable and give precise definitions. We call them identity-independent fairness (IIF) and time-independent fairness (TIF). We give polynomial-time algorithms for finding the optimal IIF/TIF stopping rules for a given instance with discrete support and we manage to recover a prophet inequality with factor 1/2 when the decision maker is required to satisfy both IIF and TIF while the prophet is unconstrained. We also consider a setting in which the decision maker doesn't know the value distributions but has access to a bounded number of independent samples from each and we provide constant-competitive, IIF/TIF algorithms.

2 Fair and Diverse Allocation of Scarce Resources

Hadis Anahideh, 1</sup

Due to disparities in socioeconomic stability and access to health care across different population subgroups in the US, certain low-income and minority groups are particularly more vulnerable to COVID-19. To provide sufficient vaccine and medical resources to all residents and effectively stop the further spreading of the pandemic, the average medical resources per capita of a community should be independent of the demographic features but only conditional on the exposure rate to the disease. To this end, we design a fairness-aware allocation framework for scarce resources that considers a trade-off between Geographical Diversity and Social Group Fairness as the guiding principles for prevention-centered strategies. We propose a tuning approach to identify an optimal range for the trade-off and investigate the price of fairness using observational data.

3 Optimality of Online Algorithms in the Presence of Fairness

Mohammad Reza Aminian[1], Rad Niazadeh[1], Vahideh Manshadi[2], [1]The University of Chicago, Chicago, IL, [2]Yale University, New Haven, CT, Contact: Mr.aminian1999@gmail.com

There has been a descent research on optimal online algorithms and their comparison with their offline benchmark. However, these proposed algorithms only try to maximize the utility and have no concern about the fairness of their output. Consequently, they are highly susceptibe to make bad use of the biased data, thereby hurting a sensitive group in an unfair fashion just to avoid some costly risks. In our work, we add some fairness restrictrictions to these problems and then try to find the optimal online and offline algorithms. We have considered the regular as well as the noisy version of Pandora's Box problem with two different notions of fairness and provide the optimal online algorithm for each of which. Additinally, we considered the noisy version of the Prophet Inequality problem, and found the optimal offline as well as a variety of online approximation algorithms.

4 An Improved Approximation Algorithm for Maximin Shares

Jugal Garg[1], Setareh Taki[2], [1]UNIV OF ILLINOIS AT URBANA CHAMPAIGN, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Urbana, IL, Contact: setareh.taki@gmail.com

Fair division is a fundamental problem in various multi-agent settings, where the goal is to divide a set of resources among agents in a *fair* manner. We study the case where m indivisible items need to be divided among n agents with additive valuations using the fairness notion of *maximin share* (MMS). While it is known that such an allocation need not exist, Ghodsi et al. 2021 showed the existence of a 3/4-MMS allocation and a PTAS to find a (3/4-⍰)-MMS allocation for an ⍰ > 0. In this presentation, we develop a new approach that gives simple proof for showing the existence of a 3/4-MMS allocation. Furthermore, we extend our result in two directions: First, we get a strongly polynomial-time algorithm to find a 3/4-MMS allocation. Second, we show that a (3/4+1/12n)-MMS allocation always exists, improving the best previous factor.

Smallholder Agricultural Supply Chains

General Session

Session Chair

Can Zhang, Duke University, Durham, NC

1 Optimizing Quality Supervision to Improve Artisans' Productivity

Bhavya Singhvi[1], Divya Singhvi[2], Somya Singhvi[3], Xinyu Zhang[4], [1]Indian Institute of Management Udaipur, Udaipur, India; [2]New York University, Drayton, SC, [3]USC Marshall School of Business, Los Angeles, CA, [4]New York University, New York, NY, Contact: xz1151@stern.nyu.edu

This work is in close collaboration with a social enterprise that works with thousands of women artisans from low-income households in India to manufacture rugs. In order to ensure timely completion of rugs without defects, the enterprise assigns quality supervisors to visit women artisans at regular frequency. In this work, we work with the enterprise to formulate the problem of supervisor assignment and routing with an objective to maximize women artisans' productivity. We show that this problem is computationally hard, and as a result, we develop a novel algorithm that produces a scheme of supervisor assignment and routing with good analytical guarantees. Finally, we show on actual data that the proposed algorithms significantly improve productivity.

2 Two-sided Benefits of Price Transparency in Smallholder Supply Chains

Yuan Shi[1], Joann de Zegher[2], Irene Yuan Lo[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT Sloan, Cambridge, MA, [3]Stanford University, Stanford, CA, Contact: yuansh@mit.edu

This paper studies the impact of price transparency on price and welfare in smallholder supply chains and identifies conditions and driving forces for creating two-sided benefits to both buyers and suppliers. With a new Hotelling model of price search, we find that a moderate increase in price transparency can lead to strong Pareto improvement in both competitive and collusive equilibria for buyers and suppliers under demand asymmetry and costly supply uncertainty. We further establish that the impact of transparency on supply uncertainty is a key determinant of welfare: the welfare benefits can only be fully realized if transparency is created without increasing supply uncertainty. Our analyses reveal important nuances about the interplay between transparency, pricing and supply uncertainty, bringing managerial insights for information platform designers.

3 Operational Challenges for EMS Platforms in Developing Countries

Pieter van den Berg[1], Andre Du Pin Calmon[2], Andreas Kilian Gernert[3], Stef Lemmens[4], Gonzalo Romero[5], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, [3]Kühne Logistics University, Hamburg, Germany; [4]Rotterdam School of Management, Rotterdam, Netherlands; [5]Rotman, University of Toronto, Toronto, ON, Canada. Contact: s.lemmens@rsm.nl

Many developing countries lack the health-emergency infrastructure of the developed world. In this context, our industry partner Flare (operating in Nairobi, Kenya) coordinates existing ambulance providers by operating a platform. Flare aggregates the available ambulance capacity and demand for emergency services. Since ambulance platforms in developing countries make use of independent ambulance providers, the ambulance fleet can only be partially relocated. We study the operational challenges for such platforms as they often lack the knowledge about all ambulances' future availability and their location at a tactical level and typically do not fully control these ambulances.

4 Index-based Yield Protection for Smallholder Farmers

Kehan Lu, Can Zhang, Jing-Sheng Jeannette Song, Duke University, Durham, NC, Contact: kehan.lu@duke.edu

Government subsidies are common in the agricultural sector to protect farmers from unexpected losses due to low prices or low crop yields. However, implementing indemnity-based yield protection schemes that subsidize farmers when the yield level is low is challenging in emerging economies due to small farm sizes and high costs of yield assessment. To overcome this challenge, an innovative index-based approach has emerged in recent years, under which farmers receive a payment when a predetermined index (e.g., rainfall level) predicts a low yield level. This paper explores the design and value of such a government-issued index-based yield protection policy.

1 Balancing Wildlife Habitat Protection and Wildfire Hazard Mitigation with a Critical Nodes Detection Approach

Denys Yemshanov[1], Denyse Dawe[2], Amanda Bakalarzcyk[1], Ning Liu[1], Yan Boulanger[3], Jonathan Boucher[3], Alexandre Beauchemin[4], Dominique Arseneault[5], Marc-André Parisien[2], [1]Natural Resources Canada, Sault Ste. Marie, ON, Canada; [2]Natural Resources Canada, Edmonton, AB, Canada; [3]Natural Resources Canada, Quebec, QC, Canada; [4]Hydro-Quebec, Montreal, QC, Canada; [5]Université du Québec à Rimouski, Rimouski, QC, Canada. Contact: denys.yemshanov@canada.ca

We propose a bi-objective network model for a protection of human infrastructure from wildfires via fuel treatments and maintaining a critical wildlife corridor to improve viability of a threatened wildlife populations. The model combines a Critical Node Detection (CND) problem with a habitat connectivity problem that allocates a minimum-resistance corridor between isolated wildlife refuges. Our results offer optimal solutions to concurrently lessen the threat of wildfires to critical human infrastructure while meeting wildlife conservation management goals. We apply the approach to investigate the protection of the proposed high-voltage power line within the range of a boreal woodland caribou in northern Québec, Canada.

2 Fuel Break Prioritization Using Simulated Fire Events

Yu Wei[1], Erin Belval[2], Matthew Thompson[3], Dave Calkin[4], [1]Colorado State University, Fort Collins, CO, [2]USDA, Fort Collins, CO, [3]U.S. Forest Service, Fort Collins, CO, [4]USDA Forest Service, Missoula, MT, Contact: yu.wei@colostate.edu

Establishing, maintaining and improving fuelbreaks could help fire managers to improve fire suppression effectiveness. Prioritizing fuelbreak management needs to consider the likelihood of future fire activities and how those established fuelbreaks may interact with fire and influencing fire spreads. A two-stage MIP model is developed to use the spatially explicit footprints of a large number of simulated fires to inform the first-stage fuelbreak management decisions. Our presentation introduces the general modeling concepts, the MIP model, the input data requirements and the data processing steps to populate the model. We also present a case study in Southern California that uses this MIP model to support their fuelbreak management.

3 *Igen* a Rule Based System to Link Forest Reality to Mathematical Programming

Silvana Nobre[1], Marc Eric McDill[2], Luiz Carlos E Rodriguez[3], Luis Diaz-Balteiro[1], [1]Universidad Politecnica de Madrid, Madrid, Spain; [2]Pennsylvania State University, University Park, PA, [3]University of Sao Paulo, Piracicaba, SP, Brazil. Contact: silvana.rnobre@gmail.com

Forest managers have used mathematical programming modeling techniques since the early 60s. No matter how diverse the forest is, foresters still need to optimize strategic goals, setting possible management alternatives subject to complex constraints. Generating management alternatives consumes most of the time to formulate the models. This work presents iGen, an Artificial Intelligence approach to develop a flexible rule-based builder to generate forest management alternatives. An Inference Engine applies user-defined rules to a particular forest reality and generates the alternatives in a graph structure. The graph is an easy-to-read stable structure to provide a complete source for the forest models to address each specific forest.

New Frontiers in Revenue Management

General Session

Session Chair

Omar Besbes, Columbia University, New York, NY

Session Chair

Santiago Balseiro, Columbia University, Armonk, NY

1 Column Randomized Linear Programs: Performance Guarantees and Applications

Velibor Misic, Yi-Chun Chen, UCLA Anderson School of Management, Los Angeles, CA, Contact: velibor.misic@anderson.ucla.edu

Many important problems, in revenue management and other areas, give rise to large scale linear programs (LPs), where the number of columns n far exceeds the number of constraints m. In this talk, we propose the column randomization method, which involves randomly sampling a set of columns according to a user-specified randomization scheme and then solving the sampled problem. Our main contribution is a high probability bound on the optimality gap attained by this column randomization method that holds for general LPs and relies only on elementary arguments (LP sensitivity analysis and McDiarmid's inequality). Through numerical experiments with the cutting stock problem and the ranking-based choice estimation problem, we show that column randomization can attain a fixed positive optimality gap in significantly less time than classical column generation.

2 Designing Service Menus for Bipartite Queueing Systems with Strategic Users

Rene A. Caldentey[1], Lisa Hillas[2], Varun Gupta[1], [1]The University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL, Contact: lhillas@chicagobooth.edu

We consider a multi-class multi-server queueing system, in which customers of different types have heterogenous preferences over the many servers available. A service provider designs a menu of service classes that balances maximizing the customers' average service reward and minimizing customers' average waiting time. Customers act as rational self-interested utility maximizing agents when choosing which service class to join. We study the problem of designing an optimal service menu under heavy traffic conditions.

3 Joint Product Design and Assortment Optimization

Mengxin Wang[1], Paat Rusmevichientong[2], Heng Zhang[3], Zuo-Jun Max Shen[4], [1]University of California-Berkeley, Albany, CA, [2]USC Marshall School of Business, Los Angeles, CA, [3]Arizona State University, Tempe, AZ, [4]University of California Berkeley, Berkeley, CA, Contact: mengxin_wang@berkeley.edu

We study the integration of strategic and tactical decisions by examining a setting in which the strategic decision is to choose product designs and the tactical decision is the dynamic assortment optimization. Our formulation has many applications, including optimizing products' return eligibility and determining discounts. We develop an approximation framework for jointly optimizing these decisions and create metrics that measure the individual effectiveness of strategic and tactical decisions. Numerical experiments based on data from a major U.S. retailer show that our method is over 95% effective, representing 10% improvements over methods that fail to integrate strategic and tactical decisions. The experiments also show the prominent role of the strategic design, which explains 85% of the total variation in observed effectiveness across different methods.

4 On the Robustness of Second-price Auctions in Prior-independent Mechanism Design

Jerry Anunrojwong, Santiago Balseiro, Omar Besbes, Columbia University, New York, NY, Contact: jerryanunroj@gmail.com

The seller wants to sell an item to n buyers such that the buyers' valuation distribution is from a given class (i.i.d., mixtures of i.i.d., affiliated and exchangeable, exchangeable, and all distributions) and the seller minimizes worst-case regret. We derive in quasi closed form the minimax values and the associated optimal mechanism. In particular, we show that the first three classes admit the same minimax regret value, decreasing in n, while the last two have the same minimax regret equal to that of the case n = 1. Across all settings, the optimal mechanisms are all second-price auctions with random reserve, which shows its robustness in prior-independent mechanism design. En route to our results, we develop a principled methodology to determine the form of the optimal mechanism and worst-case distribution via first-order conditions that is of independent interest.

New directions in Revenue Management and Pricing

General Session

Session Chair

Elaheh Fata, ON, Canada.

1 Use Neural Networks to Guide Data-driven Operational Decisions

Ningyuan Chen[1], Saman Lagzi[2], Joseph Milner[3], [1]University of Toronto, Mississauga, ON, Canada; [2]Wilfrid Laurier University, Waterloo, ON, Canada; [3]University of Toronto, Toronto, ON, Canada. Contact: saman.lagzi@rotman.utoronto.ca

We use Neural Networks as approximation algorithms to address complex problems. Given sample data that includes observations of decision variables, covariates and the objective function value, we train a neural network, where the input of the neural network is the covariates and decision variables, and its output is the predicted value for the objective function. Then, for a given set of covariates, the decision variable is chosen so the predicted value of the neural network is optimal. We characterize the performance of our methodology in terms of the generalization bound of the Neural Network and show strong performance on both the Newsvendor problem and the assortment pricing problem.

2 Selling and Renting Mechatronics (Digitally Controlled Physical Goods)

Xianfeng Meng, Guang Li, Anton Ovchinnikov, Queen's University, Smith School of Business, Kingston, ON, Canada. Contact: 16xm4@queensu.ca

Firms that sell digital goods routinely utilize free-premium-upgrade business models for product differentiation. When downloading an app, one can try a free version first, then pay to unlock permanent premium functionality or rent additional temporary functionality. Recent technological advances allow physical goods firms to do the same: they can create products with identical hardware that are digitally controlled to allow for similar differentiation. This paper presents a stylized model to explore when physical goods firms should adopt such digitally-enabled product differentiation instead of the traditional product line design with high- and low-end products.

3 Assortment Optimization Under a Multi-item Choice Model

Milad Mirzaee[1], Guang Li[2], Elaheh Fata[2], [1]Queen's University, Kingston, ON, Canada; [2]Queen's University, Kingston, ON, Canada.

We propose a multi-stage choice model under which a customer can purchase multiple products and multiple units of each product in a single shopping incidence. We characterize the structure of the optimal solutions for the assortment optimization problem under various constraints, including cardinality, capacity, and maximum basket size constraints. We prove the problem become NP-hard when it is under the capacity constraint or the maximum basket size constraint . We also consider the price optimization problem under this model and propose efficient algorithms to find the optimal prices.

4 Price and Quantity Promotions for Clearance Sales

Arvind Sainathan[1], Fang Liu[2], [1]NEOMA Business School, Reims, France; [2]University of Chinese Academy of Sciences, Beijing, China. Contact: arvind.sainathan@neoma-bs.fr

We consider a retailer who does clearance pricing to sell off the excess inventory of a certain product. In this context, we compare Buy-One-Get-One (BOGO) and Buy-Two-Get-One (BTGO) policies with traditional price discounts. Specifically, we develop models to examine how customers' discount factors for buying additional units and the amount of inventory affect which promotion policy performs the best.

Fairness in Operations

General Session

Session Chair

Vahideh Manshadi, Yale University, New Haven, CT

1 **Presenter**

Siddhartha Banerjee, Cornell University, Ithaca, NY

2 **Equity Promotion in Online Resource Allocation**

Will Ma[1], Karthik Sankararaman[2], Aravind Srinivasan[3], Pan Xu[4], [1]Columbia University, Cambridge, MA, [2]Meta AI, Menlo Park, CA, [3]University of Maryland, College Park, MD, [4]New Jersey Institute of Technology, Newark, NJ, Contact: pxu@njit.edu

We consider two models for real-time equitable resource allocation problems motivated from applications such as COVID-19 medical supply allocation and food donation problems. The first is called external equity promotion where agents arrive sequentially and have heterogeneous demands, where the demand is drawn from a prior distribution known ahead of time. The goal is to allocate a fair share of resources proportional to the agent's demand. The second is called internal equity promotion, where arriving agents have uniform demands but are heterogeneous in internal traits such as demographics. In particular, each requester can be identified as belonging to one or several groups. An allocation of resources is regarded as equitable when every group of requesters can receive a fair share proportional to the percentage of that group in the whole population.

3 **Designing Online Platforms to Incentivize Outcomes**

Rim Hariss[1], Shreyas Sekar[2], [1]McGill University, Montreal, QC, Canada; [2]University of Toronto, Toronto, ON, Canada.

Recently, there has been a growing concern that the adopted policies by online platform can exacerbate the biases present in the data and lead to outcomes that favour specific groups of popular users. This can affect the long-term health of the marketplace by endangering users' trust in the platform and lead to lopsided growth.This work tackles the problem of designing data-driven policies for online platforms that lead to diverse/fair outcomes. We focus on one lever used by the platform: pricing/revenue sharing. We adopt a two-pronged approach: 1) Use publicly available data from platforms such as Spotify to quantify how current policies lead to undesirable outcomes that only benefit some users; 2) Design policies for revenue sharing that benefit a broad spectrum of users operating on the platform.

The Future of COIN-OR

Panel Session

Session Chair

Matthew J. Saltzman, Clemson University, Clemson, SC

1 **The Future of COIN-OR**

Matthew J. Saltzman, Clemson University, Clemson, SC

The COIN-OR initiative is 22 years old, and the foundation that manages the publication of COIN-OR software is 18. Until a few years ago, the COIN-OR Fountation's mission has been to provide infrastructure for the developer and user communities contributing projects. We have also supported a number of key projects with build systems, packaging for various operating systems, and other tools. In recent years we have moved projects to GitHub to take advantage of contribution and testing infrastructure, giving us the opportunity to redirect our focus to new initiatives. The Foundation is looking to the community to help us plan how to best support the OR community with open-source software and tools and how to find the support (financial and personnel) to accomplish those objectives. Join the discussion here.

Social Media Analytics: Methods, Tools and Platforms
General Session

Session Chair
Tung Cu, Northeastern Illinois University, Chicago, IL

1 **Predicting Poverty Using Socio-Economic Indicators - The Case of Shelby County**
Srikar Velichety, University of Memphis, Cordova, TN
We develop a model to predict poverty in Shelby County and similar United States Metropolitan areas using traditional data sources such as the federal, state, and local agencies and big-data sources such as Google Earth Satellite Images, school catchment area maps to develop features for predicting poverty rates. Finally, we quantify how the location of a census tract predicts its poverty using social network analysis. In doing so, we not only provide ways for researchers to use a combination of deep learning and social network analysis techniques to formulate relevant measures but also provide an overarching framework for policy makers to use multiple sources of data and make decisions that fight poverty effectively. Our work has major implications for researchers using deep learning and social network analysis for policy and decision making.

2 **Analyzing Sparse Consumer Data for Strategic Planning**
Amy Lynn Magnus, Quantum Autonomy LLC, Yellow Springs, OH
We analyze sparse consumer data that are collected via social media to inform strategic planning in retail. We demonstrate how actionable information may be pulled from corpi of less than 5000 words. By ranking responses according to the apparent level of effort demonstrated by respondents, we separate concepts that are easy to convey from those that are difficult. Next, we group concepts with respect to consumer interaction: interactions with tangible elements, cognitive abstractions, social organization, or regulatory behaviors. In this way, we extract overall trends in retail consumer experiences and how consumers problem solve within these experiences. We pay particular attention to transitional concepts that is, those concepts that lie between what consumers grasp easily and what they find difficult to resolve but worthy of effort.

3 **#ad - Analyzing the Differential Impact of Social Media Influencers Ad-disclosure on Consumer Engagement**
Sae Hoon Chang, Ceren Kolsarici, Queen's University, Kingston, ON, Canada. Contact: 13shc3@queensu.ca
We investigate the impact of ad disclosure by influencer type on consumer engagement in social networks. Using deep-learning-based NLP methods and difference-in-difference analysis, we examine how Instagram post characteristics by micro vs. celebrity influencers in ad-disclosure/non-disclosure environments influence re-posts, likes, and comments of platform users. The results suggest ad disclosure leads to generally lower (higher) engagement for micro (celebrity) influencers.

1 **Dependence Learning of Asynchronous Sequences - A Co-evolving Neural ODE Approach**
Yijun LI[1], Leung Cheuk Hang[1], Chaoqun Wang[1], Yiyan Huang[1], Qi Wu[1], Dongdong Wang[2], Zhixiang Huang[2], [1]City University of Hong Kong, Kowloon Tong, Hong Kong; [2]JD Digits, Beijing, China. Contact: yijunli5-c@my.cityu.edu.hk
A challenge of using GRUODE to model multivariate sequences which are both serially and cross-sectionally dependent is that if the components are not in sync, asynchrony would confuse the training process. This is because the architecture of GRUODE makes no distinctions between those representing the path-dependencies in the marginal dynamics and those representing the path-dependencies in the copula dynamics. Targeting asynchrony, we design a new architecture that seamlessly integrates continuous-time ODE solvers with a set of memory-aware GRU blocks. It learns memory profiles separately and addresses the issue of the asynchronous arrival of randomly occurring events cleanly. Numerical results confirm that this new architecture is effective and notably superior compared with a variety of state-of-the-art baseline models on simulated and real-world datasets.

2 **NEEDS TITLE**
Haoyang Cao, École Polytechnique, Palaiseau, France. Contact: haoyang.cao@polytechnique.edu
Inverse reinforcement learning attempts to reconstruct the reward function in a Markov decision problem, using observations of agent actions. It has been observed that the problem is ill-posed, and the reward function isn't identifiable, even with perfect information about optimal behavior. We provide a resolution to this non-identifiability for problems with entropy regularization. For a given environment, we fully characterize the reward functions leading to a given policy and demonstrate that, given demonstrations of actions for the same reward under two distinct discount factors, or under sufficiently different environments, the unobserved reward can be recovered up to a constant. We also give general necessary and sufficient conditions for reconstruction of time-homogeneous rewards on finite horizons, and for state-only rewards.

3 **Menuless and Preference-free Screening Contracts for Fund Managers**
Steven Kou[1], Xuedong He[2], Sang Hu[3], [1]Boston University, Boston, MA, [2]The Chinese University of Hong Kong, Shatin, Hong Kong; [3]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: kou@bu.edu
We propose a family of incentive contracts that can attract some fund managers who are favored by investors and deter any manager who is unfavored by some investors. The contract problem has hidden types, hidden actions, hidden knowledge of preferences, and opportunity cost. In contrast to standard screening contracts, our contracts neither depend explicitly on the utilities of the managers and investors nor have a menu of choices. The contracts have two crucial components: (i) a first-loss deposit to be used to offset some of the principal's losses and (ii) a liquidation boundary. A case study is also given.

1 **1+1>2? Infomation, Humans, and Machines**
Tian Lu[1], Yingjie Zhang[2], [1]Arizona State University, Phoenix, AZ, [2]Peking University, Beijing, China. Contact: lutiansteven@gmail.com
Inspired by the information processing literature, we introduce information volume and identify its roles in determining collaboration performance. We conduct a two-stage field experiment. First, we show that humans, especially experienced ones, might resist alternative information sources but make decisions via a traditional process with small information volumes. Second, machines perform better on larger information scales and better than humans but would unintentionally incur decision biases. Third, in the human-machine collaboration mode, the

presence of machine interpretations could reduce humans' potential resistance to machines' recommendations. More importantly, the co-existence of large-scale information and machine interpretations can invoke humans' systematic rethinking, which in turn, shrinks biases and increases prediction accuracy.

2 The Merton Model Re-visited: Design of Optimal Incentives for Traders in Copy Trading

Kai Sun[1], Mingwen Yang[2], Vijay S. Mookerjee[3], [1]University of Texas at Dallas, Richardson, TX, [2]University of Washington, Seattle, WA, [3]University of Texas- Dallas, Richardson, TX

Copy trading allows retail investors (followers) to automatically copy the trades of experts (traders) in real time after paying following fees to the platform. To help mitigate the potential principle-agency problem, we propose a model that compensates the trader in a way that his trading behavior will not be altered.

3 Impact of Resale Royalty on Sale Prices and Market Liquidity in the NFT Marketplace

Murat M. Tunc[1], Thomas van den Heuvel[1], Hasan Cavusoglu[2], Zhiqiang Eric Zheng[3], [1]Tilburg University, Tilburg, Netherlands; [2]University of British Columbia, Vancouver, BC, Canada; [3]University of Texas-Dallas, Richardson, TX, Contact: m.m.tunc@tilburguniversity.edu

Non-fungible token (NFT) marketplaces facilitate users to mint and trade digital assets. To protect creators, many NFT platforms adopt resale royalty which pays back the creator a certain percentage of future resale amount. The adoption of resale royalty is seemingly beneficial for token creators. However, it may have unintended consequences on the sale prices and liquidity of the underlying NFT. In this paper, we investigate the impact of resale royalty on average sale prices both on the primary market and the secondary market. We find that a higher resale royalty rate leads to a significant decrease in the average primary sale price, however the average secondary sale price significantly increases. Moreover, we find that resale royalty has a negative influence on the liquidity of NFT marketplace, specifically success rate of a sale listing and the duration to sale.

1 Integrated Showroom Locating, Inventory Management, and Pricing

Dincer Konur, Texas State University, San Marcos, TX, Contact: d_k141@txstate.edu

Showrooms are used in practice by many online only brand-name companies for customer engagement. In this paper, we analyze integrated showroom locating, inventory management, and pricing problem. Complexity of the problem is presented. Several properties for the optimum solution are characterized and a solution approach is discussed.

2 Controlling Inventories in Omni / Multi - Channel Distribution Systems with Variable Customer Order-sizes

Peter Berling[1,2,3], Johan Marklund[4], Lina Johansson[5], [1]Norwegian university of science and technology, Trondheim, Norway; [2]Linnaeus University, Växjö, Sweden; [3]Lund University, Lund, Sweden; [4]Lund University, Lund, Sweden; [5]Lund University, Lund, Sweden. Contact: lars.p.berling@ntnu.no

The fast growth of e-commerce and omni/multi-channel retailing brings new challenges for efficient inventory management. One such challenge concerns service differentiation across channels when upstream central warehouses satisfy both direct customer demand and replenishment orders from downstream retailers. Motivated by industry collaboration we address this issue by developing a combined stock method and computationally efficient heuristics designed to deal with real systems characterized by highly variable customer order-sizes and fill rate constraints. A numerical study, including real data, shows that the heuristics provides near optimal solutions and significant opportunities to reduce total inventory costs.

3 The use of Purchase Limits During Shortages

Jihwan Moon[1], Steven Mark Shugan[2], [1]UNSW, Sydney, Australia; [2]University of Florida, Gainesville, FL, Contact: steven.shugan@warrington.ufl.edu

Pandemics, natural disasters, strikes, piracy, and other events can unexpectedly disrupt supply or spike demand, creating shortages. Unlike ordinary stock-outs, shortages involve the entire supply chain. One tool for managing shortages is purchase limits which restrict the quantity each shopper can purchase of the scarce product possibly increasing availability to others. Although altruistic stores might use purchase limits for egalitarian goals (e.g., reducing hoarding, waste, panic buying, arbitrage, and unfair distribution), we find that profit-maximizing stores can use purchase limits to increase profits during shortages. Our findings suggest that stores' price-and-limit strategies depend on shortage severity, store size, competition, and seasonality. Interestingly, purchase limits can improve both store profits and consumer surplus.

4 Product Line and Capacity Decisions for the Real Estate Industry Under Willingness-to-pay Uncertainty

Muge Yayla Kullu[1], Jennifer K. Ryan[2], Jayashankar M. Swaminathan[3], [1]University of Central Florida, Orlando, FL, [2]University of Nebraska–Lincoln, Lincoln, NE, [3]University of North Carolina Chapel Hill, Chapel Hill, NC, Contact: muge@ucf.edu

A residential construction firm's product mix and land investment decisions are highly complex due to the need for long-term planning. We study these decisions using a 3-stage capacity-constrained stochastic optimization model with a heterogeneous consumer base under willingness-to-pay distribution uncertainty. Among others, we find that the land investment increases with uncertainty. We also discuss the impact of competition and housing affordability regulations and find non-intuitive results.

5 End-of-life Product Collection Strategy and Remanufacturing Technology Portfolio Planning

Ying Cao[1], Kai Meng[2], Guang Li[3], Richard Peng[4], Xianghui (Richard) Peng[5], [1]Penn State Erie The Behrend College, Erie, PA, [2]Massachusetts Institute of Technology, Nanjing, China; [3]Queen's University, Kingston, ON, Canada; [4]CAMBRIDGE, MA, [5]Penn State Erie The Behrend College, Fairview, PA, Contact: yxc673@psu.edu

End-of-Life (EOL) product collection rate is an important input in the closed-loop supply chain, which impacts the remanufacturing technology portfolio selection for a remanufacturer who is exposed to various technology alternatives. And, the remanufacturer's technology portfolio decision in return influences his preference for EOL product collection. In this research, we study remanufacturer's joint decision of EOL product collection pricing and remanufacturing technology portfolio planning in order to maximize the expected profit. We derive the properties of optimal pricing strategy and technology portfolio structure. In addition, we conduct numerical study and develop managerial insights for remanufacturing industry.

6 To Clean or to Compensate - How to Manage Data Inaccuracy in Inventory Decisions

Michael Becker-Peth[1], Kai Hoberg[2], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Kühne Logistics University gGmbH, Hamburg, Germany. Contact: m.beckerpeth@rsm.nl

The quality of any operational decision depends on the quality of the input data. However, data used for supply chain decision making is often inaccurate. In our study we focus on inventory management decisions that are subject to inaccurate inventory data. Due to shrinkage and loss, the available physical inventory can be lower than recorded system inventory. To handle this inaccuracy decision makers can decide to invest into cleaning data before placing order decisions. Alternatively, decision makers can deliberately decide to not clean the data, but to account for the inaccuracy by compensating the actual order decision. Depending on cleaning cost and the efficiency loss due to compensation, decision makers have an incentive to either clean or compensate. We present a set of hypotheses on the cleaning-compensation trade-off and test these hypothesis in a lab experiment.

7 Characterizing Human-Automated Vehicle Interactions: An Investigation into Car-following Behavior

Yanlin Zhang, Alireza Talebpour, Yalda Rahmati, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: yanlinz4@illinois.edu

Automated vehicles are expected to influence human drivers' behavior. Accordingly, capturing such changes is critical for planning purposes. Focusing on the car-following behavior, a key question is whether existing car-following models can replicate such changes in human behavior. Using a dataset collected from the car-following behavior of human drivers when following automated vehicles, this presentation offers a robust methodology based on the concept of dynamic time warping to capture the critical parameters that can best substantiate the behavioral changes in human drivers. The findings suggest that some common car-following models cannot capture the changes in human behavior in response to automated vehicles and imply that a stochastic extension to car-following models is needed when analyzing and simulating a mixed-autonomy traffic flow environment.

8 Order Quantity or Total Consumption? How Consumers Mode of Payment Affect Gasoline Retailer's Profitability

Nathan C. Craig[1], Ananth Raman[2], Ehsan Valavi[3], [1]Ohio State University, Columbus, OH, [2]Harvard University, Boston, MA, [3]Harvard Business School, Boston, MA

Gasoline is believed to be an inelastic commodity. Yet, its high price volatility raises questions about how consumers react to its price variation. In this research, we curated a dataset from a large gasoline retailer to study the effect of consumers' mode of payment on their order quantity.

9 An Online Platform's Pricing and Sourcing Decisions with Vendor Managed Inventory

Dennis Yu, Clarkson University, Potsdam, NY, Contact: dyu@clarkson.edu

We study an online platform's optimal pricing and sourcing decisions when the platform can purchase from a manufacturer who also provides VMI option to the platform while having its own OEM direct channel. We consider two competing distribution channels including the platform's online selling channel and the manufacturer's direct channel by using the platform's online retailing services. Both the platform and the manufacturer need to determine the retail prices to compete for the market demand with customers who have a diversified preference in retail channels. We take the platform's perspective to investigate the platform and the manufacturer's optimal pricing decisions under two different scenarios with a cooperative dual-channel competition framework.

1 Bounded Rationality in Capacitated and Multi-variate Sourcing Decisions

Thomas B. Cassidey[1], Nickolas K. Freeman[2], Sharif Melouk[2], [1]The University of Alabama, Tuscaloosa, AL, [2]The University of Alabama, Tuscaloosa, AL, Contact: tcassidey@crimson.ua.edu

We study the decision making behavior of concurrent sourcing firms subject to all-or-nothing outsource supply disruptions. The sourcing decision maker must balance capacity constraints, demand risk, supply uncertainty, and costs to determine component production and order amounts under the supplier delivery and disruption scenarios. We show that diversification and order volume error is predicted by bounded rationality. We perform a laboratory experiment to test the effect of differing production capacity constraints on decision behavior. Although the ability to concurrently source is a sunk cost and supply disruption is mitigated by contingent planning, we find strong evidence for diversification error, both when sole and dual sourcing are optimal, accompanied by evidence of bounded rationality.

2 Building a Bidirectional Supply Chain for Farm to Rural Grocery to Wholesale

Karen L. Donohue, University of Minnesota, Minneapolis, MN

This talk highlights results from a multi-year USDA sponsored project developing a new model for small and medium-sized crop producers to access wholesale markets in the Midwest. The proposed Farm to Rural Grocery to Wholesale (F2G2W) model leverages an existing network of rural grocery stores and their wholesale suppliers to "backhaul" locally grown produce on emptied wholesale trucks for redistribution through wholesale markets. The project aims to increase the viability, competitiveness, and sustainability of rural produce supply chains. In piloting the model, a special focus is placed on how to align objectives and counter-act potential behavioral detractors across diverse stakeholders.

3 Voluntary Disclosure, Endogenous Matching and Bargaining: Theory and Experiments

Kyle Hyndman[1], Andrew M. Davis[2], [1]University of Texas at Dallas, Richardson, TX, [2]Cornell University, Ithaca, NY

We study bargaining with private information in which the privately informed player may voluntarily and truthfully disclose their private information. We do this both when there is and is not a potential matching benefit to disclosure, whereby a disclosing player may be matched with a better partner than a non-disclosing player. We generate theoretical predictions and then test these predictions in two laboratory studies. A key insight is that disclosure may actually be driven by the demands of uninformed players, particularly those strong enough, or attractive enough, to be able to insist upon it as a requirement for doing business.

4 The Market Value of Sustainability Disclosure: A Cross-cultural Study

Tim Kraft[1], Douglas Thomas[2], Yanchong (Karen) Zheng[3], [1]NC State - Poole College of Management, Raleigh, NC, [2]University of Virginia, Charlottesville, VA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: thomasd@darden.virginia.edu

Partnering with Goodio, a Finland-based craft chocolate producer, we explore how consumers react to story-based and fact-based messaging regarding supply chain (internal) and community development (external) initiatives. We test the effects of transparency in Goodio's two largest markets - the US and Finland. We find that consumers in both markets prefer messaging on internal intiatives over external initiatives. However, Finnish consumers prefer story-based messaging, while US consumers prefer fact-based messaging. To further the latter result, we test the effects of cultural differences between the two subject pools.

5 Exclusive or Not an Experimental Analysis of Parallel Innovation Contest

Ramazan Kizilyildirim[1], Gizem Korpeoglu[2], Ersin Korpeoglu[3], Mirko Kremer[4], [1]UCL, London, United Kingdom; [2]Eindhoven University of Technology, Eindhoven, Netherlands; [3]University College London, London, United Kingdom; [4]Frankfurt School of Finance and Management gGmbh, Frankfurt Am Main, Germany. Contact: ramazan.kizilyildirim.19@ucl.ac.uk

We study parallel innovation contests. The quality of a solver's solution in a contest can be improved by exerting effort, yet it is also subject to an output uncertainty. Theory shows that organizers should discourage solvers from participating in multiple contests under low output uncertainty to benefit from solvers focusing their efforts into a single "exclusive" contest rather than splitting them across multiple "non-exclusive" contests. In a controlled laboratory experiment, we find that non-exclusive contests are attractive for organizers even at low output uncertainty levels. We link this to behavioral drivers that lead to a smaller average and a larger variance of solvers' effort.

6 Ups and Downs: How to Shape Spectators' Sentiment

Hongqiao Chen[1], Ming Hu[2], Jingchen Liu[3], Yaniv Ravid[4], [1]Nanjing University, Nan Jing Shi, China; [2]University of Toronto, Minneapolis, MN, [3]Nanjing University Business School, Nanjing, China; [4]University of Toronto, Toronto, ON, Canada. Contact: y.ravid@rotman.utoronto.ca

Under the application of prospect theory, this paper considers a decision maker who wishes to maximize an audience's experienced utility under three different settings. First, we investigate the problem of simultaneous vs. sequential release of content such as songs or TV episodes, where the decision maker may not know a priori the audience's valuation of each item. Second, we study the problem of releasing a piece of good vs. bad news, where the decision maker may preempt the release with other pieces of their choice. Lastly, we consider the problem of sequencing experiences of known valuations, such as in a concert, and provide guidelines on the decisions which give the most pleasant experiences.

7 Censorship Bias and Self-inflicted Stockouts in Grocery Retail Replenishment

Bengu Ozdemir, Antti Tenhiala, IE Business School, Madrid, Spain. Contact: bengu.ozdemir@student.ie.edu

In the retail industry, store managers are typically empowered to adjust the proposals of automatic store replenishment (ASR) systems to incorporate their private knowledge. Apart from occasionally improving ordering decisions with human insights and information that is not available to the algorithms of the ASR system, we show that the store managers are suspect to biases. We examine the prevalence and performance implications of censorship bias, which explains a paradox where retailers order less after a stockout. Accounting for the endogeneity of ordering decisions, we show that censorship bias is equally prevalent and detrimental as the well-known anchoring bias of ordering behavior.

9 Who Should Bear the Risk? A Theoretical and Behavioral Investigation of After-sales Service Contracts

Rob Basten[1], Ozge Tuncel[2], Michael Becker-Peth[3], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Maastricht University, Eindhoven, Netherlands; [3]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands.

Using the right after-sales service contract is key to achieve high equipment availability. Resource-based contracts fail to motivate suppliers to provide reliable products as they are paid for their after-sales services. Performance-based contracts shift much of the downtime risk to the supplier, but then customers might reduce care efforts. We propose the full-care contract (FCC) to achieve both high reliability and care. We analytically find that only the FCC can achieve full chain efficiency. We conduct a lab study with decision makers as suppliers. It confirms that the FCC achieves highest total profits. We further observe that effort levels set by suppliers are above normative predictions.

1 **Aggregating Privacy-Sensitive Forecasters**
Marat Salikhov[1], Ruslan Momot[2], [1]New Economic School, Moscow, Russian Federation; [2]Kellogg School of Management, Northwestern University, Ann Arbor, MI, Contact: msalikhov@nes.ru
Organizations often make forecasts by eliciting inputs from their internal experts and then aggregating these inputs for decision-making. Experts are generally interested in providing quality forecasts, however, in some cases their incentives may be distorted by fears for their privacy. Allowing experts to have "plausible deniability" about their forecasts may improve both the participation rates and forecast quality. We propose introducing such deniability by adding noise to all publicly made forecasts. Adding noise has two effects on forecasting performance: a negative effect - noisy forecasts are less efficient to aggregate, and a positive effect - the experts have weaker incentives to bias their forecasts. We construct an analytical model that describes the optimal level of noise and analyze its implications for forecast aggregation.

2 **Can Crowdsourcing Cure Misinformation? The Impact of Twitter's Birdwatch Program on Content Generation**
Sameer Borwankar, Jinyang Zheng, Karthik Kannan, Purdue University, West Lafayette, IN, Contact: sborwank@purdue.edu
All content-sharing sites, including social media platforms, face the creation and spread of misinformation, which leads to wrong beliefs, a hyper-partisan atmosphere, and public harm. Experts have suggested leveraging the "wisdom of crowds" to identify misinformation. However, the implication of such crowdsourcing programs on their participants is not carefully studied in the field. We take the first step and leverage the quasi-field experiment of Twitter's Birdwatch program to investigate the causal effect of participating in the crowdsourcing program on the subsequent activities of the participants. The results show negative impact on the quantity of the generated content and some positive impact on the quality of the content.

3 **Growth Versus Competition in Emerging Digital Marketplaces: Evidence from Amazon Prime's Effect on Competitors**
Kevin Zhu[1], Zhe Zhang[2], Xiaofeng Liu[3], [1]University of California-San Diego, La Jolla, CA, [2]University of California-San Diego, San Diego, CA, [3]UC San Diego, La Jolla, CA, Contact: kxzhu@ucsd.edu
It is important to understand the impacts of a dominant player's growth on its competitors in an emerging digital market. Amazon has been a dominant flagship retailer in online markets. As Amazon Prime membership is a discrete moment when adopters significantly increase their Amazon usage, we analyze the impacts of Prime adoption on adopters' non-Amazon spending. The results show that Prime adoption has a positive spillover on adopters' non-Amazon spending. More specifically, the positive spillover is more salient for novice adopters, but not significant for experienced adopters. We propose and validate a potential mechanism: the positive spillover is from increased comfort gained through the increased Amazon usage, and also rule out other possible explanations. The results highlight the potential value of dominant player's growth in market expansion.

Decision Making in Innovation Settings
General Session

Session Chair
Param Pal Singh Chhabra, University of Alberta, Edmonton, AB, Canada.

1 **It'S Time to Break Up: Dynamics Surrounding Young-established Firm Alliance Duration**
Navid Asgari[1], Annapoornima Subramanian[2], Moren Levesque[3], Pek-Hooi Soh[4], [1]Fordham University, New York, NY, [2]National University of Singapore, Singapore, Singapore; [3]York University, Toronto, ON, Canada; [4]Simon Fraser University, Toronto, BC, Canada. Contact: mlevesque@schulich.yorku.ca
While young firms often benefit from their relationships with established firms, these relationships can be risky. We adopt the young firm's perspective and dynamically weighs the tradeoffs between risks of continuing and discontinuing a relationship with an established firm, thereby deciding its alliance duration. We first develop an analytical model to understand how the alliance duration (time between alliance formation and termination) between the young and established firms is affected by each firm's alliance portfolio size, the young firm's IP portfolio size, and the number of technologies underlying the alliance that were affected by a technological discontinuity. We then test the resulting hypotheses on a large sample of alliances between biotechnology and pharmaceutical firms during the 1986-2000 period, which straddles a technological discontinuity.

2 **Causal Gradient Boosting**

Amandeep Singh, Wharton Business School, philadelphia, PA

Recent advances in the literature have demonstrated that standard supervised learning algorithms are ill-suited for problems with endogenous explanatory variables. In this paper, we propose an alternative algorithm called boostIV that builds on the traditional gradient boosting algorithm and corrects for the endogeneity bias. We demonstrate that our estimator is consistent under mild conditions. We carry out extensive Monte Carlo simulations to demonstrate the finite sample performance of our algorithm compared to other recently developed methods. We show that boostIV is at worst on par with the existing methods and on average significantly outperforms them.

3 **Issues and Models in Autonomous Vehicle Operations**

Amin Abbasi Pooya[1], Nagarajan Sethuraman[2], Suman Mallik[2], [1]University of Kansas, Lawrence, KS, [2]University of Kansas, Lawrence, KS, Contact: a.abbasipooya@ku.edu

The presentation is based on an ongoing research on modeling operations management issues in the autonomous vehicle market. We use game theoretical models to capture the market dynamics, characterize the equilibrium, and analyze its properties of it. Our results provide insights for autonomous vehicle manufacturers to optimize their operations.

4 **Choosing to Compete: The Role of Group Size, Prize Type, and Participant Heterogeneity on Contest Entry**

Jeeva Somasundaram[1], Konstantinos Stouras[2], [1]IE Business School, Madrid, Spain; [2]UCD, Dublin, Ireland. Contact: konstantinos.stouras@ucd.ie

This experiment compares the performance of three key contest designs: the number of potential entrants, whether to split the winning prize among entrants or not, and the heterogeneity among entrants. We find that participation is maximized when the contest has higher potential entrants, offers a winner-takes-all prize and entrants appear ex-ante homogeneous. This contest design performs the best by mitigating the effects of competition by providing the greatest possible returns on entry and by limiting the degree to which heterogeneity discourages weaker entrants. These findings could inform the design of competitive markets with entry such as on-demand services with endogenous supply, ideation contests, and campaigns to support a philanthropic cause or a marketing promotion which mainly seek to attract entrants into the pursuit of a common objective.

1 **Network Models for Multiobjective Discrete Optimization**

David Bergman[1], Merve Bodur[2], Carlos Henrique Cardonha[1], Andre Augusto Cire[3], [1]University of Connecticut, Storrs, CT, [2]University of Toronto, Toronto, ON, Canada; [3]University of Toronto Scarborough, Rotman School of Management, Toronto, ON, Canada. Contact: bodur@mie.utoronto.ca

We propose a novel framework for solving multiobjective discrete optimization problems with an arbitrary number of objectives. Our framework formulates these problems as network models, in that enumerating the Pareto frontier amounts to solving a multicriteria shortest path problem in an auxiliary network. We design tools and techniques for exploiting the network model in order to accelerate the identification of the frontier. We show that the proposed framework yields orders-of-magnitude performance improvements over existing state-of-the-art algorithms on four problem classes containing both linear and nonlinear objective functions.

2 **Multicriteria Decision Support for the Evaluation of Electricity Supply Resilience: Exploration of Interacting Criteria**

Eleftherios Siskos, Peter Burgherr, Paul Scherrer Institute, Villigen, Switzerland. Contact: eleftherios.siskos@psi.ch

The increasing risk of extended electricity supply disruptions and severe electricity price fluctuations are stressing the need for an evaluation of electricity supply resilience. Towards this direction, this paper proposes a multicriteria decision support framework to assess resilience at a country level, on the basis of three major dimensions: Resist, Restabilize, Recover. In total, 35 European countries are ranked according to their performance on 17 indicators, through a synergy of MCDA methods, techniques and communication protocols. The assessment framework has been extended to incorporate the Choquet Integral, as an importance index, in order to accommodate potentially interacting pairs of criteria and negate their arbitrary effects on the final ranking.

3 **Incorporating Uncovered Structuralpatterns in Value Functions Construction**
Mohammad Ghaderi[1], Milosz Kadzinski[2], [1]Pompeu Fabra University (UPF), Barcelona, Spain; [2]Poznan University of Technology, Poznan, Poland.
A common approach in decision analysis and choice modeling is to infer a preference model in the form of a value function from the holistic choice examples. This paper introduces an analytical framework for estimating individuals' preferences through uncovering structural patterns that regulate general shapes of value functions. We suggest a simple characterization of structural patterns and investigate the impact of incorporating information on such patterns on the predictive validity and estimation accuracy of preferences through an exhaustive simulation study and analysis of real decision makers' preferences. We found that accounting for the structural patterns at the population level considerably improves the predictive performance of the constructed value functions at the individual level. This finding is confirmed across a wide range of settings with different levels of heterogeneity among the individuals and various complexity levels in their true preferences. We found, however, that improvement in the predictive performance is more significant when the choice examples come from a larger number of individuals, and when a smaller amount of preference information is available. The proposed model is developed based on a convex optimization problem with linear constraints, thus being computationally efficient and applicable to datasets of realistic size.

4 **Bound Set Based Branch and Bound Algorithms for Multi-objective Integer Linear Programming Problems**
Sune Lauth Lauth Gadegaard, Aarhus University, Skanderborg, Denmark.
This talk takes its outset in the paper "*Bi-objective Branch-and-Cut Algorithms Based on LP Relaxation and Bound Sets*". The concept of bound-set-based branch-and-bound algorithms will be introduced and we show how branching can be performed in both decision and objective space. The algorithm discussed computes, for each branching node, a lower-bound set and compares it with an upper-bound set. We outline approaches for fathoming branching nodes, and we propose an updating scheme for the lower-bound sets that prevents us from solving the bi-objective linear programming relaxation of each branching node. To strengthen the lower-bound sets, we propose a bi-objective cutting-plane algorithm that adjusts the weights of the objective functions such that different parts of the feasible set are strengthened by cutting planes. In addition, we discuss a recent generic branch-and-bound algorithm for solving multi-objective integer linear programming problems. In the recent literature, competitive frameworks have been proposed for bi-objective 0-1 problems, and many of these frameworks rely on the use of the linear relaxation to obtain lower bound sets. When increasing the number of objective functions, however, the polyhedral structure of the linear relaxation becomes more complex, and consequently requires more computational effort to obtain. Here, a speed-up technique is proposed to make these computations feasible. This is done by warm-starting a Benson's like algorithm. Finally, branching in the objective space is extended to higher dimensions and some computational results are presented.

Margaret Pierson, Wayfair, Seattle, WA

1 **Trailer Rebalancing at Convoy**
Yashar Khayati, Convoy, Seattle, WA, Contact: yashar.khayati@convoy.com
Semi-truck Trailers are Bigger than Scooters Supply chains are intrinsically imbalanced in terms of empty trailer needs. A mixed-integer programming (MIP) model, TRIP (Trailer Rebalancing Integer Programming), is developed at Convoy which is responsible for repositioning all the empty trailers based on real-time information. The objective of the model is to get the right amount of trailers, to the right places, at the right time to service shipper customers considering all various business constraints.

2 **Demand Shaping Via Exposure Mechanisms**
Emre Ertan, Wayfair
Wayfair has an opportunity to align supplier and Wayfair incentives using exposure as a mechanism. By nudging customers towards products that have better unit economics, we can reduce supply chain costs and incentivize suppliers to do the same. There are many challenges in implementing this strategy and we'll share our early work and learnings from taking on this question.

3 **Optimization of Pharmacy Prescription Fill Process Using Machine Learning**
Taras Gorishnyy, CVS Health, Woonsocket, RI
CVS Retail Pharmacy fills over 1.5 billion prescriptions each year. Each fill involves multiple steps which often requires interactions between a pharmacists, prescribers, payors and customers. Optimizing efficiency and effectiveness of the dispensing process in critical to ensure positive customer and colleague experience.
In this talk we will discuss how CVS Health uses machine learning to optimize its prescription fill process. We will review application areas for analytics, describe design and performance of data science models and discuss complexity of implementing real time technology at scale.

4 **Multi-Echelon Temperature-Constrained Supply Chain Management at Amazon**
Gizem Cavuslar, Amazon.com, Seattle, WA
Fresh, Amazon's grocery business, operates on a multi-echelon temperature constrained supply chain. Fast delivery and easy customer access are key to the customer satisfaction. Therefore, the end nodes of the supply chain, online and offline, should be close to the major population areas. Unfortunately, this limits the size of the stores and storage facilities, causing a year-round capacity constrained nodes. On top of that, having considerably high number of new stores with less than one year of operation and trickling effects of the pandemic are resulting in non-stationary demand and supply processes. We, the scientists at Amazon Fresh, utilize a combination of Machine Learning, Operations Research, and Reinforcement Learning approaches to model and solve this non-stationary, multi-echelon, multi-period, and perishable inventory optimization problem. In this talk, we will provide an overview of the problem space and go over modeling approaches developed by the Grocery Inventory Science team.

1 **Machine Learning based Simulation for Fault Detection in Microgrids**
Joshua Darville, Nurcin Celik, University of Miami, Miami, FL
Fault detection (FD) is crucial for a functioning microgrid (MG) but is particularly challenging since faults can stay undetected indefinitely. Hence, there is a need for real-time, accurate FD in the early phase of MG operations to mitigate small initial deviations from nominal conditions. To address this need, we propose an FD framework for MG operational planning. Our proposed framework is synthesized from i) a dataset generated by introducing faults into an MG with PV cells, ii) processing the dataset to train various machine learning (ML) models for FD, iii) benchmarking the resulting FD models using classification metrics, and iv) applying an appropriate

fault mitigation strategy. Although noisy measurements were present during the experiment due to variations in ambient temperature and solar irradiance, our proposed FD model is shown to be both computationally efficient with an average training time of 1.76 seconds and accurate with a weighted F-score of 0.96.

2 Resource Allocation Subject to Stochastic Failures: Application to Snow Plowing Operations in Utah

Yinhu Wang[1], Ye Chen[2], Ilya Ryzhov[3], Xiaoyue Liu[1], Nikola Markovic[1], [1]University of Utah, Salt Lake City, UT, [2]Virginia Commonwealth University, Richmond, VA, [3]University of Maryland, Baltimore, MD

We consider a two-stage planning problem where a fleet of snow plow trucks is first divided among a set of independent regions and then each region designs routes for efficient snow removal. However, snow plow trucks are subject to failures, which gives rise to a stochastic variant of the problem. In a risk-neutral setting, we allocate trucks such that the expected maximum turnaround time across all the regions is minimized and devise a custom branch-and-bound algorithm to solve the non-linear non-convex problem optimally. In a risk-averse setting, we allocate trucks to minimize the maximum turnaround time that can be sustained with a user-specified probability. The chance-constrained program is solved optimally with a custom solution algorithm. The benefits of the proposed methods are demonstrated through implementation in northern Utah.

3 Dynamic Data-driven Approach for Secure and Resilient Energy System Cyberinfrastructure

Kevin Jin[1], Yanfeng Qu[2], Gong Chen[2], [1]University of Arkansas, Fayetteville, AR, [2]Illinois Institute of Technology, Chicago, IL, Contact: dongjin@uark.edu

We apply the dynamic data-driven applications systems (DDDAS) paradigm to enhance cyber security and resilience of energy systems. We use software-defined networking (SDN) to monitor and control the cyberinfrastructure and explore security applications that consider both the cyber and physical characteristics of the grid to detect and mitigate attacks, such as the emerging MadIoT attack, a variant of Internet of Things (IoT) botnet attacks, allow an adversary to disrupt the power grid's normal operation by manipulating the total power demand using compromised IoT devices of high wattage. We take a decentralized approach to selectively deploy the learning-based detection engine on switches for fast detection. We also utilize the global visibility and direct network control offered by SDN to design algorithms to mitigate the attack traffic and self-heal the network.

4 Multimodal Fusion of Satellite and Radar to Predict Future Weather Events

Grace Metzgar[1], Nathan Gaw[2], [1]Air Force Institute of Technology, Wright-Patterson AFB, OH, [2]Air Force Institute of Technology, Wright-Patterson AFB, OH, Contact: Grace.Metzgar@afit.edu

The uncertainty of Earth's weather greatly impacts the lives of the general public inciting the application of machine learning in meteorology. However, the complexity of weather data increases the difficulty of creating models that can accurately recognize and forecast weather patterns. To address these shortcomings, we employ the Storm EVent ImagRy (SEVIR) dataset which was created to aid in the inefficiencies of developing these complex models by combing spatial and temporal weather data from multiple sensing modalities. We hypothesis that utilizing such data in machine learning techniques will allow for greater accuracy and reliability in predicting certain weather patterns.

AbstractThe fast and cost-efficient delivery of goods ordered online is logistically a challenging problem. Many firms are looking for ways to cut delivery times and costs by exploring opportunities to take advantage of drone technology. Deploying drones as a promising technology is more efficient from both environmental and economic perspectives in last-mile delivery. This paper considers a last-mile delivery system in which a set of drones are operated in coordination with public transportation system to deliver a set of orders to customer locations. A mathematical model based on Vehicle routing Problem (VRP) is extended to solve this problem. A real-world case inspired by Bremen 2025 transportation paradigm is also developed to validate the developed mathematical formulation. Results show that the sequence of visiting customers and public transport stations highly impacts the remaining charge and efficiency of drone tour planning. Also, using public transport vehicles, which enables drones to charge their battery or to approach customers, can reduce the number of drones required for satisfying the demands in a service area. The results show that there are high potentials to save energy for drone-enabled last-mile delivery by using the public transportation network. Problem Description and Mathematical FormulationFor this article, more than 60 research and paper written in the context of last-mile delivery and using emerging technologies, have been surveyed. Because of limitation in number of abstract pages, only nine of these references have been mentioned [1]-[9]. This section describes the main assumptions of the defined problem and presents the associated mathematical model. The objective function of the problem aims at minimizing the total required energy for the last-mile delivery of customer orders. Hence, the following key decisions must be optimized. (i) assignment of customer locations to depots, (ii) assignment of customers' packages to drones, (iii) sequence of visiting customer locations and public transport stations, and (iv) assignment of flying drones to pre-existing public transport routes, if required. In this problem, not only do drones use public transportation for charging purposes, but also, they may use them for traveling between locations without further consuming energy. Drones can only be mounted on public transport at the first (public station 1) and middle stations for charging operations, either from a warehouse node or customer node. Drones are not allowed to hop on public transport at the last station (station |B|) due to the relatively long suspension of public transport operation until its resumption. So, drones can only leave station |B| to travel toward a warehouse or customer node and are not allowed to enter the last station. Also, drones are not allowed to leave the first station toward a warehouse or customer node because the station is the start point, and the public transport has not yet resumed its operation, which as a result, the drone battery did not receive energy. After assuming additional operational assumptions, a mixed-integer linear programming has been developed based on four sets including set of drones, customers, warehouses, and public transportation vehicles. Besides, an objective function has been considered in terms of total energy consumption minimization subject to three sets of constraints including (A) route feasibility and synchronization, (B) capacity and weight tracking, and (C) energy tracking and charging policy. The developed model is validated and implemented using a real-world scenario inspired based on the actual input parameters of nodes in Bremen, Germany. To further analyze the impact of input parameters, the paper has conducted an experimental study changing the problem size in terms of the number of warehouses and customers, the warehouse locations (near to service area/far from service area), and the available number of drones at each warehouse. Finally, discussion and managerial insight were investigated based on the benefits of the proposed drone delivery system based on the public transportation network from three points of view: e-commerce companies and LSPs, customers, and the environment. References: As attached in the file sent. (Word limitation)

2 Competing on Emission Charges

Nicole Adler[1], Gianmarco Andreana[2], Gerben De Jong[1], [1]Hebrew University of Jerusalem, Jerusalem, Israel; [2]University of Bergamo, Bergamo, Italy.

Motivation

The aviation industry currently produces 2.5% of global carbon dioxide (CO_2) emissions, and this is expected to triple by 2050 if air transport continues to grow according to current trends [3,5]. In the absence of a global government, decision-makers at the local, national and supra-national levels (e.g. the European Union and ICAO) have mandated various environmental policies in an attempt to control aviation emissions [4]. However, the extent and the efficiency of these environmental measures diverge significantly across countries and regions.

Research problem

Given the existing asymmetry of environmental policies, we investigate the impacts of emission reduction schemes on competitive aviation markets. Consequently, we seek to identify a set of environmental policies that may lead to efficient social welfare allocations. We focus on the possibility of developing a cooperative and unique equilibrium strategy for all regulators, in an attempt to overcome the environmental free-riding problem [6].

Methodology

We define our game-theoretic model as a two-stage Nash game. The set of players composing the first stage is characterized by multiple local and regional regulators in addition to supra-national decision-makers. Each regulatory body maximizes the social welfare of the area under its control by setting the level of environmental taxation applied, including charges on passengers and airline taxes per ton of CO_2 produced. In the second stage, airlines compete through profit maximizing, best response functions that set airfares and service frequencies, hence market shares per city pair [1-2].

To respond to changes in the climate policies, airlines may choose to (i) sell off less efficient aircraft and possibly replace them with newer technologies, (ii) utilize higher emission aircraft less, (iii) reallocate higher emission aircraft to routes with lower environmental taxes and/or (iv) reduce frequencies on regulated routes. These decisions will impact the capacity offered per city pair.

The game is solved iteratively by developing a grid-search algorithm in the first stage and an interior point penalization algorithm [8] in the second stage. We search for the Subgame Perfect Nash Equilibrium (SPNE) of the game in which no regulator nor airline would choose to deviate from the equilibria outcome [7].

Expected results

The main result of this research is an equilibrium outcome for airlines and regulatory bodies that ensures ongoing connectivity whilst minimizing the environmental impact of aviation. To be specific, we find the equilibrium in airfares, service frequency, fleet composition and aircraft allocation for the airlines. We also search for the efficient set of environmental charges that maximizes the social welfare of passengers, airlines and governments belonging to a regulator's jurisdiction. Finally, we test whether an awareness of the potential policy levers being set by each regulator, at the airport, country, regional and global scale, leads to more efficient and coordinated decisions.

Contribution

The contribution of this paper is threefold. First, we develop a game-theoretic framework that assesses the impact of environmental policies on the aviation industry a-priori, taking into account both airline and regulator competition. Second, we propose a heuristic framework to solve two-stage games by addressing the double dynamics resulting from the nature of the consecutive stages of implementation. Third, the proposed framework will provide a decision support tool and guidance to national and supra-national policymakers when defining new mechanisms to achieve environmental goals in the most efficient manner possible.

3 Award Presenter

Bazyli Szymanski, Massachusetts Institute of Technology, Cambridge, MA, Contact: bazyli@mit.edu

Most existing RM systems are built assuming monopoly, and academic work that models competition tends to seek game-theoretic equilibria given extensive knowledge and strong assumptions. In contrast, we propose a simple *competitor adjustment* approach, where airline's willingness-to-pay (WTP) estimates used for fare quotation are altered exclusively based on current competitor fare.

The adjustment is tested in the emerging context of continuous pricing, where airlines are not restricted to a small set of price points. We quantify the competitive impacts of the adjustment through simulations and discuss whether it could help pave the way to adoption of new WTP-based optimizers for continuous pricing.

4 A Market-based and Policy-based Competitor-aware Conditional Forecasting Method

Tim Yuxuan Lu, Massachusetts Institute of Technology,

Cambridge, MA, Contact: lutim@mit.edu
The proliferation of OTA, implementation of the NDC, and removal of fare class restrictions promote price transparency and amplify price competition. Forecasting demand based on observations and predictions of competitors' offerings can benefit airlines significantly. We propose a market-based and policy-based competitor-aware conditional forecaster, which predicts competitors' policies based on historical policy observations and then explicitly constructs forecasts based on actual and predicted competitors' policies. With the proposed forecaster, forecast accuracy can be improved, and fare class forecasts can be dynamically adjusted according to competitors' offerings. The concept, methodology, process, and preliminary results are shared.

Air Traffic Management and Flight Delay

General Session

Session Chair

Ke Liu, 1</sup

1 Air Corridor Metrics Development: A Case Study Based on Traffic Within 150 Miles of Edwards Air Force Base

Xuan Jiang, UCB
Currently, the aviation metrics are mostly developed by simulation and optimization which is redundant and bulky (see Bauer et al. 2021). Our work aims on ending this trend and propose different ways of aviation metrics based on different stakeholders' interests while building an air corridor. We proposed our way of describing the corridor as a cube based on the vertical and lateral distance threshold FAA regulated. We used aircraft time, the number of aircraft within the cube within a certain period, and certain location slices of the corridor. We gave methods for choosing the best corridors from several corridors, and we proposed an innovative way to choose the best route for a given origination and destination. We demonstrate the methodology with a case study based on the data of air traffic within 150 miles of Edwards Airforce Base and the method is transferrable to other cases.

2 Benefits of Shifting Passenger Traffic from Air to Rail: A Case Study of California High-speed Rail

Kaijing Ding[1], Lu Dai[1], Mark M. Hansen[2], [1]University of California, Berkeley, Berkeley, CA, [2]University of California-Berkeley, Berkeley, CA
This study provides a method to quantify the benefit of shifting passenger traffic from air to high-speed rail from the perspective of flight delay cost reduction. We first estimate the number of flight reductions for airport pairs based on the HSR ridership forecast and then apply Lasso models to estimate the impact of the reduced queuing delay of SFO, LAX and SAN on the arrival delay of national Core 29 airports. Finally, we monetize these delay reductions and ultimately arrive at delay cost savings of $71-123 million in 2029 and $370-618 million in 2033.

3 Excess Delay from GDP: Measurement and Causal Analysis

Ke Liu[1], Mark M. Hansen[2], [1]University of California, Berkeley Berkeley, CA, Berkeley, CA, [2]University of California-Berkeley, Berkeley, CA, Contact: liuke126@berkeley.edu
GDPs have been widely used to resolve excessive demand-capacity imbalances at arrival airports by shifting foreseen airborne delay to pre-departure ground delay. While offering clear safety and efficiency benefits, GDPs may also create additional delay as a result of imperfect execution and uncertainty in predicting arrival airport capacity. This paper presents a methodology for measuring excess delay resulting from individual GDPs, and investigates factors that influence excess delay using regularized regression models. We measured excess delay for 1210 GDPs from 33 airports in 2019. On a per-restricted flight basis, the mean excess delay is 30 min with std of 20 min. In our regression analysis, the factors affecting excess delay include time variations during gate out and taxi out for flights subject to GDP, program rate setting and revisions, and GDP time duration.

4 Sensing and Learning in Aircraft Network Routing

Xiyitao Zhu[1], Jing Gao[2], Ankur Mani[3], Lavanya Marla[4], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]University of Minnesota, Minneapolis, MN, [3]University of Minnesota - Twin Cities, Minneapolis, MN, [4]University of Illinois at Urbana-Champaign, Urbana, IL, Contact: xiyitao2@illinois.edu
In the US National Aviation System (NAS), aircraft rely on weather information for routing decisions. We propose that using en-route aircraft as sensors to collect updated weather information at the right place and right time maintains high-quality weather information that benefits the NAS. Motivated by the spatial and temporal correlations in weather, we propose a novel modeling framework for routing

decisions on (airspace) networks with non-stationary Gaussian bandits, temporal information diffusion, and in particular, with combinatorial path structures. We find time and fuel savings of the order of 5% across multiple O-Ds in the NAS. Our framework is also applicable to intra-city aircraft and unmanned aircraft such as UAVs and drones.

01 Association Between Advanced Image Ordered in the Emergency Department and Subsequent Imaging for Abdominal Pain Patients

Valerie Odeh-Couvertier, University of Wisconsin, Madison, WI, Contact: odehcouverti@wisc.edu

Abdominal pain is associated with high rates of emergency department (ED) imaging utilization and revisits. A better understanding is needed on when the decision to image is justified. We evaluated associations between ED imaging on subsequent outpatient imaging and revisits among abdominal pain patients discharged from the ED. Imaging in the ED was associated with lower imaging utilization and revisit to an ED after discharge, suggesting that ED imaging may replace downstream imaging.

02 Incorporating Ventilation and Heat in Short-term Underground Mine Production Scheduling

John Ayaburi, Colorado School of Mines, Golden, CO

The accumulation of heat in underground mines not only disrupts the schedule but also affects the health and safety of mine workers. We develop a large-scale, short-term production scheduling model that minimizes deviation between i) medium- and short-term schedules and ii) production goals. Constraints include precedence, resource consumption and heat limits. We correspondingly present novel techniques to improve model tractability. The model produces a consistent schedule while ensuring the safety of the work environment.

03 Active Learning for Non-parametric Choice Models

Fransisca Susan[1], Negin Golrezaei[2], Ehsan Emamjomeh-Zadeh[3], David Kempe[4], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, [3]Meta Platforms, Inc., Seattle, WA, [4]University of Southern California, Los Angeles, CA, Contact: fsusan@mit.edu

We study the problem of actively learning a non-parametric choice model based on consumers' decisions. We show that such choice models may not be identifiable, then introduce a directed acyclic graph (DAG) representation of the choice model that captures as much information about the choice model as could information-theoretically be identified. We design an efficient active-learning algorithm to estimate the DAG representation of the non-parametric choice model, which runs in polynomial time when the set of frequent rankings is drawn uniformly at random. We show that our algorithm performs better empirically compared to the existing non-active learning algorithms.

04 Capturing Carbon but Not Its Co-pollutants: Carbon Capture, Electricity and the Challenge of Just Decarbonization

Paola Furlanetto, University of Massachussets, Boston

Carbon Capture (CC) for use or sequestration is an interesting technology for decarbonization. While its cost- and carbon-effectiveness are under debate, current technologies remove CO_2 not co-pollutants. CO_2 affects the entire planet, but co-pollutants are harmful for those directly exposed with particular consequences for people of color and low-income. This work combines power systems modeling, integrated assessment modeling, and socioeconomic data to evaluate the role of CC distributional equity considering technological uncertainties and policy design.

05 Vote-by-mail Modeling to Track Equity Concerns

Carmen Haseltine, University of Wisconsin- Madison, Madison, WI, Contact: haseltine@wisc.edu

Cyber-physical system security planning requires identifying vulnerabilities as well as selecting and deploying security mitigations to manage risk across multiple agents in resource-constrained environments. We study these issues through a case study of vote-by-mail election systems. We introduce a new Markov chain model, real-world data set, and case study analysis.

06 Data Analysis Tool to Predict Defects in Additive Manufacturing

Amrutha Amarnath, Taylor N. White, North Carolina State University, Raleigh, NC, Contact: aamarna5@ncsu.edu

The complex nature of Additive Manufacturing processes prevents in situ monitoring for defects. Due to extreme temperatures, cameras are not feasible options, x-rays are not suitable for all materials, and CT scanning is exorbitantly expensive and does not offer real time feedback. The objective of this research is to develop a data analysis tool to predict defects in additive manufacturing processes in real time, that maintains accuracy of defect recognition while cutting down on cost.

07 Predictive Factors for Number of Stages in Mohs Micrographic Surgery

Coralys M. Colon-Morales, University of Florida, Gainesville, FL

Mohs Micrographic Surgery is an iterative outpatient surgery for the treatment of skin cancer. At each iteration, a layer of skin tissue is examined for the presence of cancer cells, and this continues until a cancer-free layer is identified. This reentrance aspect, which occurs when a patient requires another iteration, can potentially add hours to the procedure, leading to long patient waiting times and clinic overtime. Therefore, this work applies stochastic programming to provide optimal surgical schedules.

08 Developing Heat Constraints for Underground Mining Production Scheduling

Aaron Swift, Colorado School of Mines, Golden, CO

Battery electric vehicles are becoming more common in mining applications. One benefit of battery electric vehicles (BEVs) in an underground mining setting is the absence of diesel emissions. However, BEVs still generate heat, which can lead to unsafe working conditions. This research compares the heat produced by BEVs relative to diesel vehicles in executing mining activities. The results inform heat constraints in a production scheduling optimization model.

09 Fair Assortment Planning

Qinyi Chen[1], Negin Golrezaei[2], Fransisca Susan[1], Edy Baskoro[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, [3]Institut Teknologi Bandung, Bandung, Indonesia. Contact: qinyic@mit.edu

Many platforms tend to feature items with the highest popularities when making assortment planning decisions. This, however, can lead to too little visibility for the rest of the items. Motivated by that, we introduce and study a fair assortment planning problem, which requires any two items with similar merits to be offered similar visibility. We propose a framework to find near-optimal solutions to this problem, using the Ellipsoid method and a separation oracle to its dual. We then develop two approximate separation oracles, which result in a polynomial-time 1/2-approx. algorithm and an FPTAS. We conclude with a case study on the MovieLens dataset, demonstrating the efficacy of our algorithms.

10 Optimizing Collaborative Energy Storage Systems and Its Equity Outcomes

Ogechi Nwadiaru, University of Massachusetts, Massachusetts, MA

The study aims to assess the benefit of co-operatively owned and operated storage systems. We model storage decisions under various pricing schemes, ownership systems, and consumer behavior. We hypothesize that there will be value delivered, including savings. The hypothesis is built on the flexibility offered by storage as a demand response asset deployed by residents in price-based demand response programs. Equally, it provides consumers with increased reliability, autonomy, and reduced cost.

11 Food Bank Responsiveness During Natural Disasters

Faith O. Idoko[1], Chrysafis Vogiatzis[2], Lauren Berrings Davis[3], [1]North Carolina A&T University, Greebnsboro, NC, [2]University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, [3]North Carolina A&T State University, Greensboro, NC, Contact: faithidoko13@gmail.com

The unpredictable nature of natural disasters leads to disruptions in supply chains. A typical aftermath of such effect is the disruption of food supply as evidenced in the role of food banks. An increase in the number of food insecure people at such times fosters a surge in demand to the food banks. Prepositioning relief items to mitigate the effect of disasters is a viable approach. In this work, we incorporate this concept while considering nonfood items, perishable, and nonperishable food as well as the road and foodbank networks post disaster. Options for self-accessible food lockers for both frozen and dry food items are also considered.

12 Importance of Covid-19 Specific Antibody Testing During Vaccine Allocation

Akane Fujimoto Wakabayashi[1], Pinar Keskinocak[1], Inci Yildirim[2], [1]Georgia Institute of Technology, Atlanta, GA,

[2]Yale University, New Haven, CT, Contact: afujimoto@gatech.edu

A compartmental model was developed to analyze the value of using antibody testing to identify individuals who have previously acquired COVID infections to prioritize the vaccination of fully susceptible individuals. The model simulates the disease spread, diagnosis and isolation of infected individuals, and testing and vaccine allocation. The use of antibody testing as part of a COVID-19 vaccine distribution plan might be effective and substantially reduces the infection attack rate and deaths.

13 Data Science Models for the Prediction of Adverse Maternal Outcomes

Meghan Meredith[1], Lauren N. Steimle[1], Sheree Boulet[2], Kait Stanhope[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University, Atlanta, GA

Racial/ethnic minority and rural populations are disproportionately affected by comorbid conditions and preventable adverse maternal outcomes. We present risk prediction models for adverse maternal outcomes that incorporate interactions between comorbid conditions. We leverage machine learning methods and consider clinical, lifestyle, and demographic information as potential risk factors to better understand their associations with adverse maternal outcomes.

01 Identifying Hotspots for Mental Health Treatment

Junyuan Quan, Anthony Bonifonte, Denison University, Granville, OH, Contact: quan_d1@denison.edu

This research attempts to estimate the unmet mental health services demand at a census tract level and identify new mental health facility locations to maximize the number of SMI patients who can receive treatment. We estimate the unmet demand in each census tract and build an optimization model to identify hotspots in need of additional treatment capacity. We find that among the total of 765,304 SMI patients in Ohio, 469,549 (61.4%) perceived an unmet need for mental health services. The model suggests 10 new potential mental health facilities can serve up to 418228 new patients, about 89.1% of the total SMI patients with unmet mental health services demand in Ohio.

02 Testing Race Differences In Risk of Gestational Diabetes Mellitus Associated with Household Food Insecurity (using NHANES 2007-2018)

Carolina Gonzalez-Canas[1], Qinglan Ding[2], Vicki L. Simpson[2], Zachary Hass[3], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, [3]Purdue University, West Lafayette, IN, Contact: gonza490@purdue.edu

We used a weighted logistic regression model to estimate the impact of household food insecurity on Gestational Diabetes Mellitus risk from the National Health and Nutrition Examination Survey (NHANES) from 2007-2018 after controlling for several theoretical and health-related risk factors like age, obstetric history, family history of diabetes, and BMI. Analyses were stratified by race/ethnicity to provide insight into how gestational diabetes risk differs by subpopulation. Results indicated that family history of diabetes is a risk factor across all races while household food insecurity is a significant risk factor for only the Hispanic subpopulation.

03 The Implications of State Aggregation for Markov Decision Process Models with Medical Applications

Madeleine Pollack[1], Lauren N. Steimle[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: mpollack9@gatech.edu

Markov decision processes (MDPs) are mathematical models of sequential decision-making under uncertainty that have found applications in chronic disease treatment. Modelers often characterize patient health by aggregating measures of disease severity into discrete health states, and transition probabilities describe the Markov process over those states. However, there are no clear guidelines as to how to construct a state space: having too many states leads to inaccurate transition probability estimates but having too few states leads to imprecision in the model. In this work, we consider how the size of the state space impacts lifetime estimates and treatment recommendations from MDPs.

04 Identification of Risk Factors Associated with Baby Low Birthweight and Health

Disparities in Prenatal Care: A Machine Learning Approach

Yang Ren, Dezhi Wu, Yan Tong, University of South Carolina, Columbia, SC

Low birthweight (LBW) is the second-leading cause of neonatal death in the U.S. after congenital malformations. The LBW babies have a higher risk of short- and long-term adverse health effects than the babies with normal birth weight. Based on 255,647 birth records from 2015 to 2021 in a large U.S. hospital system, we used six machine learning classification models to predict LBW and associated prenatal risks and health disparities between the different mom groups based on the moms' demographic and social determinants. This study provides important implications to prenatal care services and public health policymakers.

05 A Random Forest Assessment to Measure Clinical Pathway Concordance with Breast Cancer Patients' Survival

Ping Lin, Milton Soto-Ferrari, Indiana State University, Terre Haute, IN, Contact: plin4@sycamores.indstate.edu

This research aims to assess the attributes that influence the clinical pathways of breast cancer patients and their relationship with survival. The evaluation focuses on a sample of 119.000 patients collected by the SEER program from 2010 to 2015 in the US. We developed a random forest framework to measure the level of concordance for clinical pathways. We calculated the proposed model's accuracy performance to estimate the pathway concordance valuation. Our study determined that multiple factors, encompassing surgery type, age, and cancer stage, as part of the first course of treatment combined with tumor grade and behavior have a significant positive association with patients' survival.

06 Effectiveness of Social Distancing Under Partial Compliance of Individuals

Hyelim Shin, Kyeonghyeon Park, Huijae Kim, Taesik Lee, KAIST, Daejeon, Korea, Republic of. Contact: hyelim.shin@kaist.ac.kr

Assuming individual agents' social distancing decisions are driven by utility maximization, we calculate a Nash equilibrium in a community under a social distancing policy. Numerical experiments suggest that an excessively strict social distancing policy leads to non-compliance and that an appropriate level of penalty should be imposed for such violations.

07 Construction and Evaluation of Stroke Care Network in Rural Area

Po-Yi Lee[1], Yu-Ching Lee[2], [1]National Tsing Hua University, Chiayi city, Taiwan; [2]National Tsing Hua University, Hsinchu, Taiwan. Contact: benson0042@gmail.com

Recombinant tissue plasminogen activator (rt-PA) has been proved for effectively treating patients with ischemic stroke, increasing the chance of recovering. Stroke care network connects the nearby hospitals (spoke) together with the hospitals capable of providing rt-PA (hub). The aim of our study is to construct a stroke care network in rural areas of Taiwan, Pingtung county and evaluate network performance based on 2 criteria, coverage rate and total expected time. The results indicate that the current layout of the hospitals in Pingtung county covered most of the population, and will help members treating patients with rt-PA more cautiously and reducing inspection time and personnel cost.

08 A Mixed-integer Linear Programming Model for a Stochastic Elective Surgery Scheduling Problem

Nicklas Klein, University of Bern, Bern, Switzerland. Contact: nicklas.klein@unibe.ch

We consider the problem of scheduling elective surgeries in operation blocks over a fixed time horizon. The schedule has to accommodate emergency surgeries that arrive at random and must be performed on the day of their arrival. The goal is to assign a start time and a block to the elective surgeries to minimize the total cost for the block assignments plus the expected cost of delaying or canceling surgeries plus the expected cost of operating room idle- and overtime. We propose a two-stage mixed-integer linear programming model that is based on sample average approximation and analyze the impact of various parameters on the computational performance.

09 Optimization of the Hospital Selection Strategy and the Distribution of Endovascular Thrombectomy Resources

Chun-Han Wang, Yu-Ching Lee, National Tsing Hua University, Hsinchu City, Taiwan. Contact: ga2006124742@gmail.com

Nowadays, emergency medical technicians decide to send a suspected stroke patient to a primary stroke center (PSC) or to an endovascular thrombectomy (EVT)-capable hospital, based on the Cincinnati Prehospital Stroke Scale. However, if an acute ischemic stroke patient with large vessel occlusion is first sent to a PSC, and then needs to be transferred to an EVT-capable hospital, the time to get definitive treatment is significantly increased. To solve this problem, we build optimization models for the redistribution and centralization of EVT resources for stroke patients, which enables therapeutic medical teams to increase their experience and skills efficiently within a short period of time.

10 A Vehicle Routing Problem for Massive Covid-19 Testing in Antofagasta, Chile

Hernan Caceres[1], Javiera Auad[1], Andrea Fernández[2], Blanca Peñaloza[2], María Soledad Zuzulich[2], [1]Universidad Catolica del Norte, Antofagasta, Chile; [2]Pontificia Universidad Católica, Santiago, Chile. Contact: hcaceres@ucn.cl

The COVID-19 pandemic has demanded massive and recurrent testing due to the high number of cases that have been found in the last two years. Mass testing requires significant resource management to develop, which is why a useful tool to manage them is optimization. A project was developed in Antofagasta, Chile, to help small businesses to have more control over positive cases in their establishments. A medical team would visit them regularly to have greater control and provide them with more security. To do that efficiently, a vehicle routing problem with multiple time windows was developed to optimize the time of visit routes and medical equipment necessary to carry out the testing.

11 Does New Knowledge of Disease or Screening Matter in the Cancer Screening Education? Evidence from a Randomized Controlled Trial

Xiaodong Wang[1], Yongjian Zhu[2], Yini Gao[3], Zhichao Zheng[3], [1]Singapore Management University, Singapore, Singapore; [2]University of Science and Technology of China, Hefei, China; [3]Singapore Management University, Singapore, Singapore. Contact: xdwang.2020@pbs.smu.edu.sg

Colorectal cancer (CRC) is reported as the most/second most frequent incidence of cancer for males/females in Singapore. Although deadly, it's 5-year relative survival rate is 90% if detected in the early/localized stage. Given the low initial screening rate in Singapore, this study empirically examined the effectiveness of health education on self-reported screening intention for CRC via a randomized controlled trial (RCT). We found education effect exists and new knowledge of screening rather than that of disease matters. Different subgroups of age, gender, baseline knowledge, and subjective belief are moderators, providing practical implications for the future health education.

12 Logistics for Diagnostic Testing: An Adaptive Decision-support Framework

Hannah Bakker[1], Fabian Dunke[1], Viktor Bindewald[2], Stefan Nickel[3], [1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]Universität Siegen, Siegen, Germany; [3]Karlsruhe Insitute of Technology, Karlsruhe, Germany. Contact: hannah.bakker@kit.edu

Diagnostic testing is a fundamental component of effective outbreak containment during a pandemic. When health care providers are privately owned, the assignments of samples from test facilities to laboratories are determined by individual stakeholders. While may effectively match supply and demand during normal times, dispersed outbreaks as encountered during the COVID-19 pandemic, lead to imbalanced requests for diagnostic capacity. Local backlogs build up rapidly leading to increased waiting times for test results. We present a rolling horizon framework that supports a coordinating authority in matching supply and demand in an otherwise decentrally operating system.

13 Analyzing the Effect of Social Connections on Opioid Overdose Deaths

Kushagra Tiwari[1], M.Amin Rahimian[1], Mary G Krauland[2], Mark S Roberts[1], Jeanine M Buchanich[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA, Contact: kut20@pitt.edu

During the past two decades, the Opioid Epidemic has been a major cause of concern in the US. There has been an increasing recognition that its etiology is rooted in part in the social contexts that mediate substance use and access. We analyze the significance of effect size of Meta's Social Connectedness Index (SCI) on Opioid Overdose Deaths (OOD) in ZIP codes by controlling for physical proximity. We lay the groundwork to depict the use of SCI for creating proxies for Social Network and further find its application in planning and developing intervention strategies against Opioid Epidemic.

14 Using Data Analytics for Telehealth Utilization: A Case Study in Arkansas

Aysenur Betul Cengil[1], Sandra D. Eksioglu[1], Burak Eksioglu[1], Hari Eswaran[2], Corey J. Hayes[3], Cari A. Bogulski[3], [1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas for Medical Sciences, Little Rock, AR, [3]University of Arkansas for Medical Sciences, Fayetteville, AR

Telehealth may allow clinics to service more patients without increasing the healthcare workforce. We use data analytics techniques to understand which patients utilize telehealth. We build a random forest regression model to identify the important factors in telehealth utilization. We analyze how telehealth services impact waiting time and appointment length.

15 Identifying Prenatal Alcohol Exposures and Its Determinants on Twitter

Dezhi Wu[1], YANG REN[2], Yuqi Wu[1], Peiyin Hung[3], Shan

Qiao[3], Phyllis Raynor[3], Xiaoming Li[3], Jiajia Zhang[3], Constance Guille[4], Kacey Eichelberger[5], [1]University of South Carolina, Columbia, SC, [2]UNIVERSITY OF SOUTH CAROLINA, WEST COLUMBIA, SC, [3]University of South Carolina, Columbia, SC, [4]Medical University of South Carolina, Columbia, SC, [5]University of South Carolina, School of Medicine Greenville |Prisma Health Upstate, Columbia, SC

Alcohol consumption during pregnancy is a prevalent health concern, causing fetal alcohol spectrum disorders (FASDs) and risks for miscarriage, stillbirth, and other adverse events. This study collected over six million tweets related to perinatal substance use disorder on Twitter. After segmenting perinatal alcohol use tweets, we used topic modeling, sentiment analysis, text mining, and machine learning techniques to identify determinants of FASD-related adverse events. Study implications are informative to alcohol health services and public health policies related to prenatal alcohol exposure, alcohol drug abuse, addiction, and prenatal and postpartum care.

16 Blockchain-based Data Transparency in Pharmaceutical Supply Chain

Alejandro E. Chicas, Afrooz Moatari-Kazerouni, Amin Keramati, Widener University, Chester, PA, Contact: amoatarikazerouni@widener.edu

The unpredictability of clinical trial processes increases the cost for developing pharmaceutical drugs across the supply chain. Data is subject to both intentional and accidental tampering, threatening the correct representation of a clinical trial analysis. The use of blockchain technology allows storing time stamped transaction records, making it near impossible to steal or alter clinical trials data. This study explores how blockchain supports clinical data management throughout the pharmaceutical supply chain. Such intelligent supply chain allows patients to have control over their medical data and researchers to meet reporting requirements.

17 Managing Covid-19 Pandemic: Lessons from an Indian City

Ravichandran Narasimhan, Indian Institute of Management-Ahmadabad, Ahmedabad, India. Contact: nravi@iima.ac.in

In a large city in India the Covid -19 epidemic was effectively controlled by a combination of Centralized resources, decentralized planning and a purposeful leadership. The frontline workers were motivated to be effective. The treatment plan optimized utilization of scared resources. Resource constraints on manpower, infrastructure ,medical facilities were resolved by innovation. A modular structure and a comprehensive information dash board was an enabler. The sample collection to patient treatment was seamlessly managed. The consequence of all these is an admirable reduction in the spread of the infection. This work documents this practical application.

18 Multi-secant Extensions of BFGS

Mokhwa Lee, Yifan Sun, Stony Brook University, Stony Brook, NY, Contact: mokhwa.lee.726@gmail.com

When dealing with a large-scale optimization problem, classical second-order methods are no longer practical. Therefore, Quasi-Newton methods are introduced because they are more efficient. This project focuses on multi-secant extensions of the BFGS method, to improve its Hessian approximation properties by applying a perturbation strategy to construct an almost-secant positive-definite Hessian estimate matrix to guarantee the descent direction. This strategy has a low computational cost, involving only rank-2 updates with variable and gradient successive differences. We also explored several ways of accepting and rejecting older updates according to several nondegeneracy metrics.

19 Improving Temporal Graph Network Messaging

Celeste Groux, McGill University, Montreal, QC, Canada. Contact: celeste.groux@mail.mcgill.ca

The Temporal Graph Network algorithm introduced by Rossi et al. was found to efficiently outperform multiple recent algorithms for the task of link prediction in networks that change over time. In this algorithm, each change is introduced as input to a message function whose output is then used to update the affected node’s memory. Improvements to the message function are explored, particularly to share messages to a node’s neighbourhood so as to take into account neighbourhood changes when making predictions. Results for the proposed variants show very small inconsistent improvements for both networks tested.

20 Taxi Routing Optimization

Tinghan Ye[1], David B. Shmoys[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, Contact: ty357@cornell.edu

A taxi routing problem can be solved via bipartite matching, where a maximum matching corresponds to the minimum number of taxis needed to cover all trips. We demonstrate this problem on an NYC dataset and prove a min-max theorem: the maximum number of pairwise incompatible trips equals the minimum number of taxis needed.

21 Tractability of Optimizing over Multi-constrained Knapsack Sets Using Multi-module Capacitated Lot-sizing Problem

Kartik Kulkarni, Virginia Tech, Blacksburg, VA, Contact: kartikrf@vt.edu

We address the existence of polynomial time algorithms for optimizing a linear function over certain structured mixed-integer sets. These sets arise as substructures in several problems related to production planning, facility location, and capacitated network design. These sets have nT number of integer variables where T is the number of constraints, and n is the number of integer variables in each constraint. We address these open questions by establishing the equivalence between optimizing over these sets and generalizations of constant capacitated lot-sizing problems.

22 Metaheuristics vs. Exact Solvers: Finding Optimal Solutions to the Minimum Sum Coloring Problem

Yu Du, University of Colorado Denver, Denver, CO, Contact: duyu197@gmail.com

The minimum sum coloring problem (MSCP) is a well-known NP-hard problem. Exact methods(like Gurobi) and metaheuristic solvers have greatly improved in recent years enabling optimal solutions to be found to a growing set of MSCP problems. We introduce several alternative models for MSCP and provide a computational study using a standard set of test problems from the literature that compares the general-purpose exact solver from Gurobi to the leading metaheuristic solver NGQ™. Our results show that a constrained version of binary quadratic model (QUBO-Plus) using NGQ™ provides the best performance for finding optimal solutions to these important problems

23 Optimum Space Utilization in Block Stacking Storages System: Temporary Warehousing Case Study

Amir Hossein Sadeghi, Amirreza Sahebifakhrabad, North Carolina State University, Raleigh, NC, Contact: asadegh3@ncsu.edu

Stock Keeping Unit (SKU) loading and unloading are fundamental to logistics management systems in temporary warehouses, such as production lines, and ports. The present study is a simulation-based model to measure warehousing KPIs(key performance indicators) in temporary warehouses' administrative decisions during the two phases of the warehouse's transportation and space operations. This research provides a simple, yet comprehensive simulation approach, which can be used in all temporary warehousing problems.

24 Scalable Learn-to-optimize Frameworks for Networks

Babak Aslani[1], Shima Mohebbi[2], [1]George Mason University, Fairfax, VA, [2]George Mason University, Fairfax, VA, Contact: baslani@gmu.edu

Network optimization methods have become popular for addressing combinatorial optimization problems in various network applications. Most problems are defined as Mixed Integer Programming (MIP) models, which become *NP-hard* for large-scale problems. To overcome this challenge, leveraging the information during the search process to embed machine learning methods in optimization algorithms has emerged as a promising research area. Hence, this work seeks to develop scalable Learn-To-Optimize frameworks for deterministic and stochastic formulations concerning large-scale networks.

25 A Fast Modified Hungarian Algorithm to Solve Optimal Transport

Yiling Xie[1], Yiling Luo[2], Xiaoming Huo[3], [1]ISyE Georgia Tech, ATLANTA, GA, [2]ISyE Georgia Tech, Atlanta, GA, [3]ISyE Georgia Tech, Marietta, GA, Contact: yxie350@gatech.edu

We propose a modified Hungarian algorithm to exactly solve a special type of the optimal transport (OT) problem. For an OT problem between marginals with m and n atoms (m ≥ n), the computational complexity of the proposed algorithm is O(m^2n), while other algorithms, like the Hungarian algorithm, have the best possible order of O(m^3). We also show that computing the empirical Wasserstein distance in the independence test requires solving this special type of OT problem, where we have m=n^2. After adopting our modified Hungarian algorithm, the computational complexity is O(n^5), while the order of the classic Hungarian algorithm is n^6). Numerical experiments validate our theoretical analysis.

26 Sparse Optimization and Distributed Control for Large-scale Autonomy

Yang Zheng, University of California San Diego, San Diego, CA, Contact: zhengy@eng.ucsd.edu

This poster focuses on distributed control and scalable optimization techniques to ensure the efficient and reliable operation of large-scale autonomous systems. In particular, I will present a new technique that allows us to recover convexity for a class of distributed control problems, and show how to exploit sparsity structures to design scalable algorithms for solving large-scale convex optimization problems (especially semidefinite optimization). By exploiting the properties of chordal graphs and sparse positive semidefinite matrices, I will introduce a decomposition method that can scale sparse semidefinite optimization to large-scale instances, achieving massive scalability.

27 When to Relocate Vehicles of a Variable Size Fleet to Maximize Coverage

Gianfranco Cossani, Hernan Caceres, Universidad Catolica del Norte, Antofagasta, Chile. Contact: gianfranco.cossani@ce.ucn.cl

Vehicles relocation is a joint research topic in operations research. In this work, we will analyze the need to re-optimize the deployment points for a fleet of first response vehicles when one or more of them are unavailable while attending an emergency. This new optimization could include moving vehicles short distances or impractically short periods. We present an algorithm using DEA and heuristics to determine areas where we should not move the ambulances even if the new optimization result recommends it.

28 Mathematical Modeling for Containers with Dangerous Goods in the Multi-port Master Bay Planning Problem

Kiros Kebedow, Hawassa University-Ethiopia, Hawassa, Ethiopia. Contact: kirosmaths@gmail.com

In this talk, we extend existing models for Master Bay Planning by handling containers holding dangerous goods, so-called IMO containers. Incompatible IMO containers must be separated from each other on board a vessel according to specific rules. These rules affect both Master Bay Planning and Slot Planning,
which are the two planning problems normally handled in container stowage planning. To the best of our knowledge, this is the first time handling of
IMO containers is included in Master Bay Planning. We present results from computational tests showing that our model can be solved to optimality, or near optimality, in a reasonable time for realistically sized instances.

29 Patterns Matter: Evaluating Effects of Spatial Patterns for the Vehicle Routing Problem

Melissa Tilashalski, Virginia Polytechnic Institute and State University, Blacksburg, VA, Contact: mtilashalski@vt.edu

This research focuses on how spatial patterns of customer locations affect vehicle routing problem heuristic solutions. Both standard and industry are characterized to demonstrate differences in customer locations. The performance of the heuristics is evaluated and the findings demonstrate that spatial patterns influence the quality of heuristic solutions.

30 Dual-objective Optimization Methodology for Order Picking Process

Seungwon Park, Kyungmin Kim, Myongji University, Yongin-si, Korea, Republic of. Contact: benny0215@naver.com

Growing e-commerce market has enforced distribution companies to provide faster and more accurate delivery services. Order picking process is the most time-consuming and labor-intensive of the logistics processes carried out at the distribution center. In this paper, we consider the problem of distributors who want to change order picking sequence to minimize the total order picking time as well as workspace capacity simultaneously. We propose MINLP(Mixed Integer Non-Linear Programming), MILP(Mixed Integer Linear Programming), and NSGA-II(Non-dominated Sorting Genetic Algorithm-II) models. Through numerical experiments, we compare and verify their performances.

31 A Storage Assignment Heuristic for Order Picking Problem in the Mixed Shelves Warehouses

Takashi Irohara, Sophia University, Chiyoda-Ku, Japan.

In this research, a new model for a storage assignment problem is considered in the mixed shelves warehouses where multiple storage positions per one stock keeping unit can be available. For this model, mathematical optimization formulation and the heuristic approaches are proposed to solve the storage assignment problem for order picking. Effectiveness of the proposed methodologies are validated by conducting numerical experiments.

32 Algorithms Using Local Features to Predict Epidemics:

Yeganeh Alimohammadi[1], Christian Borgs[1], Amin Saberi[2], [1]Stanford University, Stanford, CA, [2]Stanford University, San Francisco, CA, Contact: yeganeh@stanford.edu

We study a simple model of epidemics: each node infects its neighbors independently with a probability p. In this setting, we ask: what information is needed for general networks to predict the size of an outbreak? Is it possible to make predictions by accessing small subgraphs?
We answer the question in the affirmative for large-set expanders with Benjamini-Schramm limits. We show that there is an algorithm that gives a (1−⍰) approximation of the probability and the size of an outbreak by sampling a constant-size neighborhood of a constant number of nodes chosen uniformly at random. We also present corollaries for the preferential attachment and study generalizations with household structure.

33 Distributionally Risk-receptive and Risk-averse Network Interdiction Problems with General Ambiguity Sets

Sumin Kang[1], Manish Bansal[2], [1]Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Virginia Tech., Blacksburg, VA, Contact: suminkang@vt.edu

We introduce generalizations of stochastic network interdiction problem with distributional ambiguity: a distributionally risk-averse (or robust) network interdiction problem (DRA-NIP) and a distributionally risk-receptive network interdiction problem (DRR-NIP) where a leader maximizes a follower's minimal expected objective value for either the worst-case or the best-case, respectively, probability distribution belonging to a given set of distributions (referred to as ambiguity set). We present solution approaches for DRA-NIP and DRR-NIP with a general ambiguity set and conditions for which these approaches are finitely convergent.

34 Online Learning for Traffic Routing Under Unknown Preferences

Devansh Jalota[1], Karthik Gopalakrishnan[1], Navid Azizan[2], Ramesh Johari[1], Marco Pavone[1], [1]Stanford University, Stanford, CA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: djalota@stanford.edu

The efficacy of road tolling schemes, designed to cope with efficiency losses due to selfish user routing, often relies on complete information on users' trip attributes, such as their values-of-time. Since these user attributes are typically unknown to a central planner, we propose an online learning approach to set tolls to drive users with different values of time to a system-efficient traffic pattern. Our algorithm adjusts tolls based on observed aggregate flows without relying on user attributes, thus preserving privacy. We establish the efficacy of our approach through performance bounds and demonstrate its superior performance relative to benchmarks on a traffic network.

35 On the Convergence of Stochastic Extragradient for Bilinear Games Using Restarted Iteration Averaging

Chris Junchi Li, UC Berkeley, Berkeley, CA, Contact: junchi.li.duke@gmail.com

I will present an analysis of the same-sample Stochastic ExtraGradient (SEG) method with constant step size, and also variations of the method that yield favorable convergence for stochastic bilinear minimax optimization problem. In sharp contrasts with the basic SEG method whose last iterate only contracts to a fixed neighborhood of the Nash equilibrium, SEG augmented with iteration averaging provably converges to the Nash equilibrium under the same standard settings, and such a rate is further improved by incorporating a scheduled restarting procedure. I will also discuss the generalization of this idea to achieve lower bounds for a class of convex-concave minimax optimization problems.

36 Improving Safety Stock Calculations in Semiconductor Supply Chain

Aparna Komarla, Solidigm (formerly Intel), Folsom, CA, Contact: aparnax.sk.komarla@intel.com

Traditionally, safety stock calculations in a SSD (Solid State Drive) semiconductor supply chain are performed with historical data of the SSD's true or forecasted demand. In particular, these calculations model demand at any given time using a normal distribution. Here, I introduce a new model for safety stock calculation that utilizes not just the demand data of the SSD in question, but also the historical data of past SSDs that have completed their life cycle. Additionally, this model leverages kernel density estimation, a non-parametric probability distribution to model SSD demand, instead of a normal distribution which is shown to have limitations with capturing the true behavior of demand.

37 Design of Urban Logistics Networks to Support Home Delivery with Driverless Vehicles

Ekin Yalvac[1], Michael G. Kay[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, Raleigh, NC, Contact: eyalvac@ncsu.edu

An urban logistics network model for home delivery is proposed in this presentation. Our model uses only five parameters and location information. On top of Delaunay triangulation and Dijkstra's algorithm, we used lesser-known methods like aggregate distance and proximity factor are used. The algorithm finds the most optimal warehouse locations by minimizing the distance a unit of load travels. We tried our algorithm for different-sized cities and for a range of parameters to check its validity for different circumstances. Our results indicate that the algorithm provides an optimal result for almost all types of parameter-city sets when we tried our algorithm for different circumstances.

38 Revisiting Supply Chain Flows: A Road Map Through Paradox Theory

Muhammad Hasan Ashraf, University of Rhode Island, United States, RI, Contact: mashraf@uri.edu

While there have been numerous supply chain flows (SCF) papers published in last few years, they appear to mostly address four most acknowledged flows i.e*., material, service, information* and *financial*. However, COVID-19 posed new threats to supply chains, triggering interactions among SCF that may possibly have caused certain insufficiently researched flows to become more influential in managing operations. We recommend that time is ripe for supply chain scholars to broaden their horizon, and consider flows that have been understudied or overlooked in the literature. We aim to conduct a multi-method qualitative study, involving researchers and professionals from various industry sectors.

39 The Effects of Competition Between Fair Trade Organizations

Daehun Chung, Seung Jae Park, Yonsei University, Seoul, Korea, Republic of. Contact: hooney@yonsei.ac.kr

In this study, we explore the effects of competition on fair trade operations. Specifically, as abenchmark, we explore a model with one fair trade organization (FTO), i.e., the monopoly FTO. We thenconsider two competing FTOs, i.e., the duopoly FTOs. We show that the benefit to farmers per unit ofproduct sold is greater with the monopoly FTO, but the aggregate benefit to farmers is greater with theduopoly FTOs due to higher consumer demand. We also show that utilizing blockchain technologyfurther benefits farmers and alleviates the effects of competition because consumers directly connectwith farmers through the blockchain.

40 The High Cost of Low-cost Food Supply in U.S.

Chen Zhou, ISyE Georgia Tech, Atlanta, GA, Contact: cz3@gatech.edu

The cost of foods in US is lower than the other developed counties. This is a great achievement by many sectors in the food supply chain. However, US has the shortest Healthy Life Expectancy, according to the World Health Organization (WHO) countries and highest healthcare costs among all the developed countries. The over consumption of low cost, strong flavored, always available and heavily processed food is one of the major contributors. This research is to analyze the processed and fresh food supply chain and find the direct costs and indirect costs associated with the low-cost processed food.

41 Reman-FMEA: A New Tool to Sustain Remanufacturability

Mehnuma Tabassum[1], Gul Kremer[2], [1]Iowa State University, Ames, IA, [2]University of Dayton, Dayton, OH

This work develops a new tool (Reman-FMEA: Remanufacturing Failure Modes and Effects Analysis) that regards crucial elements of product and process FMEA and brings a newer systematic approach for ranking failure modes (FM) for remanufactured products. Expert opinion on frequency, severity, and prevention of the FM is collected through Z-numbers instead of the standard risk priority number to capture the subjective uncertainty. We employ a Z-number based VIKOR technique to prioritize the FM. Also, we suggest design and process changes and evaluate their technical, economic, and environmental feasibility. The value gain from Reman-FMEA is demonstrated through an engine cylinder head case study.

42 Adaptive Sample Robust Optimization for Bidding of a Virtual Power Plant in a Day-ahead Electricity Market

Seokwoo Kim, Dong Gu Choi, Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of. Contact: seokwookim@postech.ac.kr

In this study, we try to solve the optimal bidding problem for a virtual power plant (VPP) in a day-ahead electricity market. In the problem, supply uncertainty should be taken into account for two distributed resources, PV (photovoltaics) and DR (Demand Response). At the same time, decision-making should be suitable for the incentive-based market structure. After modeling this as an Adaptive Sample Robust Optimization (ASRO) problem, this study established an effective bidding algorithm by applying the duality-based reformulation and decomposition method.

43 An Inexact Variance-reduced Method for Stochastic Quasi-variational Inequality Problems with an Application in Healthcare

Zeinab Alizadeh[1], Brianna Otero[2], Afrooz Jalilzadeh[2], [1]The University of Arizona, Tucson, AZ, [2]The University of Arizona, Tucson, AZ, Contact: zalizadeh@email.arizona.edu

This paper is focused on a stochastic quasi-variational inequality (SQVI) problem with a continuous and strongly-monotone mapping over a closed and convex set where the projection onto the constraint set may not be easy to compute. We present an inexact variance reduced stochastic scheme to solve SQVI problems and analyzed its convergence rate and oracle complexity. A linear rate of convergence is obtained by progressively increasing sample size and approximating the projection operator. Moreover, we show how a competition among blood donation organizations can be modeled as an SQVI and we provide some preliminary simulation results to validate our findings.

44 Sinkhorn Distributionally Robust Optimization

Jie Wang, Georgia Institute of Technology, Atlanta, GA, Contact: jwang3163@gatech.edu

We study distributionally robust optimization with Sinkhorn distance -- a variant of Wasserstein distance based on entropic regularization. We derive convex programming dual reformulations when the nominal distribution is an empirical distribution and a general distribution, respectively. Compared with Wasserstein DRO, it is computationally tractable for a larger class of loss functions, and its worst-case distribution is more reasonable. To solve the dual reformulation, we propose an efficient batch gradient descent with a bisection search algorithm. Finally, we provide various numerical examples using both synthetic and real data to demonstrate its competitive performance.

45 Strongly Monotonic Efficiency Measures in Data Envelopment Analysis

Yu Zhao[1], Kazuyuki Sekitani[2], [1]Tokyo University of Science, Tokyo, Japan; [2]Seikei University, Tokyo, Japan. Contact: yu.zhao@rs.tus.ac.jp

This study investigates the monotonicity issue of efficiency measures for data envelopment analysis (DEA) models with nonlinear objective functions. We propose a class of DEA models, including variants of the Russell graph measure, BRWZ measure, slack-based measure, and geometric distance function. The proposed DEA models provide monotonic maximum efficiency measures and can be solved by linear programming. We show that the maximum efficiency measure can be explicitly expressed as a decreasing function of the least Manhattan distance. We further show that the maximum efficiency measure satisfies strong monotonicity by adding certain consistent weighting restrictions to the DEA models.

46 When Do Models Make Money? A Path from Return Predictability to Profitability

Ruixun Zhang, Yufan Chen, Lan Wu, Peking University, Beijing, China. Contact: zhangruixun@pku.edu.cn

In the context of a single-asset market, we propose an analytical framework to link the profitability of a model-driven investment strategy to the predictability of the underlying model. Our framework accounts for trading costs, applies to general return-forecast models with arbitrary precision--recall curves, and yields an explicit solution to strategy profit as a function of model performance metrics. We demonstrate the applicability of our model with tick-level data that accounts for the bid-ask spread and actual liquidity in the limit order book. Empirical results show that the model-implied analytical profitability aligns with estimates of profitability from a simulation engine.

47 Supply Chain Finance Tools and Their Impact on Operations Management in Africa: The Case of Moroccan Firms

Jamal Elbaz[1], Jean Noel Beka Be Nguema[2], [1]Ibn Zohr University, Agadir, Morocco; [2]Rabat Business School UIR, Rabat, Morocco. Contact: j.elbaz@uiz.ac.ma

The purpose of this research is to investigate how Supply Chain Finance (SCF) tools are employed in the context of Moroccan firms. Based on several interviews with Moroccan executives, the authors identfiy the drivers of SCF applications categorized as internal (e.g. top management involvement and technical infrastructure) and external (institutional factors, collaboration with partners and quality of financial services providers) drivers. The authors alsoo examine the outcomes of SCF on firms' performance. Based on the results, a conceptual model linking SCF drivers and the outcomes of SCF tools is proposed by the authors.

48 Automated Rebate Computation Modelling

Alexander Billups[1], Shubhi Asthana[2], Nitin Ramchandani[1], Pawan Chowdhary[1], [1]IBM Research, San Jose, CA, [2]IBM Research, SAN JOSE, CA, Contact: abb5975@psu.edu

Suppliers offer different types of rebates to customers, in order to sign multiple contracts with customers. Typically in financial services sector, there is no uniform rebate structure followed when offering these rebates. Suppliers may alter rebate terms, payment terms that provision how customers would be invoiced, for multiple contracts each week . In order to streamline the process, we propose the Automated Rebate Computation Model. Our model performs smart selection of contract and invoice features in order to automate rebate computation and validate the rebates signed with the invoice billed.

49 Optimization of Travel Subscription Use

Jiang Jiang[1], Chris K. Anderson[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, Contact: jj438@cornell.edu

Travel subscription provides limited guidance to consumers when they make travel plans. The value of the subscription is difficult to evaluate. This study demonstrates that the service providers can assist consumers to maximize total nights of stay by adding functions like sort by cost per night. Three ways of making travel plans are compared: (1) random selection; (2) the heuristics, where listings with lower cost get higher priority; and (3) Integer Linear Programming. Using synthetic data and real listings from one subscription platform, we showed that on average, the heuristics can increase the total nights by 26% of the optimal solution compared to the random selection.

50 Revenue Management Under a Price Alert Mechanism

Nanxi Zhang, University of British Columbia, Vancouver, BC, Canada. Contact: sufenanxizhang@163.sufe.edu.cn

Many online platforms adopt a price alert mechanism to facilitate customers tracking the price changes. This mechanism allows customers to register their valuation to the system when they find the price is larger than the valuation on their arrival period. In this paper, we study the optimal pricing problem under this mechanism. When customers are truthtelling, it is optimal for the seller to use a threshold to

decide whether to accept or reject a registered price, and the price trajectory under the optimal policy has a stochastic cyclic decreasing structure. The case when the customers can strategically react to the price alert mechanism by reporting false valuations is also discussed.

51 A Dynamic Programming Model for Standardized Cargo Revenue Management

Lama Moussawi-Haidar[1], Nagihan Comez Dolgan[2], Fatima Allouch[1], [1]American University of Beirut, Beirut, Lebanon; [2]Ozyegin University, Istanbul, Turkey. Contact: lm34@aub.edu.lb

We consider the resource allocation of a standardized cargo transportation problem, faced by sea freight operators. The standardized cargo capacity of a sea liner is sold to big shippers through allotment contracts or on the spot market. Capacity reserved to allotments is sold in advance and may not be fully utilized due to no-shows. The remaining capacity is sold in the spot market over the entire booking horizon, taking into consideration the allotment no-shows. The objective is to develop and solve a dynamic programming model based on which spot market requests are dynamically accepted/rejected, given the allotment dynamic arrivals.

52 An Integrated Approach for Social Distancing and Revenue Optimization in Long Distance Passenger Trains

Md Tabish Haque, Faiz Hamid, Indian Institute of Technology Kanpur, Kanpur, India. Contact: tabish@iitk.ac.in

The unprecedented spread of COVID-19 has prompted government bodies to implement strict measures to curtail people's mobility. However, they had unintended results owing to a disastrous impact on economy. Train operators also face a similar outturn and require strategies to combat both simultaneously. In this regard, we examine the potential effects of seat inventory management for passenger trains that create stability between safety and economics. A MILP model has been proposed that optimizes operator revenue as well as reduces virus spread. Encouraging results in terms of limiting virus spread and increasing revenue even at higher capacity utilization were found.

53 Reverse Supply Chain Network with Return Products Quality Consideration

Sahar Ebrahimi Bajgani[1], Sara Saberi[1], Fuminori Toyasaki[2], [1]Worcester Polytechnic Institute (WPI), Worcester, MA, [2]York University, Toronto, ON, Canada. Contact: ssaberi@wpi.edu

Reverse logistics activities can be implemented as an agile solution in response to the shortage in production capacity of certain products during the pandemic and a convenient alternative to the raw materials extraction in post pandemic course. However, collecting and inspecting returned products is a complex process due to the different conditions in which the products have been kept. We designed a reverse supply chain network with competing collection centers, 3rd party remanufacturers, and recyclers to define the minimum quality of return products based on customer demands. The equilibrium condition is governed using a variational inequality model.

54 Multilayer Networks with Higher-order Interaction Reveal the Impact of Collective Behavior on Epidemic Dynamics

Jinming Wan, State University of New York at Binghamton, Vestal, NY, Contact: jwan8@binghamton.edu

The ongoing COVID-19 implies that population behavioral response to infection risk and intervention policy could significantly reshape the evolution of spreading dynamics, which is also the major drive underlying the resurgent outbreaks. To reveal such interplays, we present a three-layer network model: the contagion dynamics occur on two physical layers (the two distant communities) following the susceptible-exposed-infectious-recovered (SEIR) principle; agents from those two communities interact on the social layer, and adapt their behaviors in view of infection risk, government intervention, compliance cost, as well as behavioral response of their social contacts.

55 Rearranging the Deck Chairs on the Titanic: A Simulation Model of Behavioral Resource Utilization Under Crisis

James E. Paine, Massachusetts Institute of Technology, Cambridge, MA, Contact: jpaine@mit.edu

'Rearranging the deck chairs on the Titanic' is typically used metaphorically to refer to occupying oneself with trivial activity while ignoring something much more important. However, during an actively unfolding crisis the ability to identify activities as 'trivial' versus 'meaningful' can be unclear, and some activities could prevent a crisis or even recover from it, or conversely consume resources better spent in outright evacuation. This work develops a differential equation model to explore how the actions of the people during an evolving crisis affect both physical and behavioral dynamics, and identifies boundary conditions and separates trivial from meaningful mitigation activities.

56 Opinion-disease Integrated Simulation Model: Examination of Social Features' Impact on Disease Spread

Geonsik Yu[1], Mario Ventresca[2], Michael Garee[3], Yuehwern Yih[4], [1]Purdue University, West Lafayette, IN, [2]Purdue University, Lafayette, IN, [3]Air Force Institute of Technology, Wright-Patterson AFB, OH, [4]Purdue University, West Lafayette, IN, Contact: yu851@purdue.edu

We develop a two-layer epidemic simulation framework that includes intervention, disease dynamics, and opinion dynamics regarding the intervention. Using the framework, we examine the roles, and relative importance of social features - such as news audience polarization, echo chamber structure, and initial opinion distribution - in disease spread.

57 Plausible Screening for Multiple Simulated Responses

Jinbo Zhao, David J. Eckman, Texas A&M University, College Station, TX, Contact: jinbozhao@tamu.edu

Plausible screening is a nascent statistical framework that uses limited simulation experiments and properties of performance measures to screen out unacceptable solutions. Plausible screening is effective on problems with large solution spaces and high simulation cost. We extend plausible screening to the setting of multiple performance measures (responses), as arises in simulation-optimization problems with stochastic constraints or multiple objectives. We provide guarantees on confidence and consistency and demonstrate via numerical experiments how functional properties like convexity, Lipschitz continuity and monotonicity can help to eliminate unacceptable solutions.

58 Fixed Budget Ranking and Selection with Streaming Input Data

Yuhao Wang, georgia institute of technology, atlanta, GA, Contact: yuhaowang@gatech.edu

In a fixed budget ranking and Selection problem with streaming input data, one aims to efficiently identify the best among a finite number of designs by allocating a simulation budget in the presence of streaming input data, which is used to estimate the unknown input distribution. We formulate a stage-wise budget allocation problem and derive the optimality conditions for sampling policy by applying the large deviations theory, based on which we design two dynamic optimal budget allocation procedures tackling the optimality conditions in different ways. We theoretically guarantee their consistency and asymptotic optimality and numerically demonstrate practical efficiency.

59 Optimization of Autonomous Vehicle Model Parameters for Transient Mixed Traffic Network

Jinkun Lee, Matthew Carroll, East Carolina University, Greenville, NC, Contact: leejin18@ecu.edu

As self-driving has become a standard technology in major automobile manufacturers, autonomous vehicles driving with human drivers will impact the performance of current traffic network. Since the transformation of the current road network into autonomous driving network will be a gradual progress depending on the penetration rate of autonomous vehicles, the road traffic network may show a transient system behavior. We investigate the traffic network performance by simulating it with various vehicle models, identify key factors that may impact the traffic flow during the transitional period, and suggest optimal autonomous driving parameters found with genetic algorithm.

60 Min-time Coverage in Constricted Environments

Young In Kim, Georgia Institute of Technology, Atlanta, GA, Contact: ykim902@gatech.edu

This work concerns the employment of networked robotic fleets for the support of inspection operations in subterranean utility and transport networks. We formulate a set of scheduling problems for these operations, and we provide a structural analysis for these problems and an effective and computationally efficient methodology for their solution.

61 Estimating Path Travel Cost in Large-scale Networks Using Machine Learning Techniques

Alireza Rostami, Ali Zockaie, Michigan State University, East Lansing, MI, Contact: darzianr@msu.edu

This study proposes a heuristic algorithm utilizing machine learning methods to predict Origin-Destination (OD) travel distance, time, and cost using historical vehicle trajectory data generated at the DTA level. This study utilizes an ellipse boundary around OD to truncate the network and extract the relevant vehicle sub-trajectories. Numerical results of applying the proposed method to the Greater Chicago network showed promising performance in travel cost measures estimation and faster solution time.

62 Evacuation Route Planning for Alternative Fuel Vehicles

Denissa Sari Darmawi Purba, Eleftheria Kontou, Chrysafis Vogiatzis, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: dpurba2@illinois.edu

As the use of alternative fuel vehicles increased in public, it is important to consider evacuation plans that accommodate these vehicles in the emergency state. Under different alternative fuel vehicle types, plans for conventional vehicles could be infeasible for alternative fuel vehicles due to different fuel range capacity and recharging needs to reach safety. We propose a novel |K|-evacuation tree route plan problem with hop constraints to accomodate refueling needs of *k* vehicle fuel type during evacuation. We implement our model to design evacuation route plan of South Florida network and propose policy recommendations.

63 A Branch-cut-and-price Algorithm for the Dial-a-ride Problem with Minimum Disease-transmission Risk

Shuocheng Guo[1], Iman Dayarian[2], Xinwu Qian[3], Jian Li[4], [1]The University of Alabama, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, [3]The University of Alabama, Tuscaloosa, AL, [4]Tongji University, Shanghai, China. Contact: sguo18@crimson.ua.edu

This paper investigates a Risk-aware Dial-a-ride-problem (RDARP) with a particular focus on the disease-transmission exposed risk for onboard passengers in addition to total travel cost. The exposed risk is strongly associated with the dynamic time windows and contact duration for onboard passengers. To effectively solve the RDARP, we propose an exact Branch-Cut-and-Price (BCP) algorithm. Using the column generation method, we develop a tailored labeling algorithm and introduce families of risk-related resources. The numerical results using the real-world paratransit trip data indicate that our BCP algorithm can optimally solve 23 of 30 large instances of 39 to 55 passengers within one hour

64 Optimizing Routing and Sorting of Shipments for India's Largest E-commerce Company

Gowtham Bellala, Aditya Prasanth Bandaru, Vikas Goel, Flipkart, Bangalore, India.

We consider optimal network design for India's largest e-commerce company. At source hubs, it is not feasible to sort shipments for thousands of destination hubs due to layout constraints. Hence we aggregate loads until intermediate hubs, where we resort or cross-dock. We propose an automated network design approach which optimises for speed, cost and ensures network agility and reliability in a reasonable turnaround time. The challenge lies in the amount of path choices (~ 1 Billion). We formulate a large scale network flow model and present specialized algorithms. This enabled significant reduction in turnaround time (14 to 2 days), faster delivery, and improved network cost and reliability.

65 MaaS with UAM

Sungho Kang, Taesu CHOENG, KOREA University, Seoul, Korea, Republic of. Contact: ght2game@korea.ac.kr

We propose a UAM operation strategy to efficiently operate MaaS.

66 Optimizing Multi-trip Mobility Allowance Shuttle Transit (MAST): Capacity Constraints, Valid Inequalities, and Frequency

Reza Shahin[1], Pierre Hosteins[2], Paola Pellegrini[3], Pierre-Olivier Vandanjon[4], [1]University of Gustave Eiffel, VILLENEUVE-D'ASCQ, France; [2]University of Gustave Eiffel, Villeneuve d'Ascq, France; [3]University of Gustave Eiffel, Villeneuve d'Ascq, France; [4]University of Gustave Eiffel, Bouguenais, France. Contact: rezaa.shahin.1992@gmail.com

The Mobility Allowance Shuttle Transit (MAST) system is a type of public transportation where vehicles may deviate from a fixed route to serve clients who wish to get on or off within a service area. We study an extended version of the problem with a fleet of shuttle and a finite shuttle capacity. We study the impact of the shuttles capacity and trip frequency on the level of service and the possibility of rejecting a request. We develop a Mixed-Integer Linear Programming (MILP) and study the numerical impact of several valid inequalities.

67 Rebalancing an E-scooter Sharing System with En Route Charging Capability

Xiangyu Jin[1], Yufeng Cao[1], Yu Yang[2], [1]Shanghai Jiao Tong University, Shanghai, China; [2]University of Florida, Gainesville, FL, Contact: 2016-jinxiangyu@sjtu.edu.cn

Electric scooters (e-scooters) have emerged as a popular means of transport. However, the rapid growth of the e-scooter riding demand imposes significant operational challenges for its operators, especially the charging and rebalancing issues. It is vital for the operators to find efficient ways to accomplish the work while keeping their customers satisfied.

We consider a setting where e-scooters can be charged on the rebalancing truck en route or while the truck is waiting at each site. We proposed an effective algorithm to solve the problem based on Benders decomposition. Finally, we validated the proposed algorithm with extensive numerical experiments.

68 The Stack Loading Problem with Load-bearing Limit

Xinbo ZHANG[1], Minming LI[1], Zhou XU[2], Yingchao ZHAO[3], [1]City University of Hong Kong, Hong Kong, Hong Kong; [2]Hong Kong Polytechnic University, Hong Kong, Hong Kong; [3]Caritas Institute of Higher Education, Hong Kong,

Hong Kong, Hong Kong. Contact: xinbzhang3-c@my.cityu.edu.hk

This paper is the first study on the stack loading problem with the load-bearing constraint with an aim to minimize the number of stacks and the number of blockages. We show that this problem is strongly *NP*-hard even when the number of stacks is given and equals 2. For the case where the number of stacks is given and bottom jobs are fixed, we show that the problem can be solved by dynamic programming in pseudo-polynomial time. For the general problem, based on a two-index integer linear programming formulation and a tabu search heuristic, we develop a binary-search based matheuristic. Our experimental results demonstrate the efficiency and effectiveness of the newly developed matheuristic.

69 How Will Shared Mobility Reshape the Travel Demand: Evidence from Indianapolis

Hao Luo, Hua Cai, Purdue University, West Lafayette, IN, Contact: luo296@purdue.edu

The transportation system has recently been reshaped because of shared mobility. This research conducted a survey study in Indianapolis to analyze how people would shift their decision-making on travel mode choice from traditional modes to shared mobility and multi-modal system. We also developed an agent-based simulation model to investigate the potential impacts of shared mobility on vehicle ownership and travel demand changes at the city level under different future development scenarios. Policies on system integration towards a more sustainable transportation system will be provided based on the research results.

70 An Optimal Order Consolidation Policy in Last-mile Delivery

Seokgi Lee[1], Hyeong Suk Na[2], Yooneun Lee[3], [1]Youngstown State University, Youngstown, OH, [2]South Dakota School of Mines & Technology, Rapid City, SD, [3]University of Dayton, Dayton, OH, Contact: slee10@ysu.edu

As large-scale online markets have a high split rate of orders, consolidating and delivering split orders from the same customer has been addressed as a major problem in leveraging green logistics. In this research, the last-mile logistics situations are analyzed to address two interrelated questions: what would be the optimal order consolidation policy considering expected operational and economic efficiency in the resulting vehicle routing plan. Finally, we develop an integrated decision-making framework that simultaneously determines vehicle routing plans and order consolidation policies by reinforcement learning and feedback control approaches.

71 Staffing of Sequential Heterogeneous Servers Under Uncertain Arrivals

Randy Grivel[1], Berkin Tan Arici[1], Shreyas Ravishankar[1], Ron Askin[2], Jorge A. Sefair[3], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Scottsdale, AZ, [3]University of Florida, Gainesville, FL

Airport security services in the United States can be modeled using sequential heterogeneous servers with dynamic processing rates and pooled resources. Modeling the system as a mixed integer program with an objective of minimizing the expected wait time of passengers under the uncertainty of passenger arrivals improves system performance.

72 A Random Forest Algorithm to Analyze Litter Chemical Dynamics Throughout Decomposition in Agroecosystems

Parvin Mohammadiarvejeh[1], Marshall D. McDaniel[1], Becky Ball[2], Kyle Wickings[3], Guiping Hu[1], [1]Iowa State University, Ames, IA, [2]Arizona State University, Phoenix, AZ, [3]Cornell University, Ithaca, NY, Contact: pmohamm@iastate.edu

Decomposition of plant litter is a critical process in agroecosystems. The litter decomposition has been investigated with the rate of litter mass loss in the current literature, however, the pattern of changes over time in litter chemistry is largely unknown. In this research, we applied the random forest regression model to the archived decomposition samples and data from across the U.S. Long-Term Ecological Research Network to evaluate decomposition rate and remaining mass across decomposition stages as the outcome of dynamic litter chemistry over time.

73 Physics-constrained Deep Active Learning for Spatiotemporal Modeling of Cardiac Electrodynamics

Jianxin Xie[1], Bing Yao[2], [1]The University of Tennessee, Knoxville, Knoxville, TN, [2]The University of Tennessee, Knoxville, Knoxville, TN, Contact: jxie15@vols.utk.edu

This work presents a physics-constrained deep active learning (P-DAL) framework to reconstruct the spatiotemporal cardiac electrodynamics from sparse physical observation. We develop the physics-constrained deep learning (P-DL) framework which integrates the physical laws of the cardiac electrical wave propagation and deep learning to model the heart electrical behavior from sparse sensor measurements. Furthermore, a novel active learning strategy is proposed to seek informative spatial locations on the heart surface for data collection to further increase the predictive power of the P-DL method. The performance of P-DAL framework is evaluated in both healthy and diseased heart systems.

74 A Machine Learning Analysis of the Relationship Between Some Underlying Medical Conditions and Covid-19 Susceptibility

Mostafa Rezapour, Colin Varady, Wake Forest university, Winston Salem, NC, Contact: rezapom@wfu.edu

In this presentation, we investigate the relationship between the COVID-19 vaccines and boosters and the total case count for the Coronavirus across multiple states in the USA. Additionally, we discuss the relationship between several, selected underlying health conditions with COVID-19. To discuss these relationships effectively, we utilize statistical tests and machine learning methods for analysis and discussion purposes. Furthermore, we discuss conclusions made about the relationship between educational attainment, race, and COVID-19 and the possible connections that can be established with underlying health conditions, vaccination rates, and COVID-19 total case and death counts.

75 Towards Futuristic Autonomous Experimentation - A Surprise-Reacting Sequential Experiment Policy

Ahmed Shoyeb Raihan, Imtiaz Ahmed, West Virginia University, Morgantown, WV, Contact: ar00065@mix.wvu.edu

An autonomous experimentation platform is capable of conducting a sequential search for finding suitable manufacturing conditions for advanced materials by itself with minimal human intervention. The core of the intelligent control of such platforms is the policy guiding the sequential experiments which inevitably trades off exploitation versus exploration. We discuss whether such a trade-off is beneficial by measuring the element and degree of surprise associated with the immediate past observation. Using two existing surprise metrics, we devise a surprise-reacting policy which can quickly characterize the overall landscape of a response surface under resource constraints.

76 AI-driven Automated Purchase Order Management System

Bing Zhang[1], Shubhi Asthana[2], Pawan Chowdhary[3], Taiga Nakamura[4], [1]IBM-Research, San Jose, CA, [2]IBM Research - Almaden, SAN JOSE, CA, [3]IBM Research, San Jose, CA, [4]IBM Research-Almaden, San Jose, CA, Contact: bing.zhang@ibm.com

The transactions of goods and services between enterprises are often driven by purchase orders (POs) and invoices. Every month thousands of invoices are billed to customers who settle them. Datasets across POs and invoices that are otherwise in silos need to be mapped for faster and more efficient operational analysis. In addition, the invoices may get into a dispute due to over exhaustion of allocated funds or may be billed to an expired PO. Managing the billing service is a huge undertaking along with increased costs. In this work, we develop an AI-driven purchase order management system to automate PO-invoice mapping and a risk analytics algorithm to decrease disputes as well as increase renewals.

77 A Deep Learning Model for the Classification of Supraspinatus Fatty Infiltration from Shoulder Magnetic Resonance Images

Juan Pablo Saavedra[1], Guillermo Droppelmann[2], Nicolás García[2], Felipe A. Feijoo[3], [1]Pontificia Universidad Católica de Valparaíso, Valparaiso, Chile; [2]MEDS Clinic, Santiago, Chile; [3]Pontificia Universidad Católica de Valparaíso, Valparaiso, Chile. Contact: juan.saavedra.g@mail.pucv.cl

Rotator cuff tears are among the most common conditions of the shoulder. One of the criteria that clinicians use to decide the correct treatment for a patient is the fatty infiltration of the muscle. Patients with low amounts of fatty infiltration in the supraspinatus muscle will probably have better outcomes than those with higher amounts, and thus, assessing the quality of the muscle is crucial for medical staff. In this study, we trained a two-step deep learning model. In the first step, the model performed the segmentation of the region of interest from the image. Then, in the second step, the model classified the image as "risky" or "not risky", based on the the Goutallier's fatty infiltration scale.

78 Collaborative Discrimination-enabled Generative Adversarial Network (CoD-GAN) for Data Augmentation

Ziyang Zhang[1], Yuxuan Li[2], Chenang Liu[2], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Stillwater, OK, Contact: jan.zhang@okstate.edu

This study aims to modify GAN to optimize data augmentation when data from two classes are imbalanced. Hence, a creative and effective GAN structure, collaborative discrimination-enabled generative adversarial network (CoD-GAN) is proposed. The main novelty lies in integrating multiple discriminators to improve the robustness of its discrimination and the diversity of the synthetic samples. The effectiveness of the proposed method is validated by simulation data and a real-world dataset.

79 Failure-averse Active Learning for Physics-constrained Systems

Cheolhei Lee, Virginia Tech, Blacksburg, VA, Contact: cheolheil@vt.edu

Engineering systems are subject to implicit physics-constraints, while constraints are underestimated in active learning. We develop a failure-averse active learning considering physics constraints. It realizes two tasks: safe variance reduction and safe region expansion, with theoretical guarantees. This method achieved zero-failure in composite structure assembly without knowing explicit failure regions.

80 Traffic Shaping and Hysteresis Mitigation Using Deep Reinforcement Learning in a Connected Driving Environment

Rami Ammourah[1], Alireza Talebpour[2], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]University of Illinois at Urbana-Champaign, Champiagn, IL, Contact: ramiaa2@illinois.edu

A multi-agent deep reinforcement learning framework is proposed for traffic shaping, i.e., maintaining a desirable traffic flow given a certain traffic density. The key advantage of the framework is its ability to mitigate hysteresis phenomena. Partial connectivity is assumed where connected automated vehicles share information amongst each other. A centralized training, centralized execution approach based on the DQN algorithm is adopted where control is defined by signals of acceleration or deceleration commands. We demonstrate the ability of the model to shape the state of traffic, mitigate the negative effects of hysteresis, and even improve traffic flow beyond its original level.

81 Model-informed Generative Adversarial Network (MI-GAN) for Learning Optimal Power Flow

Yuxuan Li, Chenang Liu, Oklahoma State University, Stillwater, OK, Contact: yuxuan.li@okstate.edu

The optimal power flow (OPF) problem remains challenging due to variability, intermittency, and unpredictability of renewable energy brought to power system. The capability of existing optimization approaches is insufficient when the problem scale is large. Hence, this work proposed a novel model-informed GAN (MI-GAN) method to handle the OPF problem, which can ensure optimality, flexibility, and efficiency by a proposed new model-informed generator with a developed recursive iteration algorithm. The numerical experiments using the IEEE test systems showed this method was very promising.

82 Bayesian Optimization Enabled Rapid Calibration of Molecular Modeling Forcefields

Montana Carlozo[1], Bridgette Befort[1], Nilay Kumar[1], Edward Maginn[1], Alexander Dowling[2], [1]The University of Notre Dame, South Bend, IN, [2]The University of Notre Dame, Notre Dame, IN, Contact: mcarlozo@nd.edu

Hydrofluorocarbons (HFCs) must be phased out of use and replaced, but a lack of data on HFCs limits advances in separation processes design. Gaussian process regression can be used with Bayesian optimization (GPBO) to rapidly regress predictive molecular model parameters for HFC data generation to be used in process design. We demonstrate the use of two formulations of GPBO, finding that a formulation which emulates the molecular model output, instead of model error, captures the overall model behavior best for parameter calibration. We compare the results of both formulations to non-linear regression. Future work will include modifying the BO acquisition function to improve accuracy and speed.

83 An Empirical Evaluation of Unfairness Mitigation Algorithms for Predicting Micro-mobility Demand

Ayan Mukhopadhyay, Vanderbilt University, Nashville, TN

Data-driven forecasting models are used for resource allocation, such as in optimizing shared micro-mobility programs by optimizing the location of bike stations. However, such an approach to allocation may unintentionally incorporate implicit bias, resulting in inequity in resource allocation. I will talk about the performance of state-of-the-art unfairness mitigation algorithms coupled with fairness constraints, specifically in the context of predicting micro-mobility demand.

84 Early Disease Prediction of Swine Considering Daily Feed, Water Intake, and Weight Change Pattern Using Machine Learning Models

Saiara Samira Sajid[1], Guiping Hu[1], Jack Dekkers[2], [1]Iowa State University, Ames, IA, [2]Iowa State University, Ames, IA, Contact: sajids@iastate.edu

Swine Farms have a large economic component in livestock farming. Concurrently, swine are susceptible to a larger number of diseases. Hence, diseases have the largest economic impact on the swine industry. We propose Machine Learning (ML) based prediction models to predict the treatment requirement of an individual pig of a batch. The daily feed intake, water intake, and weight change were given as input to the prediction model. We compared several state-of-the-art ML models and found that Random Forest outperforms other models (accuracy of 60.8%). The proposed model ranks swine within a batch based on the probability of getting sick, promoting sustainable pork production.

85 An LSTM-autoencoder Based Online Monitoring Approach for Cyber-physical Attack Detection in Additive Manufacturing

Zhangyue Shi[1], Chenang Liu[2], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Stillwater, OK, Contact: zhshi@okstate.edu
How to effectively monitor and accurately detect cyber-physical attacks becomes a critical barrier for the broader adoption of additive manufacturing (AM) technology. In this study, we propose a machine learning-driven online side channel monitoring approach for AM process monitoring. A data-driven feature extraction approach based on LSTM-autoencoder is developed to detect unintended process/product alterations caused by cyber-physical attacks. Both supervised and unsupervised monitoring schemes are implemented based on the extracted features. Case study in FFF process demonstrates the effectiveness of the proposed method.

86 Analysis of Occurrence Pattern in Wildfire Cases in California Using NLP Methods

Seonho Woo[1], Seungho Woo[2], [1]University of Michigan - College of Engineering, Ann Arbor, MI, [2]Purdue University, West Lafeyette, IN, Contact: clairewo@umich.edu
As the climate goes drier, keeping track of increasing wildfire cases is helpful to be prepared for this natural disaster. Natural Language Processing methods are used to extract key quantitative data for damage from online articles, which is a reasonable means for data collection. Analysis of terminologies using various methods is conducted to retrieve information listed in the text. Mapping and a pattern analysis are done by using the mapper feature in the nltk package to demonstrate the damage size and location. This could track the actual wildfire cases and show the pattern of the trend. This study could be expanded into the larger locational aspect, and add more factors in tracking the major causes.

87 Multiclass Classification of Detected Anomalies by Combining Root Cause Analysis and Machine Learning Techniques

Pooyan Mobtahej, Lamar University, Beaumont, TX
A gas compressor system consists of different components in which any defects in each of them could cause the overall system failure which is costly. Therefore, the early diagnosis of failures in compressor systems is essential to reduce the risk of system shutdown and increase production line reliability. Hence, this research proposes a hybrid anomaly detection approach by employing both Root Cause Analysis and Machine Learning decision algorithms to combine for the detection of each component failure and conduct a multi-class classification of unseen anomalies captured in time-series cleaned data. 10-Fold cross-validation was conducted to evaluate the performance of the models. The proposed method for decision tree-based multiclass classification has been chosen from the evaluated methods as the best-scored model with a 99.99% AUC and Accuracy score.

88 Targeting High-value Customers: Optimizing Marketing Strategy Through Consumer Behavior Analysis

Ilyas Ustun, Mengfan Ying, DePaul University, Chicago, IL, Contact: ilyasustun@gmail.com
This poster presents the usage of machine learning models to identify high-value customers. From the transaction data, Recency, Frequency, and Monetary (RFM) values have been calculated. These RFM values have been used in the K-means algorithm to cluster the customers into different segments. Customer lifetime value is obtained from the RFM values, and the clusters are ranked accordingly to identify high-value customers. Using customer demographics and past purchases, machine learning algorithms have been applied to classify new customers. The proposed approach has been used in a case study to better serve the customer base of a medium-sized bike and cycling accessories company.

89 Data-driven Adaptive Testing Resource Allocation Strategies for Real-time Monitoring of Infectious Diseases

Xin Zan[1], Jaclyn Hall[2], Tom Hladish[3], Xiaochen Xian[1], [1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, [3]University of Florida, Gainesville, FL, Contact: xin.zan@ufl.edu
Infectious diseases have continued to be a major global public health threat and effective methods are in critical need to quickly detect disease outbreaks. However, limited testing availability that leads to insufficient data poses challenges to effective monitoring in practice. By integrating nonstationary MAB techniques on top of a physics-informed model, this work proposes adaptive allocation strategies to intelligently allocate limited testing resources among communities, which enables collection of high-quality testing data for quick outbreak detection. Theoretical analysis and a comprehensive simulation study are conducted to evaluate the performance.

1 Projected Randomized Smoothing for Certified Adversarial Robustness

Samuel Pfrommer, Brendon Anderson, Somayeh Sojoudi, University of California, Berkeley, Berkeley, CA

We propose a classifier architecture that first projects onto a low-dimensional approximation of the data manifold and then applies a standard classifier. By performing randomized smoothing in the low-dimensional projected space, we characterize the certified region of our smoothed composite classifier back in the original input space and prove a tractable lower bound on its volume. We show experimentally that classifiers without the initial projection are vulnerable to perturbations that are normal to the data manifold yet are captured by the certified regions of our method. We compare the volume of our certified regions against various baselines and show that our method improves on the state-of-the-art by many orders of magnitude.

2 Exploring the Whole Rashomon Set of Sparse Decision Trees

Rui Xin[1], Takuya Takagi[2], Chudi Zhong[1], Zhi Chen[1], Margo Seltzer[3], Cynthia Rudin[1], [1]Duke University, Durham, NC, [2]Fujitsu Laboratories Ltd., Tokyo, Japan; [3]The University of British Columbia, Vancouver, BC, Canada.

In any given machine learning problem, there may be many models that could explain the data almost equally well. The Rashomon set is the set of these all almost-optimal models. Rashomon sets can be extremely complicated, particularly for highly nonlinear function classes such as decision trees. We provide the first method for completely enumerating the Rashomon set for sparse decision trees. We show three applications of the Rashomon set: 1) it can be used to study variable importance for the set of almost-optimal trees, 2) the Rashomon set for accuracy enables enumeration of the Rashomon sets for balanced accuracy and F1-score, and 3) the Rashomon set for a full dataset can be used to produce Rashomon sets for subsets of the dataset.

3 Federated Gaussian Process: Convergence, Automatic Personalization and Multi-fidelity Modeling

Xubo Yue, Raed Al Kontar, University of Michigan, Ann Arbor, Ann Arbor, MI

In this paper, we propose FGPR: a Federated Gaussian process (GP) regression framework that uses an averaging strategy for model aggregation and stochastic gradient descent for local client computations. Notably, the resulting global model excels in personalization as FGPR jointly learns a global GP prior across all clients. The predictive posterior then is obtained by exploiting this prior and conditioning on local data which encodes personalized features from a specific client. Theoretically, we show that FGPR converges to a critical point of the full log-likelihood function, subject to statistical error. Through extensive case studies we show that FGPR excels in a wide range of applications and is a promising approach for privacy-preserving multi-fidelity data modeling.

4 PERCEPT: A New Online Change-point Detection Method using Topological Data Analysis

Xiaojun Zheng[1], Simon Mal[1], Liyan Xie[2], Yao Xie[3], [1]Duke University, Durham, NC, [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]Georgia Institute of Technology, Atlanta, Georgia.

Topological data analysis (TDA) provides a set of data analysis tools for extracting embedded topological structures from complex high-dimensional datasets. We propose a new method, called PERsistence diagram-based ChangE-PoinT detection (PERCEPT), a topology-aware, non-parametric framework for online high-dimensional change-point detection. PERCEPT follows two key steps: it first learns the embedded topology as a point cloud via persistence diagrams, then applies a non-parametric monitoring approach for detecting changes in the resulting point cloud distributions. We demonstrate the usefulness of PERCEPT in two applications on solar flare monitoring and human gesture detection.

1 Super-resolution of Turbulent Flows in the Absence of the High-resolution Ground Truth

Kyongmin Yeo[1], Malgorzata Zimon[2], Mykhaylo Zayats[3], Sergiy Zhuk[3], [1]IBM Research, Yorktown Heights, NY, [2]IBM Research, Warrington, United Kingdom; [3]IBM Research,

Dublin, Ireland. Contact: kyeo@us.ibm.com
Super-resolution (SR) refers to the problem of reconstructing high-resolution (HR) information from low-resolution (LR) data. SR of physical data has attracted a great attention with the advent of deep learning. While most of the SR models assume existence of HR ground truth data to train a deep learning model, in real-life problems, such HR ground truth data is scarce. Here, we present a deep learning model for SR of turbulent flows trained without such HR ground truth. We propose to use the conservation laws to regularize the solution of the SR model. It is shown that the SR model can reliably reconstruct unseen high-resolution turbulent flows.

2 Some Recent Advances on Statistical Learning for Remote Sensing Data and Wildfire Risk Assessment on Networks

Guanzhou Wei[1], Xiao Liu[1], Feng Qiu[2], [1]University of Arkansas, Fayetteville, AR, [2]Argonne National Lab, Lemont, IL, Contact: gwei@uark.edu
This talk introduces some of our recent work on statistical learning for (1) wildfire smoke propagation modeling using remote sensing data, and (2) wildfire risk assessment for power grids. Under the first topic, we focus on the suppression of Gibbs phenomenon for a recently proposed physics-informed statistical spatio-temporal model. Under the second topic, we describe a new statistical model for point processes on linear networks that enables us to assess wildfire risks on power grids.

3 Digital Twin Based Framework for Joint Optimization of Yield, GHG Emissions, Revenue and Soil Carbon Sequestration for Agriculture

Ranjini Guruprasad, [1</sup]
Agriculture contributes about 26% to global GHG emissions. Reducing GHG emissions impacts the farming inputs and in turn, the agricultural yield and revenue. Hence, food companies want to jointly optimize yield, revenue and GHG emissions. In addition to reducing GHG emissions, food companies are adopting farming practices to sequester carbon in the soil to have a positive environmental impact and increase revenue. In this talk, we present a comprehensive framework that includes revenue estimation models and digital twin (includes physics based models) to jointly optimize revenue, yield, GHG emissions and amount of soil carbon sequestered. The framework performs counterfactual analysis to recommend farming practices based on geos and periods of interest to increase/maintain yield, reduce GHG emissions and increase the carbon sequestered in the soil and revenue.

4 Geospatial Multi-Model Carbon Sequestration and Green House Gas Emission Framework

Ademir Ferreira da Silva[1], Levente Klein[2], Jitendra Singh[3], [1]IBM Research Brazil, Rio de Janeiro, Brazil; [2]IBM, New York, NY, [3]IBM Research India, Gurgaon, India. Contact: ademir.ferreira@br.ibm.com
Climate Change mitigation efforts require accurate assessment of local GHG emissions and carbon sequestration (CS) at less than 1km2 spatial resolution with flexibility to adjust based on local model and user input. Current approaches of GHG emissions rely on generic and coarse models not amenable to capture the local variations necessary to make these data useful for operational decisions. We demonstrate a geospatial framework where CS in soil and forest is combined with emission of CO2, CH4 and N2O from land management. The framework uses machine learning techniques on satellite and ground measurement data for land-cover classification, data imputation and multi-model validation, allowing estimation of CS and GHG emissions at a farm level.

Recent Statistical Innovations for Analyzing Big and Complex Data: Methods and Applications

General Session

Session Chair

Trambak Banerjee, University of Kansas, Lawrence, KS

1 Community Gifting and Recipients Engagement with Peers and Influencers Evidence from Natural Experiments on Twitch

Alexander Chaudhry[1], Yang Wang[2], Erya Ouyang[2], Xueming Luo[2], [1]Southern Utah University Leavitt School of Business, Cedar City, UT, [2]Temple University Fox School of Business and Management, Philadelphia, PA
Community gifting on live streaming platforms enables a user to donate gifts to other members of the community. The authors exploit community gifting's random assignment on Twitch as a collection of natural experiments in a difference-in-differences framework. The results demonstrate that receiving a gift increases financial engagement with peers but not streamers while social engagement with both peers and streamers increases. The authors reveal that the sentiment of social engagement reflects gift recipients' elevated

happiness. Moreover, a novel measure of chat continuity is used to reveal that gift recipients, while surprised by a gift, join the ongoing conversation in the stream. The combined results of increased engagement volume, happiness, and chat continuity indicate that community gifting can improve the recipients' engagement with the community.

2 Evaluating Mental Health Care from a Natural Language Perspective: How Consistent is Your Teletherapist?

Courtney Paulson, 1</sup

Modern healthcare is increasingly embracing the advantages of telehealth, particularly in the wake of COVID-19 and other recent community health concerns. Patients and providers alike often appreciate the flexibility of conducting visits and updates via video call, text message, or phone. One area of telehealth that has seen particular growth is teletherapy, or the practice of providing mental health care through methods other than in-person visits. But how do we know if the care a patient is receiving through teletherapy matches the expectation of a more traditional patient-therapist relationship? In this study, we consider the text of thousands of messages between deidentified patients and their therapists as well as survey and other data provided by patients and the teletherapy platform. By combining natural language processing methodology (e.g., Latent Dirichlet Allocation for topic sorting) with machine learning methodology (e.g., penalized regression methods), we investigate characteristics of the teletherapy experience such as response time, message length, and message content to determine the effect such measures have on therapy satisfaction and overall outcomes.

3 An Efficient Monte Carlo EM Clustering Algorithm in GLMM

Rashmi Ranjan Bhuyan[1], Gourab Mukherjee[1], Wreetabrata Kar[2], [1]University of Southern California, Los Angeles, CA, [2]Krannert School of Management, Purdue University, West Lafayette, IN, Contact: bhuyanr@usc.edu

The use of generalized linear mixed-effects models (GLMM) is popular across social and medical sciences. High dimensionality and class imbalance are two extremely common characteristics in such datasets. Under these settings, fitting GLMMs and estimating all the effects become immensely difficult. We propose a Monte Carlo EM algorithm to recover the heterogeneous effects in imbalanced GLMM and simultaneously implement model based clustering. We provide theoretical guarantees for consistent estimates of the clustering and other effects. The algorithm is designed to work in the high dimensional regime, and it scales up efficiently. We compare the performance of the proposed algorithm on a range of simulation setups and observe encouraging performance. We demonstrate the applicability of our method by analyzing consumer behavior in email marketing dataset.

4 Large-scale Importance Selection on Heteroscedastic Contenders

Luella Fu[1], Bowen Gang[2], Gareth James[3], Wenguang Sun[3], [1]San Francisco State University, San Francisco, CA, [2]School of Management, Fudan, China; [3]Marshall School of Business, Los Angeles, CA, Contact: luella@sfsu.edu

Choosing candidates to whom a limited set of resources will be distributed is a pervasive dilemma. In multiple testing procedures that can be used to choose such candidates, power is traditionally defined as the number or proportion of correctly selected non-null hypotheses. We generalize power so that researchers can better select more desirable testing units and propose a specific formulation to capture not only if a unit has been correctly categorized as null or alternative but also to better reward the detection of larger effect sizes. We demonstrate the effectiveness of the proposed method in picking out mutual funds with positive returns.

1 Regression Trees on Grassmann Manifold for Adapting Reduced-order Models

Xiao Liu, University of Arkansas, Fayetteville, AR, Contact: liuxiaodnn_1@hotmail.com

Reduced-Order Models (ROMs) often lack robustness against the change of parameters. This talk proposes to use regression trees to learn the mapping between parameters and POD bases that span the low-dimensional subspace onto which the full-order model is projected. Motivated by the fact that a subspace spanned by a POD basis can be viewed as a point in the Grassmann manifold, we propose to grow a tree by splitting the tree node to maximize the Riemannian distance between the two subspaces spanned by the predicted POD bases on the left and right daughter nodes. Five numerical examples are presented to demonstrate the performance of the proposed method, and compare the proposed tree-based method to the existing interpolation method for POD basis and the use of global POD basis.

2 A Deep-learning-based Surrogate Model for Thermal Signature Prediction in Laser Metal Deposition

Shenghan Guo[1], Weihong Guo[2], Linkan Bian[3], Yuebin Guo[2], [1]Arizona State University, Mesa, AZ, [2]Rutgers, The State University of New Jersey, Piscataway, NJ, [3]Mississippi State University, Mississippi State University, MS, Contact: shenghanguo@gmail.com

Transient thermal signatures generated during Laser metal deposition (LMD), such as the in-situ thermal images of melt pool, contain rich information about process performance and defects. This paper develops a deep-learning-based surrogate model, called LMD-cGAN, to predict and emulate the transient thermal signatures in LMD. The model generates images for the thermal dynamics of melt pool conditionally on the deposition layer. It enables early prediction of future-layer thermal signatures for an in-process part based on its early-layer thermal signatures. A physics-guided image selection mechanism is integrated with LMD-cGAN to calibrate the predictions against physical benchmarks of transient melt pool for the process. The effectiveness and efficiency of the proposed method are demonstrated in a case study on the LMD of Ti-4Al-6V thin-walled structures.

3 Closed-loop Machine Learning and Compensation for Geometric Accuracy Control of Additively Manufactured Products

Wenbin Zhu[1], Arman Sabbaghi[2], [1]Purdue University, West Lafayette, KS, [2]Purdue University, West Lafayette, IN, Contact: sabbaghi@purdue.edu

Additive manufacturing (AM), or 3D printing, systems enable direct printing of physical products from computer-aided design (CAD) models. One of the significant limitations of AM is shape deviations between the printed product and the nominal CAD. This talk presents a closed-loop machine learning and compensation framework for improved accuracy control in AM. The closed-loop nature is fully sequential in that it requires printing only one new shape at a time, and accurate products can be printed in a small number of iterations. As demonstrated in our case studies using a Markforged Metal X AM machine, our framework can reduce shape inaccuracies by 30% to 60% in at most two iterations. Our closed-loop framework addresses the significant challenge of "few shot" learning and control of AM systems by means of knowledge transfer across different products and iterations in AM.

4 Tensor-on-tensor Regression Neural Networks for Process Monitoring with High Dimensional Data

Qian Wang, Kamran Paynabar, Georgia Institute of Technology, Atlanta, GA, Contact: wang.qian@gatech.edu

Modern technology enables the collection of enormous amount of measurements over processes in the areas such as manufacturing. The regression modeling between the collected high dimensional (HD) data is crucial for understanding the underlying system. HD data are heterogeneous including profiles, images and point clouds, usually formed into tensors. Linear methods, mostly tensor techniques, have been discussed in the literature to model the relationship between HD process variables while capturing their spatial structure and reduce high dimensionality. However, most of the real-world processes possess nonlinear nature which fails to be captured by these methods. This article proposes novel tensor-on-tensor regression neural networks to model nonlinear relationship between sources of HD data, whose performance is evaluated using simulation and case studies.

1 Why are U.S. Parties so Polarized? A "Satisficing" Dynamical Model

Vicky Chuqiao Yang, MIT, Cambridge, MA, Contact: vicky.chuqiao.yang@gmail.com

Since the 1960s, Democrats and Republicans in US Congress have taken increasingly polarized positions, despite the lack of clear evidence for voters doing the same. We explain this apparent contradiction by developing a dynamical model that predicts ideological positions of political parties. Our approach integrates satisficing decision making---voters settle for candidates who are "good enough." We test the model using data from the US Congress over 150 years and find that our predictions are consistent with the two major political parties' historical trajectories. In particular, the model explains how polarization between parties could be a consequence of increasing ideological purity within the parties.

2 Quantifying Public Uses and Public Funding of Science

Yian Yin, Northwestern University

Knowledge of how science is consumed in public domains is essential for understanding the role of science in human society. Here we examine public use and funding of science, by linking 36M scientific publications from all fields to their upstream funding support and downstream uses across government documents, news media, and marketplace invention. We find that different public domains draw in specialized ways across scientific fields. Amidst these differences, we find universal alignment between what the public consumes and what is highly impactful within science. A field's public funding is further strikingly aligned with the field's collective public use. Overall, public uses of science present a rich landscape of specialized consumption, yet collectively science-society interface with remarkable assignment between scientific use, public use, and funding.

3 Firms' Returns to Search and Their Knowledge

Seyed Mohamad Hosseinioun, UIC, Chicago, IL

Innovation is the outcome of a search process for better solutions and is integral to firms' business. There is tension between local search, which leads to competence rigidity, and distant search, which is costly and uncertain. Despite rich research in balancing local and distant search, we do not yet understand why some firms are better suited for one vs. the other. We argue firm's knowledge generality is the key determinant of its search behavior. We consider the search space a network, wherein nodes are technical domains and edges are established search paths between them. Hence, firms' knowledge generality allows for a more central position in the search space. We examine how firm's knowledge moderates search using cross-sectionally and longitudinally rich data on firms' patents. Finally, we examine returns to search and how firm's knowledge influences such returns.

4 Unsupervised Embedding of Trajectories Captures the Latent Structure of Mobility

Jisung Yoon[1], Dakota Murray[2], Sadamori Kojaku[3], Rodrigo Costas[4], Woo-Sung Jung[5], Stasa Milojevic[3], Yong-Yeol Ahn[3], [1]Northwestern University, Evanston, IL, [2]Northeastern University, Boston, MA, [3]Indiana University, Bloomington, IN, [4]Leiden University, AX Leiden, Netherlands; [5]POSTECH, Pohang, Korea, Republic of. Contact: jisung.yoon92@gmail.com

Human mobility drives major societal phenomena including economies and innovation. Historically, mobility was constrained by geographic distance, however, in the globalizing world, language, culture, and history are increasingly important. We propose using the neural embedding model word2vec for studying mobility and capturing its complexity. Word2ec is shown to be mathematically equivalent to the gravity model of mobility, and using three human trajectory datasets, we demonstrate that it encodes nuanced relationships between locations into a vector-space, providing a measure of effective distance. Focusing on the case of scientific mobility, we show that embeddings uncover cultural, linguistic, and hierarchical relationships at multiple levels of granularity. Connecting neural embeddings to the gravity model opens up new avenues for the study of mobility.

Emerging Machine Learning Algorithms for Advanced Manufacturing

General Session

Session Chair

Ying Lin, University of Houston, Houston, TX

Session Chair

Chenang Liu, Oklahoma State University, Stillwater, OK

1 Grouping and Spatially Correlated Sparse Bayesian Learning with Application to Multi-stage Assembly Systems

jihoon Chung, Zhenyu James Kong, Virginia Tech, Blacksburg, VA, Contact: zkong@vt.edu

Grouping and Spatially correlated Sparse Bayesian Learning with Application to Multi-Stage Assembly Systems This paper addresses the problem of fault diagnosis in multi-station assembly systems. The main challenges to be resolved in this work include (1) the number of measurements is less than the process errors, which is typical in practice but results in an ill-posed estimation problem, (2) there exist non-stationary patterns of process faults among the samples, and (3) there exist spatial correlations among the process faults. To address these challenges, a novel hierarchical Bayesian model, which is Grouping and Spatially correlated Sparse

Bayesian Learning (GSSBL), is proposed in this work. The actual autobody assembly process is also used to illustrate the superiority of the proposed method.

2 Solving Supply-demand Matching of Manufacturing Resources Using Model-free RL Algorithms

Saunak Kumar Panda, University of Houston, Houston, TX, Contact: spanda@cougarnet.uh.edu

We consider the problem of dynamically matching supply-demand quantities of heterogeneous types of manufacturing resources. We model it using an MDP framework where the outstanding demand is the state vector with the optimal action being the supply-demand quantities matched to maximize the total discounted reward. Preliminary results show that increase in the state vector dimension exponentially increases the number of feasible actions, which greatly increases the solution time by model-based methods like dynamic programming. This has motivated us to turn to model-free reinforcement learning (RL) methods like Q-learning and Deep Q network algorithms like DQN and DDPG. We further develop smart action exploration and action manipulation strategies for DQN and DDPG respectively to improve the performance. Finally, we compare the performance of all these algorithms.

3 Enhance In-situ Anomaly Detection Performance Using Knowledge Distillation in Additive Manufacturing System

Zhangyue Shi, Chenang Liu, Oklahoma State University, Stillwater, OK, Contact: zhshi@okstate.edu

The incorporation of advanced online sensing technology in the manufacturing system provides valuable data to achieve efficient in-situ process monitoring. Several machine learning based in-situ monitoring methods have been developed to detect both internal and external quality issues. However, machine learning based methods have comparably high requirement on data quality and quantity, which hinders broader application of machine learning methods. To resolve these challenges, this study develops a knowledge sharing framework based on knowledge distillation to effectively share the informative knowledge learnt by the data-rich agent with data-poor agents. Using the distilled knowledge, anomaly detection accuracy of the data-poor agents could be improved with the help from the data-rich agent.

4 An Engineering-informed Automated Point-cloud Segmentation Algorithm for Geometric Quality Assessment of Thick Layers in Additively Manufactured Metallic Structures

Cesar Alexander Ruiz, Qiang Huang, University of Southern California, Los Angeles, CA

Additive manufacturing (AM) of complex metal parts promises to improve the sustainability of the aerospace and oil industries. Wire-arc AM (WAAM) offers high deposition rates on large printing areas by welding a few thick layers. However, WAAM technologies suffer from poor geometric accuracy due to unstable high temperature processes. Moreover, partial layer melting and severe out-of-plane layer displacement difficult the identification of each layer for building a prescriptive model for geometric accuracy improvement. Standard semantic segmentation and clustering algorithms cannot process dense point clouds with the overlapping structures observed in WAAM. In this talk, we propose an efficient ML algorithm that utilizes the knowledge of the as-deposited geometry to select features to identify the boundaries between overlapping layers.

1 Determinants for Intention to Purchase a Mobile Device: A User-centric Approach

Yashica Pandey, Ahamed Shamly Anvar Mackey, University of North Texas, Denton, TX

There has been a substantial increase in mobile device usage in the last decade among students. To target this segment, mobile companies must take a user-centric approach to understand the factors for mobile device purchase. Survey data from the University students were analyzed utilizing a user-centric approach to identify determinants for intention to use a mobile device.

2 The Impact of Buyers' Bidding Dynamics on Sellers' Pricing Strategy: A Machine Learning Approach

Yeun Soo Park, Gu Pang, Joseph Sanderson, University of Birmingham, Birmingham, United Kingdom. Contact: yxp089@student.bham.ac.uk

The information asymmetry associated with remanufactured products appears to be worse than for their new product counterparts. This is likely due to the high-level uncertainty and perceived risks. We collect eBay auction data of remanufactured electronics to explore how buyers bidding dynamics impact sellers' pricing strategy and how such dynamics advance the buyers' knowledge on information asymmetry. Using machine learning methods, our study suggests that existing models based on statistical analysis are less capable of identifying the non-linear relationships. Our results show advanced machine learning models better predict non-linear relationships.

3 Hyperparameter Optimization over Data Hierarchy for Model Selection in Time Series Forecasting

Arindam Jati[1], Vijay Ekambaram[1], Brian Quanz[2], Wesley Gifford[2], Pavithra Harsha[3], Stuart Siegel[2], Chandra Narayanaswami[2], [1]IBM Research, Bangalore, India; [2]IBM Research, Yorktown Heights, NY, [3]IBM Research, Pleasantville, NY

Time series data is sometimes associated with a hierarchy. The data at the bottom level is often sparse and incoherent (for example, in the retail domain), which makes it hard to obtain optimized forecasting models. We propose a novel model selection method for time series forecasting, that exploits the data hierarchy during the hyperparameter optimization (HPO) of the model being trained at the bottom level, by leveraging the better predictability of the higher-level aggregated time series and incorporating the prediction errors at all levels in the HPO objective. Experiments on several public hierarchical time series datasets demonstrate the efficacy of the proposed method over standard model selection techniques.

4 Actual Events Vs. Perceived Reporting: Modeling Firm Performance Under Environmental Uncertainty Using Machine Learning

Minh Nguyen, University of Hawaii at Manoa, Honolulu, HI, Contact: duyminh@hawaii.edu

Not all companies respond the same to natural disaster events. This study investigates two ways that natural disasters affect firm performance: actual events vs. perceived reporting. In this study, I consider the billion-dollar natural disasters as the actual events and the number of words related to natural disasters in the Management Discussion and Analysis section in Form 10-Ks filing by the U.S. public companies as the perceived reporting. The results show that both actual events and perceived reporting of natural disasters this year negatively affects return on assets in the next year. Comparing among classification and regression trees (CART), neural networks, and linear regression models, I find that CART and neural networks outperform linear regression models in predicting U.S. firm performance under environmental uncertainty.

1 Analysis of Human Behavior in Human Robot Interaction for Manufacturing

Sara Masoud, Wayne State University, Detroit, MI, Contact: saramasoud@wayne.edu

Despite its complexity, human behavior follows structured principles. Creation of more reliable and efficient collaborative robotic environments becomes possible through better understanding the underlying concepts of human behavior. Previously, robots served in production lines in co-existing capacities, where no interaction took place between the operators and robots. Industry 5.0 has equipped us with technologies such as industrial internet of things, big data, and artificial intelligence, facilitating the realization of full collaborative environments, where robots can interact with humans in unseen situations through sensing, processing, and predicting human behaviors.

2 Decision Focused Utility Learning

Harshal D. Kaushik, Virginia Tech, Blacksburg, VA

From the available finite set of actions, how can we design the utility of players that are competing against each other? This question arises naturally in many real-life scenarios as its famous counterpart of conventional game theory. In this work, we consider a mathematical program with equilibrium constraints and propose a game-theoretic pipeline that spans from data, to prediction, to a downstream optimization problem.

3 High-throughput Characterization via Automated Sensing and Machine Learning

Junru Zhang[1], Blake Johnson[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Blacksburg, VA, Contact: junru6@vt.edu

High-throughput characterization (HTC) of composition-process-structure-property relations is essential for accelerating materials manufacturing paradigms. Here, we present a new method for HTC of hydrogel library rheological properties via robotically-directed sensing. We also demonstrate that supervised machine learning enables accurate classification of material phase using sensor data. Ultimately, creating HTC methods for soft materials that synergize with well plate formats can accelerate the pace of soft materials, biomaterials, and sensors research across various fields as well as improve capabilities for quality assurance and control of hydrogel-based products

4 Multi-task Learning for Pricing

Yuhang Wu, Columbia University, New York, NY, Contact: yw3453@columbia.edu

Multi-task Learning For Pricing Multi-task Learning For Pricing Multi-task Learning For Pricing

5 Fairness in Federated Learning

Raed Al Kontar, University of Michigan, Ann Arbor, MI

We propose GIFAIR-FL: a framework that imposes Group and Individual FAIRness to Federated Learning settings. By adding a regularization term, our algorithm penalizes the spread in the loss of client groups to drive the optimizer to fair solutions. Our framework GIFAIR-FL can accommodate both global and personalized settings. Theoretically, we show convergence in non-convex and strongly convex settings. Our convergence guarantees hold for both i.i.d. and non-i.i.d. data. To demonstrate the empirical performance of our algorithm, we apply our method to image classification and text prediction tasks.

6 Evaluation of Privacy Preservation Capacity of Thermal History Features in Metal-based Additive Manufacturing

Mahathir Bappy[1], Wenmeng Tian[2], [1]Mississippi State University, Starkville, MS, [2]Mississippi State University, Mississippi State, MS, Contact: mmb888@msstate.edu

Large-scale data sharing can promote the performance for metal-based additive manufacturing (AM) certification. However, the broader adoption of the sharing platform is significantly hindered by the AM user's intention of intellectual property (IP) protection. This work evaluates the capacity of privacy preservation of the state-of-the-art feature extraction methods, which were originally proposed for AM process anomaly detection. Specifically, the extracted features are assessed for their capacity to disclose printing trajectory related information. Subsequently, their capacity to facilitate privacy preserving AM certification is discussed.

7 Time Series Analysis for Interval-valued Data: Theory and Applications

S. Yaser Samadi[1], Lynne Billard[2], [1]Southern Illinois University, Carbondale, IL, [2]University of Georgia, Athens, GA, Contact: ysamadi@siu.edu

Many series of data record individual observations as intervals, such as stock market values with daily high-low values, or min and max temperatures, recorded over time. With the advent of supercomputers, datasets can be extremely large, and it is frequently the case that observations are aggregated into intervals, histograms, or other forms of so-called symbolic data. In this talk, we present an interval-valued autoregressive model. ML estimators are derived by using the ideas of composite likelihood and the pairwise likelihood functions, and their asymptotic properties are derived. Simulation studies show that the new estimators perform considerably better than those obtained previously.

8 Online Point Cloud Fusion for Quality Assurance of Additive Manufacturing

Chen Kan, University of Texas at Arlington, Arlington, TX

This study develops a new monitoring framework that leverages online point cloud sensing and modeling to detect and characterize geometric defects in additive manufacturing (AM). We evaluated and validated the developed framework in the fused filament fabrication process. Results have shown that the developed framework effectively captures and characterizes geometric defects of each printed layer and it has a great potential to be used for online quality assurance of AM.

9 Machine Learning-based Process Modeling for Superconductor Manufacturing

Mai Li, Shenglin Peng, Ying Lin, Qianmei Feng, Wenjiang Fu, University of Houston, Houston, TX, Contact: ylin58@uh.edu

With high efficiency and low energy loss, high-temperature superconductors (HTS) have demonstrated their profound applications in various capital-intensive systems, such as energy and transportation. However, the wide commercialization of these applications has not been achieved due to the difficulty in producing large-scale superconductor tapes with uniform performance. To help achieve the uniform performance of large-scale HTS tapes, this study employed machine learning techniques to model the uniformity of HTS tapes in terms of various summary statistics and identified critical process parameters that need to be closely monitored and controlled.

10 Cyberattack Detection in Multi-stage Manufacturing Systems

Dan Li, Clemson University, Greenville, SC

The digitization and automation in the era of Industry 4.0 has enabled more accurate and efficient manufacturing systems. However, these data intense manufacturing systems also have increased vulnerability to cyberattacks. In fact, manufacturing industry has become the top target of cyberattacks. This presentation focuses on data integrity cyberattacks that perturbs sensor and control data in multi-stage manufacturing systems. The objective is to develop a data-driven framework that helps address the challenges in real-time attack detection, identification, and localization.

1 Content Creator Versus Brand Advertiser? The Effect of Inserting Advertisements in Videos on Influencers

Tengteng Ma[1], Yingda Lu[2], Yuheng Hu[2], Xi Chen[3], Yuxin Chen[4], [1]University of Illinois-Chicago, Chicago, IL, [2]University of Illinois-Chicago, Chicago, IL, [3]Zhejiang University, Zhejiang, China; [4]New York University - Shanghai, Shanghai, China.

Influencer advertising has become an indispensable component of online marketing due to the exponential growth of social influencers and their influence. We empirically examine the instantaneous and longer-term influence of inserting advertisements in videos on influencers' reputations. We further investigate the moderator effect when influencers demonstrate stronger endorsement by showing their faces during advertisements. Our result suggests that inserting advertisements have a negative impact on both instantaneous and longer-term viewer engagement; advertisements with influencers' face showing moderate the negative effect of advertisements on viewers' instantaneous response, while the different impact between advertisements with/out influencers showing their faces is not significant in the longer term.

2 Modeling Co-engagement Patterns in Brand Information Networks

Pankhuri Malhotra[1], Yaxin Cui[2], Keran Zhao[3], [1]University of Oklahoma, Norman, OK, [2]Northwestern University, Evanston, IL, [3]University of Houston, Stafford, TX, Contact: yaxincui2023@u.northwestern.edu

Information networks have become pervasive with the rise of electronic interactions, and their social and economic values have been explored by research across multiple domains. While most existing research focuses on descriptive and predictive aspects of information networks, statistical analysis of their "generative features" has been largely ignored. Our goal is to build large-scale brand information networks using Twitter followership data and to model the generative aspects of the observed network structures. We employ Exponential Random Graph Models to reveal a mix of network and brand characteristics that contribute to the formation of links between brands. Since links between brands arise from the aggregated interest patterns of Twitter users, the ERGM model reveals the characteristics associated with high user co-engagement patterns on social media.

3 The Role of Dislike Rating in Digital Media Platform: A Natural Experiment

Ahreum Kim, Yingda Lu, Tengteng Ma, Ali Tafti, University of Illinois at Chicago, Chicago, IL, Contact: akim239@uic.edu

The like and dislike buttons enable users to simply represent their opinions by rating with a single click of a button. This study investigates the effect of the change of the like and dislike rating features on user engagement in a digital media platform. We leverage a unique exogenous shock in which YouTube's recently made the number of dislike buttons hidden from the public. We study if the change of rating feature of YouTube affected the consumption and participation engagement behaviors, represented as the number of views, likes and comments and sentiment scores of the comments. We also look into if there are relative changes on such engagement behaviors compared to the viewership. We employ a DID method to understand the role of the dislike button in digital media platforms and provide managerial implications.

4 Recommending for a Three-sided Food Delivery Marketplace: A Multi-objective Hierarchical Approach

Yuyan Wang[1], Long Tao[2], Xian Xing Zhang[3], [1]Google Brain, Mountain View, CA, [2]Uber, San Francisco, CA, [3]Pinterest, San Francisco, CA, Contact: yuyan@alumni.princeton.edu

We develop MOHR, a general recommendation framework for three-sided food delivery platforms that optimizes multiple objectives for the eaters, restaurant partners and delivery partners, and addresses the challenge of hierarchical food recommendation where a recommendation item can be either a single restaurant or a group of similar restaurants. We combine machine learning with scalable multi-objective optimization to improve eater happiness, marketplace fairness and partner earnings, and design a probabilistic structural model for hierarchical recommendation which accounts for users' scrolling patterns. MOHR is launched globally at Uber Eats, one of the largest food delivery platforms in the world. It led to a significant increase in user conversion, retention and gross bookings, which combined translate to $1.5M weekly gain in revenue.

1 Multi-Armed Bandits for Repeated Principal-Agent Models with Unobserved Agent Rewards

Ilgin Dogan[1], Anil Aswani[2], Zuo-Jun Max Shen[3], [1]University of California, Berkeley, Berkeley, CA, [2]UC Berkeley, Berkeley, CA, [3]University of California Berkeley, Berkeley, CA, Contact: ilgindogan@berkeley.edu

We study designing data-driven incentives for repeated principal-agent games under adverse selection. The principal's problem comprises estimating the agent's unknown utility model with a finite set of actions and designing adaptive incentives to steer the agent's decisions by only watching their past actions. The agent trains a parallel learning algorithm on top of these incentives to maximize their expected utilities. This dynamic interaction brings a trade-off to the principal between learning the agent's model consistently *(exploration)* and maximizing their expected net reward *(exploitation)*. First, we propose a statistically consistent estimator for a non-parametric agent model. Then, we prove that the proposed bandit policy for the principal attains a low regret. Lastly, we show our framework is applicable to the incentive programs for medical adherence.

2 When Machines Will Take Over? Algorithms for Human-Machine Collaborative Decision Making in Healthcare

Mehmet Eren Ahsen[1], Mehmet U.S. Ayvaci[2], Radha Mookerjee[3], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas- Dallas, Richardson, TX, Contact: ahsen@illinois.edu

We study a hospital's optimal acquisition of single or multiple predictive AI algorithms for redesigning work to allocate tasks between humans and machines. We analytically characterize whether and when human-machine collaboration strategy is desirable against the machine-alone strategy or human-alone strategy. We use data from a recent crowdsourced deep-learning mammography challenge to demonstrate the value of the optimal use of AI in radiology. Our findings can inform efforts in reimagining work in the age of AI.

3 Incorporating Fairness into Incentive Design in Principal-Agent Models with Adverse Selection and Moral Hazard

Yoon Lee, Ilgin Dogan, Anil Aswani, Zuo-Jun Max Shen, UC Berkeley, Berkeley, CA, Contact: yllee@berkeley.edu

A limitation of existing approaches for incentive design in cyber-physical systems (CPS) is that they do not incorporate fairness. Fairness is crucial for incentives because improper design can harm people of certain classes (e.g., race or gender). In this study, we develop optimization problems for CPS that incorporate notions of fairness into the model. Here, we formulate quantitative notions of fairness in the settings of principal-agent models with adverse selection and moral hazard. We derive the policy structure for an optimal fair contract, discuss the intuition of this optimal design, and provide a numerical case study to show how fairness affects incentive design in CPS.

4 Power and Resistance to Medical AI in Treatment Planning Decisions

Eugene Chan[1], Ali Gohary[2], [1]Toronto Metropolitan University, Toronto, ON, Canada; [2]Monash University, Caulfield East, Australia. Contact: ehchan@outlook.com

Patient empowerment is a guiding principle in the healthcare literature. But, we posit that power increases resistance toward medical AI in the treatment planning stage of the healthcare journey. This is because power increases autonomy, and there is the misperception that medical AI takes away—or at least reduces—patient autonomy. We find support for our hypotheses in four studies. Our research contributes to an understanding of how power is relevant to healthcare customers and healthcare outcomes. Our work also investigates why people resist medical AI at the treatment stage of the healthcare journey beyond existing examinations at the diagnosis stage. Importantly, our work emphasizes the need to correct what patients know and believe about medical AI, in both the treatment planning as well as other stages of a patient's medical decision-making.

Search Optimization and Threat Analytics

General Session

Session Chair

Jeremy Eckhause, RAND Corporation, Arlington, VA

1 **Adversarial Deep Reinforcement Learning Enabled Threat Analytics Framework for Constrained Spatio-temporal Movement Intelligence Data**

Dinesh Sharma, Ankit Shah, Soumyadeep Hore, Jalal Ghadermazi, University of South Florida, Tampa, FL

Intelligence, surveillance, and reconnaissance (ISR) systems assist the defense and military in their tactical operations by gathering movement intelligence data for tracking adversaries and their activities in an area-of-interest. However, short track durations and discontinuous coverage results in significant spatio-temporal gaps in the collected data. As a result, the ISR analysts are unable to connect the incomplete set of movements to detect threats in the form of salient activities of the adversaries. To this regard, we develop a novel threat analytics framework that consists of a deep reinforcement learning-based adversarial agent and a machine learning-based threat detector to help analysts identify salient adversarial activities. The experiment results on simulated data show that the proposed framework identifies, on an average, 99% of the threats.

2 **On Solving Fortification Games: A Heuristically-Enhanced Exact Algorithm**

Ramy Abdallah[1], Elkafi Hassini[2], Wael El-Dakhakhni[3], [1]DeGroote School of Business, McMaster University, Hamilton, ON, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]McMaster University, Hamilton, ON, Canada. Contact: ramy.fakhry@mcmaster.ca

This research examines a special class of tri-level optimization problems. In general terms, the three-level non-cooperative game, with perfect information. We propose a heuristically-enhanced exact algorithm for solving the aforementioned class of tri-level problems, where the most lower-level problem can be NP-hard. Moreover, we rely on heuristics gained from structural domain-knowledge of the application to enhance the formation of the feasible region. We demonstrate the effectiveness of our proposed solution on two applications; defending critical infrastructure, and the capacitated lot-sizing problem with a the capability of interdiction and fortification. We test our solution approaches on three electrical networks and randomly generated instances of lot-sizing problems.

3 **Uav Search Optimization for Recording Emerging Targets with Camouflaging Capabilities**

John Becker[1], Rajan Batta[2], Adil Baran Narin[3], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo (SUNY), Buffalo, NY, [3]University at Buffalo, Buffalo, NY, Contact: becker6@buffalo.edu

This extension to work in the emerging target information gathering domain introduces a camouflaging component to target behavior and also allows for multiple UAVs. Our extension considers that emerged targets will camouflage themselves and become undetectable after a period of time according to independent uniform distributions. We also investigate the impact of using multiple UAVs for this operation scenario. We generate routes using the Team Orienteering Problem with Time Windows, and evaluate these routes using a series of simulations. We perform a factorial experiment to study the impact of network structure, camouflaging distribution, and UAV service time on the number of targets detected. Additionally, a framework is developed for comparing routes by determining the probability that a route will out-perform the other route(s) being considered.

Large-scale Data Analytics for Transportation Systems (CAV + Shared Mobility)

Joint Session

Session Chair

Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA

Session Chair
Wei Ma, The Hong Kong Polytechnic University, Kowloon

1 **A Unified Network Equilibrium for E-hailing Platform Operation and Customer Mode Choice**
Xu Chen, Columbia University, New York, NY, Contact: xc2412@columbia.edu
This work aims to combine both economic and network user equilibrium for ride-sourcing and ride-pooling services, while endogenously optimizing the pooling sequence of two origin-destination (OD) pairs. With the growing popularity of ride-sourcing and ride-pooling services provided by transportation network companies (TNC), there lacks a theoretical network equilibrium model that accounts for the emerging ride-pooling service, due to the challenge in enumerating all possible combinations of OD pairs pooling and sequencing. This paper proposes a unified network equilibrium framework that integrates three modules, including travelers' modal choice between e-pooling and e-solo services, e-platforms' decision on vehicle dispatching and driver-passenger matching, and network congestion.

2 **Identifying Critical Transfer Zones to Coordinate Transit with On-demand Services Using Crowdsourced Trajectory Data**
Jiahua Qiu[1], Yue Jing[2], Wang Peng[1], Yujie Hu[1], Lili Du[1], [1]University of Florida, Gainesville, FL, [2]University of Florida, GAINESVILLE, FL, Contact: jq22@ufl.edu
This study develops a data-driven approach for identifying critical transfer zones in the city to facilitate the coordination of transit and on-demand services. First, we mesh the trajectory data with an optimal 3D grid. Built upon that, we study the cube trajectory density of each mode and present the results by heatmaps. After that, we explore two patterns on heatmaps through clustering algorithms: the ridesharing swarm (RS) zones and the "sandwich pattern" (SP) zones. Our numerical analysis confirms that these RS zones are well correlated to the promising areas for integrating transit and on-demand services; the SP zones help discover first/last mile (FLM) gaps. Last, we adopt ConvLSTM network to predict the FLM gaps so that adaptive services can be planned. A case study based on the field data of Chengdu city confirms the effectiveness of our analysis approach.

3 **Using Connected Automated Vehicles as Mobile Controllers in Single-lane Roundabouts**
Veronica Diaz Pacheco[1], Ali Hajbabaie[2], Ramin Niroumand[2], [1]University of Puerto Rico at Mayagüez, Mayagüez, Puerto Rico; [2]North Carolina State University, Raleigh, NC
This study utilizes connected automated vehicles (CAV) as mobile controllers to improve traffic operations in single-lane roundabouts. CAVs negotiate the right of way with each other and control the flow of vehicles into the roundabout to improve traffic operations and safety. We have formulated this concept as a mixed-integer non-linear program and have utilized alternating direction method of multipliers to find near-optimal solutions. The numerical results showed that CAVs improved both traffic operations and safety significantly.

Sunday, 2 PM–3:15 PM

Health Policy Modeling and Analysis
General Session

Session Chair
Jagpreet Chhatwal, Harvard Medical School, Mass General Hospital, Boston, MA

Session Chair
Ali Hjaar, MGH Institute for Technology Assessment / Harvard Medical School, Boston, MA

1 **A Model-based Study of Preventions and Outbreak Response Options to Eliminate Circulating Vaccine-derived Poliovirus Type 2**
Yuming Sun[1], Pinar Keskinocak[1], Stephanie Kovacs[2], Lauren N. Steimle[1], [1]ISyE Georgia Tech, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA, Contact: ysun608@gatech.edu
The Global Polio Eradication Initiative coordinated global cessation of type 2 containing oral poliovirus vaccine (OPV) in 2016, following the eradication of wild poliovirus type 2. The polio program continues to respond to circulating vaccine-derived poliovirus type 2 (cVDPV2) outbreaks through supplementary immunization activities using monovalent OPV type 2 (mOPV2). However, the attenuated live virus in mOPV2 can, in rare occurrence, mutate to regain neurovirulence and cause cVDVP2 outbreaks in areas with low population immunity. In our study, we build a compartmental model to capture dynamics of poliovirus transmission involving OPV virus reversion and evaluate different preventions and outbreak response options to achieve a polio free world. We focus on Northern Nigeria in our study given its ongoing cVDPV2 transmission.

2 **At What Prevalence of Resistance Should Empiric Antibiotic Treatment for Gonorrhea Change? A Cost-effectiveness Analysis**

Xuecheng Yin[1], Minttu Rönn[2], Song Li[3], Yue Yuan[4], Thomas L. Gift[5], Joshua A. Salomon[6], Yonatan H. Grad[7], Reza Yaesoubi[1], [1]Yale School of Public Health, New Haven, CT, [2]Harvard T.H. Chan School of Public Health, Boston, MA, [3]Zhejiang University, Hangzhou, China; [4]Altfest Personal Wealth Management, New York, NY, [5]Centers for Disease Control and Prevention, Atlanta, GA, [6]Stanford University School of Medicine, Palo Alto, CA, [7]Harvard T. H. Chan School of Public Health, Boston, MA, Contact: xuecheng.yin@yale.edu

Common diagnostic tests for gonorrhea do not provide information about the susceptibility of infection to antibiotics. Guidelines recommend changing antibiotics used for empiric therapy once resistance prevalence exceeds 5%. However, the basis for this threshold is not clear. We developed a model of gonorrhea transmission to project gonorrhea-associated costs and loss in quality-adjust life-years (QALYs) under different switch thresholds among men who have sex with men in the US. Using cost-effectiveness analysis, we identify hypothetical switch thresholds for varying values of willingness-to-pay per QALY and showed the health and economic burden of gonorrhea and the effective lifespan of antibiotics depends on the selected threshold.

3 **Evaluating Deceased-donor Kidney Allocation Policies via a Discrete-event Simulation Model**

Kirthana Hampapur, Pinar Keskinocak, David Goldsman, Georgia Tech, Atlanta, GA, Contact: kirthana@gatech.edu

The allocation of organs for transplantation is a complex process that requires policy makers to consider many factors, including the efficiency of the process and equity among the candidates waiting to receive a life-saving transplant. In the United States, there is a large gap between the supply and demand of organs, especially in certain geographical regions. Because of this disparity, a candidate's place of listing is among the most-significant factors impacting their timely access to transplant. Thus, there is an urgent need to develop and evaluate allocation policies considering equity and health outcomes. We developed a discrete-event simulation model that mimics the current deceased-donor kidney allocation system. Using the model, we quantified the differences among different allocation policies by comparing their system- and candidate-level outcomes.

4 **Optimal Vaccination Campaigns Under Opinion and Physical Networks**

Serin Lee, Shan Liu, Zelda B. Zabinsky, University of Washington, Seattle, WA, Contact: serinlee@uw.edu

As the anti-vaccination movement has increased significantly, governments are trying to prevent the spread of dis- and misinformation about vaccines. Using coupled dynamics of disease transmission in physical networks and opinion propagation in virtual networks, we identify optimal vaccination campaigns that minimize the burden of infectious diseases. We use a networked compartmental model consisting of several groups, representing opinion characteristics. We identify an optimal policy regarding vaccination campaigns that yields lowest deaths. The model is sensitive to vaccine effectiveness, size of anti-vaccination population, opinion and physical network structure, and power of persuasion.

Operations Research for Medical Decision Making

General Session

Session Chair

Lauren N. Steimle, ISyE Georgia Tech, Atlanta, GA

1 **Collaborative Simulation Modeling to Estimate the Impact of the Covid-19 Pandemic on Breast Cancer Mortality in the U.S.**

Oguzhan Alagoz[1], Kathryn Lowry[2], Allison Kurian[3], Jeanne Mandelblatt[4], Mehmet A. Ergun[5], Hui Huang[6], Sandra Lee[7], Clyde Schechter[8], Anna Tosteson[9], Diana Miglioretti[10], Amy Trentham-Dietz[1], Sarah Nyante[11], Karla Kerlikowske[12], Brian Sprague[13], Natasha K. Stout[14], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Washington, Seattle, WA, [3]Stanford University, Palo Alto, CA, [4]Georgetown University, Washington, DC, [5]Istanbul Technical University, Istanbul, Turkey; [6]Dana Farber Cancer Institute, Boston, MA, [7]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, [8]Albert Einstein College of Medicine, Bronx, NY, [9]Dartmouth College, Hanover, NH, [10]University of California at Davis, Davis, CA, [11]University of North Carolina at Chapel Hill, Chapel Hill, NC, [12]University of California at San Francisco, San Francisco, CA, [13]University of Vermont, Burlington, VT, [14]Harvard Medical School/Harvard Pilgrim Health Care Institute, Boston, MA, Contact: alagoz@engr.wisc.edu

The coronavirus disease 2019 (COVID-19) pandemic has disrupted breast cancer control through short-term declines in screening and delays in diagnosis and treatments. We utilized three established National Cancer Institute's Cancer

Intervention and Surveillance Modeling Network (CISNET) breast cancer models to estimate the impact of COVID-19 on future breast cancer mortality between 2020 and 2030. The models considered reductions in mammography screening use, delays in symptomatic cancer diagnosis, and reduced use of chemotherapy for women with early-stage disease for the first 6 months of the pandemic with return to prepandemic patterns after that time. We also conducted sensitivity analyses to determine the effect of key model parameters, including the duration of the pandemic impact, on our results.

2 Unsupervised Clustering Analysis Using Non-Surgical Care and Surgical Care Features for Trauma/Non-Trauma Centers

Xiaonan Sun, Shan Liu, Charlie Mock, Monica Vavilala, Eileen Bulger, Rebecca Maine, University of Washington, Seattle, WA, Contact: xnsun@uw.edu

Trauma center (TC) designation standards establish the key resources and processes for each TC level to ensure injured patients receive appropriate care. These standards do not proscribe which injuries or procedures each TC should do, and little information exists about this variation across TCs in practice. We performed 3 sets of unsupervised clustering algorithms to a statewide hospital discharge database to determine whether different hospital features including surgical and non-surgical care for trauma and non-trauma patients can distinguish TCs level. The clusters only partially aligned with the TC levels, suggesting unsupervised machine learning could provide insight into the key features that can help optimal designate TC levels.

3 Machine Learning to Estimate Risk of Adverse Maternal Outcomes in a Cohort of Nulliparous Women

Lauren N. Steimle[1], Meghan Meredith[2], [1]Georgia Tech ISyE, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA

Racial/ethnic minority and rural populations are disproportionately affected by comorbid conditions and preventable adverse maternal outcomes. We present risk prediction models for adverse maternal outcomes that incorporate interactions between comorbid conditions. We leverage machine learning methods and consider clinical, lifestyle, and demographic information as potential risk factors to better understand their associations with adverse maternal outcomes. We discuss the implications for clinical practice.

4 Quickest Change Detection and Sequential Hypothesis Testing for Statistically Periodic Data

Taposh Banerjee, University of Pittsburgh, Pittsburgh, PA, Contact: taposh.banerjee@pitt.edu

In many anomaly detection problems in science and engineering, observed data often exhibit nonstationary statistical behavior that is repeated after a fixed amount of time. A new class of stochastic processes called independent and periodically identically distributed (i.p.i.d.) processes is introduced to model such data. Theory and algorithms are developed for sequential analysis problems in i.p.i.d. processes. In the optimal algorithms for these problems, a sequence of statistics is computed over time and an alarm is raised the first time the sequence touches a periodic sequence of thresholds. It is also shown that single-threshold algorithms are asymptotically optimal for both problems as the error rate goes to zero.

Panel: Finding Research Success in the Medical Community
Panel Session

1 HAS Panel: Finding Research Success in the Medical Community

Christopher Sun, Massachusetts Institute of Technology, Cambridge, MA

With the increasing complexity of healthcare problems, amounts of health data, and stakeholder openness to data-driven decision making, there is both a need and opportunity to innovate in healthcare through analytics. But given the multidisciplinary nature of this field and the dependency on collaborators and medical expertise, how does one navigate conducting research in this area? In this session, panelists will discuss how those in the OR/OM community can establish health-related research programs, reach a broader medical audience with their work, and find success within the medical community. Time will be provided for questions from the audience.

1 Smart Product-service Systems in the Healthcare Industry
Yeneneh Negash, Asia University, Taichung, Taiwan.
Conditions regarding the adoption of smart product-service systems (PSS) remain unclear, requiring the identification of driving attributes & the attributes' interrelationship for its implementation in the health care industry. Data were collected from healthcare industry practitioners. Exploratory factor analysis determines the attributes' structure & validity. In addition, 17 practitioners who treat a patient with chronic conditions are interviewed to understand the interrelationship among the attributes. The fuzzy decision-making trial & evaluation laboratory determines the interrelationship of aspects and criteria. 24 criteria are found to be valid drivers of smart PSS adoption. Intelligent connected products & stakeholder communication are the causal attributes of improving digital health services adoption & providing alternative user schemes.

2 Information Discloser in the Context of Smart IoT: A Systematic Literature Review and Future Research Agenda
M A Shariful Amin[1], Abhijeet Kumar[2], Gayle Prybutok[3], Victor R. Prybutok[3], Vess Johnson@unt.edu[1], [1]University of North Texas, Denton, TX, [2]University of North Texas, Denton, TX, [3]University of North Texas, Denton, TX
This research aims to study the privacy information disclosure in the context of smart IoT: a PRISMA-style systematic literature review and future research agenda. Only peer-reviewed scholarly publications were analyzed. The study reveals an exponential growth in the number of articles published in the last decade. A wide variety of information discloser related publications and research design were indicating a promising future research potentiality. The paper also highlights key insights for the prime research contexts and identifies research gaps and future research directions.

3 Optimal Timing to Initiate Renal Replacement Therapy Among Critically Ill Patients

Han Zhou, Jingui Xie, Technische Universität München, Heilbronn, Germany. Contact: han.zhou@tum.de

Whether and when to initiate renal replacement therapy (RRT) is a controversial question in critical care. Benefits of delaying therapy include enabling a substantial number of patients to recover from acute kidney injury without undergoing RRT, and avoiding exposure to an unnecessary therapy with its negative side effects and costs. On the other hand, early therapy could improve electrolyte and fluid balance, enhance the removal of toxins, and thereby prevent potential life-threatening harm. Thus, there is a trade-off between short-term benefits and long-term recovery risks. Aiming to identify a treatment policy to minimize the mortality of a patient, we develop Markov decision processes. We prove conditions that establish the structural properties of the optimal solution. To estimate model parameters, we utilize instrumental variables and prediction methods.

4 Sensor-based Co2 Monitoring System and Simulation for Human Respiratory

Yijie Chen, Young-Jun Son, University of Arizona, Tucson, AZ, Contact: yijiechen@email.arizona.edu

Exhaled CO2 accumulates near the face during regular human breathing, forming a bubble-shape CO2 zone. And, the CO2 bubble may impair human cognitive abilities as the CO2 concentration increases. In this study, we designed a non-invasive sensor-based system to monitor CO2 concentration around human face under different situations, and developed a continuous time CO2 dispersion model based on discrete CO2 sensory data. In addition, we integrated the CO2 distribution model with a time-series-based dynamic model of the human breath cycle to better understand the fluctuation of CO2 bubble with self-adaption in the human body. The integrated model can be utilized to predict human physiological responses and cognitive performance under varying CO2 levels, as well as make recommendations for optimal ventilation scenarios.

Decision Support for Executives

General Session

Session Chair

Jen McIntosh, Department of Defense

1 The Importance of Promoting a Common Frame of Reference to Ensure Effective Decision-making Between Information Technology and Business Organizations

Efrain Rodriguez, Department of Defense, Fort George G. Meade, MD, Contact: frao74@gmail.com

At the Department of Defense, we see Information Technology (IT) organizations as key mission enablers, allowing Business/Mission units to effectively execute their chartered functions. Often times, IT and Business/Mission Organizations make Operations and Tactical decision unilaterally, driven by their own priorities and budget constraints, leading to second/third order unintended consequences, impacting how each organization operates in support of time sensitive/mission critical activities. This presentation will discuss the benefits of promoting the creation of a common frame of reference framework, establishing a common ground for both organizations to gauge mission cross-organization impacts, promoting effective communication between IT and Business/Mission, allowing for proper activity orchestration.

2 Starting by Stopping: Perspectives on Getting Unstuck

Lincoln J. Chandler, Chandler Decision Services, Chicago, IL

In this talk, I will share a collection of tools and tactics that have helped my clients become unstuck when working with, and acting on, data. Over time, these tools have helped clients across the private, public, and nonprofit sectors:
*Cultivate the will to take action
*Improve their ability to collaborate across various groups of stakeholders
*Develop a shared, structured approach to decision making
*Gain confidence in connecting strategic goals to daily activities
Using examples inspired by one of my longest client relationships, I'll share my perspective on the challenges we faced and the lessons learned along the way.

3 Practical Recommendations for Presenting Analytics to Executives

Brian L. Morgan, US Navy, Monterey, CA

Senior executives must often synthesize information from a multitude of sources prior to making a decision. The ability to present analytic work to executive-level decision makers is a necessary soft skill for every operations research professional. The panelist introduces a number of practical recommendations, applicable in a wide variety of government and business environments, that are motivated from over five years of military service performing analysis on the Navy Headquarters staff in the Pentagon.

4 Anatomy of a Decision: Guiding NSA's Covid-19 Response with Data Analysis

Kyle Hovey, Raleigh, NC

COVID-19 highlighted the importance of quick, data-driven decision making to respond to rapidly changing conditions. Decision makers required actionable, sustainable, and straightforward metrics they trusted to affect positive change. These types of metrics desired by leaders are often at odds with the complex nuances of real systems and the difficulty of analyzing messy or incomplete datasets. We discuss the data analysis process that guided NSA's COVID-19 response and the necessary considerations when building metrics to bridge the gap between data analyst and decision makers.

5 Decide Better - How An Entrepreneur and Educator Embraced Decision Science

Matthew Brady, University of Colorado Boulder, Boulder, CO, Contact: matthew.brady@colorado.edu

How do you decide who to hire, when a phase-gate has been achieved, or which project to resource next? Chances are, you rely on intuition... which could otherwise be known as habits, biases, and, group-think. What if you could elevate your decision-making... to decide using information. To decide better?

This presentation will engage the audience with real examples of how leading companies are using structured Decision Science techniques, and how individuals, teams, and entire organizations can be empowered to use these techniques. Further, demonstrations of how Behavioral Science can be incorporated to allow for qualitative aspects like post-mortems (and pre-mortems!).

Attendees will leave informed on these innovative uses of analytics to support decision-making, and equipped with tools and examples to see the world a little differently.

Sunday, 2 PM–3:15 PM

CC - Room 126

Decision Making with Societal Impact

General Session

Session Chair

Nicolo Bertani, Universidade Católica Portuguesa, Fontainebleau, France.

1 Ambiguity in Voting

Ilke Aydogan[1], Yu Gao[2], Ning Liu[3], Uyanga Turmunkh[4], [1]IESEG School of Management, Lille, France; [2]Guanghua School of Management, Beijing, China; [3]Beihang University, Beijing, China; [4]IESEG School of Management, Lille, France. Contact: u.turmunkh@ieseg.fr

Riker and Ordershook (1968) proposed that voters' beliefs about the closeness of an election outcome is a key determinant of their decisions to participate in the election. To date, however, direct tests of the determinants of voting behavior have found little support for the influence of beliefs, finding instead that voting behavior is mostly driven by factors other than beliefs, e.g., the perceived level of importance attached to the election outcome. This is puzzling, because presumably the importance attached to an election outcome ought to be moderated by whether or not people consider their votes to have any impact on bringing about the outcome in the first place. In this paper, we hypothesize that beliefs about closeness, like most beliefs about real-world events, cannot easily be probabilized. Ambiguity (unknown probabilities) plays a role.

2 Attribute Ambiguity and Justification in Environmental Decision Making

Nicolo Bertani[1], Enrico Diecidue[2], Anouk Festjens[3], [1]Universidade Católica Portuguesa, Lisbon, Portugal; [2]INSEAD, Fontainebleau, France; [3]Maastricht University, Maastricht, Netherlands.

The environmental consequences of our actions are plagued by uncertainty: their severity, likelihood, and time horizon are deeply ambiguous. We devise a lab experiment to study and compare attitude towards risk and towards ambiguity when choices entail real environmental consequences. We explore the differential role of attribute ambiguity, as well as the effect of accountability on environmental choices. We operationalize real environmental incentive 1) by offering the participants the possibility to nullify CO_2 certificates and 2) by asking them to justify their choices. Understanding environmental choices in the face of uncertain information is key to foster more conscious environmental behavior.

3 Overestimation of Foregone Alternatives as a Hidden Source of Regret

Johannes Müller-Trede[1], Daniel Feiler[2], [1]IESE Business School, Barcelona, Spain; [2]Dartmouth College, Tuck School, Hanover, NH, Contact: jmuller@iese.edu

Past research has established that observing the outcome of the foregone alternative is an important driver of feeling regret. We predict and empirically demonstrate a seemingly opposite result: Decision-makers are more likely to experience regret when they do *not* observe the outcome of a foregone alternative than when it is revealed. Our prediction draws on the observation that when there are many alternatives to choose from under uncertainty, the perceived attractiveness of the almost-chosen alternative tends to exceed its reality. In four pre-registered studies, we find that participants predictably overestimate the foregone path, and that this overestimation causes undue regret.

4 **Big Moves: Understanding Migration and Relocation Dynamics**

Isabella Loaiza, MIT, Cambridge, MA, Contact: isal@mit.edu

The challenge of making relocation decisions is fertile ground to pose a new direction in the quest for extended human intelligence. This paper explores the impact of social connectivity, job history, and homphily on the decision to relocate and migrate, and suggests ways in which these insights can be used to build systems to aid in relocation decisions.These systems seek to foster social learning between community members to improve the match between migrants and their potential new communities so that both can reap the benefits of the move. This approach stands in contrast to top-down approaches that use algorithms to match individuals and places, as is the case for some refugee relocation programs.

1 **Why Harry Won't Meet Sally: Gender Disparity in Online Learning Forums**

Helen Zhihan Wang, Jun Li, Andrew Wu, Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: helwang@umich.edu

Education technology innovations such as Massive Open Online Courses (MOOCs) platforms could potentially enable a more inclusive learning environment by delivering education to traditionally-disadvantaged learners. However, inclusivity does not necessarily translate into equal treatment on the platform. Utilizing a large-scale, interaction-level dataset on 174 courses on Coursera, we uncover a noted gender disparity in learners' interaction with the teaching staff. Also, we show that receiving staff response in forum leads to significant improvement in course passing rate. Our results provide direct managerial implications to platform managers and course providers. A more equal and inclusive online learning environment could be achieved with gender-sensitive platform design, which could potentially be achieved through simple user interface changes.

2 **Female Representation at Different Organizational Levels and Firm Environmental Footprint**

Priyank Arora[1], Vivek Astvansh[2], Zach Sheffler[3], [1]University of Massachusetts Amherst, Easthampton, MA, [2]Kelley School of Business, Indiana University Bloomington, Bloomington, IN, [3]University of Massachusetts Amherst, Amherst, MA, Contact: zsheffler@isenberg.umass.edu

Research has documented that female representation at firm leadership levels impacts firm financial performance. Recent research has extended these insights to relate female representation to firm's supply chain and sustainability performance. We add to this evidence by examining whether and when female representation at multiple organizational levels impacts a firm's environmental footprint. Our specification includes firm and year fixed effects with a three-stage least squares method to control for the endogeneity of female representation. Results suggest that female representation on the TMT lowers environmental footprint. Interestingly, female representation on the board weakens this effect.

3 **The Impact of the Gig-economy on Financial Hardship Among Low-income Families**

Kaitlin Daniels, Washington University in St. Louis, Olin Business School, Saint Louis, MO

The gig-economy offers workers discretion over their work schedules at the expense of traditional worker guarantees. We study the impact of this new work arrangement on the financial health of workers. We find a differential impact across workers with different earning potential outside of gig work.

4 **Going the Distance: Commute to the Capitol, Workplace Flexibility, and Female Participation in Politics**

Vanitha Virudachalam[1], Dawson Kaaua[2], [1]Gies College of Business, UIUC, Champaign, IL, [2]Georgetown University,

Washington, D.C., DC
Women have been shown to prefer jobs with a better work-life balance across many fields. Given that serving as a state political representative requires a significant amount of travel between one's home district and the state capitol, this suggests that long commute times may reduce the number of women that seek political office in the United States. We investigate whether this is true and, if so, potential policies to mitigate this effect. Leveraging differences in distance to the state capitol among legislative districts, we conduct a two-stage least squares analysis to show that state legislative districts with a higher percentage of female candidates tend to be closer to the state capitol. Then, using a conjoint survey experiment, we find that paid parental leave is the policy most likely to temper the differential effect of a longer commute time on women entering politics.

Sunday, 2 PM–3:15 PM

Panel Session

Session Chair
Justin J. Boutilier, University of Wisconsin - Madison, Fitchburg, WI

Session Chair
Mahyar Eftekhar, Arizona State University, Tempe, AZ

1 **Moderator**
Justin J. Boutilier, University of Wisconsin - Madison, Madison, WI
This panel session will host four editors from departments or areas that encompass public sector operations research / operations management from the journals Management Science, Operations Research, Manufacturing and Service Operations Management, Transportation Science, and Production and Operations Management. During the first portion of the session, the moderators will facilitate a discussion where the panelists will discuss their views on public sector research and share their insights about how to publish public sector research in their journals. During the second portion, we will open the floor for audience Q&A.

2 **Panelist**
Subodha Kumar, Fox School of Business, Temple University, Philadelphia, PA

3 **Panelist**
Ozlem Ergun, Northeastern University, Boston, MA

4 **Panelist**
Karen Smilowitz, Northwestern University, Evanston, IL

5 **Panelist**
Jayashankar M. Swaminathan, University of North Carolina Chapel Hill, Chapel Hill, NC

Technology Tutorial

1 **Nonlinear Optimization Using Artelys Knitro**
Richard Waltz, Artelys, Los Angeles, CA, Contact: richard.waltz@artelys.com
Nonlinear optimization is used in many applications in a broad range of industries such as economy, finance, energy, health, 3D modeling, and marketing. With four algorithms and great configuration capabilities, Artelys Knitro is the leading solver for nonlinear optimization and demonstrates high performance for large scale problems. This session will introduce you to Artelys Knitro, its key features and modeling capabilities, with a particular emphasis on the latest major improvements including recent advances in solving mixed-integer nonlinear optimization problems. We will also provide benchmarks highlighting the power of Knitro to efficiently solve large-scale, nonlinear models with hundreds of thousands of variables and constraints.

1 Prescriptive PCA: Dimensionality Reduction for Two-stage Stochastic Optimization

Ho-Yin Mak[1], Long He[2], [1]University of Oxford, Oxford, United Kingdom; [2]George Washington University, Washington

We consider a prescriptive analytics context that involves a learning phase of learning a low-dimensional representation of a set of high-dimensional data, and an optimization phase of solving a stochastic program with random parameters specified by said representation. We develop a prescriptive dimensionality reduction framework that aims to minimize the degree of suboptimality in the optimization phase. We show that prescriptive dimensionality reduction can be performed via solving a distributionally-robust optimization problem, which admits a semidefinite programming relaxation. Computational experiments based on a warehouse transshipment problem and a vehicle repositioning problem show that our approach significantly outperform principal component analysis with real and synthetic datasets.

2 Activated Benders Decomposition for Paratransit Workforce Scheduling Under Cancellation Uncertainty

Kayla Spring Cummings[1], Alexandre Jacquillat[2], Vikrant Vaze[3], [1]Massachusetts Institute of Technology, Allston, MA, [2]MIT Sloan School of Management, Cambridge, MA, [3]Dartmouth College, Hanover, NH, Contact: kaylac@mit.edu

Paratransit operators receive advance reservations but also face trip cancellations and driver no-shows. Our 2-stage stochastic program optimizes driver itineraries in reservation-based systems while capturing routing adjustments following disruptions. We incorporate a shareability network representation from Santi *et al.* (2014) to tightly embed 2nd-stage routing operations at the cost of exponential size. Our exact, generalizable *Activated Benders Decomposition (ABD)* algorithm exploits linking relationships between 1st and 2nd stages to construct global optimality cuts from restricted subproblems with a primal-dual approach. Strengthened *locally Pareto-optimal cuts* are adapted from Magnanti and Wong (1981). We use data from a major provider to show that ABD scales and outperforms many benchmarks. Our model enables flexible, robust driver shifts.

3 A Fast Column-generation-based Heuristic for Electric Bus Scheduling

Guy Desaulniers[1], Juliette Gerbaux[1], Quentin Cappart[2], [1]Polytechnique Montreal & Gerad, Montreal, QC, Canada; [2]Polytechnique Montréal, Montreal, QC, Canada. Contact: guy.desaulniers@gerad.ca

Planning the operations of electric vehicles is challenging as it includes battery recharging operations during the day. In this paper, we consider the multi-depot electric vehicle scheduling problem (MDEVSP) with a piecewise-linear recharging function and capacitated recharging stations that consists in determining the schedules of electric buses to cover at minimum cost a daily set of timetabled bus trips. We develop an iterative heuristic that solves at each iteration a reduced MDEVSP by column generation. The reduction is obtained by selecting a small subset of arcs to consider in the network for generating bus schedules. This selection is based on weights assigned to the arcs that are initially set using a machine learning model and, then, updated at each iteration according to the current solution and additional information collected during the solution process.

4 The Multi-depot Electric Vehicle Scheduling Problem with Stochastic Travel Time and Energy Consumption

Léa Ricard[1], Guy Desaulniers[2], Andrea Lodi[3], Louis-Martin Rousseau[4], [1]Universite de Montreal, Montreal, QC, Canada; [2]Polytechnique Montreal & Gerad, Montreal, QC, Canada; [3]Cornell Tech, New York, NY, [4]Polytechnique Montreal, Montreal, QC, Canada. Contact: lea.ricard@umontreal.ca

Zero emission policies in urban centers are forcing many transit agencies to convert their fleets to electric buses. The shorter driving range and the need for special charging infrastructure, among other things, must be taken into account when planning and scheduling electric buses. This talk presents the Multi-Depot Electric Vehicle Scheduling Problem with Stochastic Travel Time and Energy Consumption (S-MDEVSP). Vehicles are allowed to be partially recharged and a non-linear charging function is considered. Our model takes advantage of the full information on the current state of charge that is available in operation by allowing planned charge time to be extended when energy consumption deviations are observed. We formulate the S-MDEVSP as an integer program and a column-generation-based heuristic is provided to solve real-life instances.

Designing More Sustainable Supply Chains

General Session

Session Chair
Robert Swinney, Duke University, Durham, NC

Session Chair
Ali Kaan Tuna, Duke University, Durham, NC

1 Waste Not Want Not? The Environmental Implications of Quick Response and Upcycling
Xiaoyang Long[1], Luyi Gui[2], [1]University of Wisconsin-Madison, Madison, WI, [2]The Paul Merage School of Business, UC Irvine, Irvine, CA, Contact: luyig@uci.edu
Overproduction is often cited as the fashion industry's biggest environmental issue, as textile production is notoriously resource intensive and pollutive, and much of the textile produced may end up as "deadstock" fabric or finished products that do not sell. In this paper, we study two major approaches commonly adopted by the fashion industry to address this issue: quick response, whereby finished product inventory is replenished on demand, and upcycling, whereby deadstock fabric is reused to make new clothes.

2 Ride-hailing Platforms in the Presence of Dual Distribution Channels
Jianing Li, Gokce Esenduran, Purdue University, West Lafayette, IN, Contact: li3193@purdue.edu
We consider a dual-distribution channel in the auto industry where a manufacturer sells cars to a dealer and a rental agency. With the ride-hailing platform's entrance, some customers may rely on using the platform instead of buying/renting a car, while some others who buy a car may choose to provide rides on the platform. In this paper, constructing a detailed consumer utility model, we identify how the dealer and rental agency decisions, and thus the total ownership change after the platform's entrance. Our results show that when the unit manufacturing cost is sufficiently high, the number of rental cars decreases while the number of cars sold increases leading to an increase in the overall ownership and thus the environmental impact.

3 Circular Diffusion: The Missing Link in Circular System Design
Clara Carrera[1], Atalay Atasu[1], Luk N. Van Wassenhove[2], [1]INSEAD, Fontainebleau, France; [2]INSEAD, Fontainebleau Cedex, France. Contact: clara.carrera@insead.edu
The transition into a circular economy entails non-ownership-based business models (e.g., leasing) and new product designs (e.g., modular product architectures). In this paper, we leverage a new product diffusion approach to formally model the forward and reverse flows in such new systems. In our model, forward flows capture new leases and replacements, and reverse flows capture end-of lease returns (in reusable form or to be disposed of). The formal characterization of these flows allows us to demonstrate that the recycling needs in these systems exhibit uneven multi-peak volumes over time and that remanufacturing needs exhibiting relatively stable flows over a short time span. Motivated by an industry partner's practice, we further analyze how a firm's optimal lease duration and new product introduction timing choices influence these flows and disposal needs.

4 Are Fast Supply Chains Sustainable?
Ali Kaan Tuna, Robert Swinney, Duke University, Durham, NC, Contact: alikaan.tuna@duke.edu
We consider the environmental implications of a critical decision made by many firms: whether to adopt a responsive supply chain (prioritizing speed) or an efficient supply chain (prioritizing cost). We analyze a model wherein responsiveness increases marginal costs, decreases leadtimes, and changes the per-unit environmental impact of production. We distinguish between responsive nearshore and offshore supply chains: in the former, responsiveness is achieved by reducing the physical distance between source and destination, while in the latter, it is achieved by using expedited production and transportation methods. We observe that, regardless of how it is achieved, firms will likely have the greatest incentive to invest in responsiveness when it is most detrimental to the environment. We also discuss the implications of our observations for policymakers as well.

Data Driven Operations: Balancing Privacy and Efficiency
General Session

Session Chair
Karan Girotra, Cornell Tech/Johnson Cornell University, New York, NY

Session Chair
Lorraine Yuan, Cornell Tech and Johnson College of Business, New York, NY

1 Privacy, Service-levels and Firm Profits in the (Customer-)data Driven News Vendor
Lorraine Yuan[1], Elena Belavina[2], Karan Girotra[1], [1]Cornell Tech/Johnson Cornell University, New York, NY, [2]Cornell

University, New York, NY, Contact: hy557@cornell.edu

The use of customer data (demographics, past purchases, etc.) for inventory management can improve firm profits and customer service levels. Yet, large-scale use of such data in production environments increases the risks of breaching customers' privacy. In this study, we adapt state of the art data-driven algorithms for Newsvendor decisions to prescribe privacy-preserving ordering quantities. We derive bounds on the tradeoff between firm profitability, consumer surplus, and privacy loss. The ordering quantity prescribed by our algorithm achieves approximately optimal expected profit and consumer surplus, while sacrificing only a negligible degree of privacy. However, the misalignment of customer and firm incentives may lead to underuse or overuse of private information, compared to the goldilocks privacy level prescribed by our algorithm.

2 Differential Privacy in Personalized Pricing with Nonparametric Demand Models

Yining Wang[1], Xi Chen[2], Sentao Miao[3], [1]University of Texas at Dallas, Richardson, TX, [2]New York University, New York, NY, [3]McGill University, Montreal, QC, Canada. Contact: ynwang.yining@gmail.com

In the recent decades, the advance of information technology and abundant personal data facilitate the application of algorithmic personalized pricing. However, this leads to the growing concern of potential violation of privacy due to adversarial attack. To address the privacy issue, this paper studies a dynamic personalized pricing problem with unknown nonparametric demand models under data privacy protection. Two concepts of data privacy, which have been widely applied in practices, are introduced: central differential privacy (CDP) and local differential privacy (LDP), which is proved to be stronger than CDP in many cases. We develop two algorithms which make pricing decisions and learn the unknown demand on the fly, while satisfying the CDP and LDP gurantees respectively.

3 Privacy-Preserving Personalized Revenue Management

Yanzhe (Murray) Lei[1], Sentao Miao[2], Ruslan Momot[3], [1]Smith School of Business, Queen's University, Kingston, ON, Canada; [2]McGill University, Montreal, QC, Canada; [3]Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: momot@umich.edu

We examine how data-driven personalized decisions can be made while preserving consumer privacy. Our setting is one in which the firm chooses a personalized price based on each new customer's vector of individual features; the true set of individual demand-generating parameters is unknown to the firm and so must be estimated from historical data. We extend this estimate-then-optimize framework of personalized pricing by requiring also that the firm's pricing policy preserve consumer privacy, or (formally) that it be differentially private. Our analysis suggests that with sufficient amount of historical data in hand, firms can achieve privacy at a cost of the same order as the loss in revenue due to estimation error. We also extend our analysis to the setting of personalized assortment optimization.

4 Learner-Private Convex Optimization

Dana Yang[1], Jiaming Xu[2], Kuang Xu[3], [1]Cornell University, Ithaca, NY, [2]Duke University, Durham, NC, [3]Stanford Graduate School of Business, Stanford, CA, Contact: dana.yang@cornell.edu

Convex optimization with feedback is a framework where a learner relies on iterative queries and feedback to arrive at the minimizer of a convex function. The paradigm has gained significant popularity recently thanks to its scalability in large-scale optimization and machine learning. The repeated interactions, however, expose the learner to privacy risks from eavesdropping adversaries that observe the submitted queries. In this work, we study how to optimally obfuscate the learner's queries in convex optimization with first-order feedback, so that their learned optimal value is provably difficult to estimate for the eavesdropping adversary.

Incentives and Risk
General Session

Session Chair
Nitin Bakshi, University of Utah, Salt Lake City, UT

1 Peer Reporting to Avoid Disasters: The Externalities of Misplaced Ethics

Nitin Bakshi, Manu Goyal, University of Utah, Salt Lake City, UT, Contact: manu.goyal@eccles.utah.edu

In team settings that are vulnerable to disasters, it is critical to mitigate the propensity for moral hazard, and induce prompt reporting of any shirking. However, agents can free-ride, which exacerbates moral hazard; and deep-rooted loyalty considerations prevent peer reporting. We study moral hazard and peer reporting in a team of one principal and two agents. One of the agents may be loyal: doesn't shirk (loyalty to principal) and doesn't report shirking (peer loyalty). We show that even a small probability of such a loyal agent engenders *tacit collusion*: shirking happens and goes unreported even by a rational agent. Thus, the principal cannot resolve moral hazard despite attractive contracts and rewards (for peer reporting). We label the moral compulsion for loyalty as *misplaced ethics*, the externalities of which must be recognized, understood and corrected.

2 Recommender Systems with Privacy Concerns

Can Kucukgul[1], Ozalp Ozer[2], Shouqiang Wang[1], [1]The University of Texas at Dallas, Richardson, TX, [2]Amazon, Richardson, TX

The hallmark feature of digital platforms is their capability of keeping track of users' online browsing activities and using this information to personalize recommendations. Various regulations are established to grant users of these platforms the right to privacy, i.e., they can choose whether to share their personal data with the platforms for product recommendation purposes. Using an information design framework, we study how an online platform should design its recommender policy under such regulatory provisions. We show that when the platform and users' incentives are sufficiently aligned, it is optimal for the platform to adopt a personalized recommender policy. Perhaps surprisingly, when the incentives are sufficiently misaligned, we find that the right to privacy may in fact reduce the overall user surplus.

3 Optimal Delay Messages

Laurens G. Debo[1], Seyed Iravani[2], Robert Shumsky[1], Sina Ansari[3], Liu Zhonghao[2], [1]Dartmouth College, Hanover, NH, [2]Northwestern University, Evanston, IL, [3]Driehaus College of Business, DePaul University, Chicago, IL, Contact: laurens.g.debo@tuck.dartmouth.edu

When customers wait for service, providers often announce forecast information about delays to reduce customer uncertainty and anxiety. Forecasts, however, are imperfect and when delays are longer than predicted, customers can be disappointed. Here we examine how to design delay forecasting and message systems that take into account both the anxiety caused by uncertainty and the relative disappointment of customers when delays are longer than expected.

4 Firm-level Supply Chain Risk and Performance Implications

Keno Theile[1], Christian Hofer[2], Kai Hoberg[3], [1]Kuehne Logistics University, Hamburg, Germany; [2]University of Arkansas, Fayetteville, AR, [3]Kühne Logistics University gGmbH, Hamburg, Germany. Contact: keno.theile@the-klu.org

Supply chain risk—broadly defined as the collection of vulnerabilities that emerge along a firm's supply chain and have the potential to affect the firm adversely—is of great concern to both managers and investors. We propose a firm-specific measure of supply chain risk based on a textual analysis of quarterly conference calls. Leveraging this measure of supply chain risk, we investigate its effects on operational and financial performance. Addressing these questions adds both nuance and breadth to the existing literature and paves the way for further empirical research.

Supply Chain Risk Management

General Session

Session Chair

Florian Lucker, Bayes Business School, London, London, United Kingdom.

Session Chair

Oben Ceryan, 1</sup

1 The Effects of Cyberattacks Along the Supply Chain

Yiyi Fan, Lancaster University, Lancaster, United Kingdom. Contact: y.fan1@lancaster.ac.uk

Cybersecurity risks in supply chains are not well understood, despite growing interest by the media and policymakers. Although we are often aware of the impact on individual firms, such firms are often embedded in global supply chains which are digitally connected, and so successful cyberattacks may impact many customers and suppliers of the target firms. Even if major organisations have a good level of cybersecurity, they may still be vulnerable because of the weaknesses elsewhere in their supply chain. This study examines the wealth effects - and their determinants - of cyberattacks on suppliers and customers of the target firms. I also analyse the target firms' responses to the disruptions caused by cyberattacks.

2 Building Resilience Through Supply Chain Finance (SCF): An Empirical Investigation

Begimai Marlenova[1], David Wuttke[2], Eve Rosenzweig[3], [1]Technical University of Munich, Heilbronn, Germany; [2]Technical University of Munich, Heilbronn, Germany; [3]Emory University, Atlanta, GA

COVID-19 has disrupted many supply chains around the world. In this paper, we examine the various ways buyers and their suppliers can use SCF to mitigate the effects of such disruptions. We rigorously test several hypotheses using a global dataset provided by a leading SCF provider.

3 Risk-sensitive Optimal Execution via a Conditional Value-at-risk Objective

Seungki Min[1], Ciamac Cyrus Moallemi[2], Costis Maglaras[2], [1]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of; [2]Columbia University, New York, NY, Contact: skmin@kaist.ac.kr

We consider a liquidation problem in which a risk-averse trader tries to minimize the conditional value-at-risk (CVaR) of the implementation shortfall when liquidating a fixed quantity of an asset in the presence of market impact and random price fluctuations. Remarkably, we are able to derive closed-form expressions for the optimal dynamic (adaptive) liquidation strategy and its value function, and show that this optimal dynamic policy exhibits "aggressiveness-in-the-money" and outperforms the optimal static policy by 5-15% for moderate levels of risk aversion. In its derivation, we exploit the dual representation of CVaR to convert the problem to a continuous-time, zero sum dynamic game, and leverage the idea of state-space augmentation.

4 Limiting the Impact of Supply Chain Disruptions in the Face of Distributional Uncertainty in Demand

Anna Timonina-Farkas, EPFL, TOM, St.-Sulpice VD, Switzerland.

Service level requirements play a crucial role in eliminating stock-outs in a production pipeline. However, delivering a specific service level can become an unattainable goal given the various uncertainties influencing both the production pipeline and customer demand and causing the manufacturer to adapt the initial strategy in response to disruptions. Such deviations from optimality frequently result in unexpected (and potentially very high) costs and are complex to manage. On the one hand, the manufacturer can use a robust or distributionally robust approach to prepare for the worst-case disruption, ensuring that the realized cost will be lower than the estimated cost with high probability. On the other hand, this solution may lead to overly conservative production schedules. In this work, we take a different approach and develop a bilevel stochastic optimization model with chance constraints, which allows us to make the production more predictable in the event of disruptions by driving costs and optimal schedules closer to the benchmark for each scenario considered. We introduce doubly probabilistic service level requirements to account for two interdependent layers of uncertainty, i.e., production disruptions and distributional uncertainties in customer demand. This allows us to make high-quality production decisions with only a limited understanding of the demand pattern. Approximating the problem for numerical solution, we guarantee tight optimality gaps for high service levels and propose an efficient solution scheme, combining robust scenario reduction with a customized Benders decomposition procedure.
In the managerial section, we use the Omega x Swatch MoonSwatches example to demonstrate that a desirable doubly probabilistic service level can be attained for disruptions with a drop in demand. In the case of disruptions followed by a peak in demand, one can tighten the optimality gaps if the service level is reduced.

Emerging Issues in Supply Chain and Marketing

General Session

Session Chair

Yulan Amanda Wang, The Hong Kong Polytechnic University, Kowloon, Hong Kong.

Session Chair

Xin Wang, The Hong Kong University of Science and Technology, Kowloon

1 A Model of Coalition Reward Programs

Yan Liu[1], Jingmai Wang[1], Yulan Amanda Wang[1], Dan Zhang[2], [1]The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]University of Colorado, Boulder, CO, Contact: yan.y.liu@polyu.edu.hk

This paper studies the optimal design of coalition reward programs. A coalition reward program consists of n independent and symmetric firms, each of which sells a non-durable product to infinitesimal customers over an infinite horizon. Time is continuous, and a customer visits each firm following a Poisson process at a rate lambda. Thus, a customer visits the coalition at a rate nlambda. Any purchase from a firm in the coalition earns the customer a reward that can be redeemed across the firms before the reward expires. The coalition manager chooses the price, the reward, the expiration term, and the size n to maximize the program's long-term average revenue. We analyze the coalition's optimal decisions based on the customer's behavior and compare the coalition's profit with that of the proprietary reward program. Finally, we investigate how to determine the optimal size.

Sustainability in Supply Chain and Retail
General Session

Session Chair
Guangzhi Shang, Florida State Unviersity, Los Angeles

1 **The Role of Supply Chain in Retailer Take-back: An Empirical Study**
Yuqi Peng[1], Yan Dong[2], Sriram Venkataraman[2], Mark Ferguson[2], [1]Salisbury University, Salisbury, MD, [2]University of South Carolina, Columbia, SC, Contact: yqpeng@salisbury.edu
While manufacturers are regulated to take back their end-of-life products, retailers are not. From a supply chain perspective, we empirically investigate why retailers have the incentive of offering take-back services. We find that a retailer's take-back decision can be affected by its manufacturing suppliers and its market competition.

2 **Examining Sustainability as a Service Model in Retail**
Huseyn Abdulla[1], Seulchan Lee[2], Han Kyul Oh[3], [1]Haslam College of Business, University of Tennessee - Knoxville, Knoxville, TN, [2]Michigan Technological University, Houghton, MI, [3]Tilburg University, Tilburg, Netherlands. Contact: habdulla@utk.edu
As the pressure from investors, government institutions, and consumers on firms to improve environmental sustainability performance increases, new business models emerge to facilitate the firms' sustainability efforts while generating profit. One such model, known as Sustainability as a Service (SaaS), helps retailers to estimate and offset emissions from the delivery of online orders in real-time. In this paper, we analytically examine this new business model in the context of an online retailer who has made a sustainability commitment to become carbon neutral and a SaaS provider.

3 **Making the Case for Sustainable Supply Management: Supply Chain Transparency and Ethical Consumption**
Yanji Duan[1], John Aloysius[2], Christian Hofer[2], [1]University of North Florida, Jacksonville, FL, [2]University of Arkansas, Fayetteville, AR, Contact: yanji.duan@Unf.edu
Can firms recoup the cost of engaging in and disclosing sustainable supply management (SSM) efforts? We conduct a field experiment to investigate whether consumers will favor or pay a premium for products from firms that disclose SSM information over those do not. We find conclusive evidence that consumers will *buy more* from firms that disclose SSM and mixed evidence that some consumers may be also willing to *pay more* for products from such firms. Consistent with the individual-level findings, the analysis of firm-level archival data from U.S. manufacturing industries shows that providing SSM information in CSR reports results in a greater relative change in market share than when there is no SSM information. The empirical evidence suggests that firms can indeed benefit from engaging and communicating SSM efforts.

1 **Multiechelon, Multicommodity Supply Chain Design with Uncertain Demand from a Climate Change Mitigation Perspective**
Reza Alizadeh[1], Janet K. Allen[2], Farrokh Mistree[2], [1]University of Oklahoma, TULSA, OK, [2]University of Oklahoma, Norman, OK, Contact: REZA.ALIZADEH@OU.EDU
Supply chains (SC) generate about 42% of greenhouse gas. Thus, designing a green supply chain (GSC) is a reasonable solution to mitigate climate change. A multi-channel, multi-echelon supply chain is designed using a bi-level, mixed-integer programming model. On the upper level, the layout of the SC, including the network of customers, stores, and warehouses, and the number and location of stores and warehouses for two channels of in-store and online shopping are determined to find a low-cost and low emission configuration. On the lower level, the tour distance for the online shopping channel is modeled as a TSP and solved using an evolutionary algorithm. In this study, we present

a surrogate-assisted optimization approach to reduce the inordinate amount of function evaluations of the lower-level search conducted for evaluating each upper-level solution.

2 Comparisons of Behavioral Model-based and Fully Model-free Cost Minimizing Agents in a Simulated Multi-echelon Supply Chain

James E. Paine, Massachusetts Institute of Technology, Cambridge, MA, Contact: jpaine@mit.edu

Behavioral Operations Management research emphasizes behavioral influences on supply chain phenomenon and correspondingly leverages behavioral models to suggest interventions. However more recently model-free approaches have also seen success. Using a simulated model of a multi-echelon supply chain built from prior behavioral research, this work develops algorithmic approaches towards mitigating the costs of bullwhip using both model-based approaches alongside model-free optimization and reinforcement learning approaches. This work directly compares the performance of these approaches under various combinations of information availability and agent environmental assumptions. In doing so, this work emphasizes the complementary nature of model-based and model-free approaches in approaching behaviorally grounded supply chain management problems.

3 An Optimal Tree Search Algorithm for TSp with History-and-Payload Based Risk Measure

Hyungjoo Cha[1], Chanho Lee[1], Joonyup Eun[2], Taesu Cheong[1], [1]Korea University, Seongbuk-Gu, Korea, Republic of; [2]Korea University, Seongbuk-Gu, Korea, Republic of. Contact: hyungjoo_cha@korea.ac.kr

In this talk, we introduce an optimal tree search algorithm to solve the traveling salesman problem regarding the risk current freight residual possesses. Although the past studies dealt with the risk minimization transportation problems, most of them heavily rely on complex optimization techniques. However, in this research, we present an optimal tree search-based algorithm, without the use of a state-of-the-art solver. The problem is also formulated in non-linear mixed-integer linear programming. The computational results show that the proposed search algorithm outperforms the mathematical model in terms of search efficiency and solution quality.

4 A Mixed Integer Linear Model for Biomass Supply Chains

Nasim Zandi Atashbar[1], Christian Prins[2], Nacima Labadie[2], Kuntal Bhattacharyya[1], [1]Indiana State University, Terre Haute, IN, [2]University of Technology of Troyes, Troyes, France. Contact: nzandiatashba@sycamores.indstate.edu

Biomass is a critical source of renewable energy. Efficient biomass supply chains must be designed to provide bio-refineries with adequate quantities of biomass at reasonable prices, and at appropriate times. This paper proposes a multi-period mixed-integer linear programming model to optimize a multi-biomass supply chain for several bio-refineries, both at the tactical as well as at strategic levels. Our model minimizes total costs, including biomass production, storage, handling, refineries setup, and transportation, while satisfying the demand of refineries in each period.

Optimization under Uncertainty: Theory and Applications (iii)

General Session

Session Chair

Elizabeth Jordan, University of Maryland, College Park, MD

1 Evidence-based Simulation-based Optimization of Resources and Improvement of Patient Flows in a Multi-Specialty Clinic Design

Maryam Hosseini[1,2], Alice M. Gittler[2], Mohammad T. Khasawneh[1], [1]Binghamton University, Binghamton, NY, [2]EwingCole, New York, NY, Contact: mhossei1@binghamton.edu

A fundamental activity in designing a floor layout for a multispecialty clinic is predicting the consequences of different alternative design options while providing a balance between future demand and needed resources. This study proposes an iterative approach in which different scenarios with consideration of future demand and self-service technology adoption rates were tested and evaluated while the model iteratively refreshed and inspired the evolution of design alternatives. Discrete event simulation (DES) combined with mixed-integer nonlinear programming is used for optimizing resources under demand uncertainty and scheduling policies. The results give insight to a multidisciplinary collaborative team to build consensus around a new layout by understanding the optimal capacity for the waiting and registration areas while meeting the constraints.

2 On-street Parking Space Allocation Considering Double-parking Impact, Modal Priority, and Parking Time Limit

Xiaoyu Ma[1], Xiaozheng He[2], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Rensselaer Polytechnic Institute, Troy, NY, Contact: max8@rpi.edu

The conflict between increasing and diversified parking demand in limited space calls for integrated curb space management for cities. Among all users, freight and service vehicles can cause severe congestion when their parking needs are unsatisfied. However, parking allocation solutions rarely account for this impact. To this end, this study proposes an optimization model for multimodal parking allocation. The model optimizes parking space allocation and parking time limit for cars while considering the impact of freight vehicles' double parking. The model also formulates vehicles' arrival and parking duration as random variables to ensure parking service reliability. Numerical results suggest a high priority of parking allocation to freight and service vehicles while setting a proper car parking time limit can further improve overall serviceability.

3 Optimizing Thresholds of Multi-tiered Non-pharmaceutical Intervention Strategies During a Pandemic

Elizabeth Jordan, Shapour Azarm, University of Maryland, College Park, MD

For mitigating the effects of COVID-19, or any pandemic, non-pharmaceutical intervention strategies can be used to follow a multi-tiered approach. Typically, certain policies (e.g., social distancing, masking) are adopted once some threshold values are set, following a community incidence rate (e.g., number of infections/100,000 population). However, these thresholds are often set rather arbitrarily. Our aim in this research is to develop an approach for optimized thresholds which can be maintained against uncertainty and/or over time. Practical implications of the proposed approach with corresponding results will be discussed.

The use of machine learning techniques to improve the performance of branch-and-bound optimization algorithms is a very active area in the context of mixed integer linear problems, but little has been done for non-linear optimization. To bridge this gap, we develop a learning framework for spatial branching and show its efficacy in the context of the Reformulation-Linearization Technique for polynomial optimization problems. The proposed learning is performed offline, based on instance-specific features and with no computational overhead when solving new instances. Novel graph-based features are introduced, which turn out to play an important role for the learning. Experiments on different benchmark instances from the literature show that the learning-based branching rule significantly outperforms the standard rules.

2 Computing and Applying Tailored Power Flow Approximations and Relaxations in Power System Optimization Problems

Daniel Molzahn, Georgia Institute of Technology, Atlanta, GA, Contact: dan.molzahn@gmail.com

Relaxations and approximations of the power flow equations are key tools for addressing challenges associated with nonlinearities inherent to power system optimization problems. This presentation discusses recent developments in power flow relaxations and approximations, including methods for tightening relaxations by exploiting coordinate transformations, data-driven techniques for constructing approximations that are tailored to specific systems and operating ranges of interest, and approaches for recovering feasible solutions that utilize many types of information from an inexact solution. Results demonstrate the benefits of tailoring power flow relaxations and approximations relative to traditional methods used for several applications.

3 On Semidefinite Representations of Second-order Conic Optimization Problems

Pouya Sampourmahani[1], Mohammadhossein Mohammadisiahroudi[2], Tamás Terlaky[2], [1]Lehigh University, Bethlehem, PA, [2]Lehigh University, Bethlehem, PA

Current literature states that Second-order Conic Optimization (SOCO) problems can be embedded in Semidefinite Optimization (SDO) problems using the arrow-head notation. However, primal-dual SOCO pairs cannot be embedded simultaneously without losing duality. To map SOCO properly, we introduce admissible mappings that preserve both feasibility and optimality. We also discuss how the optimal partition of SOCO problems map to the ones of their SDO counterparts.

4 A Machine Learning Approach to Solving Large Bilevel and Stochastic Programs: Application to Cycling Network Design

Bo Lin, Timothy Chan, Shoshanna Saxe, University of Toronto, Toronto, ON, Canada. Contact: imbo.lin@mail.utoronto.ca

We present a novel ML-based approach to solving bilevel programs that involve a large number of independent followers, which as a special case include two-stage stochastic programming. We propose an optimization model that explicitly considers a sampled subset of followers and exploits a machine learning model to estimate the objective values of unsampled followers. Unlike existing approaches, we embed machine learning model training into the optimization problem. We prove bounds on the optimality gap of the generated leader decision as measured by the original objective function that considers the full follower set. Using real and synthetic instances of a cycling network design problem, we demonstrate the strong computational performance of our approach versus baseline methods.

1 On a Fair and Risk-averse Urban Air Mobility Demand Problem Under Demand and Capacity Uncertainties

Luying Sun[1], Weijun Xie[1], Peng Wei[2], [1]Virginia Tech, Blacksburg, VA, [2]George Washington University, Washington

Demand capacity balancing in Urban Air Mobility (UAM) is critical to mitigate potential traffic congestion and address operating uncertainty. This paper studies a fair and risk-averse UAM model to minimize the overall route and delay cost, achieving fairness as well as efficiency while hedging against future demand and capacity uncertainties. We show that the proposed model is NP-hard in general and can be strengthened by developing valid inequalities and stronger formulations. To solve it, we develop customized decomposition methods with effective cut-generating procedures. Our numerical study demonstrates the efficacy of the proposed methods.

2 Robustness Analysis of Demand Capacity Balancing for Advanced Air Mobility Operations

shulu chen[1], Peng Wei[2], Antony D. Evans[3], Maxim E. Nova[3], [1]George Washington University, Washington, DC, [2]George Washington University, Washington, [3]Airbus UTM, Sunnyvale, CA, Contact: shulu@gwu.edu

Demand capacity balancing (DCB) has been proposed as a strategic mechanism to balance efficiency and predictability for Urban Air Mobility (UAM) operations when operational uncertainties are high. In this presentation, we implement DCB in coordination with a tactical deconfliction system to ensure safe and efficient UAM and seek to analyze the robustness of the deconfliction system by introducing additional sources of uncertainty. We model three uncertainty factors - canceled and delayed flights, variable flight performance, and dynamic weather conditions - which are then applied to a hypothetical UAM network to test system robustness. The results suggest that DCB may be a feasible mechanism to ensure safe and efficient UAM operations. The results also reveal some early insights into interactions between the strategic DCB and the tactical deconfliction.

3 Airline Disruption Management with Delay Ledgers

Christopher Chin, Massachusetts Institute of Technology, Cambridge, MA

When disruptions result in reduced capacities at airports, airlines may be interested in swapping slots with each other. One approach to identify optimal slot swaps between airlines would be for airlines to share specific delay costs of each flight, but doing this could reveal sensitive business practices. We propose the use of a procedure called the Delay Ledger Mechanism (DeLed), which enables airlines to identify a set of beneficial slot swaps across a network of airports while ensuring that no private flight-specific valuations are shared. DeLed is guaranteed to lower airline delay costs, incentivizes truthful airline participation, and supports flexible airline privacy preferences. We evaluate DeLed across 30 days with 8 major US airlines, resulting in average reductions in private delay costs of 8-22% per day compared to current approaches.

Computational Optimization and Software for PSE and Grid Applications

General Session

Session Chair

Oluwamayowa Amusat, Lawrence Berkeley National Laboratory, Berkeley, CA

1 Transmission Constraint Screening for Production Cost Modeling at Scale

Bernard Knueven, National Renewable Energy Laboratory, Golden, CO

Transmission constraint calculation and screening, for both unit commitment and economic dispatch, is a critical feature of a performant solution method, but one that is often overlooked in the literature. In this talk, we will discuss the transmission constraint calculation and screening algorithm implemented in the open-source Egret package for electrical grid optimization and compare it against the more straightforward approach Egret originally implemented. Finally, we discuss the implications for transmission constraint sharing within a production cost modeling simulation.

2 Advances in Solving Infinite-dimensional Optimization Problems with Infiniteopt.jl

Joshua Pulsipher[1], Carl Laird[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Fayetteville, AR

Infinite-dimensional optimization (InfiniteOpt) problems are ubiquitous with challenging application classes in process systems engineering. InfiniteOpt.jl builds upon a unifying abstraction InfiniteOpt problems to provide a powerful tool for modeling and solving these problems in new and innovative ways. This talk will present recent and ongoing advances to InfiniteOpt.jl that enable a wide collection of transformation methods to be used to solve InfiniteOpt problems.

3 Co-optimizing the Design and Operation Strategy of Solid Oxide Fuel Cell-based Hydrogen-electricity Co-production Systems

Nicole Cortes[1], John C. Eslick[2], Alexander Noring[2], Naresh Susarla[2], Chinedu Okoli[2], Miguel A. Zamarripa[2], Arun Iyengar[2], Anthony P. Burgard[3], David C. Miller[3], Douglas Allan[2], Alexander Dowling[4], [1]University of Notre Dame, Notre Dame, IN, [2]National Energy Technology Laboratory Site-support Contractor, Pittsburgh, PA, [3]National Energy Technology Laboratory, Pittsburgh, PA, [4]University of Notre Dame, Notre Dame, IN, Contact: ncortes@nd.edu

Energy infrastructures and markets are becoming more volatile, requiring more flexible energy systems, such as Integrated Energy Systems (IES). Market analysis of IES is challenging, requiring models of system operations as well as capturing complex economic interactions. In this work, we present a framework for optimization-based market-informed techno-economic analysis (TEA) of IES, formulated as a generalized disjunctive programming (GDP) model and embedded with surrogates derived from detailed process models in the IDAES platform. We demonstrate the platform's capabilities by optimizing system design and operation of solid oxide fuel cell (SOFC)-based IES that coproduce electricity and hydrogen. We find that SOFC systems offer economic and technical advantages over alternatives, which is consistent with prior TEA.

4 Cost Optimization of Desalination Systems Using WaterTAP Incorporating Detailed Water Chemistry Models

Oluwamayowa O. Amusat[1], Adam A. Atia[2], Timothy V. Bartholomew[2], [1]Lawrence Berkeley National Laboratory, Berkeley, CA, [2]National Energy Technology Laboratory, Pittsburgh, PA, Contact: oluwamayowa.amusat@gmail.com

The Water treatment Technoeconomic Assessment Platform (WaterTAP) seeks to advance next generation water treatment technologies by providing a computational tool to assess the viability of technologies within a treatment train. WaterTAP is an open-source Python-based model library that is based on the IDAES Platform, an advanced process systems engineering tool. WaterTAP and IDAES provide modular, multi-hierarchical, customizable, and equation-oriented software tools that support advanced modeling and optimization capabilities. In this work, we demonstrate the capabilities of WaterTAP for the cost optimization of desalination plants with state-of-the-art detailed modeling of water chemistry and properties.

1 Inexact Proximal Gradient Methods with Optimal Support Identification

Yutong Dai, Daniel P. Robinson, Lehigh University, Bethlehem, PA, Contact: yud319@lehigh.edu

We consider the proximal-gradient method for minimizing an objective function that is the sum of a smooth function and a non-smooth convex function. A feature that distinguishes our work from most in the literature is that we assume that the associated proximal-gradient subproblem does not admit a closed-form solution. To address this challenge, we study two *adaptive* and *implementable* termination conditions that dictate how accurately the proximal-gradient subproblem must be solved. We prove that the iteration complexity for the resulting inexact proximal-gradient method to reach an □ first-order stationary point is O(□^-2). In addition, using the overlapping group L1 regularizer as an example, we propose a new approach for approximately solving the proximal-gradient subproblem, and then establish the support identification complexity result.

2 A Trust Region Method for the Optimization of Noisy Functions

Shigeng Sun[1], Jorge Nocedal[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: shigengsun2024@u.northwestern.edu

Classical trust region methods were designed to solve problems in which function and gradient information are exact. This paper considers when there are bounded errors (or noise) in the above computations and proposes a simple modification of the trust region method to cope with these errors. The new algorithm only requires information of the size of the errors in the function evaluations and has no additional computational cost. It is shown that, when applied to a smooth (but not necessarily convex) objective function, the iterates generated visit a neighborhood of stationarity infinitely often, and that the rest of the sequence cannot stray too far away, as measured by function values. Numerical results illustrate the classical trust region algorithm may fail in the presence of noise, and the proposed algorithm ensures steady progress towards stationarity in these cases.

3 Balancing Communication and Computation in Gradient Tracking Distributed Optimization

Gupta Shagun[1], Raghu Bollapragada[2], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, Contact: shagungupta@utexas.edu

Gradient tracking optimization algorithms have received significant attention over the past years for distributed optimization over networks due to their ability to converge to the solution under a constant step size. At every iteration, these algorithms require a computation step of calculating gradients at each node and a communication step to share the iterate and a gradient estimate among nodes. The complexity of these two steps varies significantly across different applications of distributed optimization. We present variations of the push-pull gradient methods to decompose and provide flexibility among the communication and computation steps within iterations. We illustrate the performance and flexibility of the proposed variations on quadratic functions and classification problems.

Network Optimization and Applications
General Session

1 The Service Agent Transport Interdiction Problem

Ankan Mitra[1], Jorge A. Sefair[2], Matthew J. Bays[3], [1]Arizona State University, Tempe, AZ, [2]University of Florida, Gainesville, FL, [3]Naval Surface Warfare Center, Panama City Division, Panama City, FL, Contact: amitra16@asu.edu

We study the interdiction variant of the service agent transport problem (SATIP). The goal of SATIP is to schedule a set of transport and service agents to complete a set of tasks in a network in the presence of an adversary. Service agents move on their own or using fast-moving autonomous transport agents. The budget-constrained adversary aims to maximize the mission's completion time (all tasks) by delaying service or transport tasks. We present a branch-and-cut algorithm to solve this two-stage interdiction problem as a single stage mixed-integer linear program. We also propose network reduction techniques and valid inequalities to strengthen the model.

Session Chair
Ankan Mitra, Arizona State University, Tempe, AZ

2 Models and Network Insights for Edge-based Districting

Zeyad Kassem, Adolfo R. Escobedo, Arizona State University, Tempe, AZ, Contact: zekassem@asu.edu

We introduce an edge-based districting optimization model with no pre-fixed centers to partition a road network into a given number of compact, contiguous, and balanced districts. The model is applicable to logistics applications. The model has cut set-based contiguity constraints and is paired with an iterative branch and bound algorithm with a cut generation scheme (B&B&Cut). We show that the underlying problem is NP-hard. Moreover, we derive network insights, from which cutting planes that enable a reduction in the solution space can be generated. The cuts are tested on road networks with up to 500 nodes and 687 edges, leading to speed up in computational time up to almost 27x relative to the computational time of solving the optimization model exactly with only B&B&Cut.

3 An Integer Programming Approach for Hydropower Planning in a Single Reservoir River System

Fatemeh Karamyar[1], Jorge A. Sefair[2], Yuhang Wei[1], John Sabo[3], [1]Arizona State University, Tempe, AZ, [2]University of Florida, Gainesville, FL, [3]Tulane University, New Orleans, LA, Contact: fkaramya@asu.edu

We present a mixed-integer programming model for hydropower operations planning in a single-reservoir river system. The proposed model schedules water release from a reservoir with the objective of maximizing hydropower generation. This problem incorporates realistic features such as power generation constraints and reservoir's characteristic features. Our modeling approach includes a discretization of the reservoir's water level along with function approximations to simplify the nonconvex dynamics of the system. We also propose a methodology to produce easy-to-use operational curves that prescribe the reservoir's water release based on upstream conditions. We test our methods using real data from the Lower Mekong Basin in Southeast Asia.

1 The Power of Greedy for Online Minimum Matching on the Line

Noemie Perivier, Columbia University, New York, NY

We consider the online minimum matching problem on the line, where n requests that arrive in an online manner must be immediately and irrevocably matched to a given set of n servers and the goal is to minimize the sum of the distances between the matched pairs. This is a central problem in applications such as ride-hailing platforms and food delivery services. Despite achieving a worst-case competitive ratio that is exponential in n, the simple greedy algorithm, which matches each request to its nearest available free server, performs extremely well in practice. A major question is thus to explain this strong empirical performance. In this talk, we aim to understand the role of randomization in greedy's performance. In particular, we prove optimal or near-optimal bounds on greedy's competitive ratio in different scenarios, improving over several results from the literature.

2 The Simultaneous Semi-random Model for TSP

Eric Balkanski, Yuri Faenza, Mathieu Kubik, Columbia University, New York, NY

Worst-case analysis is a performance measure that is often too pessimistic to indicate which algorithms we should use in practice. For Euclidean TSP, local search performs very well in practice even though it achieves an Omega(log n / log log n) worst-case approximation. A natural alternative approach to worst-case analysis in such cases is semi-random models. In this talk, we propose a novel semi-random model, called the simultaneous semi-random model, where an instance over n points consists of the union of an adversarial instance over (1-□)n points and a random instance over □n points. As with smoothed analysis, this model interpolates between distributional analysis and worst-case analysis. In contrast to smoothed analysis, it trades off allowing some completely random points in order to have other points that exhibit an arbitrary structure.

3 Smoothed Analysis of Online Decision Making

Abhishek Shetty[1], Nika Haghtalab[1], Tim Roughgarden[2], [1]University of California Berkeley, Berkeley, CA, [2]Columbia University, New York, NY, Contact: shetty@berkeley.edu

We establish novel techniques to analyze algorithms in the smoothed analysis model for online decision making. In this model, at each step, an adversary chooses the input from distribution with density bounded above by the uniform distribution. Crucially, these techniques hold for adaptive adversaries that can choose distributions based on the decisions of the algorithm and the previous realizations of the inputs. Our technique effectively reduces the setting of adaptive adversaries to the simpler oblivious adversaries. The main application is to show that, in this model, online learning is as easy as offline learning. That is, we show that the regret against smoothed adversaries is captured by the offline complexity measure, VC dimension. Furthermore, we design efficient algorithms for online learning, circumventing impossibility results in the worst case.

4 Budget-Smoothed Analysis for Submodular Maximization

Junyao Zhao, Aviad Rubinstein, Stanford University, Stanford, CA

The greedy algorithm for monotone submodular maximization subject to cardinality constraint guarantees a 1−1/e approximation. Although it is well-known that this guarantee is tight in the worst case for any efficient algorithm, experiments show that greedy performs better in practice. We observe that for many applications in practice, the distribution of the budgets (i.e., cardinality constraints) is supported on a wide range, and moreover, all the existing hardness results break under a large perturbation of the budget. To understand the effect of the budget, we introduce the budget-smoothed analysis. We prove that greedy is optimal for every budget distribution and enjoys provably better approximation guarantees under realistic budget distributions. On the hardness side, we construct hard functions that are fairly robust to all the budget distributions.

1 Small is Beautiful: A Scalable Iterative Heuristic for Shared Micromobility Network

Pushpendra Singh[1], Vikrant Vaze[2], [1]Dartmouth College, Hanover, NH, [2]Dartmouth College, Hanover, NH, Contact: pushpendra.singh.th@dartmouth.edu

Shared micromobility systems (SMS), e.g., bike-sharing, are experiencing strong revival after a sudden disruption in the early months of COVID-19 pandemic. With over half of US car trips being under 5 miles long, SMS offers tremendous sustainability promise. The key question is: Can we design superior SMS networks lowering travel times & raising reliability without increasing costs? We formulate a non-convex mixed integer program (NCMIP) for strategic SMS design, endogenizing demand & approximating operating & rebalancing dynamics. We design an original fast iterative heuristic to solve this NCMIP. Our heuristic provides provably near-optimal solutions in much smaller runtimes compared to state of the art exact methods & scales successfully to real-world instances. Results highlight the drivers of our superior network design, & shows strong systemwide benefits.

2 Learning While Repositioning in On-demand Vehicle Sharing Networks

Shunan Jiang[1], Hansheng Jiang[2], Zuo-Jun Max Shen[3], [1]University of California, Berkeley, Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA, [3]University of California Berkeley, Berkeley, CA, Contact: shunan_jiang@berkeley.edu

We consider the on-demand vehicle repositioning problem with a fixed number of vehicles distributed across multiple locations. Due to uncertainty in both customer arriving and vehicle returning, the service provider needs to periodically reposition the vehicles while minimizing the total costs of repositioning labor and lost sales. Existing literature assumes that the demand distribution is either known or can be simulated effectively from samples collected beforehand. In contrast, we develop an online learning method to dynamically reposition vehicles without knowing the demand distribution in advance. We study the performance of our algorithm by comparing it with the best generalized base-stock policy. We prove that the T-period regret of our algorithm is bounded sublinearly. Numerical experiments on synthetic data demonstrate the effectiveness of our method.

3 Online Facility Location

Junyu Cao[1], Wei Qi[2], Yan Zhang[3], [1]The University of Texas at Austin, Austin, TX, [2]McGill University, Montreal, QC, Canada; [3]McGill University, Montreal, QC, Canada. Contact: yan.zhang13@mail.mcgill.ca

We formulate an online facility location problem, joint with operational-level decisions. The scope of facility location problems continues to expand, while the models of facility location problems have been so far largely restricted to be in a static, offline fashion, prescribing one-shot facility placement based on past and current data on hand. In an online setting, the decision maker is subject to parameter uncertainties. However, she is able to adjust facility locations over time while updating her parameter estimation from historical observations. To this end, we propose an online algorithm that integrates the continuous approximation approach. The algorithm is both computationally efficient and has a near-optimal regret guarantee.

4 On-demand Multi-modal Transit: Design, Operations, and Pilots

Pascal Van Hentenryck, ISyE Georgia Tech, Atlanta, GA

This presentation gives an overview of On-Demand Multi-Modal Transit Systems (ODMTS) which combines fixed rail and bus routes with on-demand shuttles to serve the first and last mile. It considers the design of ODMTS (which bus routes to open), their operations, and report experience with MARTA Reach, an ODMTS pilot in Atlanta.

1 Resource-Directive Train Rescheduling with Cross-Layer Problem Decomposition

Shuguang Zhan[1], S. C. Wong[2], Jiemin Xie[3], Xuesong Zhou[4], [1]Hefei University of Technology, Hefei, China; [2]The University of Hong Kong, Hong Kong, China; [3]Sun Yat-sen University, Guangzhou, China; [4]Arizona State University, Tempe, AZ, Contact: shuguangzhan@hfut.edu.cn

In a disrupted situation, balancing and coordinating temporal and spatial capacity-allocation among a large number of disrupted trains constitute a challenging problem. Herein, a resource allocation-oriented perspective is taken, and a multi-commodity flow-based integer linear-programming model is introduced to solve the train-rescheduling problem. We systematically define resource space-time networks (RSTNs) and assign resources to trains with different priorities. A cross-layer decomposition approach is used to decompose the optimization model. Conflicts between different classes of trains are directly mitigated via an explicit phase of resource division in an RSTN. The alternating direction method of multipliers (ADMM) is applied to further decompose the network flow subproblem. Near-optimal solutions can be obtained in a short computational time.

2 A Deep Reinforcement Learning Approach for the Traffic Management of High-speed Railways: Comparison and Case Studies

Jiateng Yin, Beijing Jiaotong University, Beijing, China.

Our study proposes a deep reinforcement learning (DRL) approach for rescheduling the trains in case of disruptions. We develop a deep learning based value functionapproximation technique combined with a greedy algorithm, in order to further improve the training efficiency of the deep neural network. We use the Beijing-Zhangjiakou high-speed railway network as the simulation environment and conduct several sets of experiments. We also compare the DRL approach with several benchmarks, such as MIP, greedy, and other heuristics rules.

1 An Algorithm for Winter Road Maintenance During Snowy Weather Condition that Generates the First-tier Road Network & Design Vehicle Routing

Jiajun Pang[1], Irina Benedyk[2], [1]University at Buffalo, SUNY, Buffalo, NY, [2]University at Buffalo, SUNY, Buffalo, NY, Contact: jiajunpa@buffalo.edu

The snowy weather conditions result in significant adverse impacts on traffic. In reality, the road networks can be only plowed in sequence based on predefined priority. However, it is critical to consider the connectivity of the first-tier roadway networks to guarantee the accessibility, mobility, and equity of communities during heavy snow events. This study proposes an algorithm based on the set covering problem that generates a first-tier road network with the highest priority. The routing schedule for plowing/salting the first-tier road network is a model based on the dynamic traveling salesman problem that responds to real-time information on traffic and road conditions. The proposed method is able to improve the equity of traveling during snowy conditions and allow the transportation system operator to allocate resources in a more efficient and timely manner.

2 Setting up a Refueling Infrastructure for Public Transportation Services Conducting Dedicated Urban Delivery Operations

Sara F. Abu Aridah[1], Omar Abbaas[1], Jose Antonio Ventura[2], [1]Pennsylvania State University, State College, PA, [2]Pennsylvania State University, University Park, PA

This study considers the continuous deviation-flow refueling station location problem for vehicles traveling along dedicated routes on a transportation network. The objective is to optimally locate a set of refueling stations along the network to serve the vehicles on the dedicated routes, like public transportation vehicles. The proposed algorithm finds the candidate locations along all line segments in the network that can hold refueling stations. The set of candidate locations can then be used in a set covering model that minimizes the number refueling stations required to cover all routes, or maximize the amount of flow covered by a predetermined number of stations.

3 Vulnerability of Collaborative Transport Networks Under Disruptions

Rob Zuidwijk[1], Camill Harter[2], Otto Koppius[3], [1]Erasmus University Rotterdam, Rotterdam, Netherlands; [2]Erasmus University-Rotterdam, Rotterdam, Netherlands; [3]Erasmus University, Rotterdam ZH, Netherlands. Contact: rzuidwijk@rsm.nl

Collaboration in transport enables efficient use of transport resources operated by different organizations, but also comes with dependencies, which can have an adverse impact under disruption. While the synergy potential of collaborative transport is widely addressed in literature, existing transportation research models are less able to capture dependencies induced by collaboration and the concomitant vulnerabilities. We fill this gap by establishing a novel multi-layer network model capturing the functional dependence between the physical transport network, impacted by the disruptions, and the network of carrier collaborations, which is being disrupted. We show that market structure, represented by disparity in carrier sizes, has a non-trivial impact: Networks are most vulnerable if they have intermediate disparity in carrier sizes.

1 EMbark: ExxonMobil’s LNG Shipping Optimization

Jose S Rodriguez[1], Kevin C. Furman[2], Mustafa Kilinc[2,2], [1]ExxonMobil, Houston TX, TX, [2]ExxonMobil, Houston, TX

EMbark: ExxonMobil’s LNG Shipping Optimization; J.S. Rodriguez, M. Kilinc, K. Furman; ExxonMobil Upstream Research Company; EMbark - a best-in-class LNG shipping optimization software - has the goal to optimize schedule economics to reduce cost, ensure operability, mitigate and quickly recover from disruptions, and capture value opportunities in ExxonMobil’s operations. Highly sophisticated mathematical methods automatically generate LNG shipping and logistics schedules that meet all constraints and optimize economics. In this presentation, we will provide an overview of EMbark’s capabilities. We will discuss the MILP formulations implemented in EMbark, the matheuristic algorithms that are based on large neighborhood search operators, and the computational results obtained for a set of real business cases collected since the application’s deployment.

2 Workload Balancing in Periodic Distribution Scheduling and Routing Optimization

Aliakbar Izadkhah[1], Akang Wang[2], Jose M. Lainez-Aguirre[3], Jose M. Pinto[4], Chrysanthos E. Gounaris[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Shenzhen Research Institute of Big Data, Shenzhen, China; [3]Digital Americas, Linde PLC, Woodlands, TX, [4]Digital Americas, Linde PLC, Danbury, CT, Contact: aizadkha@andrew.cmu.edu

When planning last-mile delivery operations, objectives such as balancing the daily served load are often viewed as equally important to the classical focus on limiting routing costs. However, cost-efficient routes stemming from traditional periodic vehicle routing problem solutions often represent a very uneven load for distribution, with some days being extremely burdensome for the fleet, while other days requiring only very little effort to execute. In this work, we integrate an epsilon-constraint method with a branch-price-and-cut routing solver, introducing also relevant strengthening inequalities, to co-optimize daily load levels alongside routing costs.

3 Modelling a Cyclic Maritime Inventory Routing Problem

Sebastian Urrutia[1], Lars Magnus Hvattum[2], Amir Zojaji[2], Kiarash Soltaniani[2], [1]Molde University College - Science College in Logistics, -, Norway; [2]Molde University College - Science College in Logistics, Molde, Norway. Contact: sebastian.a.urrutia@himolde.no

The inventory routing problem (IRP) arises when a company is responsible for the transport of goods from a production site to consumption sites, as well as maintaining proper inventory levels in the clients. Typically, IRPs are solved for a fixed time horizon leading to solutions with poor decisions near the end of the time horizon. In this work we model a cyclic maritime IRP, where the goal is to have a stable system: at the end of the planning horizon, all vessels and all inventory levels should be identical to where they started out. This ensures that the solution can be executed indefinitely, and there are no end-of-horizon effects. In order to obtain feasible cyclic solutions we consider all initial inventory levels and the initial position of each vessel as decision variables. These are usually consider as parameters in the maritime IRP literature.

4 Mobile Parcel Lockers with Individual Customer Service

Jan Fabian Ehmke[1], Rico Kötschau[1], Ninja Soeffker[2], [1]University of Vienna, Vienna, Austria; [2]University of Vienna, Wien, Austria. Contact: jan.ehmke@univie.ac.at

To handle the ongoing growth of last-mile deliveries, we propose to integrate the individuality of customers in the planning process. We present a mixed-integer program to evaluate different innovative delivery services: fixed parcel lockers, mobile parcel lockers, attended home deliveries, and their combinations. A fixed fleet is applied to maximize the number of customers served, respecting individual customer preferences in terms of their willingness to travel and time window flexibilities. We evaluate the impact of structural demand differences and different fleet sizes, as well as the operational fleet utilization and the individual customer experience. Results show the potential to increase the number of customers served by about 12-17% through the use of mobile parcel lockers while considering individual customer preferences.

1 Algorithmic Bias in Online Game Matchmaking

Xingchen Xu[1], Yifan Yu[2], Wendao Xue[2], Yong Tan[1], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle, WA, Contact: xcxu21@uw.edu

Matchmaking algorithms, which allocate multiple players into games, can affect players' experience and further influence their engagement. Reinforcement learning algorithms are widely adopted to understand players' dynamic behavior and optimize engagement. However, combining simulation study and empirical analyses, we find that although reinforcement learning can increase players' activity, it will also induce unintended bias. Our research offers important implications to both academia and industry.

2 Understanding Partnership Formation and Repeated Contributions in Federated Learning: An Analytical Investigation

Mochen Yang, University of Minnesota, Minneapolis, MN

Limited access to large-scale data is a key obstacle to building machine learning (ML) applications, partly due to a reluctance of information exchange among data owners out of privacy and data security concerns. To address this ``information silo'' problem, federated learning (FL) techniques have been proposed to enable decentralized model training via an orchestrating central server. However, practical adoption of FL is partly limited by a lack of understanding of the economic incentives and trade-offs involved in partnership formation and long-term contributions. We take an analytical approach to answer two questions: (1) when do data owners prefer to form a FL partnership over building ML models by themselves, and (2) how can different contractual mechanisms be used to promote repeated contributions to FL (the cooperative outcome that benefits all participants).

3 Correcting Missing Value Bias Caused by Platform Content Management

Mengke Qiao[1], Qinglai He[2], [1]University of Science and Technology of China, Hefei, China; [2]University of Wisconsin - Madison, Madison, WI

Social media and user-generated content platforms increasingly enable content moderation and user self-deletion to manage their online content. These rising platform content management pose a missing data challenge for researchers who collect available online data for their empirical study. Researchers may obtain biased estimation results in their empirical analyses without carefully assessing and addressing the missing data issue. We propose theoretical formulas to correct the estimation bias caused by platform content management using identified partial missing data. Our simulation results indicate that our proposed method can effectively reduce the estimation bias in MNAR compared to two traditional missing values handling methods, LD and MAR. Furthermore, we conduct real-world applications with Reddit data and validate our model effectiveness.

4 Improving Fairness and Efficiency Using Estimates of User Preferences for Profile Characteristics in Online Marketplaces

Emil Palikot[1], Yuan Yuan[2], Dean Karlan[3], Susan Athey[1], [1]Stanford University, Stanford, CA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Kellogg School of Management, Northwestern University, Stanford, IL, Contact: palikot@stanford.edu

We consider the problem of a marketplace seeking to balance fairness and efficiency when users have preferences for features revealed in images. In the setting of a microlending marketplace, we use observational data to estimate the effects of image features on funding rates. We find that lenders prefer non-body shot images of smiling female borrowers. To address the potential for confounding, we conduct an experiment with recruited subjects, who choose between profiles generated using Generative Adversarial Networks that differ in the chosen features; the results are consistent with the observational data estimates. Finally, high-performing borrowers are more likely to smile and not use body shots which exacerbate inequities. Simulations of counterfactual policies show that recommending profile images can reduce inequity without sacrificing efficiency.

1 Prediction-Driven Surge Planning with Application in the Emergency Department

Yue Hu, Columbia University, New York, NY

We consider the nurse staffing problem arising in emergency departments where the base staffing decision is typically made months in advance while the surge staffing decision is made only hours prior to the actual start of the shift. We develop a unified framework that consists of 1) a two-stage prediction model for patient demand, and 2) a prediction-driven staffing rule with supporting theoretical guarantees. The proposed framework was approved for pilot implementation at a partner hospital starting from April 11, 2022.

2 Optimization & Planning of Limited Resources for Assisting Non-Profits in Improving Maternal Health

Aditya Mate, Harvard University, Cambridge, MA

NGOs working to address woeful maternal mortality rates via automated messaging programs are faced with dwindling engagement rates, severely hurting the health outcomes for expectant mothers. Our partner NGO has limited intervention resources to encourage beneficiaries to improve engagement. To maximize the benefit of these interventions, we use OR tools to optimally plan the resource allocation. Our first-of-its-kind, large-scale field trial deploying our algorithm, involving 23,000 beneficiaries over a period of 7 weeks, showed that it cut engagement drops by ~30% compared to the status quo

3 Designing School Choice for Diversity in San Francisco

Katherine Mentzer, Stanford University, Stanford, CA

Many cities have adopted school-choice policies with the goal of reducing school segregation resulting from residential segregation. We worked with the San Francisco Unified School District (SFUSD) to design a new policy for student assignment system that optimizes for the district's goals of diversity, predictability, and proximity. To develop potential policies, we used optimization techniques to design and evaluate the drawing of zones, student priority rules, and reserved seats. Our work informed the design and approval of a zone-based policy for use starting the 2025-26 school year.

4 Optimizing Vaccine Distribution in Developing Countries under Natural Disaster Risk

Bonn Kleiford Seranilla, Université du Luxembourg, Esch-sur-Alzette, Luxembourg.

We present Project FALCON - an optimization tool aiming to assist local government units to select optimal facilities for their COVID-19 vaccination rollout plans. These optimal facility locations do not only incur minimum total operations costs but also hedge from the risk of natural disasters. It was implemented in a highly urbanized, flood-prone city in the Philippines, Cagayan de Oro, which posted one of the highest vaccination rates in the country by the start of 2022, inoculating more than 89% of the target population. Project FALCON yields 30-40% lower cost than a baseline approach.

5 Discovering Opportunities in New York City's Discovery Program

Xuan Zhang, Columbia University, New York, NY

Discovery program is a policy used by NYC DOE to increase admissions for disadvantaged students at specialized high schools (SHS). However, empirical analyses from recent academic years show that the current implementation could hurt disadvantaged students and unintentionally create an incentive to under-perform. We explore two alternative policies that can be used to address these issues with minimal modification: JSA and MR. We characterize a condition (high competitiveness) under which JSA dominates MR. Thus, we propose a change to JSA, given the competitive nature of the NYC SHS market.

Scheduling in Supply Chain and Healthcare

General Session

Session Chair

Zhi-Long Chen, University of Maryland, MD

1 Coordinating Parallel Batch Scheduling with Job Compatibility

Zhixin Liu[1], Guo-Qiang Fan[2], Jun-Qiang Wang[3], [1]University of Michigan-Dearborn, Dearborn, MI, [2]Xidian University, Xi'an, China; [3]Northwestern Polytechnical University, Xi'an, China. Contact: zhixin@umich.edu

We consider parallel batch machine scheduling with job compatibility. Each job has a processing time interval. A parallel batch machine can process several jobs as a batch simultaneously given that the total size of jobs in the batch does not exceed the machine capacity and the processing time intervals of any two jobs in the batch overlap. The processing time of a batch is the maximum normal processing time of jobs in the batch. Each job can select a machine for its processing to minimize its completion time. The system aims to minimize the makespan. We design an FCBLNPT coordination mechanism, and an LNPT algorithm to obtain a Nash equilibrium. We prove that the set of all Nash equilibria is precisely the set of schedules that can be obtained by the LNPT algorithm. We find an upper and a lower bounds of the price of anarchy of our FCBLNPT coordination mechanism.

2 Fulfillment Scheduling for Buy-online-pickup-in-store Orders

Zhi-Long Chen[1], Xueqi Wu[2], [1]University of Maryland, College Park, MD, [2]SJTU, Shanghai, China. Contact: zlchen@umd.edu

We study fulfillment scheduling decisions of BOPS orders destined for a single store of a retailer. BOPS orders can be either processed at a fulfillment center (FC) and delivered to the store, or processed at the store without needing delivery. Two types of trucks are available to deliver the BOPS orders fulfilled at the FC: prescheduled trucks that are already committed to replenishing store inventory and have some spare capacity that can be utilized, and additional trucks that can be hired from 3PL providers. The retailer needs to find where to fulfill each order, how to deliver the orders fulfilled at the FC to the store, and how to schedule the orders processed at the store such that all orders are ready for pick up by their deadlines at the minimum total cost. We study various cases of the problem by designing exact and heuristic algorithms, and derive important managerial insights.

3 Appointment Scheduling in Multi-stage Outpatient Clinics under Patient Heterogeneity

Pelin Kesrit[1], Chelliah Sriskandarajah[2], Jon M. Stauffer[2], [1]Mays Business School Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: pkesrit@mays.tamu.edu

We design effective appointment schedule templates, based on the block scheduling concept, for two-stage outpatient clinics under patient heterogeneity having different mean service times. Our objective is to find daily appointment schedules that minimize a weighted sum of patients' waiting time, the physician's and physician assistant's idle time, and overtime.

1 Common Value Procurement Auctions with Resale

Bernardo (Bernie) F. Quiroga[1], Rodrigo Harrison[2], Roberto Muñoz[3], [1]West Virginia University, Morgantown, WV, [2]Adolfo Ibanez University, Peñalolén, Santiago, Chile; [3]Universidad Técnica Federico Santa María, Vitacura, Santiago, Chile. Contact: bfquirog@uc.cl

We study the effects of resale opportunities on auction bidding behavior under asymmetric information and common values. The information asymmetry arises due to the combination of (a) new information on the worth of the auctioned contract obtained by the winner after the auction, and (b) a potential negative shock received by the winner after the auction that forces the sale of the contract regardless of its true worth. We analyze the bidding behavior under different informational scenarios and discuss policy implications for each of them.

2 Social Learning with Polarized Preferences on Content Platforms

Bharadwaj Kadiyala[1], Dongwook Shin[2], [1]University of Utah, Salt Lake City, UT, [2]HKUST Business School, Clear Water Bay, Hong Kong.

Motivated by a number of socioeconomic and political issues that attract polarizing beliefs in the society, we study the impact of such beliefs on content consumption and production on a platform. Consumers are initially uninformed about the content quality but they learn about it using aggregate consumption metrics on the platform. We find that a social learning (SL) mechanism can mislead consumers to incorrectly perceive low-quality content to be of higher quality. SL may lower the incentive for the content provider to improve the content quality, and the platform may prefer to facilitate SL by displaying consumption metrics to mask the underlying low quality of the content.

3 A Multi-treatment Forest Approach for Analyzing the Heterogeneous Effects of Team Familiarity

Minmin Zhang[1], Guihua Wang[1], Wallace J. Hopp[2], Michael Mathis[3], [1]University of Texas at Dallas, Richardson, TX, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan Medical School, Ann Arbor, MI

We examine the effect of team familiarity on the speed of surgical procedures and extend the literature on team dynamics by examining whether the effect of team familiarity is heterogeneous across patients. Because we use multiple variables to measure team familiarity, we first develop a new approach, which we call the "MT forest" approach, to estimate the heterogeneous effects of multiple treatments. Then, we apply the MT forest approach to an orthopedic surgery setting to estimate the heterogeneous effects of team familiarity on surgery duration. Finally, we develop an optimization model to assess the value of leveraging team familiarity to better match surgical teams with patients.

4 Market Thickness and Pooling Efficiency in Meal-Delivery Platforms

Wenchang Zhang[1], Ruomeng Cui[2], Zhanzhi Zheng[3], [1]Kelley School of Business, Indiana University, Bloomington, IN, [2]Emory University, Decatur, GA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

While meal-delivery platforms are racing to expand their size, little is known about how the expansion has influenced restaurant performance. Adding more restaurants that are close to each other (i.e., *market thickness* increases) may improve drivers' delivery efficiency because drivers can travel shorter distances to pick up multiple orders (i.e., *pooling efficiency*). Yet, restaurants can be hurt by increased market thickness due to cannibalization. We build a stylized model to predict how delivery time and customers' behaviors change as the market thickens. Then, we empirically examine the model's predictions using proprietary data from a leading meal-delivery platform in China.

5 Can Autonomous Vehicles Solve the Commuter Parking Problem?

Neda Mirzaeian[1], Soo-Haeng Cho[2], Sean Z. Qian[2], [1]University of Texas at Dallas, Dallas, TX, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: neda.mirzaeian@utdallas.edu

We investigate the effect of autonomous vehicles (AVs) on the morning commute, and characterize a user equilibrium for commuters by developing a continuous-time model that takes into account parking fees and traffic congestion as key economic deterrents to driving. We illustrate our results using data from Pittsburgh, and show that AVs result in a high total system cost. To reduce this cost, a social planner can regulate commuters' decisions by adjusting parking fees and congestion tolls, and/or adjusting infrastructure (e.g., converting downtown parking spots to drop-off spots). Our results indicate that these measures can reduce the total system cost substantially (e.g., by 70% in Pittsburgh).

6 Embedding Sustainability in Digital Servitization Journeys

Juliana Hsuan, Copenhagen Business School, Frederiksberg, Denmark.

“Embedding sustainability in digital servitization journeys” - Servitization is about competing through value propositions that integrate service with product offerings, prominently strategized by manufacturing companies. Digital servitization integrates product, service and software into the offerings. As manufacturers embrace sustainability into their strategic agenda, they have to consider the tradeoffs and risks (between standardization and innovation) in the configuration of required resources for business model innovation. This flash talk shares insights from an ongoing servitization project in Denmark and suggests opportunities for research.

7 A Semi-parametric Bayesian Model for Call Center Arrivals

Kaan Kuzu[1], Refik Soyer[2], Murat Tarimcilar[3], [1]Univ of Wisconsin-Milwaukee, Milwaukee, WI, [2]George Washington University, Washington, DC, [3]The George Washington University, Washington, DC, Contact: kuzu@uwm.edu

We use a Bayesian framework to forecast call arrivals by proposing a nonparametric form for the intensity function and introduce a robust semi-parametric model. The model is suitable for analyzing both interval censored count data and time of arrival data and can capture both monotonic and non-monotonic call arrival intensity. We consider a Markov evolution of daily effects on the intensity function and implement the model on two real call center data sets. We show that our proposed model has robust performance and provides higher accuracy than existing models.

8 Market Thickness in Online Food Delivery Platforms: The Impact of Food Processing Times

Yanlu Zhao[1], Felix Papier[2], Chung-Piaw Teo[3], [1]Durham University Business School, Durham, United Kingdom; [2]Essec Business School, Cergy Pontoise Cedex, France; [3]National University of Singapore Business School, Singapore, Singapore. Contact: felix.papier@gmx.de

Online food delivery (OFD) platforms are expanding rapidly worldwide; the pace of this expansion accelerated during the COVID-19 pandemic. We develop real-time algorithm to match drivers with orders on OFD platforms. The algorithm uses the (highly variable) food processing time to delay the assignment of drivers to orders to thicken the `market’ of orders and drivers. We evaluate the performance of our policy on a simplified model and derive the quasi-convexity of the total costs, implying that an intermediate level of thickness is optimal. Numerical experiments based on a real dataset from Meituan show that our policy reduce total costs by 42% compared to matching policies that are currently in use.

Stochastic Systems Under Large Scales, Sudden Demands, and Large Deviations

General Session

Session Chair

Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

1 An Asymptotic Systemic Failure Time Result for Mixed Coherent Systems

Guido Lagos[1], Javiera Barrera[2], Juan Valencia[3], Pablo Romero[4], [1]Universidad Adolfo Ibanez, Vina del Mar, Chile; [2]Universidad Adolfo Ibanez, Penalolen, Chile; [3]Universidad de Santiago de Chile, Santiago, Chile; [4]Universidad de la Republica, Montevideo, Uruguay. Contact: guido.lagos@uai.cl

In this work we show a limit result for the probability of a system being in an operational state as the size of the system grows to infinity. More specifically, we consider a sequence of *mixed coherent systems* whose components are homogeneous and non-repairable, with failure times of its components governed by a *Levy-frailty Marshall-Olkin* (LFMO) distribution — a distribution that allows simultaneous failures. We show that under measurability conditions the system failure time converges in distribution to a first-passage time of a Levy subordinator process. To illustrate, we give a parametric family of systems where the time of systemic failure converges to an exponential distribution. To the best of our knowledge, this is the first result to tackle the asymptotic behavior of the system failure time as the number of components of the system grows.

2 An Online Learning Algorithm for Capacity Sizing in Queues with Hawkes Arrivals

Xinyun Chen[1], Guiyu Hong[2], Xiuwen Wang[2], [1]Chinese University of Hong Kong, Shenzhen, Shenzhen, China;

[2]Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: guiyuhong@link.cuhk.edu.cn

We investigate the capacity sizing problem for a single-sever queue with Hawkes arrivals and general service time distributions. Due to the complexity of system dynamics, there is no analytic solution to this problem. We develop an online learning algorithm to numerically compute the optimal service capacity with a theoretic guarantee. In particular, we prove that our algorithm obtains regret of logarithmic order with properly chosen hyper-parameters. In the end, we apply the online learning algorithm to solve the capacity sizing problem for various single-server queues with Hawkes input. The numerical results indicate a sharp difference between GI/GI/1 and Hawkes/GI/1 queues, especially in some asymptotic regimes, indicating significant impact of autocorrelation in arrival processes to queueing control problems.

3 Maximizing Utilization in Large Systems Serving Jobs with Time-varying Resource Requirements

Yige Hong[1], Qiaomin Xie[2], Weina Wang[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Wisconsin-Madison, Madison, WI, [3]Carnegie Mellon University, Pittsburgh, PA, Contact: yigeh@andrew.cmu.edu

Today's datacenters need to serve jobs whose resource requirements vary over time. The existence of such jobs makes it hard to fully utilize resources while not exceeding capacity constraints. The exact trade-off between utilization and capacity violation is not well-understood in the literature. In this paper, we study an infinite-server computing system where each server has a finite resource capacity, and jobs have time-varying resource requirements. Our goal is to design a job assigning policy that minimizes the number of occupied servers while keeping the cost of capacity violation within certain budget. We propose a novel framework that reduces the policy design problem under study to a problem in a single-server system through policy conversion techniques. This allows us to design an asymptotically optimal policy by solving a simple linear programming problem.

4 Sample-path Large Deviations for Unbounded Additive Functionals of Lindley Recursion

Chang-Han Rhee, Northwestern University, Chicago, IL

We prove a sample-path large deviation principle (LDP) with sub-linear speed for unbounded functionals of Lindley recursion. The LDP holds in the Skorokhod space D[0,T] equipped with the M1' topology. Our technique hinges on a suitable decomposition of the Markov chain in terms of regeneration cycles. Each regeneration cycle denotes the area accumulated during the busy period of the reflected random walk. We prove a large deviation principle for the area under the busy period of the MRW, and we show that it exhibits a heavy-tailed behavior.

Recent Advances and Future Challenges in Online Decision-making

General Session

Session Chair

Debankur Mukherjee, 1</sup

Session Chair

Daan Rutten, Georgia Institute of Technology

1 Chasing Convex Bodies and Functions with Black-Box Advice

Nicolas Christianson, Tinashe Handina, Adam Wierman, California Institute of Technology, Pasadena, CA, Contact: nchristianson@caltech.edu

Modern AI/ML algorithms have the potential to improve performance over traditional algorithms for online optimization, which are designed to give worst-case guarantees. However, while AI/ML algorithms might perform well when the training data accurately reflects the deployment environment, they lack worst-case performance guarantees, e.g., under distribution shift. This hinders their use in real-world settings where safety/performance guarantees are crucial. In this talk, I will discuss recent work designing algorithms for online optimization with "black-box" advice that bridge the gap between the good average-case performance of AI/ML and the worst-case guarantees of traditional algorithms. We focus on the problem of chasing convex bodies and functions, discussing several algorithms and fundamental limits on algorithm performance in this setting.

2 Advances in Online Algorithms with Unreliable Predictions

Daan Rutten[1], Nicholas Christianson[2], Debankur Mukherjee[3], Adam Wierman[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]California Institute of Technology, Pasadena, CA, [3]ISyE Georgia Tech, Atlanta, GA, Contact: drutten@gatech.edu

We discuss recent advances and techniques in online algorithms with unreliable predictions. The online algorithm has access to a black-box oracle, such as a machine learning model, that provides untrusted and potentially inaccurate predictions of future input. The goal of the algorithm is to exploit the predictions if they are accurate, while guaranteeing performance that is not much worse than the hindsight optimal sequence of decisions, even when predictions are inaccurate. We discuss two problems: capacity scaling in data centers based on unknown future demand and the general framework of online optimization with switching costs. We prove theoretical guarantees on the competitive ratio using a potential function approach and show their optimality by lower bounds.

3 Accelerate Learning for Two-sided Bandits with Many Arms

Wanning Chen[1], Mohsen Bayati[2], Junyu Cao[3], [1]University of Washington, Seattle, WA, [2]Stanford University, Stanford, CA, [3]The University of Texas at Austin, Austin, TX

Multi-armed bandit (MAB) algorithms are used by companies instead of randomized experiments to find the best product from periodically refreshed product catalogs since they can reduce the opportunity costs efficiently. Due to a lack of knowledge of customer preferences for new products (i.e. cold start), MAB algorithms involve an initial data collection phase called the burning period. During this period, they operate like randomized experiments, incurring large burning costs that scale with the large number of products. We design an algorithm based on the low-rank matrix estimator to reduce the burning, by identifying that many products can be cast into two-sided products. The rewards of such products are modeled with a low-rank matrix, whose rows and columns represent the two sides. We show that our algorithm reduces costs with both theoretical and empirical evidence.

4 Online Learning with Hints

Manish Purohit, Google, Mountain View, CA

In this talk, I provide a brief overview of "Learning-augmented algorithms": algorithms that have access to predictions made by a machine learning oracle.
I will present an application of this framework to the classical online learning problem where the online player receives a "hint" regarding the upcoming cost vector before choosing an action for that round. Our goal is to design an algorithm that exploits good hints to obtain regret that grows only logarithmically with the number of time steps (thus circumventing well known lower bounds), while at the same time being resilient to bad hints. We develop a general framework for online learning with hints that obtains near-optimal regret bounds with respect to the quality of the hints. I shall conclude with different extensions of this framework such as reducing the number of hints utilized, and exploiting multiple hint sources.

Data-driven E-commerce Inventory Management

General Session

Session Chair

Will Ma, Columbia University, Cambridge, MA

1 Integrated Conditional Estimation-optimization with Its Application in Multi-product Newsvendor Problem

Meng Qi[1], Paul Grigas[2], Zuo-Jun Max Shen[3], [1]Cornell University, Ithaca, NY, [2]UC Berkeley, Berkeley, CA, [3]University of California Berkeley, Berkeley, CA

Many real-world optimization problems, such as the multi-product Newsvendor problem, involve uncertain parameters with probability distributions that can be estimated using contextual feature information. In contrast to the standard approach of first estimating the distribution and then optimizing the objective based on the estimation, we propose an integrated conditional estimation-optimization(ICEO) framework that estimates the underlying conditional distribution of the random parameter while considering the structure of the optimization goal. We show that our ICEO approach is asymptotically consistent under moderate regularity conditions and further provide finite performance guarantees in the form of generalization bounds. We also investigate the computational difficulties and conduct numerical experiments to show the empirical success of ICEO.

2 Adaptive Algorithms for Multi-Warehouse Multi-Store Inventory System with Lost Sales

Xiuli Chao[1], Stefanus Jasin[2], Sentao Miao[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]McGill University, Montreal, QC, Canada. Contact: sentao.miao@mcgill.ca

We consider a two-echelon inventory control problem for a Multi-Warehouse Multi-Store (MWMS) system with lost sales. We focus on a time horizon with no external replenishment, or the problem of "what to do until your (external) shipment comes in". The warehouses are stocked with inventories at the beginning of the horizon, and the stores dynamically replenish from the warehouses in each period. In this paper, we develop provably near-optimal algorithms by integrating and extending two key ideas/approaches: (i) Lagrangian relaxation of the original complex dynamic inventory control problem, and (ii) dynamic re-adjustments of both replenishment and allocation policies. Our results show that adaptive readjustments significantly improve the performance of the base algorithm both theoretically and numerically.

3 Order Selection Problems in Hiring Pipelines

Boris Epstein[1,1], Will Ma[2], [1]Columbia University, New York, NY, [2]Columbia University, Cambridge, MA

We study problems faced by firms which are running recruitment processes and must decide the order in which to send offers to candidates. The firm has a pool of candidates, from which at most k of them can be hired. There are also constraints on the total number of candidates who can receive offers. Each candidate has a probability of accepting the offer and provide a value to the firm when they accept. The goal of the firm is to maximize the sum of the values of hired candidates.

We study two different variants of the problem. In the sequential offering model, offers are sent one-by-one and at most T offers can be sent in total. In the parallel offering model, the firm can send, at each stage, as many offers as positions left in that stage. Our algorithms are static, implying bounds on the adaptivity gaps for these problems.

4 Online Multi-Item Order Fulfillment and Prophet Inequality

Ayoub Amil, Ali Makhdoumi, Yehua Wei, Duke University - Fuqua School of Business, Durham, NC, Contact: ayoub.amil@duke.edu

We study a problem in which an e-commerce platform (or online retailer) with multiple warehouses and finite inventory is faced with the choice of deciding from which warehouse each of the items in the arriving order(s) should be fulfilled. Online retailers, unlike traditional retailers, must quickly make a series of decisions, such as deciding from which facility the items will ship, by what shipping method, or whether or not multi-item orders will be split. We formulate this problem as an online decision problem in which a platform sequentially decides a shipping method to adopt to fulfill the arriving order, subject to warehouses' inventory constraints. By building connections to the *prophet inequality* and *magician problem* literature, we design an online algorithm that is both asymptotically optimal and has a strong approximation guarantee in the non-asymptotic setting.

Congfang Huang, UW Madison, Madison, WI

Session Chair

Jaesung Lee, University of Wisconsin, Madison, WI

1 A Bayesian Framework of Markov Decision Process with Uncertain Transition Probabilities

YUE SHI, Yisha Xiang, Texas Tech University, Lubbock, TX

This study considers a Markov decision process model whose transition probabilities are unknown to the decision maker and need to be estimated from historical transition data. Due to limited availability of data and/or data errors, such an estimation is often subject to large statistical estimation errors, making the estimated transition probabilities significantly deviated from the true ones.

To mitigate the impact of the parameter uncertainty on optimal policies, we use a Bayesian approach to model the uncertainty in transition probabilities and propose a second-order approximation model to obtain optimal policies.

We assess the utility of the proposed method using a remanufacturing planning problem.

2 HMM-based Joint Modeling of Condition Monitoring Signals and Failure Event Data for Prognosis

Akash Deep[1], Shiyu Zhou[2], Dharmaraj Veeramani[2], Yong Chen[3], [1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, [3]University of Iowa, Iowa City, IA, Contact: adeep@wisc.edu

Accurate estimation of remaining useful life (RUL) of a unit is critical to fulfill reliability commitments. In presence of hard failures, accurate prognosis of RUL using condition monitoring (CM) signals becomes challenging. To tackle this problem, we present a prognostic framework by jointly modeling CM signals and failure event data. Development of the presented method depends on the idea that while the unit operates, it continually degrades through a series of hidden states until the unit reaches the dead state, and the CM signals are functionally related to this hidden failure process. Through this modeling, requirement of a failure threshold on CM signals is eliminated. We provide a modified EM procedure to estimate parameters, and through a comprehensive set of numerical as well as real-world experiments we demonstrate superior prognosis performance.

3 Applying Machine Learning Methods to Improve All-terminal Network Reliability

Jose Azucena[1], Haitao Liao[2], [1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas, Fayetteville, AR, Contact: jch051@uark.edu

We propose a novel framework for improving network reliability using Deep Reinforcement Learning (DRL) and Deep Neural Networks (DNNs). With the help of DNNs and Stochastic Variational Inference (SVI), the DRL agents will effectively compute the all-terminal reliability for multiple network configurations during training. The Bayesian nature of the SVI+DNN model allows for quantifying the estimation uncertainty while enforcing regularization and reducing overfitting.

Advanced Data Analytics and Statistical Modeling for Smart Heath

General Session

Session Chair

Bing Yao, Oklahoma State University, Stillwater, OK

Session Chair

Cheng-Bang Chen, University of Miami, Miami, FL

1 Calibration of Patient Flow Model in Hospital via Gaussian Processes Based Bayesian Optimization

You Zhou, Purdue University, West Lafayette, IN, Contact: zhou1129@purdue.edu

Smart hospital is an important cornerstone of smart healthcare. It has become a research hotspot on how to assist hospital managers to make better decisions based on history data. In this study, we investigated a state transition model over the patient flow inside the hospital and calibrated the parameters of the model against the daily census data. We employed a Gaussian Process based Bayesian Optimization approach to identify the best parameter design. We compared our methods with direct employment of Nelder-Mead and the surrogate function using Gaussian Process trained with a fixed set of sampling points. Overall, our method showed better goodness-of-fit and achieved better validation results given limited number of calls of simulator. Our method can assist hospital manager to better monitor medical needs and allocate the corresponding resources.

2 A Novel Recurrence Quantification Analysis for Cardiac Arrhythmia Detection in Multichannel ECG Signals

Yujie Wang[1], Ayush Manojkumar Lodha[2], Cheng-Bang Chen[3], [1]University of Miami, Miami, FL, [2]Indian Institute of Technology Gandhinagar, Ahmedabad, India; [3]University of Miami, Miami, FL, Contact: yxw509@miami.edu

Cardiac arrhythmias reflect various irregular conditions of the heart. It is crucial to accurately identify the arrhythmias from the electrocardiogram (ECG) signals. Prior research has shown that recurrence analysis (RA) is robust in characterizing the complex ECG; however, the dynamic recurrences within and between heterogeneous transitional states, which contain rich information, have not been thoroughly investigated. This research proposes a novel RA framework addressing this gap. We coordinate two different RAs to characterize the subtle dynamic in ECG and develop new quantifications to delineate these recurrences precisely. Experimental results show that our methodology accurately depicts the ECG and detects arrhythmias.

3 Heart Rate Variability Feature Selection Method for Mental Stress Detection

Joseph Nuamah, Oklahoma State University

Advances in wearable sensor technologies have led to various approaches for detecting mental stress using physiological signals, including heart rate variability (HRV). In a binary classification task, we combined feature selection methods with different machine learning (ML) models (SVM, XGBoost, Random Forest and LASSO) to a publicly available dataset, WESAD, to determine HRV features that best distinguish stress and non-stress states. Based on the macro-averaged F1 score, the best result of 0.80 was obtained with recursive feature extraction combined with XGBoost when the number of features was 11 out of a total of 25. We evaluated the performance of our model with data obtained from participants from a different stress response study. Results obtained is a step towards evaluating reproducibility of ML models for mental stress detection.

4 RL-Driven Information Broadcasting Policies for Early Task Initiation in Healthcare Systems for Improved Patient Flow

SeungJin Wang, Wayne State University, Troy, MI
Emergency Department (ED) patient boarding, the process of patients being held up in ED for hours on due to admission delays and reactive hospital bed management, has been a national and international crisis for years. Modern Electronic Health Record (EHR) systems have been shown to enable real-time predictions around ED patient length-of-stay and disposition decisions to facilitate proactive coordination of downstream resources to streamline patient flow from ED to the Inpatient Unit (IU) network. Given the evolving uncertainty in prediction accuracies and resource states, there is need for optimal information broadcasting policies around future demand to downstream resources. We explore reinforcement learning algorithms to best balance broadcast lead-times with information reliability

Condition Monitoring, Operations and Maintenance in Power Systems

General Session

Session Chair

Farnaz Fallahi, Wayne State University, Detroit, MI

Session Chair

Murat Yildirim, Wayne State University, Detroit, MI

1 Transitioning to Sensor-driven Asset Management in a Hydropower System Domain

Farnaz Fallahi, Wayne State University, Detroit, MI, Contact: farnaz.fallahi@wayne.edu
This paper proposes a unified condition-based maintenance and operations scheduling approach for hydropower systems that models the non-linearity in power production as well as uncertainties related to water inflows and market price. The problem is formulated as a two-stage stochastic programming model to minimize the operations and maintenance cost. Our results on a comprehensive set of experiments demonstrate that the proposed approach provides significant improvements in asset availability, market revenue and maintenance costs in a large-scale hydropower system.

2 Differentially Private Decentralized Generator Maintenance and Operations for Power Networks

Paritosh Ramanan, Georgia Institute of Technology, Atlanta, GA
Decentralized methods have been popular for their computational scalability while enabling data ownership by utility stakeholders. However, decentralization also requires sharing network flow estimates over public channels raising privacy concerns. In this talk, we present a differential privacy driven, ADMM approach for decentralized, mixed integer optimization of operations and maintenance problems which preserves network flow privacy. Our solution relies on strong privacy guarantees regarding phase angles and flow. We introduce an exponential moving average based consensus mechanism to enhance convergence, coupled with a control chart based convergence criteria to improve stability. Our results demonstrate that our privacy preserving approach is robust to a range of noise levels and operational scenarios remaining on par with benchmark methods.

3 A Robust Optimization Framework for Operations and Maintenance in Multi-component Systems

Deniz Altinpulluk[1], Farnaz Fallahi[2], Mohammad Javad Feizollahi[3], Murat Yildirim[4], [1]Wayne State University, Detroit, MI, [2]Wayne State University, Birmingham, MI, [3]Georgia State University, Atlanta, GA, [4]Wayne State University, Detroit, MI, Contact: deniz.altinpulluk@gmail.com
Regular maintenance policies face reliability and profitability issues due to frequent maintenance requirements while facing significant unexpected failure risks. Recent developments in sensor technology provide asset-specific degradation information from components that can be harnessed to improve operational and maintenance effectiveness. The degradation rate of a component highly depends on the production load and conditions of other components in the system. This allows us to tame the degradation rate by reducing production load or maintaining its degraded pairs. Rates of these contributions to the total degradation rate from these dependencies are uncertain. We introduce a robust optimization model that accommodates maintenance and production decisions to minimize maintenance costs and penalties from unsatisfied demand.

4 Predicting Remaining Useful Life in Complex Systems with Multiple Failure Modes

Benjamin G. Peters, University of Texas Rio Grande Valley, Edinburg, TX, Contact: benjamin.peters01@utrgv.edu

Modern industrial systems are comprised of multiple components with complex degradation processes. To address this complexity, modern systems are equipped with several sensors for condition monitoring, a process that utilizes sensor data for predicting the system's remaining useful life (RUL). RUL prediction is challenging for complex systems due to the large volume of data collected by these sensors and because complex systems are subject to multiple failure modes. High-dimensional (HD) data analytics holds potential for enabling the development of robust prognostics frameworks for complex systems due to its ability to process the large data structures generated by these sensors. Therefore, we present an HD data analytics framework for predicting RUL in complex systems with multiple failure modes.

IISE Transaction Invited Session

Panel Session

Session Chair
Jionghua Jin, University of Michigan, Ann Arbor, MI

1 **Moderator**
Jionghua Jin, University of Michigan, Ann Arbor, MI
This is a special invited Panel Session of IISE Transactions on Data Science, Quality & Reliability (IISE-DSQR). In the session, three panelist speakers will present their recently published papers in IISE-DSQR, which show a few examples of frontier research topics promoted by the IISE-DSQR journal. The discussion with the journal editor about the journal scope and review process is followed.

2 **Panelist**
Yuxin Wen, Chapman University, Santa Ana, CA

3 **Panelist**
Honghan Ye, University of Wisconsin- Madison, Woodbury, MN

4 **Panelist**

Smart Power-grid and Mobility Toward Carbon Neutrality

General Session

Session Chair
Kai Pan, Hong Kong Polytechnic University, Kowloon, Hong Kong.

Session Chair
Ziliang Jin, The Hong Kong Polytechnic University

1 **Algorithmic Privacy for Energy Systems Optimization**
Vladimir Dvorkin, Massachusetts Institute of Technology, Cambridge, MA
Decision-making in energy systems is often guided by optimization models that use sensitive, private energy optimization data (e.g., energy demands, prices, etc.). Optimization outcomes may unintentionally expose this data, thus leading to privacy breaches. We introduce differentially private energy system optimization models that make different, yet adjacent in some sense, energy datasets statistically similar in randomized optimization outcomes, thereby proving probabilistic privacy guarantees for energy

data owners. We explain how stochastic programming and differential privacy achieve algorithmic privacy in energy optimization, and we provide illustrative examples of private energy system control, forecasting and classification.

2 Auction Designs to Increase Incentive Compatibility and Reduce Self-scheduling in Electricity Markets

Conleigh Byers[1], Brent Eldridge[2], [1]ETH Zurich, Zurich, Switzerland; [2]Pacific Northwest National Laboratory, Baltimore, MD, Contact: cbyers@ethz.ch

The system operator's scheduling problem in electricity markets, called unit commitment, is a non-convex mixed-integer program. The optimal value function is non-convex, preventing the application of traditional marginal pricing theory to find prices that clear the market and incentivize market participants to follow the dispatch schedule. Units that perceive the opportunity to make a profit may be incentivized to self-commit (submitting an offer with zero fixed operating costs) or self-schedule their production (submitting an offer with zero total cost). We simulate bidder behavior to show that market power can be exercised by becoming a price taker. We investigate different pricing mechanisms over multi-period commitment windows and show that convex hull pricing can minimize producer incentives to deviate from the central dispatch decision.

3 Achieving Power Sector Carbon Neutrality in a Low-cost Renewable Era

Gang He, Stony Brook University, Stony Brook, NY

Clean power transition is at the center to achieve mid-century carbon neutrality goals. The cost of solar and wind has plummeted in the past decade, and solar and wind electricity has been achieving grid parity. Low-cost renewables offer new perspectives for energy system decarbonization that was less visioned before. In this talk, Dr. He will discuss the pathways of clean power transition and their system impacts using high-resolution models, to reflect the need for integrating variable renewable energy and phasing out coal to achieve carbon neutrality in the power sector at a low-cost renewables era.

4 Equity by Design in Electric Vehicle Charging Networks

Yen-Chu Wu, Eleftheria Kontou, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: kontou@illinois.edu

In this study, we optimize electric vehicle charging station deployment by integrating equity objectives in this facility location problem. We aim to reduce detours and improve the ability to complete long-distance trips for low-income electric vehicle travelers and multi-unit dwelling residents. We use a genetic algorithm with a column generation approach to solve the nonlinear mixed integer programming problem. We provide insights on equitable charging siting by applying this framework to the state of Illinois interstate network.

Control and Optimization Solutions to Safeguard Against Cyber-physical Adversaries in Energy Grids

General Session

Session Chair

Nawaf Nazir, 1</sup

Session Chair

Soumya Kundu, 1</sup

1 A Conditional Value at Risk (CVaR) Based Mode-selection Framework to Safeguard Against Adversarial Attacks in Microgrids

Nawaf Nazir, Soumya Kundu, Pacific Northwest National Laboratory, Richland, WA, Contact: nawaf.nazir@pnnl.gov

The increasing penetration of distributed generation in the energy grids has created challenges for power system operations including safeguarding against various cyber-physical attacks. Hence, the need is to develop resilient methods, such as chance constraints, that provide guarantees on system stability and security. However, traditional methods do not consider the wide range of possible adversarial events, especially low probability high impact events. In this work, we develop a mode-selection based framework that firstly forecasts the probability of various adversarial events and then based on this chooses a mode of operation amongst a finite number of modes, in order to counter the effects of the adversarial events in a scalable approach. Finally we develop CVaR based algorithms to dispatch flexible resources and validate the results on a microgrid test case.

2 Enabling DER Participation in Frequency Regulation Markets

Adil Khurram[1], Priyank Srivastava[2], Sonia Martínez[3], Jorge Cortes[4], Jan Kleissl[3], [1]University of California, San Diego, San Diego, CA, [2]Massachusetts Institute of Technology,

Cambridge, MA, [3]University of California, San Diego, San Diego, CA, [4]University of California-San Diego, La Jolla, CA, Contact: akhurram@ucsd.edu

This work develops a hierarchical framework for aggregators to participate in the ancillary services market, where each aggregator manages a microgrid consisting of a collection of heterogeneous DERs. Meaningful abstractions of aggregators are developed using the second-order cone relaxation of the AC optimal power flow problem. These abstractions are used to identify bids for the market clearing stage as well as for the real-time disaggregation of the regulation signal in a distributed fashion. This type of formulation preserves the privacy of DERs by abstracting the operating constraints of an individual DER into cost function, capacity limits and ramp rate limits for the entire microgrid operating under the aggregator, mitigating attacks by cyber physical eavesdropping adversaries.

3 Stochastic Linearization: Review and Recent Advances

Hamid Ossareh, University of Vermont, Burlington, VT

Quasilinear Control (QLC) Theory provides a set of methods intended for the analysis and design of stochastic feedback systems with static nonlinearities such as actuator saturation. QLC leverages the method of Stochastic Linearization (SL), which linearizes the nonlinear functions by utilizing the statistical properties of the inputs to the nonlinearities. This results in an approximation that can predict the mean and variance of the signals in the loop with reasonable accuracy, which can in turn be used for the purpose of planning and controller design. In this talk, we review SL and several key QLC methods, and present recent advances in these areas, such as handling systems with multivariate nonlinearities and systems with multiplicative noise, which arise in power system applications.

4 Risk-aware Learning for Scalable Voltage Optimization in Distribution Grids

Shanny Lin, Shaohui Liu, Hao Zhu, The University of Texas at Austin, Austin, TX, Contact: shaohui.liu@utexas.edu

By capitalizing on a scalable neural network architecture and the conditional value-at-risk (CVaR), we develop a decentralized risk-aware learning framework to attain safe decision rules for distributed energy resources to support distribution grid voltage optimization. To address the sample dispersion issue, we leverage the CVaR as a regularization term on the prediction error and voltage deviation to systematically reduce the worst-case scenarios to improve the system safety. In addition, we propose a mini-batch selection algorithm to accelerate the training speed. Numerical tests using real-world data on the IEEE 123-bus test case demonstrate computation and safety improvements.

Learning and Data-driven Algorithms for Revenue Management

General Session

Session Chair

Negin Golrezaei, Massachusetts Institute of Technology, Lexington, MA

Session Chair

Jason Cheuk Nam Liang, MIT, MA

1 Intertemporal Pricing via Nonparametric Estimation: Integrating Reference Effects and Consumer Heterogeneity

Hansheng Jiang[1], Junyu Cao[2], Zuo-Jun Max Shen[3], [1]University of California, Berkeley, Berkeley, CA, [2]The University of Texas at Austin, Austin, TX, [3]University of California Berkeley, Berkeley, CA, Contact: hansheng_jiang@berkeley.edu

We consider intertemporal pricing in the presence of reference effects and consumer heterogeneity with arbitrary distributions. We use a nonparametric estimation method to learn consumer heterogeneity from transaction data. Further, we formulate the pricing optimization as an infinite horizon dynamic programming problem and solve it by applying a modified policy iteration algorithm. Moreover, we investigate the structure of optimal pricing policies and prove the sub-optimality of constant pricing policies even when all consumers are loss-averse according to the classical definition. Our numerical studies show that our estimation and optimization framework improves the expected revenue of retailers. We validate our model using real data from JD.com, a large E-commerce retailer, and find empirical evidence of consumer heterogeneity.

2 Decentralized Online Convex Optimization in Networked Systems

Judy Gan[1], Yiheng Lin[2], Guannan Qu[3], Yash Kanoria[1], Adam Wierman[2], [1]Columbia Business School, New York, NY, [2]California Institute of Technology, Pasadena, CA, [3]Carnegie Mellon University, Pittsburgh, PA, Contact:

ygan23@gsb.columbia.edu

We study the problem of networked online convex optimization, where a central planner must make individual node decisions online with the goal of minimizing a global cost. The global cost is a sum of three parts: convex node costs, temporal interaction costs, and spatial interaction costs. In deciding individual node's action at each time, an online algorithm has access to the exact predictions of local cost functions for the next k time steps in an r-hop neighborhood. Our work proposes a novel algorithm, Localized Predictive Control (LPC). We show that LPC achieves a competitive ratio approaching 1 exponentially fast in the lookahead steps k and locality radius r in an adversarial setting. Further, we show that the dependence on k and r in our results is near optimal by lower bounding the competitive ratio of any decentralized online algorithm.

3 Algorithmic Pricing in Competitive Markets with Consumer Reference Effects

Negin Golrezaei[1], Patrick Jaillet[2], Jason Cheuk Nam Liang[3], [1]Massachusetts Institute of Technology, Lexington, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]MIT Operations Research Center, Cambridge, MA

Algorithmic pricing has become prevalent in online markets, where interactions between pricing algorithms have trained consumers to form price expectations (reference prices) over time. In this work, we study the interplay between algorithmic pricing and dynamic reference prices, and focus on long-term Stable Nash Equilibria (SNE), at which firms do not deviate and reference prices are invariant.

Under a cumulative-memory reference dynamic, we show SNEs always exist for markets where consumers are risk-neutral (RN) or risk-averse (RA), but does not necessarily exist for risk-seeking consumers. Focusing on the class of Online Mirror Descent algorithms, in RN markets we first show suitable step sizes allow global last-iterate convergence to an SNE. In RA markets with vanishing step sizes, we show that prices converge locally to an SNE in its last iterate.

4 Reducing Marketplace Interference Bias via Shadow Prices

Ido Bright[1], Arthur J. Delarue[2], Ilan Lobel[3], [1]Lyft, Seattle, WA, [2]Lyft, Cambridge, MA, [3]New York University, New York, NY, Contact: arthur.delarue@isye.gatech.edu

Marketplace companies rely on experimentation when making changes to their platforms, in particular using randomized controlled trials (RCT). However, marketplace interference leads to bias in standard RCT metrics. We propose a technique to reduce this bias in a setting where the platform explicitly matches supply with demand via an algorithm. Instead of comparing the total value accrued by the treatment and control groups, we instead compare each group's average shadow price in the matching linear program. In the fluid limit, our proposed technique corresponds to the correct first-order approximation of the value function of interest. Under reasonable assumptions, our estimator is less biased than the RCT estimator. Our key idea is that interference can be modeled explicitly in matching marketplaces since the platform itself mediates the spillover.

Emre Nadar, Bilkent University, Ankara, Turkey.

1 Innovative Business Models in Ocean-bound Plastic Recycling

Opher Baron[1], Gonzalo Romero[2], ZHUOLUO ZHANG[3], Sean Zhou[4], [1]University of Toronto, Toronto, ON, Canada; [2]Rotman, University of Toronto, Toronto, ON, Canada; [3]Chinese University of Hong Kong, Hong Kong, Hong Kong; [4]Chinese University of Hong Kong, New Territories, Hong Kong. Contact: gonzalo.romero@rotman.utoronto.ca

30 million tons of plastic waste reach the ocean each year, most from developing countries. We study novel business models to address this global problem. Firms aim at profitably recycling plastic to reduce ocean pollution while positively impacting local communities. They sell (a) plastic offsets and (b) segregated plastic. We find that adopting both attains more environmental impact, gives a higher income to the collectors while enjoying a higher profit than (a) or (b) alone. However, the largest collectors' share of the local supply chain profit is attained by (b). Moreover, the largest social impact may be attained by (a). We use empirical data to calibrate our model and unveil additional insights.

2 Retreat, Defend, or Attack? Optimal Investment Decisions in Green Technology Under Competition

Osman Alp[1], Tarkan Tan[2], Maximiliano Udenio[3], [1]University of Calgary, Calgary, AB, Canada; [2]University of Zurich, Zurich, Switzerland; [3]KU Leuven, Leuven, Belgium. Contact: osman.alp@ucalgary.ca

Firms that invest in more sustainable technologies as a proactive measure against changing market dynamics are likely to gain a significant competitive advantage. We analyze a firm's optimal green investment strategy, accounting for the uncertainty in the competitors' actions and the future green market size. We develop a stylized model under three stages and characterize the optimal policy as `Retreat', `Defend', or `Attack' strategy when green market size is known, one of which is optimal based on the problem parameters. We conduct theoretical and numerical analyses regarding the optimal solution and the regret associated with making sub-optimal decisions, when the green market size is random.

3 Making Community Solar Work for the Community

Siddharth Singh[1], Owen Wu[2], [1]UCL School of Management, London, United Kingdom; [2]Indiana University, Bloomington, IN, Contact: siddharth.singh@ucl.ac.uk

Fueled by policy effortsto decarbonize the electricity grid, intermediate scale solar projects aregaining traction through community solar, an innovative business model in whichresidential customers pay an ongoing subscription fee for a share of solarcapacity. These customers are compensated for the generation of their share bythe utility, at a bill credit rate set by the regulator. This bill credit rateis typically a flat per-unit credit, independent of customer type andsubscription size. Using an analytical model that that endogenizes the adoptiondecisions of heterogeneous customers, we illustrate the importance of using anappropriate, and possibly richer, bill credit rate structure to ensure thatcommunity solar really works for the community in terms of generating anddistributing value to the community members.

4 Optimal Procurement in Remanufacturing Systems with Uncertain Used-item Condition

Emre Nadar[1], Mustafa Akan[2], Laurens G. Debo[3], Alan Scheller-Wolf[4], [1]Bilkent University, Ankara, Turkey; [2]Carnegie Mellon University, Pittsburgh, PA, [3]Dartmouth College, Hanover, NH, [4]Tepper School of Business, Pittsburgh, PA, Contact: akan@cmu.edu

We consider a single-product remanufacture-to-order system with multiple uncertain quality levels for used items. The quality level of a used item is only revealed after it is acquired and inspected; the remanufacturing cost is lower for a higher quality item. Modeling this system as a Markov decision process, we seek an optimal policy that specifies when a used item should be procured, and whether an arriving demand for the remanufactured product should be satisfied and which available item should be remanufactured to meet this demand. Taking into account the system congestion level measured as the number of available items and their quality levels, we establish the optimality of a state-dependent non-congestive acquisition policy.

Energy Supply Chain Optimization

General Session

Session Chair

Merve Merakli, ExxonMobil, Woodlands, TX

1 Integrated Network Optimization for Oil Production Using Mixed-integer Linear Programming

Emmanuel Ogbe[1], Jose Santiago Rodriguez[2], Francisco Trespalacios[2], Neal Adair[1], Keith Zorn[2], [1]ExxonMobil, Spring, TX, [2]ExxonMobil, Spring, TX, Contact: emmanuel.ogbe@exxonmobil.com

Maximizing oil production requires the optimization of a complex system involving intricate nonlinear relationships between wells, flowlines, and surface equipment. In this presentation, we establish a mixed-integer linear model for global optimization of an integrated oil production network. The model integrates piecewise-linear approximations for nonlinear multiphase flow behavior in wells and pipelines into a production system model whose objective is to maximize oil rate. When compared to well-established oil optimization tools, the proposed approach achieves both increased production and a significant reduction in computational time. We will discuss the mathematical model and present results for two real offshore production systems.

2 Spatially Explicit Optimization of Biofuel Supply Chains

Christos Maravelias, Eric O'Neil, Princeton University, Princeton, NJ

Producing a substantial amount of biofuel from dedicated cellulosic biomass requires a significant amount of land to be converted to growing energy crops; however, the locations best suited to plant crops are dependent on supply chain (SC) factors such as facility location, technology selection, carbon capture and storage (CCS) considerations. We introduce a spatially explicit MIP model that considers the upstream design of the landscape (crop establishment and fertilization), the SC network design (including inventory, transportation, and biorefinery location and capacity) and technology selection with CCS from a wide array of options. The uneven spatial distribution of biomass, and the differences in price and GHG impact between electricity grids motivate studying biorefinery technology tradeoffs (including CCS) and biomass SCs simultaneously.

3 Marine Circuit Inventory Routing

Rick Zhu[1], Ben Sauk[2], Ryan Ryan Gwaltney[2], Stefanos Baratsas[1], [1]ExxonMobil Technology and Engineering Company, Spring, TX, [2]ExxonMobil Technology and Engineering Company, Spring, TX

Marine Circuit Inventory Routing

We focus on a marine circuit inventory routing problem including: inventory levels and demand for multiple products at multiple ports, tank limits, vessel and port constraints, multiple relative operating costs, and a variety of objectives. We utilize several advanced mathematical programming techniques with a proprietary in-house heuristic algorithm to determine optimal sequence of port visits and product discharge rates to achieve lowest cost, with excellent computational performance.

We handle a complex inventory routing problem considering 20+ ports across several sub regions, multiple products with different priority, and varying numbers of vessels. Our optimal solution can not only consistently outperform existing routes the user derived but also identify non-intuitive opportunities.

4 Assessing Mixed-integer Optimization Models for the Design of Shale Oil Gathering Networks

Demian J. Presser[1], Renzo O. Piccoli[1], Diego Cafaro[2], Ignacio E. Grossmann[3], Yufen Shao[4], Yuanyuan Guo[5], Kevin C. Furman[6], [1]INTEC (UNL-CONICET), Santa Fe, Argentina; [2]INTEC(UNL-CONICET), Santa Fe, Argentina; [3]Carnegie Mellon University, Pittsburgh, PA, [4]ExxonMobil Upstream Research Co, Spring, TX, [5]ExxonMobil Upstream Research, Conroe, TX, [6]ExxonMobil, Houston, TX, Contact: demianup@gmail.com

The design of shale oil gathering networks comprises topological and fluid dynamics considerations. While topological decisions define connections between wellheads, junction nodes and processing facilities, complex fluid dynamics models determine the performance of the pipeline network, and the feasibility of managing production flows over time. The optimal design of gathering networks is addressed in this work with mixed-integer programming models at different levels of detail and complexity, assessing their impact on the quality of the solution. We investigate the effects of alternative topologies and correlations, and provide insights on the need of more detailed approaches, as well as the computational cost of more accurate solutions.

Machine Learning and Data Analytics for Revenue Management

General Session

Session Chair

Ruihao Zhu, Purdue Krannert School of Management, Chicago, IL

1 Detecting Production Planning Problems in Commercial Kitchens

Elena Belavina[1], Yu Nu[2], Karan Girotra[3], [1]Cornell University, New York, NY, [2]Cornell Tech/Cornell University, New York, NY, [3]Cornell Tech/Johnson Cornell University, New York, NY, Contact: belavina@cornell.edu

Sub-optimal inventory management decisions are the root cause of food waste. While laboratory experiments have identified several behavioral errors that drive this sub-optimality, detecting instances of such errors in real-time in a real-world food production environment remains a challenge. In this study, we develop several econometric-modeling based and deep-learning based classifiers to detect common production problems using real-world data streams. We assess the performance of different estimators in different data environments, ranging from full instrumentation—where ordering, production, consumption, and waste data are all recorded—to settings where only the food waste may be recorded. We also evaluate the importance of auxiliary data (such as cooking time, shelf life, batch size) in problem detection.

2 Deep Learning for Visual Advertising on Digital Platforms: Asymptotically Optimal Image Selection

N. Bora Keskin[1], Yuexing Li[1], Shaoxuan Liu[2], Jing-Sheng (Jeannette) Song[1], [1]Duke University, Durham, NC, [2]Shanghai Jiao Tong University, Shanghai, China. Contact: yl492@duke.edu

We consider a digital platform that aims to crop and display a large number of images to maximize customer conversions, i.e., the customer purchasing decisions. For each image, the platform chooses a cropping window and observes the resulting conversions. The platform does not know how cropped images influence conversions. We design a novel two-stage deep learning policy that dynamically learns this relationship and adjusts images to maximize conversions. We derive a theoretical performance guarantee proving the asymptotic optimality of our policy. The A/B testing results showcase that our policy increases the platform revenue by a substantial amount. The case studies based on a real-life data set also reveal that our policy exhibits good performance even if the functional relationship between images and conversion is misspecified.

3 Optimal Experimental Design for Staggered Rollouts

Ruoxuan Xiong[1], Susan Athey[2], Mohsen Bayati[2], Guido Imbens[2], [1]Emory University, Atlanta, GA, [2]Stanford University, Stanford, CA, Contact: ruoxuan.xiong@emory.edu

In this paper, we study the design of experiments that are conducted on a set of units for multiple time periods. These experiments are particularly useful to study the treatments that have causal effects on both current and future outcomes. The design problem involves selecting a treatment time for each unit to most precisely estimate the treatment effects, post experimentation. The optimization is an NP-hard integer program. We provide a near-optimal solution when the design decisions are performed all at the beginning. Next, we study sequential experiments that allow for adaptive decisions during the experiments, and early stops of the experiments. We propose a new algorithm, PGAE, that combines ideas from Bayesian statistics, dynamic programming, and sample splitting. PGAE can adaptively make treatment decisions and draw valid post-experimentation inferences.

4 Context-based Dynamic Pricing with Separable Demand Model

Chonghuan Wang[1], David Simchi-Levi[2], Jinzhi Bu[3], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Massachusetts Institute of Technology, Hong Kong, Hong Kong. Contact: chwang9@mit.edu

We consider context-based dynamic pricing with unknown demand over a selling horizon of T periods. Motivated by the empirical evidence from the real-world dataset, we consider the demand function with a separable structure of the form $f(p)+g(x)$, where p and x denote the price and features. We systematically characterize the statistical complexity of the online learning problem under different assumptions of $f(p)$ and $g(x)$. Specifically, we study three different demand models: (i) $f(p)$ is linear and $g(x)$ is non-parametric; (ii) $f(p)$ is non-parametric and $g(x)$ is linear; and (iii) $f(p)$ and $g(x)$ are non-parametric. For each model, we design an efficient algorithm with provable regret upper bound, and establish a matched lower bound except for an extreme case in model (iii). Finally, we extend to the setting where $g(x)$ is also separable, and show the regret can be further reduced.

Advances in Revenue Management

General Session

Session Chair

Tarek Abdallah, Northwestern University, Kellogg School of Management, Chicago, IL

1 New Approach to Dynamic Pricing

Tarek Abdallah, Northwestern University, Kellogg School of Management

We study a dynamic pricing problem when the firm is selling a single item with limited inventory. We propose a new scaling regime to study this problem where we scale the arrival rate in order to capture markets where demand is high but inventory is limited. We provide closed form asymptotic solutions for the optimal static and dynamic pricing policies in this regime.

2 Pricing Strategies for Online Dating Platforms

Titing Cui, Michael L. Hamilton, University of Pittsburgh, Pittsburgh, PA, Contact: tic54@pitt.edu

In recent years dating apps have become the most common way for new couples to meet. Many of these dating apps use subscription based pricing (SP), where subscriptions to the app are sold at a fixed price. In online dating SP may be controversial as it potentially misaligns the incentives of the platform and its users. The length of these subscriptions periods varies across platforms, but the most extreme version is contract pricing (CP), where the dating app is contracted at a one time price. We study the profit and welfare trade-offs associated with the length of the subscription period, and show that SP offers robust profit guarantees, but for some markets CP may increase both profit and welfare while correcting incentive issues.

3 Hybrid Model for Sequential and Simultaneous Choice with Search Cost

Ruxian Wang, Johns Hopkins University, Carey Business School, Kensington, MD, Contact: ruxian.wang@jhu.edu

We propose a hybrid model to study sequential and simultaneous choice behavior in the presence of search cost. After examining all products in an assortment, a rational consumer decides whether to continue searching. Switching from one assortment to another often incurs a search cost related to transportation expense or time.

4 Learning Consumer Valuation from Bundle Sales

Ningyuan Chen, Setareh Farajollahzadeh, Guan Wang, University of Toronto, Toronto, ON, Canada. Contact: ningyuan.chen@utoronto.ca

When the firm offers bundles of products at discounted prices, one cannot observe the information of the consumers' valuations for individual products from the sales data. Instead, we can only infer the valuation of the bundle. To learn the consumer valuations for individual products from such data, we formulate the inference problem to estimate the distribution of consumers' valuations from the transaction data with bundles and show the equivalence to an inference problem when the observations are censored by polyhedral regions. We develop EM algorithms to estimate the mean and variance of the high-dimensional valuation distribution and provide theoretical guarantees.

Session Chair

Tianyi Peng, Pasadena, CA

1 Markovian Interference in Experiments

Vivek Farias, MIT, Cambridge, MA

We consider experiments in dynamical systems where interventions on some experimental units impact other units through a limiting constraint (such as a limited inventory). Despite outsize practical importance, the best estimators for this `Markovian' interference problem are largely heuristic in nature, and their bias is not well understood. We formalize the problem of inference in such experiments as one of policy evaluation. Off-policy estimators, while unbiased, apparently incur a large penalty in variance relative to state-of-the-art heuristics. We introduce an on-policy estimator: the Differences-In-Q's (DQ) estimator. We show that the DQ estimator can in general have exponentially smaller variance than off-policy evaluation. At the same time, its bias is second order in the impact of the intervention. This yields a striking bias-variance tradeoff so that the DQ estimator effectively dominates state-of-the-art alternatives. From a theoretical perspective, we introduce three separate novel techniques that are of independent interest in the theory of Reinforcement Learning (RL). Our empirical evaluation includes a set of experiments on a city-scale ride-hailing simulator.

2 Synthetic Interventions (i.e., Synthetic A/B Testing)

Anish Agarwal, Massachusetts Institute of Technology, Newton, MA

We introduce the synthetic interventions (SI) framework which connects causal inference with tensor completion. We represent the various potential outcomes (i.e., counterfactuals) of interest through an order-3 tensor. The key theoretical results presented are: (i) Formal identification results establishing under what missingness patterns, latent confounding, and structure on the tensor is recovery of unobserved potential outcomes possible. (ii) The SI estimator to recover these unobserved potential outcomes and proving it is finite-sample consistent and asymptotically normal. We use SI on high-impact applications: (i) TaurRx Therapeutics to identify patient sub-populations where their therapy was effective. (ii) Uber Technologies on evaluating the impact of driver engagement policies without running an A/B test.

3 Provably Efficient Reinforcement Learning for Partially Observable Systems

Masatoshi Uehara, Cornell, New York, NY

We study Reinforcement Learning for partially observable systems using function approximation. We propose a new PO-bilinear framework, that is general enough to include models such as undercomplete tabular Partially Observable Markov Decision Processes (POMDPs), Linear Quadratic Gaussian (LQG), Predictive State Representations (PSRs), as well as a newly introduced model Hilbert Space Embeddings of POMDPs. Under this framework, we propose an actor-critic style algorithm that is capable to performing agnostic policy learning. Given a policy class that consists of memory based policies (i.e., policy that looks at a fixed-length window of recent observations), and a value function class that consists of functions taking both memory and future observations as inputs, our algorithm learns to compete against the best memory-based policy among the policy class.

4 Regret Bounds and Experiment Design for Estimate-then-optimize

Samuel Tan, Peter Frazier, Cornell University, Ithaca, NY, Contact: sst76@cornell.edu

In many real-world applications, the pipeline from data to decisions involve two steps: estimation and optimization. First, a user employs a machine learning model to estimate parameters for an optimization problem, and then they solve that problem using the learned parameters, as if they are correct. This approach is often termed "estimate-then-optimize." However, errors in the estimation step can lead to sub-optimal decisions, where the resulting loss in objective function value is known as regret. Our contribution is a novel bound on this regret when using estimate-then-optimize for smooth and unconstrained optimization problems and a method of using the bound to guide experiment design. In particular, when the fitted parameters are asymptotically normal, we provide a general procedure for experiment design to minimize the regret from estimate-then-optimize.

1 Neural Networks and Column Generation for Parallel Machine Scheduling

Amira Hijazi, Osman Ozaltin, Reha Uzsoy, North Carolina State University, Raleigh, NC, Contact: amhijazi@ncsu.edu

We present a neural network-based column generation (CG) approach for the parallel machine scheduling problem. Each iteration of CG consists of solving a restricted master problem to construct a solution where all jobs are processed and a pricing subproblem for each machine to generate a new column for a subset of jobs to be processed on that machine. We propose to use an encoder-decoder attention model based on the transformer architecture to learn the job sequencing problem on the parallel machines and thus generate columns to add to the master problem. We train this model and present computational results.

2 Tree Search Configuration: Cutting Planes and Beyond

Maria-Florina Balcan[1], Siddharth Prasad[1], Tuomas Sandholm[1], Ellen Vitercik[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Stanford University, Palo Alto, CA, Contact: vitercik@stanford.edu

Cutting-plane methods have enabled remarkable successes in integer programming over the last few decades. State-of-the-art solvers integrate a myriad of cutting-plane techniques to speed up the underlying tree search algorithm used to find optimal solutions. In this talk, we provide the first sample complexity guarantees for learning high-performing cut-selection policies tailored to the instance distribution at hand using samples. We then develop a general abstraction of tree search that captures key components such as node selection and variable selection. For this abstraction, we bound the sample complexity of learning a good policy for building the search tree.

3 Fitting General and Regression Hyperplanes in the Presence of Confounding Outliers

John W. Chinneck[1], J. Paul Brooks[2], [1]Carleton University, Ottawa, ON, Canada; [2]Virginia Commonwealth University, Richmond, VA, Contact: chinneck@sce.carleton.ca

Finding a good hyperplane fit for a large data set in many variables in a small amount of time is a challenging computational problem. A main difficulty is recognizing and removing confounding outliers before making a fit because outliers (especially clustered outliers) can severely skew many fitting methods. We present new methods for fitting hyperplanes to general datasets (to match the points) and for regression (to match the output variable values). We compare our methods to other state-of-the-art hyperplane fitting methods and show that they produce better fits in much less time. The new methods are very fast and scalable and easily handle data sets having thousands of data points in small amounts of time.

4 Capacitated Vehicle Routing with Stochastic Loading Constraints

David Winkelmann, Jakob Schulte, André Hottung, Bielefeld University, Bielefeld, Germany. Contact: david.winkelmann@uni-bielefeld.de

Using homogenous vehicles for the shipping process of packages requires allocating customers to tours with respect to constraints resulting from the characteristics of the vehicle. However, if the shape of packages is highly heterogeneous, the achievable fill rates vary and are unknown when the tours are determined. This leads to an optimisation problem under uncertainty addressing the trade-off between routing costs and penalty costs if not all packages can be loaded into the trucks as planned. We propose to model the problem as a CVRP that integrates a binary regression model to estimate the probability that the packages do not fit into a truck. Using Taylor series expansion of the exponential function allows to reduce the transformation of the linear predictor to a polynomial term, which can be directly incorporated into the Gurobi optimiser.

Political Redistricting

General Session

Session Chair

Maral Shahmizad, Oklahoma State University, Stillwater, OK

1 A Linear-size and Integral Model for Partitioning Planar Graphs with Application in Political Redistricting

Jack Zhang[1], Hamidreza Validi[1], Austin Buchanan[2], Illya V. Hicks[1], [1]Rice University, Houston, TX, [2]Oklahoma State University, Stillwater, OK, Contact: dz27@rice.edu

In this paper, we propose a linear-size and integral formulation with size O(n) for partitioning a planar graph with n vertices into k rooted subtrees. We prove the integrality and correctness of the formulation. We employ the linear-size formulation as the base model to solve the US redistricting problem at county and tract levels respecting three basic criteria: (i) population balance, (ii) connectivity, and (iii) compactness. We conduct a set of computational experiments on the 2020 census data at county and tract levels. We also computationally compare the proposed model with an existing compact model in the literature. Our code and data are available on GitHub.

2 Political Redistricting Optimization with Recombination

Kiera W. Dobbs[1], Douglas M. King[2], Sheldon H. Jacobson[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]U of Illinois at Urbana-Champaign, Urbana, IL, [3]University of Illinois, Urbana, IL

Optimization methods can promote political fairness, transparency, and public engagement in the redistricting process. Although exact methods laid the foundation for political redistricting, realistic instances continue to require heuristics. With a case study on Illinois congressional redistricting, we examine two methods for transitioning between feasible district plans within local search optimization: a more traditional Flip iteration and a recently introduced spanning tree iteration (Recombination). Although local search with Recombination is slower than with Flip, it consistently produces district plans with better objective values.

3 Political Districting to Minimize County Splits

Maral Shahmizad, Austin Buchanan, Oklahoma State University, Stillwater, OK

When partitioning a state into political districts, a common criterion is that political subdivisions (e.g., counties) should not be split across multiple districts. While this criterion is sometimes enforced quite strictly by state law and the courts, it is typically not known how much splitting is truly necessary. We consider two related questions: What is the maximum number of counties that can be kept whole? What is the minimum number of county splits necessary? To answer these questions, we use techniques from integer programming and apply them to USA redistricting instances.

4 A Benders Decomposition Approach for Solving the Majority-minority Districting Problem

Samuel Kroger, Hamidreza Validi, Tyler Perini, Illya V. Hicks, Rice University, Houston, TX, Contact: sak8@rice.edu

Section 2 of the Voting Rights Act enacts creating majority-minority districts to provide minority groups with opportunities to elect representatives of their choice. A majority-minority district is created if at least the following conditions (“Gingles prongs”) are satisfied: (i) compactness and numerosity, (ii) political cohesion, and (iii) sufficiency of white majority vote to defeat the preferred candidate of minorities. Furthermore, if the first condition is not satisfied, then there is no requirement on creating a majority-minority district. Although the second and third Gingles prongs are qualitative measures, the first prong can be captured by mathematical models and algorithms. In this talk, we present a mixed integer programming formulation and a decomposition method for solving the majority-minority districting problem at county and tract levels.

Business Value of Social Media Analytics

General Session

Session Chair
Sukhwa Hong, University of Hawaii at Hilo, Hilo, HI

1 Predicting Mortgage Loan Origination Delays with Text Mining

David Goldberg, San Diego State University, San Diego, CA

Mortgage loan origination, or the process of initiating new loans, is a complex process involving many steps. As a result, the process is rife with delays. We analyze internal conversation transcripts from a large mortgage firm to determine unique words and phrases predictive of delays. We show that predictive models based upon these words and phrases are capable of flagging likely delays before they occur. These results enable cost-saving managerial interventions.

2 Information Disclosure Scores on the Use of Social Media

Daeeun Daniel Choi, California State University, Northridge, Northridge, CA

Smart technology (e.g., the Internet of Things, big data, and artificial intelligence) interacts with various social media to attract consumer attention and improve companies' business values. Collecting and managing consumers' personal information has become the center of their business strategies. However, severe privacy risks threaten consumers because of the disclosed new types of personal information, although many consumers do not recognize the gravity of privacy vulnerability issues. Thus, we adopt a design science research approach to educate consumers about their information disclosure tendency. This study creates individual information disclosure scores when adopting smart technology.

3 Feeling Strong by Mourning in Online Health Communities

Eduardo Villacis-Calderon, Virginia Tech

Online health communities (OHCs) provide virtual spaces where people can exchange social support. Given the nature of conversations, OHCs can quickly become negatively valenced, in which feelings of sadness, anger, and frustration are predominant. These negative emotions can create toxic virtual spaces that people might want to avoid. However, in OHCs, people find a sense of community in which negative valenced communities can bring them together with similar others instead of alienating them. We part from the premise that not all negative experiences contribute to building stronger communities. Therefore, this research investigates virtual interactions that, although negatively valenced, contribute to building strong OHCs.

4 Automated Text Summarization for the Enhancement of Effective Communication

Sukhwa Hong, University of Hawaii at Hilo, Hilo, HI

In this study, we propose a novel abstractive automatic text summarization (ATS) method that first represents the source documents as an intermediate representation and then generates the summary sentences, which do not appear in the original documents for effective communication with the stakeholders. Furthermore, we incorporate a novel deep neural machine translation for generating summary sentences into our summarization process to generate more readable and persuasive summaries. Human assessment is often used to evaluate ATS quality, which makes the evaluation process vague and inconsistent. Therefore, we further incorporate more sophisticated evaluation criteria such as readability and more complex measures such as persuasiveness into our model that are used to determine the quality of the proposed method.

Hanwei Li, Cambridge, MA

1 Course Selection Under Correlated Rankings

Zhenyu Hu, Jussi Keppo, Meixi Wu, National University of Singapore, Singapore, Singapore. Contact: meixi@u.nus.edu

When making course selections, students consider their own assessment of each course's quality and also their peers' course selections. We model each student's quality score for different classes by a factor model comprising a common factor and an idiosyncratic factor. We then analyze course bidding mechanisms, where students' priorities are correlated, and we characterize the equilibrium action profile. The model is identifiable and can be estimated using Bayesian inference. The model can also be applied to other settings, such as job applications.

2 **Managing Spatial Equity in Urban Services: Evidence from the Bike-sharing Industry**

Qihang Yang[1], Weiming Zhu[2], Victor Martinez de Albeniz[3], Jianfeng Lin[1], Zhaochen Dong[1], Jinglong Dai[1], [1]Meituan, Beijing, China; [2]HKU Business School, Hong Kong, Hong Kong; [3]IESE Business School, Barcelona, Spain. Contact: weimingz@hku.hk

Urban services such as dockless bike sharing and last-mile delivery tend to occupy public space while providing service to the targeted users. In regions where the demand for such services is high, the service level may increase, leading to public areas being used more heavily, resulting in spatial equity concerns both on consumer service and the use of public space. In this paper, using the dockless bike-sharing system as an example, we build a mixed-integer program and a reinforcement learning model to determine the optimal bike redistribution policy subject to spatial equity constraints, which are defined by imposing an upper bound on the percentage of the pedestrians that bikes can block. We then conduct a randomized field experiment with Meituan Bike to identify the potential revenue loss due to more equitable redistribution.

3 **Presenter**

Huan Cao, Greenbelt, MD

4 **Assortment Display, Price Competition, and Fairness in Online Marketplaces**

Michelle Wu, MIT Institute for Data, Systems, and Society, Cambridge, MA

Online platforms have been expanding the seller base to widen their product assortment to match the heterogeneous preferences of consumers. Nevertheless, the increasing number of sellers leads to intensified competition and results in sellers setting lower prices for the products. Thus, it is unclear whether displaying all the sellers to the entire customer base maximizes platform revenue. Motivated by the unique setting of Airbnb, we consider a game-theoretical setup in which each seller on the platform provides a single-unit product to a heterogeneous customer base and competes with one another on price. We investigate sellers' optimal pricing decisions and the platform's optimal assortment display policy, which is characterized by the partitioning of products and traffic assigned to each partition. We find that the platform should display the entire assortment to all the customers when demand is sufficiently high. Moreover, we propose a tabulation algorithm and a mixed-integer programming formulation to effectively solve for the sellers' and the platform's optimal decisions. Additionally, we incorporate constraints to guarantee a certain degree of the seller and customer fairness, on both the system and individual level, in the optimal display policy. Using data from Airbnb, we present a case study to illustrate how our model framework can be applied in practice. Finally, we extend the case in which each seller supplies a distinct product with an inventory size of one by considering scenarios in which each product has more than one unit.

Portfolio Risk and ESG

General Session

Session Chair

Steve Y. Yang, Stevens Institute of Technology, Hoboken, NJ

Session Chair

Ruixun Zhang, Peking University, Beijing, China.

1 **Quantifying the Impact of Impact Investing**

Andrew W. Lo[1], Ruixun Zhang[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Peking University, Beijing, China, China. Contact: zhangruixun@pku.edu.cn

We propose a quantitative framework for assessing the financial impact of any form of impact investing, including ESG and other non-financial criteria. We derive conditions under which impact investing detracts from, improves on, or is neutral to the performance of traditional mean-variance optimal portfolios, which depends on whether the correlations between the impact factor and unobserved excess returns are negative, positive, or zero, respectively. Using Treynor-Black portfolios to maximize the risk-adjusted returns of impact portfolios, we propose a quantitative measure for the financial reward, or cost, of impact investing compared to passive index benchmarks. We illustrate our approach with applications to biotech venture philanthropy, divesting from ``sin'' stocks, investing in ESG, and ``meme'' stock rallies such as GameStop in 2021.

2 **The Cost of ESG Investing**

Christoph Schiller, Arizona State University, Tempe, AZ

Even against increasing interest in socially responsible investing mandates, we find that implementing ESG strategies can cost nothing. Modifying optimal portfolio weights to achieve an ESG-investing tilt negligibly affects portfolio performance across a broad range of ESG measures and thresholds. This is because those ESG measures do not

provide information about future stock performance, either in relation to risk or mispricing, beyond what is provided by other observable firm characteristics. That the stock market does not reflect significant equilibrium pricing of ESG information is rationalized in a model of responsible investing wherein investors differ in which ESG-related criteria are used to weight their portfolios.

3 Financial Cost of Carbon

Zachery Halem, Lazard Climate Center, New York City, NY

This paper provides new evidence showing that carbon transition risk is becoming increasingly material and is priced both in equity and debt markets. We find that there is a widespread price-earnings discount linked to corporate carbon emissions. This discount varies, however, by sector and trends differently in Europe than in the US. We also find that a small discount emerges for corporate bonds, although it is statistically significant only for small caps. Finally, we find evidence that the pricing discount also emerges, albeit to a smaller extent, for other greenhouse gas emissions.

Recent Advances in FinTech and Quantitative Finance

General Session

Session Chair

Ning Cai, Hong Kong University of Science and Technology, Kowloon, Hong Kong SAR, China.

1 How and When are High-frequency Stock Returns Predictable?

Jianqing Fan[1], Yacine Ait-Sahalia[2], [1]Princeton University, Princeton, NJ, [2]Princeton University, Princeton, NJ

This paper studies the predictability of ultra high-frequency stock returns and durations to relevant price, volume and transactions events, using machine learning methods. We find that predictability in high frequency returns and durations is large, systematic and pervasive over short horizons. We identify the relevant predictors constructed from trades and quotes data and examine what determines the variation in predictability across different stock's own characteristics and market environments. Next, we compute how the predictability improves with the timeliness of the data. Finally, we simulate the impact of getting an (imperfect) peek at the incoming order flow in terms of improving the predictability of the following returns and durations.

2 Foreign Exchange Market Frictions and Remedies for Companies

Haokun Du[1], Yan Zeng[2], Wenhui Zhao[3], [1]UTD, Richardson, TX, [2]SYSU, Guangzhou, China; [3]SJTU, Shanghai, China.

Frictions in foreign exchange market lead to inefficiencies in internationally operating companies. The conversion costs stemmed from centralized financial market can be remedied through decentralized tradings, as inspired by a Chinese company and other anecdotal evidence. Two mechanisms, forward contract and ad-hoc contract, are considered. Although ad-hoc contract utilizes more information and is locally optimal at any information set, it distorts incentives, having less potential in raising quantities, and leading to possible coordination issues. We argue that a "one-size-fits-all" forward contract can outperform ad-hoc contract in most relevant cases. We also discuss other possibilities.

3 Robustness of Stackelberg Mean-field Games Through an Optimization Lens

Jiacheng Zhang, UC Berkeley, IEOR department, Berkeley, CA, Contact: jiachengz@berkeley.edu

We consider a discrete-time Stackelberg mean field game (SMFG) with one leader and an infinite number of homogeneous followers. Stackelberg game has attracted recent interest modeling an asymmetric, general sum game between leaders and followers. We focus on a robust setting where the followers have bounded rationality and only aim at achieving some $\ep$-Nash equilibrium (NE) while the leader wants to maximize her objective in the worst case scenario among all $\ep$-NEs. We formulate this problem into an explicit minimax optimization problem and propose algorithms to solve the problem when the leader has a finite number of actions. Finally, we also study the sensitivity analysis when the leader only has access to some perturbed model and our results suggest that one needs to be more pessimistic in this case and solve a relaxed problem to obtain a near optimal solution.

4 Total Positivity and Option Pricing

Dan Pirjol[1], Paul Glasserman[2], [1]Stevens Institute of Technology, Hoboken, NJ, [2]Stevens Institute of Technology, New York, NY, Contact: dpirjol@stevens.edu

Option prices are not convex in maturity or volatility; however it was shown recently that in the Black-Scholes model, the price of an option is convex in the price of an at-the-money option with the same maturity. We extend this result to a more general class of models satisfying a total positivity

(TP) property.We derive several implications of the TP property, including: i) monotonicity of option price ratios C(K,T)/C(F,T) in the maturity T variable; ii) constraints on the slope of the ATM skew. Empirical tests of the TP property suggest that it holds to a good approximation close to the at-the-money region.

1 Black Music Matters as Well? The Spillover Effects of #blacklivesmatter on Digital Music Consumption in the United States

Yifei Wang[1], Gorkem Ozer[2], Anandasivam Gopal[3], [1]University of Maryland, College Park, MD, [2]University of New Hampshire, Durham, NH, [3]Nanyang Technological University, Singapore, Singapore.

Social movements and music are closely intertwined. In this paper, we examine how the pattern of music consumption across popular music genres may be systematically affected by the Black Lives Matter (BLM) movement in the summer of 2020. Furthermore, we explore how changes in the music consumption associated with BLM may vary across subgroups of artists, driven by the interactive effects of artist race and gender. Using streaming data from Spotify, we observe a clear and significant effect of BLM 2020 on the diversity of music streaming across genres and artists. Our paper shows that social movements that seek to address racial equality led to meaningful changes in the music consumption patterns.

2 Online Review Censorship

Aida Sanatizadeh[1], Gordon Burtch[2], Kevin Hong[3], Yuheng Hu[4], [1]University of Illinois at Chicago, Chicago, IL, [2]Boston University, Boston, MA, [3]University of Miami, Miami, FL, [4]University of Illinois-Chicago, Chicago, IL

Ample anecdotal evidence in the media notes that many businesses seek to 'silence' negative reviews, e.g., via legal threat. Despite attention toward this issue, we are aware of no systematic analyses addressing it. We address that gap here, leveraging review data from TripAdvisor.com. We show that a 1-star decrease in rating valence is associated with an approximate 25% (0.25 pp) increase in the probability of deletion. Additionally, we examine how freedom of expression (FoE) in a country associate with characteristics of (uncensored) online reviews. Lastly, we discuss implications for online ratings platforms, consumers, and research opportunities.

3 Does Board Gender Diversity Matter in It Investment

Yen-Yao Wang, Sidi Zhao, Pei Xu, Auburn University, Auburn, AL, Contact: yenyao@auburn.edu

This paper examines the role of corporate governance on IT investment by examining whether board gender diversity would influence IT investment. To address this research question, we merged three data sources: Computer Intelligence technology database for IT investment data, Institutional Shareholder Services for board information, and Compustat for firm performance-related data. Our sample has an unbalanced panel of 10,945 firm-year observations with 1,381 firms from 2007 to 2019. Using the firm-level fixed effects and fixed effects two-stage least squares models, we provide initial evidence that increased female board representation is positively associated with IT investment.

4 Adding AI to the Shared Medical Decision Model - How Medical AI Affects Patient-clinician Relationships

Jeff Clement[1], Sofia Bapna[2], Maura Jacobi[3], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota Carlson School of Management, Minneapolis, MN, [3]United Family Medicine at Allina Health, St. Paul, MN, Contact: cleme514@umn.edu

Artificial intelligence (AI) can improve medical decision-making by providing personalized diagnosis or treatment recommendations to overcome human judgement, especially in chronic or rare conditions. There are now more than 80 medical AI tools that have received FDA approval, and research continues to enhance our understanding of how clinicians employ these systems. However, little work has been done to understand how a clinician's use of AI and their subsequent decision to disclose the use of the AI tool (or not) impacts the patient-clinician relationship. We present preliminary results of a qualitative analysis to show that disclosing use of AI can increase trust in the doctor. On the other hand, consulting an AI system could signal that the doctor is less capable and qualified. We also present initial guidelines for discussing AI tools with patients.

5 A Novel Stackelberg Game to Understand the Incentivization of Federated Learning

Chaofan Zhai, Xuan Bi, Mochen Yang, University of Minnesota, Minneapolis, MN, Contact: zhai0045@umn.edu

Federated learning (FL), as a promising paradigm for data privacy, can help organizations cooperatively train a global machine learning model without exchanging their local data. However, the situations and incentivization under which organization cooperation exists are still open to discussion. In this work, we build a novel two-stage Stackelberg model, framing the role of a leader and a follower in FL. We find organizations perform distinct strategies under the heterogeneity in terms of data size, cost-benefit ratio, and the uncertainty of model success.

6 Empathic Interaction and Knowledge Exchange in Online Communities: An Expectation-satisfaction Perspective

Tao Wang, Pek-Hooi Soh, Simon Fraser University, Vancouver, BC, Canada. Contact: wangtaow@sfu.ca

Do users in online communities gain more knowledge when they display more empathy cues such as sadness and anxiety? Adopting expectation-satisfaction theory, we examine the impact of empathic interaction on knowledge acquisition in online communities. While empathy cues may elicit other's empathy and encourage helping behaviour, they also signal seeker's high expectation and potentially high cost. We hypothesize that online inquiries with more empathy cues will likely receive fewer but better-quality responses and that the provider's empathy is the mediating mechanism that dissipates the costs and improves the reply efforts. We found support from the log data of a public online community.

7 Value of Healthcare Information Technology and Advances in Medical Sciences: Can Patients Contribute?

Ruba Aljafari[1], Franck Loic Soh Noume[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of North Carolina, Greensboro, NC, Contact: raljafari@katz.pitt.edu

Research on the value of healthcare IT (HIT) suggests that patients are key information providers/recipients who realize value or contribute to value. The main assumption is that HITs operate in environments where medical practice is based on timely findings from medical sciences. However, healthcare industries express concerns about lack of advancement in medical sciences. HIT may support medical sciences by accessing and processing rich data, but less is known about the value of research capabilities that leverage IT (e.g., analytics/artificial intelligence) and whether the patient perspective matters. We explore synergies between these capabilities and HIT from the patient perspective.

8 Flash Paper

Agnes Yang, Jason Chan, University of Minnesota, Minneapolis, MN, Contact: yang6972@umn.edu

The goal of this study is to provide the initial understanding of the role of a decentralized autonomous organization (DAO) in Decentralized Finance (DeFi), both enabled by blockchain technologies. Whereas the rise of this collective decision-making system ostensibly promises a more democratic, effective decision-making, not only decisions are de facto driven by a handful of entities but the effectiveness remains questionable. In this study, we focus on the governance of DeFi, rapidly burgeoning financial markets that aim to replace traditional finance by removing intermediaries. We utilize exogenous cyberattack on the platform which is deadlier in the crypto world where code is law.

1 Physician Discretion and Patient Pick-up: How Familiarity Encourages Multitasking in the Emergency Department

Bradley R. Staats[1], RJ Niewoehner[2], Diwas S. KC[3], [1]UNC, Chapel Hill, NC, [2]UNC Kenan-Flagler Business School, Chapel Hill, NC, [3]Emory University, Atlanta, GA, Contact: Bradley_Staats@kenan-flagler.unc.edu

What leads Emergency Department physicians to select which patients, and how many patients, they will treat? Queuing models frequently assume individual servers operate independently of other servers. In contrast, we consider how familiarity between peer physicians affects patient selection and the chosen multitasking level, a process more commonly known in the ED as patient pick-up.

2 Balancing Agent Retention and Waiting Time in Service Platforms

Marcelo Osvaldo Olivares, Andres Musalem, University of Chile, Santiago, Chile.

Online platforms have enabled service companies to access a large pool of employees with flexible working hours, operating at low levels of utilization without increasing operating costs. We conduct an empirical study in an online call-center platform to analyze how worker utilization may also effect employees attrition and show how this trade-off should be accounted for in the design of the service platform to plan capacity in order to balance responsiveness with employee retention.

3 OR Special Issue on Behavioral Queueing Science: Summary

Armann Ingolfsson, University of Alberta, Edmonton, AB, Canada. Contact: armann.ingolfsson@ualberta.ca

The intent of the special issue of Operations Reseach on behavioral queueing science is to advance the dialogue between empirical researchers, data scientists, and mathematical modelers. We outline the ways in which the papers that will be published in the special issue advance knowledge about how servers and customers behave and interact, and how such behaviors can be inferred, modelled and analyzed.

4 The Relationship Between Expected Service Times and Service Rates in State-dependent Queues

Likang Ding[1], Bora Kolfal[2], Armann Ingolfsson[2], [1]University of Alberta, Edmonton, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada. Contact: likang@ualberta.ca

Queueing models are typically formulated in terms of service rates but recent empirical queueing research focuses on expected service times. We analyze service times in Markovian queueing models with state-dependent service rates. Our primary research question is to analyze the relationship between service rates and expected service times. We provide closed-form solutions to convert service rates into expected service times and vice versa. Contrary to what is sometimes assumed, in general, expected service times are not the inverse of service rates, and service times in state-dependent Markovian systems are not exponentially distributed. We find conditions under which monotonicity in service rates implies monotonicity in expected service times and vice versa. Furthermore, we characterize service time distributions in state-dependent systems.

1 Preference or Bias: Characterizing Political Slants Toward Equity on a Donation Platform

SIyu Shi, Ian Ho, Brian Lee, Jingchuan Pu, Pennsylvania State University, State College, PA, Contact: siyu.shi@psu.edu

Political preferences refer to the support and attachment toward specific political ideologies. Political preferences directly induce political party affiliation and could indirectly affect non-political decision-making. We study the impact of political preferences on K-12 donations. Ideally, educational donations shall be need-based, i.e., the universal value across party affiliations. In our quasi-experiments, we show a fund-raising school on average suffers from a 2.82% loss of funds due to the party change of the state governor. Such a politics-driven loss leads to an additional disadvantage for majority-minority schools by 0.34%. We also confirm that the donations from the safe states (vs. swing states) are affected by the election results significantly, deviating from the original purpose of educational donations and hurting social welfare.

2 Learning from Machines: Can AI Tools Enhance Human Learning Online?

Mi Zhou[1], Arslan Aziz[1], Xiyang Hu[2], [1]UBC Sauder School of Business, Vancouver, BC, Canada; [2]Carnegie Mellon University, Pittsburgh, PA, Contact: mi.zhou@sauder.ubc.ca

The advancement of artificial intelligence (AI) has been profoundly changing business and society in different settings. In this research, we investigate whether, and how, AI tools can improve the outcome of human skill acquisition. We choose online chess as our research context as chess is a cognitively demanding analytical task that has advanced AI engines which can provide real-time performance analysis and feedback of chess games. We conduct a randomized field experiment to empirically estimate the causal impact of having access to AI-based analysis and feedback on the extent of improvement in user performance. We find that AI-based tools can significantly improve learners' performance by effectively identifying the weaknesses in their gameplay. Our paper contributes to the literature on the efficacy and efficiency of online learning with scalable AI-based tools.

3 Uncovering Demand Distributions and Consumer Network Effects --- Evidence from Vending Machine Transactions

Mingrui Zhang[1], Yong Tan[1], Xusen Cheng[2], [1]University of Washington, Seattle, WA, [2]Renmin University of China, Beijing, China. Contact: mz74@uw.edu

Vending machines are convenient and they allow customers to gain quick access to small items in a timely and cost-saving manner. We build a consumer network to uncover the consumer learning effect of visiting vending machines multiple times. Combining the settings information with the user information, we construct estimates of the vending machines' demand distributions in different settings across twenty-one million transactions from January 2019 to May 2022.

4 Product Positioning and The Value of Learning from Competitors

Jiaying Deng[1], Yingfei Wang[2], Yong Tan[2], Zhijie Lin[3], [1]Fordham University, bromx, NY, [2]University of Washington, Seattle, WA, [3]Tsinghua University, Beijing, China.

We aim to model suppliers' decision on product variety strategy. Product variety is an important strategic tool that suppliers can use to attract customers and respond to competition. However, sharing economy is different from traditional business model, because the supplier on the markets are non-professional individuals. Thus, it is still not clear whether individual suppliers learn from competitors. Some of them may lack the ability or knowledge to conduct marketing analysis, so, the variation in paying attention to the competitor's information can help us examine the value of learning from competitors. Also, we use a network embedding approach to measure the competitive market structure on the platform. In the second stage, we model suppliers' decision regarding the product variety strategy under different competition environment using a Bayesian learning model.

JWM - Room 201

Business Decision Making for Innovative Outcomes

General Session

Session Chair

Junghee Lee, University of Notre Dame, Notre Dame, IN

1 Designing Knowledge Driven Innovation Contests

Lakshminarayana Nittala[1], Sanjiv Erat[2], [1]University of Dayton, Dayton, OH, [2]University of California-San Diego, La Jolla, CA

Innovation contests are studied primarily as a mechanism to obtain extreme valued solutions. In the current work we propose that the conceptualization of innovation contests needs to be expanded to also consider the long-term benefits from the knowledge/capabilities generated by the contestants' efforts. We develop a novel framework that explicitly includes the generation and utilization of knowledge by participants in an innovation contest, and we analyze the implications of this framework for the design of serial contests.

2 Preference Uncertainty and Information Asymmetry in Online Matching Platforms

Amit Basu, Sreekumar R. Bhaskaran, Rajiv Mukherjee, Southern Methodist University, Dallas, TX, Contact: sbhaskar@mail.cox.smu.edu

Online match-seekers face two related challenges across two orthogonal dimensions of uncertainty. First, due to uncertainty in their subjective preferences, match-seekers may not know what candidates would be compatible with them. And second, due to information asymmetry in online settings, candidates may misrepresent their credentials. Using a stylized model, we analyze whether an online matching platform should enhance its search services with a counseling service that helps match-seekers determine the subjective compatibility of potential matches, and also whether it should offer an authentication service that reliably verifies the objective quality of match-seekers. One of the interesting results is that counseling and authentication can be substitutes or complements even though they address two orthogonal dimensions of uncertainty.

3 Leveraging the Potential of Outsourcing and Offshoring in Complex Product Development

Ole Frauen[1], Arnd Huchzermeier[2], Jurgen Mihm[3], [1]Volkswagen AG, Braunschweig, Germany; [2]WHU - Otto Beisheim School of Management, Vallendar, Germany; [3]Insead, Fontainebleau, France. Contact: ole.frauen@volkswagen.de

Leveraging the potential of outsourcing and offshoring remains a major challenge in complex product development. It is a question about effectively decomposing and distributing work across geographical and organizational boundaries while providing high quality products. The decisions must clearly depend on the product's characteristics and the emerging collaborative network. The study is based on an extensive data set involving all development projects of one of the largest car manufacturers worldwide. We demonstrate that a precise distinction between outsourcing and offshoring, as well as the introduction of a network perspective, are crucial to evaluate the effects in more detail.

4 **Voting Rules and Decision-Making by Committee**
Tian Chan[1], Panos Markou[2], [1]Emory University's Goizueta Business School, Atlanta, GA, [2]Darden School of Business, Charlottesville, VA, Contact: markoup@darden.virginia.edu
How do voting rules affect decision-making by committee? We hand-collect data from FDA advisory committee meetings (e.g., meeting transcripts, individual members, and voting outcomes) between 1997-2020, where experts discuss the safety, efficacy, and risk-benefit profile of novel drugs and medical devices. We study whether a 2006 change in voting rules (from sequential and visible voting, to simultaneous and anonymous voting) affected the deliberation and information-gathering process and outcome of a committee meeting.

JWM - Room 202
Negotiation Models
General Session

Session Chair
Danielle C. Costa Morais, Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil.

Session Chair
Liping Fang, Ryerson University, Toronto, ON, Canada.

1 **E-negotiation Model to Assess Offers and Select a Supplier in Agribusiness**
Over Manuel Causil, Danielle C. Costa Morais, Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil. Contact: dcmorais@insid.org.br
The negotiation process covers the exchanging of offers and counteroffers between the negotiators. In order to aid this process of making offers and counteroffers, and evaluating tradeoffs among conflicting negotiation objects an electronic negotiation support system (e-NSS) can be used. We propose a negotiation model using an e-NSS applied in agribusiness to select a packaging supplier. Price, delivery time, and green manufacturing practices were used as negotiation objects. The negotiation process was carried out with five potential suppliers where a final compromise was achieved with a single provider.

2 **Negotiations or Auctions for B2B Transactions: Lessons Learned from Comparison Studies**
Bo Yu[1], ShiKui Wu[2], Rustam Vahidov[3], [1]Dalhousie University, Halifax, NS, Canada; [2]Lakehead University, Thunder Bay, ON, Canada; [3]Concordia University, Montreal, QC, Canada. Contact: bo.yu@dal.ca
Both negotiations and auctions are capable of dynamically producing a deal between buyers and sellers. However, the choice of the appropriate exchange mechanism for various types of transactions still needs further investigation in B2B context because firms are not only concerned with economics but also with relational consequences when trading with each other. This paper reviews the studies comparing negotiations and auctions in the last three decades. The inclusion of both substantive and subjective outcomes in the assessment of the two mechanisms helps better understand their impacts. In addition, the concept of fairness helps explain how the mechanisms induce mixed motives for both competition and equity driving auctions and negotiations.

3 **Transforming Complex Social Systems: Insights from Systems Analysis and Negotiation**
Tim McDonald, Pardee RAND Graduate School, Santa Monica, CA, Contact: tmcdonal@prgs.edu
Effective response to public problems, and achieving societal goals, typically require efficient problem solving and adapting on the part of public leaders. Sometimes however effective response requires reshaping social systems to transform them over time. The challenge for leaders in democratic societies is to meet to near-term needs and expectations while also addressing the complex, systemic origins of challenges and creating new opportunities - such as promoting health, personalized learning, or rapidly pursuing renewable energy - that are only available through system transformation. This paper examines what the literatures from two fields - systems analysis and negotiation - can contribute to understanding how to transform complex systems, and how they can improve public decision making.

4 **Negotiation Support Using the Inverse Graph Model for Conflict Resolution**
Liping Fang, Ryerson University, Toronto, ON, Canada.
By using inverse graph model for conflict resolution (GMCR), a decision maker or third party can determine the required preferences to make a particular state to be individual stable or equilibrium. A survey of the current research in the inverse GMCR is presented first. The inverse GMCR analysis is being explored in two directions: (1) ascertaining all the possible required preferences for partially or completely unknown

initial preferences; and (2) determining the preferences with the minimal adjustment of decision makers' initial preferences, such that a particular state is individual stable or equilibrium. How the inverse GMCR can be utilized for negotiation support is discussed.

Sunday, 2 PM–3:15 PM

JWM - Room 203
Amazon Supply Chain Science
General Session

Session Chair
Garrett J. van Ryzin, Amazon Corporate LLC, Brooklyn, NY

1 **A Framework for Top-down Vs. Bottom-up Forecasting**
Rishab Guha, Amazon
A common question in applied forecasting is whether it makes sense to produce forecasts at the lowest possible granularity, and aggregate up to a desired top-level forecast, or forecast the top-level directly. We provide a theoretical model, and simulation evidence which shows that, in general, a top-level forecast will be able to estimate aggregate factor dynamics that may be obscured at fine granularity. We show that aggregate forecasts can be used to automatically generate features that can improve the calibration and predictive performance of bottom-level forecasts.

2 **Inventory Management in a Multi-product Capacitated Network with Dynamic Fulfillment**
Salal Humair[1], Nanjing Jian[2], Alp Muharremoglu[1], Yan Xia[3], [1]Amazon.com, Bellevue, WA, [2]Amazon.com, Bellevue, WA, [3]Amazon.com, Bothell, WA
Amazon uses automated replenishment algorithms to purchase and distribute tens of billions of inventory units through its fulfillment network every year. Those algorithms are designed to maximize the long-term profit, by optimizing the tradeoffs between local in-stock, the usage of limited capacity resources, and the end-to-end supply chain cost. To tackle this problem at Amazon scale, we formulated it into a constrained inventory optimization under a dynamic fulfillment policy with stochastic demand. We developed a distributed Lagrangian decomposition framework to solve the problem for each product independently, and a novel procedure to optimize the service-level threshold at each warehouse under the dynamic fulfillment policy. The model has been launched in North America and Europe, showing significant improvement in Amazon's long-term profit.

3 **Optimizing Large-scale Fulfillment Networks by Column Generation and Time-space Graphs**
Yufei Wang, Vinicius L. Lima, Weihong Hu, Prashant R. Nittoor, Luciana S. Buriol, Amazon, Bellevue, WA
Amazon operates a fulfillment network of an unprecedented scale with thousands of locations and shipping lanes that transport millions of packages daily from warehouses worldwide to individual customer homes. It is critical to keep the network in the most efficient state to minimize operation cost and maximize delivery speed. The optimization problem in this work involves how to change the network in a weekly basis, considering removal/addition of shipping lanes, departure times to adjust, and shipment routing. We present an integer programming model based on a time-space graph that captures both the topological and temporal aspects of the fulfillment network. As a solution approach, we modify the network topology heuristically and, for each configuration, we solve the network flow plan with a specialized column generation to scale the problem of such magnitude.

JWM - Room 205

spORts I

General Session

Session Chair

Aaron Bradley Hoskins, California State University, Fresno, Fresno, CA

1 Knuckleball Spin Rates Analysis

Aaron Bradley Hoskins, California State University, Fresno, Fresno, CA

This study investigates the reported spin rates of knuckleballs in the Statcast database. It analyzes pitches identified as knuckleballs to determine if the reported spin rates are consistent with the pitch being a true knuckleball or if the pitch is likely to be a different type of pitch.

2 Analysis of Pitcher Performance of Those Following Slow Pitchers

Parker Hill, Aaron Bradley Hoskins, California State University, Fresno, Fresno, CA, Contact: ph0011@mail.fresnostate.edu

The goal of this research is to assess the effects of slow pitchers in the MLB on the pitchers and batters that follow them. In particular, this project aims to quantify the likeliness of various scenarios including strike-outs, balls, homeruns, and other variations of play scenarios as a result of the change from slow to average/faster pitcher. The data used in this paper included all of the pitching logs for the 17 pitchers that had no pitches above 90 mph and the pitching results of those that followed immediately after them in their respective games during the 2021 baseball season.

3 Performance Enhancing Drugs in the Olympics, Russia's Role and Effective Sanctions

Raymond Stefani, California State University, Long Beach, Lake Forest, CA, Contact: Raystefani@aol.com

Performance enhancing drug use in the Ancient and Modern Olympics is reviewed. Thomas Hicks was helped by strychnine and brandy to win the 1904 Olympic marathon, although he nearly died. The first drug disqualification was in 1968 for a drunken shooter in the modern pentathlon. 100m winner Ben Johnson was famously disqualified in 1988 for steroid use, triggering drug testing in 1992 for athletics and in 1996 for swimming, immediately causing worse winning performances in both sports, indicating the extent of drug use. Russia and its former republics are responsible for 60% of Olympic medals stripped for drug use; however, most actions taken against Russia were generally not sanctions at all. A number of strong sanctions are suggested to require compliance with anti-drug standards and to put an end to psychological abuse as was seen for Kamila Valieva, once wartime sanctions end.

4 The Evolution of Seeding Systems and the Impact of Imbalanced Groups in FIFA Men's World Cup Tournaments 1954-2018

Michael A. Lapre, Vanderbilt University, Nashville, TN

We empirically assess competitive imbalance in FIFA World Cup tournaments. Using least squares, we determine ratings for all teams. For each team, we average the ratings of the opponents in the group to calculate group opponents rating. We find that even a modest decrease in group opponents rating by just a single goal can increase a team's probability of reaching the quarterfinal by 51%. None of the five seeding systems used by FIFA during 1954-2018 were effective in eliminating this unfair effect of group opponents rating. We close with several policy recommendations to restore competitive balance at the World Cup.

JWM - Room 206
Bayesian Optimization
General Session

Session Chair
Peter Frazier, Cornell University, Ithaca, NY

Session Chair
Raul Astudillo, Cornell University, Ithaca, NY

1 Multi-step Budgeted Bayesian Optimization with Unknown Evaluation Costs

Daniel Jiang[1], Raul Astudillo[2], Max Balandat[1], Eytan Bakshy[3], Peter Frazier[2], [1]Meta Core Data Science, Menlo Park, CA, [2]Cornell University, Ithaca, NY, [3]Meta Core Data Science, New York City, NY, Contact: drjiang@fb.com

Most Bayesian optimization algorithms ignore how evaluation costs, which are often unknown, may change over the optimization domain. An unknown cost function with a budget constraint introduces a new dimension to the exploration-exploitation trade-off, where learning about the cost incurs the cost itself. We propose a new dynamic programming-based acquisition function for this problem setting.

2 Bayesian Optimization for Non-Stationary Functions

Mohit Malu[1], Giulia Pedrielli[2], Gautam Dasarathy[3], Andreas Spanias[1], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Scottsdale, AZ, [3]Arizona State University, Tempe, AZ, Contact: mmalu@asu.edu

Bayesian Optimization with Gaussian Process prior typically assumes stationarity of the underlying function over the search space, but many real-world applications require optimizing non-stationary function. Non-stationary function can be considered as a set of stationary functions over the input space divided into multiple partitions with one class of stationary function in each partition. Often in control system setting we have access to class information along with the function evaluation. In this work, we propose a novel optimization technique Class-BO (Class Bayesian Optimization) for the non-stationary functions. We compare the empirical performance of Class-BO and show that it outperforms other non-stationary methods.

3 Achieving Metric Diversity for Sample-efficient Search of Multiobjective Optimization Problems

Eric Hans Lee, SigOpt, CA

Performing multi-objective optimization of important scientific applications such as materials design is becoming an increasingly important research topic. This is due largely to the high costs of said applications, and the resulting need for sample-efficient, multimetric optimization methods that efficiently explore the Pareto frontier to expose a promising set of design solutions. We propose moving away from using explicit optimization to identify the Pareto frontier and instead suggest searching for a diverse set of outcomes that satisfy user-specified performance criteria. This presents decision makers with a robust pool of promising designs and helps them better understand the space of good solutions. To achieve this outcome, we present the Likelihood of Metric Satisfaction acquisition function and demonstrate its viability on various problems.

Sunday, 2 PM–3:15 PM

JWM - Room 207
Teaching and Learning Flash Session
Flash Session

Session Chair
William P. Millhiser, Baruch College, City University of New York, New York, NY

1 Ease of Text Analytics with Visual Programming

Dursun Delen, Oklahoma State Unviersity, Tulsa, OK, Contact: dursun.delen@okstate.edu

Text analytics is the nontrivial process of converting textual data into actionable insight. The underlying framework leverages natural language processing (NLP), computational linguistic (CL), pattern recognition, and both supervised and unsupervised machine learning methods. This presentation will focus on the ease of developing text analytics projects using visual programming environment, KNIME Analytics Platform. Two of the most popular text analytics applications, namely sentiment analysis and topic detection, will be used as exemplary cases.

2 The Brain-based Learning and Teaching Relationship Map

Luis J. Novoa, Baback Vaziri, James Madison University, Harrisonburg, VA, Contact: vaziribx@jmu.edu

The Brain-based Learning and Teaching (BBLT) map relates brain-based teaching techniques that highlight the benefits of neuroplasticity with well-known teaching principles.

We identify several of these brain-based techniques and hypothesize positive and negative feedback relationships among various constructs. The identified relationships in the map allow structure to test different ways to improve teaching experiences using an active, collaborative, and experiential approach, which we consider critical nowadays in the OR/MS and business analytics education field.

3 The Future of OR/MS Education: The NSF Visioning Report

Alexandra Medina-Borja, US National Science Foundation, Alexandria, VA, Contact: amedinab@nsf.gov

What is the future of operations research and management sciences' education? In 2020, the US National Science Foundation (NSF) released a visioning report "STEM Education for the Future." At the same time, NSF funded the National Academies of Science, Engineering and Medicine to call a national and urgent conversation about the future of STEM education. Both were planned well before 2020, but the recommendations for the future were extraordinarily valid when the pandemic stroke. This presentation will discuss what is the meaning of the recommendations for the future of operations research and management science undergraduate and graduate education. The presenter will open the floor for a discussion on what are the challenges and opportunities for the formation of OR professionals.

4 Analysis of the Incorporation of Current Trends in Supply Chain Management Within Curricula

Matthew J. Drake[1], Paul H. Pittman[2], [1]Duquesne University, Pittsburgh, PA, [2]Indiana University Southeast, New Albany, IN, Contact: drake987@duq.edu

The field of supply chain management is constantly changing in response to innovation and societal developments. Curricula in supply chain management programs must update to stay current. Each year the Association for Supply Chain Management (ASCM) publishes a list of the top trends in supply chain management. We discuss results of a survey examining the extent to which these trends are being covered in supply chain management programs. We also provide suggestions for programs that wish to incorporate these trends into their curricula as well as for researchers seeking to develop effective new teaching materials.

5 Flash Paper

Sinan Tas, University of Wisconsin-Madison, Madison, WI, Contact: tas@wisc.edu

Gamification is a tool that can increase attention and promote learning. In this talk, we will talk about how this tool can be applied in a classroom setting to bolster diversity and inclusion. We will provide a multi-year study and discuss how certain components of gamification can contribute to the engagement of students from diverse backgrounds and help support an inclusive learning environment.

6 Predictive Analytics and Decision Modeling in the BBA Core Curriculum

William P. Millhiser, Amita Singh, Baruch College City University of NY, New York, NY, Contact: william.millhiser@baruch.cuny.edu

The Zicklin School of Business at Baruch College, the largest AACSB-accredited business school in North America, replaced calculus in the BBA required core curriculum with "Foundations of Predictive Analytics and Decision Modeling." The intended outcomes for this change are to enhance students' quantitative reasoning skills, to better prepare students for upper level classes, and to update the curriculum for relevancy to the current job market. This presentation describes the new course, reasons for the change, the impact on CUNY's community colleges, and what we've learned in the first two years of implementation.

AAS Best Student Presentation Competition 2/3

Award Session

Session Chair

Keji Wei, Sabre, Grapevine, TX

1 Award Presenter

Xuan Jiang, UCB

Evaluating a potential air corridor is an essential step in the planning and organization of urban air mobility operations. Metrics typically used for this purpose are evaluated by simulation and optimization, which can be time and resource consuming. We propose to explore metrics to evaluate urban air corridor design that (1) are based on traffic data, and (2) provide temporal and spatial (i.e. multi-objective) purpose-specific insights, without the need for simulation. The metrics will account for different stakeholder interests, such as, safety from legacy traffic and environmental impacts, in the evaluation of the corridor designs. For this study, the corridor is described as a rectangular cuboid composed of several smaller cuboids based on the vertical and lateral distance thresholds derived from FAA regulations. Aircraft time within a cuboid, the number of aircraft within the cuboid within a certain period and location slices of the corridor are used to evaluate the proposed air corridors. The paper also discusses methods for choosing the best corridors from a given set as well as the best corridor for a given region. The methodology is demonstrated with a case study based on air traffic data within 150 miles of Edwards Air Force Base in Los Angeles, California. Experiments show that the proposed metrics can help stakeholders gain both spatial and temporal insights without the need for simulation.

3 Identification and Prediction of Disruptions in Airline Networks

Xiyitao Zhu, University of Illinois Urbana-Champaign, Urbana, IL

Air transportation disruptions can lead to demand-capacity imbalances, resulting in flight delays and cancellations due to traffic management actions. To facilitate better system recovery and enable near-real time decision support for prescriptive management actions, it is crucial to better understand system disruptions as well as predict their evolution. We first formalize the notion of disruption-recovery trajectories (DRTs) by representing key network delay and cancellation performance metrics as transitions between discrete states. Based on the DRT framework, we then develop two distinct prediction models: The first model seeks to predict the trend of key performance metrics, the second identifies whether or not the system will recover in a few hours. We report prediction results for four major US airlines, and elaborate on next steps.

4 Airline Dynamic Offer Creation Using a Markov Chain Choice Model

Kevin Wang, MIT, Cambridge, MA

We present a novel approach to the pricing and assortment optimization of airline ancillary offers using the Markov chain choice model (MCCM). A potential breakthrough in bundle price optimization, the MCCM decomposes the complex problem into a finite number of univariate optimization problems. We show how MCCM-based pricing adapts to the customer context, either increasing revenue by incentivizing customer buy-up to bundle offers or recommending a la carte pricing, when the customer cannot afford bundles or only finds few products relevant. We quantify the revenue benefit of dynamic offer creation by comparing MCCM bundle pricing and offer set selection against an a la carte baseline, both with and without targeted offer sets and prices.

Airline Operations and Manpower Planning

General Session

Session Chair

Stacey Mumbower, Embry-Riddle Aeronautical University

1 Human Power Planning at Airlines

Burak Cankaya[1], Bulent Erenay[2], Eyyub Yunus Kibis[3], Aaron Glassman[4], [1]Embry Riddle Aeronautical University, Daytona Beach, FL, [2]Ohio University, Columbus, OH, [3]Montclair State University, Montclair, NJ, [4]Embry-Riddle Aeronautical University, Virginia Beach, VA, Contact: bcankaya@erau.edu

Human power planning for pilots is one of the major bottlenecks in all airline processes. It takes time to shape crew-fleet assignments. There are many stochastic decisions that disrupt long-term planning. In this research, we are addressing 20 years of planning by considering the stochastic nature of the problem using statistics and AI.

2 Crew Teaming in Airline Pairing Optimization

Waldemar Kocjan, Jeppesen, Goeteborg, Sweden. Contact: waldemar.kocjan@jeppesen.com

Airline crew planning is a process performed in consecutive stages. First manpower planning, estimates the crew necessary to perform planned operations. Then crew pairing phase creates a set of anonymous trips, series of flights starting and ending at a specific base. Finally, the rostering stage assigns these trips to the real crew. Creating trips in the pairing phase is subject to different requirements. Crew teaming is a requirement to keep a crew together between certain flights, during a working day or during a whole trip. Fulfilling such requirement is very important for operational stability of a schedule, however it is very difficult due to different rules and costs for different crew positions. The trade-off between cost of the solution and degree of teaming is a big challenge. This presentation shows how teaming is encourage inside the Jeppesen Crew Pairing product.

3 Strict Seniority Crew Rostering with Global Constraints - How to Measure Solution Quality?

Henrik Wallenius, Jeppesen, Gothenburg, Sweden.

In strict seniority rostering, crew bids are satisfied in strict seniority order, i.e. the bids of a senior crew are infinitely more important than all bids of junior crew. Typically this problem is solved sequentially in seniority order and while the strict seniority aspect is guaranteed, the solution is often infeasible in reality as it violates global business requirements. The Jeppesen Strict Seniority Rostering optimizer is able to obtain a solution that will satisfy global constraints. However, when global aspects are considered, seniority inversions might occur, where junior crew are given assignments that should have been assigned to a senior crew. Measuring the quality of such solution is ambiguous and in this talk we will present an alternative way of evaluating strict seniority solutions that satisfy global constraints.

4 Condition-Based Maintenance Planning of an Aircraft Fleet Under Partial Observability: a Reinforcement Learning Approach

Iordanis Tseremoglou, Bruno F. Santos, Delft University of Technology, Delft, Netherlands. Contact: b.f.santos@tudelft.nl

In this work, we present a two-stage framework for scheduling the maintenance of a commercial aircraft fleet, each aircraft having multiple monitored systems. In the first stage, we formulate the maintenance decision-making process for each monitored system as a Partially Observable Markov Decision Process, considering a partially observable prediction of the system deterioration. In the second stage, a Reinforcement Learning agent is proposed to schedule non-routine, routine, and prognostics-based tasks for a fleet of aircraft. Results indicate that 96.4% of the monitored systems were maintained on time.

Keynote: Global Health Security and Healthcare Supply Chains: Perspectives and Opportunities for Operations Research

Keynote Session

Session Chair

Enver Yucesan, INSEAD, Singapore, NA, Singapore.

1 Global Health Security and Healthcare Supply Chains: Perspectives and Opportunities for Operations Research

Prashant Yadav, INSEAD, Fontainebleau, France.

As has become abundantly obvious in the last two years, infectious diseases have the potential to endanger lives, disrupt economies, travel, trade, and have a significant impact on our mental health. The need for robust prevention, preparedness, and response mechanisms is also widely recognized and accepted. However, achieving global health security also requires coordinated actions across countries, regions, and other forms of administrative geographical units. Operations research plays a key role in many parts of global health security such as modelling and simulation of disease outbreaks, analytical models of different policy responses, and design and operation of supply chains for medical counter measures. While all aspects of global health security depend on global coordination, the supply chains for global health technologies such as vaccines, diagnostics, and therapeutics require special kinds of coordination across multiple manufacturers, purchasers, payers, and delivery partners. This talk will focus on the evolution of the field of global health supply chains, which had it origins in global health security, but over time focused more on health systems building. It will highlight areas where health care supply chain research has contributed at the forefronts of policy making regarding global pandemic response and preparedness. It will also present opportunities for OR/OM researchers to contribute more effectively to achieve direct policy impact in this area.

Sunday, 3:30 PM–4:30 PM

Keynote: Modeling Systemic Risk in Supply-Demand Networks

Keynote Session

Session Chair

Jie Xu, George Mason University, Fairfax, VA

1 Modeling Systemic Risk in Supply-Demand Networks

David D. Yao, Columbia University, New York, NY

Recent events (the pandemic, geo-political conflicts, climate change, etc) call for studies on systemic risk in supply-demand networks (SDNs). An SDN is a network with nodes (or "agents") representing resources with processing and/or storage capabilities and arcs representing their supply-demand relations. Systemic risks in the SDN arise from its interconnectedness, such that disruption (or ``shock'') at one node may quickly propagate to other nodes and possibly lead to a system-wide disaster. There are similarities to systemic risk in the financial system, but also fundamental differences. We will discuss how stochastic networks can play an essential role in modeling and analyzing systemic risk in the SDN, along with certain risk-hedging tools and other technologies such as digital twins and reinforcement learning.

Keynote: 2022 Edelman Reprise - Analytics Saves Lives during the Covid Crisis in Chile
Keynote Session

1 **Analytics Saves Lives during the Covid Crisis in Chile**
Leonardo J. Basso[1], Marcelo Olivares[2], Denis Saure[3], Charles Thraves[4], Gabriel Weintraub[5], [1]Instituto Sistemas Complejos de Ingeniería, Santiago, Chile; [2]Universidad de Chile, Santiago, Chile; [3]Proyecto Fondecyt 1211407 Etapa 2021, Santiago, Chile; [4]University of Chile, Santiago, Chile; [5]Stanford Graduate School of Business, Stanford, CA
During the Covid-19 crisis, the Chilean Ministry of Health and the Ministry of Sciences, Technology, Knowledge and Innovation partnered with the Instituto Sistemas Complejos de Ingenier´ıa (ISCI) and thetelecommunications company ENTEL, to develop innovative methodologies and tools that placed operations research and analytics at the forefront of the battle against the pandemic. These innovations have beenused in key decision aspects that helped shape a comprehensive strategy against the virus, including tools that: (i) shed light on the actual effects of lockdowns in different municipalities and over time; (ii) helpedallocate limited intensive care capacity; (iii) significantly increased the testing capacity and provided on-theground strategies for active screening of asymptomatic cases; and (iv) implemented a nationwide serologysurveillance program that significantly influenced Chile's decision regarding vaccine booster doses and that also provided information of global relevance. Important challenges during the execution of the projectincluded the coordination of large teams of engineers, data scientists, and health care professionals in the field; how to effectively communicate information to the population; and the handling and use of sensitivedata. The initiatives enjoyed ample press coverage and, by providing scientific evidence supporting the decision-making behind the Chilean strategy against the pandemic, they helped provide transparency andobjectivity to decision-makers and the general population. According to conservative estimates, the number of lives saved by all of the initiatives together is close to 3,000, equivalent to more than 5% of the total deathtoll in Chile during the pandemic. The saved resources associated with testing, ICU beds, and working days amount to more than 300 million USD.

Keynote: IFORS Distinguished Lecture - The Amazon Fulfillment Network: Topology and Capacity Planning
Keynote Session

Session Chair
Stefan Nickel, Karlsruhe Insitute of Technology, Karlsruhe, Germany.

1 **The Amazon Fulfillment Network: Topology and Capacity Planning**
Luciana Buriol, Amazon, Bellevue, WA
The Amazon fulfillment network is comprised of Amazon buildings and transportation lanes among them. In this talk, I will focus on the network with nodes representing Amazon Fulfillment Centers, Sortation Centers, and the Delivery Stations, where the links are the truck and air lanes among them. The lanes of this network are highly dynamic: their capacity can be changed a few days in advance, and they can also be deprecated or launched with short notice. On the other hand, large buildings are planned years ahead. Designing and expanding this network, as well as adjusting the nodes and links capacities for everyday operation demands an orchestration of complex OR systems. In this talk, I will describe this process.

Optimization for Data Mining and Machine Learning
General Session

Session Chair
Young Woong Park, Iowa State University, Ames, IA

1 **Optimality-Based Clustering**
Taewoo Lee[1], Zahed Shahmoradi[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]UTHealth, Houston, TX, Contact: taewoo.lee@pitt.edu

We propose a new clustering approach, called optimality-based clustering, that clusters data points based on their latent decision-making preferences. We assume that each data point is a decision generated by a decision-maker who (approximately) solves an optimization problem and cluster the data points by identifying a common objective function of the optimization problems for each cluster such that the worst-case optimality error is minimized. We propose three different clustering models and test them in the diet recommendation application.

2 Product-based Approximate Linear Programs for Network Revenue Management

Rui Zhang[1], Saied Samiedaluie[2], Dan Zhang[3], [1]Leeds School of Business University of Colorado Boulder, Boulder, CO, [2]University of Alberta, Edmonton, AB, Canada; [3]University of Colorado, Boulder, CO, Contact: rui.zhang@colorado.edu

The approximate linear programming (ALP) approach has received significant attention in the network revenue management literature. A popular approximation is separable piecewise linear (SPL) approximation. In this paper, we propose a *product-based* SPL approximation. We show that the resulting ALP admits compact reformulations, like its resource-based counterpart. Further, the new approximation allows us to derive a set of valid inequalities to speed up the computation, and select "better" optimal solutions. In a set of 192 instances, bid-price policies based on the new approximation generate higher expected revenues than resource-based policies, with an average revenue lift of 0.72% and a maximum revenue lift of 5.3%. The policy is competitive with the strongest known heuristic. In addition, the new approximation is 1.42 times faster than the resource-based one.

3 A Principled Methodology for Challenging the Single Ground Truth Assumption

Romena Yasmin, Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ, Contact: ryasmin@asu.edu

This talk introduces the Split Consensus Ranking Aggregation problem, which is founded on the assumption that multiple heterogeneous subpopulations may be present within a set of input preference rankings, each with its own underlying collective tendency. Specifically, it presents an exact mixed-integer linear programming model based on the *Kemeny* distance measure and a clustering-based heuristic algorithm for finding such split consensuses quickly. To test the proposed methodology, random instances are generated based on a modified version of the Mallows ⍰-distribution. In addition, a crowdsourcing study is featured to demonstrate the usefulness of the tools in identifying groups with contradictory opinions on everyday topics.

4 Distributionally Robust Chance-constrained Quadratic Support Vector Machines Under Moment Uncertainty

Fengming Lin, Shu-Cherng Fang, Xiaolei Fang, North Carolina State University, Raleigh, NC, Contact: flin6@ncsu.edu

Support vector machines (SVMs) are powerful in supervised classification. Basic SVMs are dealing with the situation where the exact values of data are known. When the training is plagued with uncertainty, only the moments known for the distributions, this work proposes a distributionally chance-constrained (DRC) quadratic SVM to ensure the small probability of misclassification. While such a DRC model turns out to be intractable, this work equivalently reformulates it as a semidefinite program and further yields a second-order cone program that are tractable to be solved by off-the-shelf software. Computational experiments on synthetic and real-world datasets show that the proposed classifiers are better equipped to handle data uncertainty and outperform state-of-the-art in many cases, so as on a real battery failure prediction with highly imbalanced data.

1 Conjecturing for Forensic Body Fluid Identification

Paul Brooks, David Edwards, Craig Larson, Nico Van Cleemput, Fatemeh Valizadeh, Virginia Commonwealth University, Richmond, VA

Current methods for forensic body fluid identification suffer from poor precision and inefficient use of sample material. We develop a method for identification based on measurements of the microbiome using next-generation sequencing. A conjecturing method is used to discover nonlinear and boolean relationships in the microbiome data. We evaluate approaches for leveraging conjectures to enhance multi-class classification methods.

2 A Hybrid Simulation Approach for Dynamic and Equitable Police Patrol Deployment

Prabin Lamichhane[1], Yuan Zhou[1], Victoria C. P. Chen[2], Chen Kan[3], Bahar Nasirian[1], [1]University of Texas at Arlington, Arlington, TX, [2]The University of Texas at Arlington, Arlington, TX, [3]University of Texas-Arlington, Arlington, TX

Policing is complex, involving officers, criminals, politicians, citizens, and stressful, emotional situations. Within the past decade, the predictive policing movement has sought to predict crime, but existing data are highly biased. The proposed project steps away from purely data-driven predictive learning and instead employs stochastic simulation models to overcome bias in representing the dynamic policing system. For this project, we have built a hybrid agent-based and discrete-event simulation model of police patrolling operations of the Arlington Police Department, Texas to explore how proactive police patrol deployment can balance patrol officers' workloads, decrease their stress, and reduce crime.

3 Causal Inference for Fairness in Policing and Crime Prevention

Jonathan Y. Zhou[1], Zheng Dong[2], Qiuping Yu[3], Yao Xie[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgia Institute of Technology, Atlanta, GA, Contact: jyz@gatech.edu

We study how scheduling and dispatching policies impact policing effectiveness and fairness using event-level police patrol and 911-call data between 2013-2017 from the Atlanta Police Department. We first empirically identify two major factors — police's scheduling policy and the geographic division of the police patrolling units — that lead to significant disparities in police response time to 911 calls across different neighborhoods. We then propose strategies to mitigate the disparities while also improving overall policing outcomes using a framework that combines causal inference and optimization.

Empirical Applications of Big Data, Machine Learning, and System Dynamic Modeling

General Session

Session Chair

Mengyang Pan, Swufe, Chengdu, China.

1 A Deep Autoencoder-based Scalable Reinforcement Learning Framework for Hidden Degradation State Estimation

Erotokritos Skordilis[1], Ramin Moghaddass[2], Md Tanzin Farhat[3], [1]University of Miami, Herbert Business School, Department of Business Technology, Miami, FL, [2]University of Miami, Coral Gables, FL, [3]Dept. of Industrial Engineering, University of Miami, Miami, FL

The increased complexity and inherent uncertainty of modern sensor-intensive systems present a great challenge for capturing latent system dynamics that are necessary for control and decision-making. In this work, we present a two-step approach for latent degradation state and remaining useful life (RUL) estimation. In the first step, we use a variational autoencoder (VAE) to learn a distribution over the latent state-space that characterizes the system under observation. Then, a scalable model-based reinforcement learning framework is utilized to train an agent for identifying the true values of the hidden states, as well as the RUL at specific times using the VAE decoder as the environment. Numerical experiments using the NASA CMAPSS data were conducted to prove the validity of the proposed method.

2 The Heterogeneous Impacts of China's High-speed Rail on People's Mobility

Xinyu Wang, Southwestern University Of Finance And Economics, Chengdu, China. Contact: w.xinyu0313@gmail.com

More than 100 HSR branches have been built, forming a complicated HSR network in China. Network science and empirical models are combined for research to improve the insufficient measurement of dummy variables of the existence of HSR. The heterogeneous mechanisms of HSR affecting regional economy through people's mobility are studied. Empirical results show that HSR has positive impacts on people's mobility only in the secondary and tertiary industries, thereby promoting the regional economy. HSR has a significant impact on regional economy through people's mobility in financial, health, public administration industries regardless of HSR cities. The influential mechanisms are partly heterogeneous in developed and developing HSR cities. People's mobility in construction and education industries is the only significant result for developing HSR cities.

Data Nuggets Methods for Mining Big Data

General Session

Session Chair

Javier Cabrera, Rutgers University, Piscataway, NJ

1 A New Projection Pursuit Index for Big Data

Yajie Duan[1], Javier Cabrera[2], [1]Rutgers University, Piscataway, NJ, [2]Rutgers University, Piscataway, NJ

Visualization of extremely large datasets in static or dynamic form is a huge challenge. A new visualization method for big-data is proposed based on Projection Pursuit, Guided Tour and Data Nuggets methods, that will help display interesting hidden structures such as clusters, outliers and other nonlinear structures in big-data. Different Projection Pursuit (PP) indices have been developed to detect structures of multivariate data but there are computational problems for big-data. A new PP index is developed to be computable for big-data, with the help of a data compression method called "Data Nuggets" that reduces large datasets while maintaining the original structure. Static and dynamic graphical tools for big-data can be developed based on the proposed PP index to detect nonlinear structures.

2 Sensitivity of the Deming Model to the Choice of Variance Ratio - An Application for Mining Computational Chemistry Data

Kanaka Tatikola, Janssen R & D, Raritan, NJ, Contact: KTATIKOL@its.jnj.com

Data mining methods are becoming popular in molecular binding computational chemistry. The accurate prediction of binding affinity differences between proteins and small molecules via relative binding free energy calculations has become more popular recently. In this talk, we describe statistical methodology for modeling the relationship of experimental and calculated binding affinities taking into account the ratios of standard deviations in experiment and calculation. The work extends beyond the case of binding free energies to other affinity or property prediction methods. From the technical side we introduce a diagnostics graph to evaluate the sensitivity of Deming�s regression model to the choice of variance ratio.

3 Deep Unrolled Models for the Inverse Problems in Brain Source Imaging

Feng Liu, Stevens Institute of Technology, Jersey City, NJ

Electroencephalography (EEG)/Magnetoencephalography (MEG) source imaging aims to seek an estimation of underlying activated brain sources to explain the observed EEG/MEG recording. Traditionally, the design of regularization terms is based on preliminary assumptions on the spatio-temporal structure in the source space. In this paper, we propose a novel paradigm to solve the ESI problem by using Unrolled Optimization Neural Network (UONN) (1) to improve the efficiency compared to traditional iterative algorithms; (2) to establish a data-driven way to model the source solution structure instead of using hand-crafted regularizations; (3) to learn the hyperparameter automatically in a data-driven manner.

Integer Programming for Machine Learning: Exact and Approximation Algorithms

General Session

Session Chair

Yongchun Li, Virginia Tech, Blacksburg, VA

1 Quant-BnB: A Scalable Branch-and-bound Method for Optimal Decision Trees with Continuous Features

Haoyue Wang, Rahul Mazumder, Xiang Meng, Massachusetts Institute of Technology, Cambridge, MA, Contact: haoyuew@mit.edu

Decision trees are one of the most popular methods in the machine learning toolbox. In this paper, we consider the problem of learning optimal decision trees, a combinatorial optimization problem that is challenging to solve at scale. To achieve computational scalability, most existing approaches focus on classification tasks with binary features. In this paper, we present a new branch-and-bound (BnB) method to obtain optimal decision trees. Different from existing customized approaches, we consider both regression and classification tasks with continuous features. We split the search space based on the quantiles of the feature distribution---leading to upper and lower bounds for the underlying optimization problem along the BnB iterations. Our proposed algorithm Quant-BnB shows significant speedups compared to existing approaches for shallow optimal trees.

2 Time-varying Markov Random Fields: Efficient Algorithms and Provable Guarantees

Andres Gomez[1], Salar Fattahi[2], [1]University of Southern California, Los Angeles, CA, [2]University of Michigan, Ann Arbor, MI

In this talk we study inference problems with Markov Random Fields, a class of graphical models used often to learn spatio-temporal processes. We consider problems with sparsity: instead of standard Maximum Likelihood techniques, which approximate sparsity with the convex L1 norm, we propose an alternative method that explicitly incorporates the L0 norm while maintaining computational tractability. The resulting method not only provides better statistical guarantees than state-of-the-art methods, but also scales to much larger instances.

3 Guassian Graphical Models: A Scalable Framework Based on Combinatorial Optimization

Kayhan Behdin, Wenyu Chen, Rahul Mazumder, Massachusetts Institute of Technology, Cambridge, MA, Contact: behdink@mit.edu

We consider Gaussian Graphical Models, where the goal is to estimate the precision matrix of a multivariate Normal distribution. We propose a new estimator based on pseudo-likelihood when the precision matrix is sparse. However, our estimator uses l0 regularization, unlike most current algorithms which are based on convex optimization. We show our estimator can be written as a Mixed Integer Program (MIP). We provide statistical guarantees for our estimator and discuss how the use of l0 penalty improves the behavior. We provide an optimization framework including heuristic methods to obtain good solutions to the MIP, as well as a specialized nonlinear branch-and-bound method to obtain optimal solutions to our estimator. Our numerical experiments show that our estimator is computationally scalable to 10,000 variables while leading to better statistical performance.

Lijun Ding, 1</sup

1 Unique Sparse Decomposition of Low Rank Matrices

Dian Jin[1], Xin Bing[2], Yuqian Zhang[1], [1]Rutgers University, Piscataway, NJ, [2]Cornell University, Ithaca, NY, Contact: dj370@soe.rutgers.edu

The problem of finding the unique low dimensional decomposition of a given matrix has been a fundamental and recurrent problem in many areas. In this paper, we study the problem of seeking a unique decomposition of a low-rank matrix Y that admits a sparse representation. Specifically, we consider Y=AX where the matrix $A\in \R^{p\times r}$ has full column rank, with $r < \min\{n,p\}$, and the matrix $X\in \R^{r\times n}$ is element-wise sparse. We prove that this low rank, sparse decomposition of Y can be uniquely identified, up to some intrinsic signed permutation. Our geometric analysis for its nonconvex optimization landscape shows that any strict local solution is close to the ground truth, and can be recovered by a simple data-driven initialization followed with any second-order descent algorithm. Our theoretical findings are corroborated by numerical experiments.

2 Accelerated Minimax Algorithms Have Merging Paths

TaeHo Yoon, Ernest Ryu, Seoul National University, Seoul, Korea, Republic of. Contact: tetrzim@snu.ac.kr

Recently, several new accelerated methods in minimax optimization and fixed point iterations have been discovered. Interestingly, their acceleration rely on the mechanism of anchoring, which retracts the iterates toward the initial point, and is distinct from Nesterov’s momentum-based acceleration. We introduce these accelerated algorithms and show that they exhibit what we call the merging path (MP) property; the trajectories of these algorithms merge quickly. Using this novel MP property, we establish point convergence of existing accelerated minimax algorithms and present new state-of-the-art algorithms for the strongly-convex-strongly-concave setup and for the prox-grad setup.

3 Exact Optimal Accelerated Complexity for Fixed-point Iterations

Jisun Park[1], Ernest Ryu[2], [1]Seoul National University, Seoul, Korea, Republic of; [2]Seoul National University, Department of Mathematical Sciences, Seoul, Korea, Republic of. Contact: colleenp0515@snu.ac.kr

Despite the broad use of fixed-point iterations throughout applied mathematics, the optimal convergence rate of general fixed-point problems with nonexpansive nonlinear operators has not been established. This work presents an acceleration mechanism for fixed-point iterations with nonexpansive operators, contractive operators, and nonexpansive operators satisfying a H¨older-type growth condition. We then provide matching complexity lower bounds to establish the exact optimality of the acceleration mechanisms in the nonexpansive and contractive setups. Finally, we provide experiments with CT imaging, optimal transport, and decentralized optimization to demonstrate the practical effectiveness of the acceleration mechanism.

4 Flat Minima Generalize for Low-rank Matrix Recovery

Lijun Ding, University of Washington, Seattle, WA

Empirical evidence suggests that for a variety of overparameterized nonlinear models, most notably in neural network training, the growth of the loss around a minimizer strongly impacts its performance. Flat minima—those around which the loss grows slowly—appear to generalize well. This work takes a step towards understanding this phenomenon by focusing on the simplest class of overparameterized nonlinear models: those arising in low-rank matrix recovery. We analyze overparameterized matrix and bilinear sensing, robust PCA, covariance matrix estimation, and single hidden layer neural networks with quadratic activation functions. In all cases, we show that flat minima, measured by the trace of the Hessian, exactly recover the ground truth under standard statistical assumptions.

Quality, Reliability and Statistics with Big Data

Contributed Session

Session Chair

Di Bo, University of Tennessee, Knoxville, Knoxville, TN

1 Suspicious Machine Screening in Serial-parallel Multistage Manufacturing Process with a Nominal Quality Feature: A Production Log Data-based Approach

Seung-Hyun Choi[1], Dong-Hee Lee[2], Young-Mok Bae[1], Young-Chan Oh[3], Jong-Bum Park[3], Kwang-Jae Kim[1], [1]POSTECH, Pohang, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of; [3]SK hynix, Cheongju, Korea, Republic of. Contact: seunghyun.choi@postech.ac.kr

Serial-parallel multistage manufacturing process (SP-MMP) has multiple consecutive process stages, and each stage has several alternative machines. Faulty machines negatively influence product quality; thus, identification of faulty machines is a critical task for quality enhancement. Suspicious machines, which are suspected to be faulty machines, are screened before machine diagnosis to enhance the efficiency of faulty machine identification. This study proposes a method to screen suspicious machines using production log data in SP-MMP with nominal quality features. The proposed method estimates whether a machine incurs low-quality products by itself or by its interaction with other machines. The performance of the proposed method is validated through case studies on a simulated SP-MMP and a real semiconductor manufacturing process.

2 Active Quickest Detection in Linear Regression Model

Qunzhi Xu[1], Yajun Mei[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: xuqunzhi@gatech.edu

Active quickest detection problem has received extensive attentions in modern big data age, partly due to the resource constraints either at the data acquisition level or at the communication level. Often it is required that the decision maker actively selects partial samples from the underlying raw data so as to detect the change as quickly as possible. In this talk, we consider the active quickest detection in linear regression model Y_t=X_t□+□$_t$,where the p-dimensional coefficient □ might changes from 0 to an unknown sparse vector □* at some unknown time □. Here Y_t is observed q-dimensional vector ($q \leq p$) and X_t is the $q \times p$ design matrix. We focus on how to detect the change-time □ efficiently based on the observed data (Yt,Xt) and we will share some of our preliminary results.

3 Cusum for Sequential Change Diagnosis

Austin Warner, Georgios Fellouris, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: awarner5@illinois.edu

A sequence of independent random elements is accessed sequentially and at some unknown time there is an abrupt change in its distribution. We aim to quickly detect the change and to accurately identify the post-change distribution among a finite set of alternatives. A standard change detection algorithm that raises an alarm as soon as a CuSum procedure that corresponds to one of the post-change alternatives raises an alarm is shown to control the worst-case conditional probability of false isolation under some conditions, and minimize Lorden's criterion for the detection delay to a first-order asymptotic approximation as both the worst-case probability of false isolation and the false alarm rate go to zero at certain relative rates. These properties are satisfied under some conditions which are satisfied in a special case of the multichannel problem.

4 Feature Subspace Selection for High-dimensional Experiments of Material Development Process

DI BO, Hoon Hwangbo, Stephanie TerMaath, University of Tennessee, Knoxville, Knoxville, TN, Contact: dbo@vols.utk.edu

This research proposes a novel feature selection approach capable of identifying significant feature interactions in a high-dimensional feature space. Identifying feature interactions is a hard task as it involves evaluations of a large number of potential interactions that can be defined. The proposed method generates a random subset of features with low dimensionality limiting the maximum order of interactions, evaluates its significance, and ensembles only those found significant to model a response. When applied to high-dimensional data collected from a material development process, the proposed method improves prediction and provides useful physical insights about material behaviors.

1 An Inverse Optimization Approach to Causal Inference

Elijah Pivo[1], Dimitris Bertsimas[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: epivo@mit.edu

In causal inference we typically quantify the average causal effect of applying a treatment to some unit. For example, we may wish to estimate the average causal effect of smoking on life expectancy or of a training program on wage. Current practice is to use flexible machine learning methods like neural networks or random forests to model the relationships between treatment and outcome under the doubly robust framework. In this work, we consider the case where the outcome is a decision and propose using optimization problems to model the relationship between treatment and outcome. We compare the performance of machine learning methods and optimization models for quantifying average causal effects in several examples.

2 Comparing Interpretability and Explainability for Feature Selection

Luca Mingardi, Interpretable AI, Cambridge, MA, Contact: luca@interpretable.ai

A common approach for feature selection is to examine the variable importance score of a machine learning model to understand which are the relevant features for making a prediction. Given the significance of feature selection, it is crucial for the calculated importance scores to reflect reality. Black-box models provide state-of-the art predictive performance, but rely on variable importance to offer insight into their behavior. We investigate the performance of variable importance as a feature selection by comparing the ability of CART, Optimal Trees, XGBoost and SHAP to identify the relevant features across a number of experiments. The results show that black-box models fail to distinguish between relevant and irrelevant features, while interpretable methods identify irrelevant ones, proving to be a better feature selection tool.

3 Deep Learning-based Adversarial Attacks for Time Series Data

Juheon Kwak, Soomin Lee, Dongil Kim, Chungnam National University, Daejeon, Korea, Republic of. Contact: juhun2005@cnu.ac.kr

Time series data are frequently utilized in various fields, such as music analysis, sensor networks, and weather forecasting, etc. There have been various attempts to analyze and predict time series data by using deep learning. Recently, another research area arising is the adversarial attack that generates adversarial examples to cause a malfunction in a machine learning model. In this paper, we propose a new attack method for time series data based on deep learning. The proposed model can make adversarial examples of time series, and the new examples can fool existing detection models. The experimental results guarantee the further research efforts to improve the fooling performance of the proposed method, and to develop a defense model against this attack model.

4 Automatic Manufacturing Feature Extraction and Detection

William J. Peck, The Pennsylvania State University, State College, PA, Contact: wjp16@psu.edu

A major preoccupation of Industry 4.0 is the inclusion of automation to continually transform and revolutionize manufacturing. For a given industrial good, extracting manufacturing features is often done manually with little to no help or oversight from computers. A feature point mapping method is chosen as a methodology to allow for automatic manufacturing feature extraction and detection for industrial goods. Given a series of manufacturing feature reference images, the six principal views and the isometric view of the part, our algorithm is able to extract and detect manufacturing features that are contained within the industrial good. Shifting away from human detection to computer detection for manufacturing features is an important step towards the realization of information intensive manufacturing systems defined by Industry 4.0.

1 How Diffused Emotions Affect User Contribution in Online Cancer Communities

Anqi Xu, Jennifer Xu, Haijing Hao, Bentley University, Waltham, MA, Contact: axu@bentley.edu

Online cancer communities (OCCs) provide cancer patients platforms to learn about the illness, provide and receive support, and network with others in similar situations. The majority of content in OCCs are user-generated, thus, it is essential to encourage user participation and keep the functionality of the community. When providing support or networking with other users in the community, cancer patients' emotions are also expressed in their replies to others' posts. Will these expressed emotions diffuse and affect other users', especially the post author's future engagement in the community? To answer this question, we apply machine learning techniques to identify eight categories of emotion (based on Plutchik's wheel of emotions) and employ empirical analysis to examine the effects of these emotion categories on users' future participation.

2 Consumers' Perception to AI-based Home Care System: An Empirical Study

Bijun Wang[1], Onur Asan[2], Mo Mansouri[3], [1]Stevens Institute of Technology, Hoboken, NJ, [2]Univeristy of Wisconsin-Madison, Madison, WI, [3]Stevens Institute of Technology, Hoboken, NJ, Contact: bwang27@stevens.edu

Consumer health applications and device powered by AI is a burgeoning industry in recent years. Nevertheless consumer needs and attitudes are not fully explored in the service. This study developed a research model consisting of contextual and acceptable values to explain the intention of chronic patients when using AI-based medical applications. To conduct this study, we performed an online survey in United states. More than 200 respondents provided usable data; these data were analyzed by structural equation modeling to test the proposed hypothesis. Hope this study will benefit patients, healthcare providers, and AI providers and facilitate the implementation of AI in the healthcare system.

3 Utilizing Digital Twins to Develop Semi-supervisedonline Control Model for Self-monitoring and Management of Patients with Type 2 Diabetes Mellitus

Syed Hasib Akhter Faruqui[1], Shiyu Li[2], Yan Du[2], Brittany Dennis[2], Chengdong Li[2], Jing Wang[3], Adel Alaeddini[4], [1]Northwestern University, Chicago, IL, [2]University of Texas Health Science Center at San Antonio School of Nursing, San Antonio, TX, [3]Florida State University, Tallahassee, FL, [4]University of Texas at San Antonio, San Antonio, TX

Patients with T2DM need to maintain strict glycemic control and dietary regimen to avoid the risk of hypoglycemia, hyperglycemia, and consequential complications. To help patients with T2DM maintain a healthy life, we propose using an online control model. To do so, we first developed a predictive digital twin to represent the characteristics of T2DM patients following a specific diet and exercise regimens using a deep learning model. This can facilitate the means to monitor, learn, and parameterize the control model to improve the quality of a patient's lifestyle. Next, we developed an online control algorithm utilizing particle swarm optimization to examine the impact of various behavioral changes on the next day's glucose level. Finally, the constraints of the control model are determined using the patients' digital twins' characteristics data and diet type.

AI Applications at Mayo Clinic

General Session

Session Chair

Esma S. Gel, University of Nebraska-Lincoln, Lincoln, NE

1 Implementation of an AI-based Triage Algorithm for Multidisciplinary Treatment of Complex Dizziness

Santiago Romero-Brufau, Mayo Clinic, Rochester, MN

Dizziness affects 15-20% of adults, and recurrent and chronic dizziness can be highly debilitating, but up to 85% of cases receive inappropriate diagnosis and treatment. Management of the various causes of dizziness spans several health care specialties. Ensuring consistent and appropriate triage with efficient use of clinician time remains a challenge globally. We developed a decision-tree-based automated triage system using a combination of machine learning methods and expert-based adjustment and implemented it as part of the clinical triage workflow for new patients at Mayo Clinic. The system queries patients for symptoms and history, and presents its recommended set of appointments to the clinician and scheduling staff. The system reduced clinician workload by 70% and achieved an overall accuracy of 87% with significant clinician satisfaction, all of which was maintained two years after implementation.

2 Harnessing Artificial Intelligence in Developing a Tool to Decrease the Cost and Improve Efficiency of Clinical Trials

Thomas Kingsley, Mayo Clinic, Rochester, MN, Contact: kingsley.thomas@mayo.edu

A clinical trial often costs millions of dollars and years complete. A significant reason is the challenge in identifying patients for study enrollment. The clinical research coordinator often spends 50% or more of their time manually chart reviewing data sources to identify patients. Natural language processing (NLP) algorithms can be trained to extract concepts used in study enrollment from unstructured text data. However, the challenge with training NLP models is their scalability and generalizability across a range of research disciplines. This can be solved by developing a combination of structured data querying and highly sensitive but non specific NLP models as a starting cohort for research coordinators. The selection of patients in real time using a rank order list allows for NLP model updating iteratively and improved classification performance over time.

3 Sharing in Caring: Analyzing Shared Medical Appointments Through an Operations Lens

Enver Yucesan, Sundara Natarajan Panchanatham, INSEAD, Singapore, Singapore. Contact: enver.yucesan@insead.edu

Shared medical appointments (SMA) are doctor-patient visits in which groups of patients are seen by one or more healthcare professionals in a concurrent session with the objective of enhancing patient experience, eliminating redundant work, improving medical compliance and reducing cost for certain treatments. From an operations perspective, providers face several key challenges in the effective organization of SMAs, which includes finding the optimal group size, devising robust scheduling mechanisms, determining the optimal capacity allocation, and incentivizing more patients to opt for SMA. In this work, we analyze the key operational trade-offs involved in SMAs as a service system and provide guidelines that enable providers to identify optimal settings (capacity/payment/group size) for several system configurations.

4 Intelligent Teletriage and Personalized Routing at a Neurosurgery Department

Esma S. Gel[1], Derya Kilinc[2], Aysegul Demirtas[3], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]Mayo Clinic, Rochester, MN, [3]Intel, Chandler, AZ, Contact: esma.gel@unl.edu

We consider the intake process of new low back pain (LBP) patients at a neurosurgery clinic to improve access delays through personalized routing strategies. Using clinical notes, we devise a decision-tree based intelligent teletriage tool that can be used by non-medically trained agents to predict the surgical class of a patient. We establish that the accuracy of the teletriage tool is in the order of 80% using out-of-sample testing on real-life data sets. We then show that when used in combination with the intelligent triage tool, priority based routing strategies can result in 90% reduction in access delays for the higher priority surgical patients who should be seen urgently. We comment on the potential for the use of needs-based personalized routing strategies with intelligent teletriage to reduce access delays, improve patient outcomes and provider satisfaction.

Large-scale Data Analytics for Transportation Systems (Planning + Operation)

Joint Session

Session Chair

Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA

Session Chair

Wei Ma, The Hong Kong Polytechnic University, Kowloon

1 Recsys Model to Infer Missing Transportation Mobility Data

Yiran Zhang, Xuegang Ban, University of Washington, Seattle, WA

The explosion of big data has fueled tremendous transportation studies such as CAV and shared mobility with the rapid proliferation of diverse passive and mobile sensing in recent years. However, the increasing reliance on big data also raises risks due to the inherent bias issues. To explore and identify the data bias issues, this study focuses on the bias of the data generation process (DGP) from the passively collected smartphone app-based data. A two-step model is built up to learn the DGP considering the sampling and data collection of the smartphone users. Data bias is then discussed and identified at each step, covering demographic, temporal, and spatial biases.

2 Deep Model for Traffic Prediction with Low-rank Mode and Minimal Transfer for Nonrecurrent Events

Weiran Yao, Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA

We use low-rank approximation method to connect traffic simulation and the data-driven approach. We first calibrate a dynamic traffic assignment model using dynamic origin-destination estimation to enable generalization to unobserved, nonrecurrent events. We use the calibrated model to generate typical nonrecurrent traffic data and fit the Koopman operator on the simulated data to extract both nonrecurrent and recurrent traffic modes. The model is finetuned on real-world data samples end-to-end through a gradient approach. We conducted experiments on both a toy dataset (4x4 grid network) and a real-world dataset (TSMO system 1). Experiment results demonstrate that our low-rank approximation approach could consistently adapt to unseen traffic scenarios, to which the traditional data-driven approach cannot generalize.

3 Data-driven Multi-horizon Prediction of Ridesharing Spatiotemporal Demand Pattern

Mark Hernandez[1], Fatemeh Nazari[2], Mohamadhossein Noruzoliaee[2], [1]University of Texas Rio Grande Valley, Edinburg, TX, [2]University of Texas Rio Grande Valley, Edinburg, TX, Contact: fatemeh.nazari@utrgv.edu

Technological advances in providing near ubiquitous mobility in the past decade have led to introducing on-demand shared mobility, in particular, ridesharing services. The accurate prediction of rider demand over space and time is a crucial input to improving the ridesharing system efficiency, for instance, by preemptively relocating vacant vehicles and thus slashing the rider waiting time. Focusing on the multi-horizon origin-destination (OD) demand of these services, this research presents a graph-based deep learning approach for both solo (e.g., Uber) and pooled (e.g., UberPool) ridesharing services while also investigating the impacts of COVID-19 pandemic, weather conditions, and socio-demographic attributes. A case study in a large metropolitan area in the United States is presented to demonstrate the performance of the presented model.

4 Traffic-Twitter Transformer: A Natural Language Processing-joined Framework for Network-wide Traffic Forecasting

Yinhai Wang[1], Meng-Ju Tsai[2], [1]University of Washington, [2]University of Washington, Seattle, WA

With accurate and timely traffic forecasting, the impacted traffic conditions can be predicted inadvance to guide agencies and residents to respond to changes in traffic patterns appropriately.However, existing works on traffic forecasting mainly relied on historical traffic patternsconfining to short-term prediction, under 1 hour, for instance. To better manage futureroadway capacity and accommodate social and human impacts, it is crucial to propose a flexibleand comprehensive framework to predict physical-aware long-term traffic conditions for publicusers and transportation agencies. In this paper, the gap of robust long-term traffic forecastingwas bridged by taking social media features into consideration. A correlation study and a linearregression model were first implemented to evaluate the significance of the correlationbetween two time-series data, traffic intensity and Twitter data intensity. Two time-series datawere then fed into our proposed social-aware framework, Traffic-Twitter Transformer, whichintegrated Nature Language representations into time-series records for long-term trafficprediction. Experimental results in the Great Seattle Area showed that our proposed modeloutperformed baseline models in all evaluation matrices. This NLP-joined social-awareframework can become a valuable implement of network-wide traffic prediction andmanagement for traffic agencies.

Advances in Health Care Operations

General Session

Session Chair

Joel Goh, NUS Business School, Singapore, Singapore.

1 The Impact of Historical Workload on Nurse's Perceived Workload in Intensive Care Unit

Carri Chan[1], Yi Chen[2], Jing Dong[3], [1]Columbia Business

School, New York, NY, [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]Columbia University, New York, NY

Workload balancing in service system is critical for both workers' welfare and the quality of delivered service. In this work, we examine the importance of balancing workload temporally in healthcare system. Using a dataset of more than 1000 patients over a year that records detailed nurse-patient matching and workload measures, we use an instrumental variable approach and a sample selection model to empirically quantify the effect of historical workload on nurse's perceived workload in current shift. We find that a higher historical workload can lead nurse to perceive a higher workload. Such an observation brings a nontrivial tradeoff between maintaining the continuity of care and mitigating nurses' occupational burnout as well.

2 Could Budget-neutral Incentives Increase Organ Donor Designation?

Diwakar Gupta[1], Paola Martin[2], [1]University of Texas, Austin, TX, [2]University of Texas at Austin, Austin, TX, Contact: diwakar.gupta@mccombs.utexas.edu

Organ Procurement Organizations (OPOs) decide which deceased-donor referrals to pursue for organ recovery, driven mostly by clinical reasons. In addition, a key operational factor is whether the referral was timely. In a preliminary analysis, data from an OPO showed that, after accounting for clinical variables, a referral was 58% more likely to be designated a donor if it was timely. This talk explores ways in which OPOs could incentivize hospitals to increase the proportion of timely referrals in a budget-neutral way.

3 How and in What Ways Does Colocation of Services Matter? Empirical Evidence from a Large Healthcare Setting

Vishal Ahuja[1], Carlos Alvarez[2], Bradley R. Staats[3], [1]Southern Methodist University, Dallas, TX, [2]Texas Tech University, Dallas, TX, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Location choice - especially colocation - is a key facet of operational decision-making. Thus, it is critical to understand not only whether colocation makes a difference but also under what circumstances it is most beneficial, and the mechanisms through which those benefits are realized. We consider colocation in the context of healthcare services, as primary care serves as a gateway to address mental health concerns and referrals to specialists. We ask the following three questions: Does colocation of mental and physical health resources improve patient outcomes? How do sicker patients benefit more from colocation? How does team familiarity between providers moderate colocation-outcomes relationship?

4 Providing Wait Time Information to ED Patients: Effects on Satisfaction and Reneging

Danqi Luo[1], Mohsen Bayati[2], Erica Plambeck[2], [1]UCSD Rady School of Management, San Diego, CA, [2]Stanford University, Stanford, CA, Contact: d1luo@ucsd.edu

The effect of communicating delay information to patients on their satisfaction and their likelihood to leave the ED before being treated (reneging) is investigated in a field experiment in an Emergency Department (ED). When the delay information is provided, the odds of having a higher wait satisfaction increase by 81 percent, and the odds of reneging reduce by 14 percent. The announced delay serves as a reference point against which the patients compare their actual delay. As per Prospect Theory, patients are loss-averse, hence the risk of reneging is substantially lower when they wait shorter than the displayed delay than when they wait longer: $33% lower versus $151% higher. Furthermore, we discovered that although statistically significant, the influence of actual wait time on patient satisfaction and the likelihood of reneging is negligible.

Actionable Analytics and Sequential Decision Making in Healthcare

General Session

Session Chair

Yonatan Mintz, University of Wisconsin Madison, Madison, WI

1 A Two-timescale Model for Routing Policy Optimization with Application in Community Corrections

Xiaoquan Gao[1], Pengyi Shi[2], Nan Kong[3], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, [3]Purdue University, West Lafayette, IN, Contact: gao568@purdue.edu

In the United States, the overuse of incarceration combined with a lack of social and community assistance for criminals results in a vicious cycle between incarceration and recidivism. We study incarceration diversion decisions with community corrections as an alternative to jailing to alleviate the prominent issue of jail overcrowding. We formulate an MDP model to optimize incarceration diversions for individuals of different risks. To tackle the curse-of-dimensionality caused by non-memorylessness, we develop a novel two-timescale approximation, which is embedded in an actor-critic policy gradient algorithm. We provide structured insights for diversion decisions and capacity allocation in the criminal justice system.

2 An Approximate Algorithm for Optimizing Repeated Decisions in Infectious Disease Control

Suyanpeng Zhang, Sze-chuan Suen, University of Southern California, Los Angeles, CA, Contact: suyanpen@usc.edu

The Covid-19 outbreak emphasizes the necessity of studying policies to prevent or control the transmission of infectious diseases. However, one needs to solve the dimensionality problem to tractably evaluate dynamic policies for infectious disease modeling under a discrete Markov decision process (MDP) framework. We develop an optimization algorithm for finding non-fixed grid regions for approximate MDP solutions for informing infectious disease control policies over time.

3 Thompson Sampling Techniques for Nonstationary Bandits

Jinxin Tao, Yonatan Mintz, Amy Cochran, University of Wisconsin Madison, Madison, WI, Contact: jtao34@wisc.edu

Nonstationary bandit settings, where the parameters of each arm are unknown to the decision maker but may change over time according to a set of known dynamics are common in many applications in personalized healthcare and micro randomized trials, and can be modeled as a reducing or gaining unknown efficacy (ROGUE) bandits. However, if decision makers want to estimate the effect size of bandit treatments, they require that each action be pulled a minimum number of times, thus precluding the use of UCB style policies. Here we present a novel Thompson Sampling algorithm we call ROGUE-TS to optimize this setting and show that this algorithm achieves logarithmic in time expected regret and provides the desired statistical properties. We present computational results that show that ROGUE-TS improves over state of the art algorithms in terms of cumulative regret and average reward.

4 Personalized Financial Incentives for Weight Loss

Qiaomei Li, Yonatan Mintz, Corrine Voils, Kara Louise Gavin, University of Wisconsin Madison, Madison, WI, Contact: qli449@wisc.edu

Financial weight loss incentives administered by a mobile app have been found to help patients lose weight. However, the efficacy of these interventions is dependent on patient adherence. Thus clinicians must find the appropriate incentives to administer to patients to ensure they adhere to the intervention and influence long term behavioral change. In this talk, we develop a personalized model for the patients' decision-making process in these interventions and use it to construct personalized incentives. To validate our model we perform a computational study using data from a randomized control trial. We find our method outperforms existing machine learning methods in terms of weight loss prediction at the end of the intervention using a short time-span of data and that our approach helps improve the efficacy of the intervention program with limited resources.

Optimization Models for Problems in Healthcare Delivery Systems

General Session

Session Chair

Ankit Bansal, West Virginia University, Morgantown, WV

1 A Two-stage Stochastic Program for Right-shoring Pharmaceutical Supply Chains

Martha Lucia Sabogal De La Pava[1], Emily L. Tucker[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC

In disruptive events, highly geographically concentrated pharmaceutical supply chains increase the risk of global drug shortage. Countries with low production capacity are at the highest risk. Right-shoring strategies help decision-makers balance the cost, benefits, and risks of onshoring and offshoring manufacturing plants. We present a two-stage stochastic location-distribution model that considers a joint shoring approach through international alliances. We analyze how the risk of ban export during disruptive scenarios and the drugs exports of the possible partners affect both the expected cost assumed by investors when locating a manufacturing plant and the risk of shortage in multiple countries.

2 Optimizing Channels Placement in 3D Printed Masks for High Dose Rate Brachytherapy (HDR-BT)

Nasim Mirzavand Boroujeni[1], Jean-Philippe P. Richard[2], David Sterling[1], Chris Wilke[1], [1]University of Minnesota, minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: mirza048@umn.edu

High dose rate brachytherapy (HDR-BT) is used for skin cancer treatment when surgery cannot remove all cancer cells.
Positioning needles close to the skin can be challenging in practice.
Advances in 3D printing, however, offer promise to mitigate this issue.
We introduce three optimization models for determining the position of channels inside of 3D printed masks for the treatment of skin cancers using HDR-BT.
We propose solution methods for these models that we evaluate on actual patients data.
Solution times are sufficiently fast to be useful in practice. Further, when compared to plans obtained for masks created without the use of optimization, we observe that our plans tend to be more homogeneous and to have better dosimetric indices.

3 A Multi-objective Optimization Approach for Family Medicine Residency Scheduling

Bjorn Berg[1], Nick Lawrence[2], Derek Hersch[1], Patricia Adam[1], [1]University of Minnesota, Minneapolis, MN, [2]Booz Allen Hamilton, Falls Church, VA, Contact: bberg@umn.edu

Family medicine residency training programs include both experiential and didactic education activities including inpatient hospital service time, specialty rotational training, outpatient clinic responsibilities, and other educational programming. The *Clinic First* curricular model aims to better balance the priority of residents' clinic requirements with the other educational goals. In this talk we develop a modeling framework for resident rotation scheduling which directly incorporates the Clinic First curricular approach and the operational requirements of the residency program clinic. The optimization model presented incorporates a multi-objective approach in designing family medicine resident rotation schedules. Numerical results are presented based on historic rotation schedule data from a residency program clinic.

4 Mixed-integer Linear Programming Formulations for the Robust Surgery Scheduling Problem

Ankit Bansal[1], Jean-Philippe P. Richard[2], Bjorn Berg[2], Yu-Li Huang[3], [1]West Virginia University, Morgantown, WV, [2]University of Minnesota, Minneapolis, MN, [3]Mayo Clinic, Rochester, MN

An exact mixed-integer linear program for the two-stage robust optimization surgery-to-OR allocation problem is presented. We show that the second stage problem can be formulated as a linear program through graphical interpretation. The resulting linear program of the second stage problem is then dualized and integrated into the first-stage problem to yield a monolithic MILP. Multiple reformulations of the resulting MILP are presented . Data from an academic medical center is used to compare the computational performance of these formations and its solution quality with the only known exact approach in the literature.

Medical Decision Making Research by Bonder Scholars

General Session

Session Chair

Pooyan Kazemian, Case Western Reserve University, Cleveland, OH

1 Managing Multiple Chronic Conditions

Luke DeRoos, Mariel Sofia Lavieri, University of Michigan, Ann Arbor, MI, Contact: lkbruski@umich.edu

Age-related macular degeneration (AMD) is a chronic eye disease, and the most common cause of blindness in people over 55. Treating advanced AMD typically requires frequent, expensive injections into a patient's eye. Additionally, having AMD in one eye significantly increases the likelihood of having it in the other eye. We present a dynamic programming framework designed to simultaneously schedule treatment for both eyes. We show how following our framework can reduce patient and provider costs without compromising long-term patient vision. We also demonstrate how our framework can be expanded to consider multiple chronic conditions beyond AMD.

2 Improving Tuberculosis Treatment Adherence Support: The Case for Differentiated Care

Justin J. Boutilier[1], Jonas Oddur Jonasson[2], Erez Yoeli[3], [1]University of Wisconsin - Madison, Fitchburg, WI, [2]MIT Sloan School of Management, Somerville, MA, [3]MIT Sloan School of Management, Cambridge, MA

Lack of patient adherence to treatment protocols is a main barrier to reducing the global disease burden of tuberculosis (TB). We study the operational design of a treatment adherence support (TAS) platform that requires patients to verify their treatment adherence on a daily basis. Our results indicate that, compared with a benchmark policy, the TAS platform could reach the same number of at-risk patients with 6%-40% less capacity, or reach 2%-20% more at-risk patients with the same capacity, by using various ML-based prioritization policies that leverage patient engagement data. Personal sponsor outreach to all patients is likely to be very costly, so targeted TAS may substantially improve the cost-effectiveness of TAS programs.

3 Design and Analysis of Interpretable Policies for Hypertension Treatment Planning

Gian-Gabriel P. Garcia[1], Lauren N. Steimle[1], Wesley J. Marrero[2], Jeremy B. Sussman[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Thayer School of Engineering at Dartmouth, Hanover, NH, [3]Michigan Medicine, Ann Arbor, MI, Contact: giangarcia@gatech.edu

In medical decision-making, Markov decision processes (MDPs) are useful for optimal treatment planning. Yet, optimal policies may lack interpretable structure. Interpretability is especially critical in hypertension treatment, where complicated clinical guidelines have drawn substantial controversy from practitioners. In this research, we design and analyze MDP-based interpretable policies for treatment planning which leverage the natural interpretability of monotonicity, i.e., the intensity of the prescribed action increases with the severity of the state. We apply our method to hypertension treatment planning and show that it outperforms current guidelines in terms of quality-adjusted life-years and cardiovascular events saved, with only a small loss compared to the optimal policy.

Social Justice Integration into Decision Making

General Session

Session Chair

Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA

Session Chair

Zana Cranmer, Bentley University, Waltham, MA

1 Presenter

Khalid K. Osman, Stanford University, Stanford, CA, Contact: osmank@stanford.edu

Access to clean, reliable water services is a growing concern in both developing and developed contexts. In the US, certain communities are still devoid of an effective and well-functioning water supply infrastructure. With limited budgets, typically, the "loudest voices" are prioritized, creating inequities as it is well documented that civic engagement and residential trust are lowest among poor and disadvantaged communities. This study aims to understand how existing social equity theories (e.g., utilitarianism, egalitarianism) can be quantified to improve water access in disadvantaged communities. Utilizing genetic algorithms, water utility budget allocation models that are optimized based on mathematical formulations of existing social equity theories are developed. Such models seek to reduce existing inequities in the provision of water services.

2 Capturing Carbon but Not Its Co-pollutants: Carbon Capture in the Electricity System and the Challenge of Just Decarbonization

Paola Furlanetto, University of Massachussets, Boston

Carbon Capture (CC) for use or sequestration is an interesting technology for decarbonization. While its cost- and carbon-effectiveness are under debate, current technologies remove CO_2 not co-pollutants. CO_2 affects the entire planet, but co-pollutants are harmful to those directly exposed with particular consequences for people of color and low-income. This work combines power systems modeling, integrated assessment modeling, and socioeconomic data to evaluate the role of CC distributional equity considering technological uncertainties and policy design. We hypothesize that CC is neither an ideal nor evil technology: its justice implications vary according to demographics, grid characteristics, and generator's types, and ultimately will depend on smart policy implementation that includes equity concerns.

3 Unveiling Hidden Energy Poverty and Its Impact on Energy Transitions

Shuchen Cong[1], Destenie S. Nock[1], Yueming (Lucy) Qiu[2], Bo Xing[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Maryland, College Park, MD, [3]Salt River Project, Phoenix, AZ, Contact: dnock@andrew.cmu.edu

Here we will discuss how to integrate energy poverty analysis into decision making and planning in the residential sector. Income-based energy poverty metrics ignore people's behavior patterns, particularly reducing energy consumption to limit financial stress. Our relative energy poverty metric, the energy equity gap, is defined as the difference in the air conditioning turn on points between low and high-income groups. In our study region, we estimate the energy equity gap to be between 4.7-7.5°F (2.6-4.2°C). Within a sample of 4577 households, we found 86 energy-poor and 214 energy-insecure households. This energy limiting behavior means energy policy makers need to consider the energy deficits in their residential planning.

Novel Applications of Decision Analysis

General Session

Session Chair

Onesun Steve Yoo, University College London, London, United Kingdom.

1 Search in the Dark: The Normal Case

Manel Baucells, Darden School of Business, Playa Vista, CA

The standard search problem rewards the decision maker with the highest sampled value, minus the sampling cost. If the sampling distribution is unknown, then a Bayesian decision maker faces a complex balance between learning and optionality. We tackle the stopping problem of sampling from a normal distribution with unknown mean and unknown variance using a conjugate prior, a riddle that has remained open for half a century. We find that reservation prices---prevalent in search theory---are no longer optimal. Structurally, the optimal stopping region may be empty, or comprise one or two bounded intervals. We also introduce the so-called internal cost function, which provides a computationally practical way to identify the optimal stopping rule for any given prior, sampling history, and remaining samples, and that can also be applied to the case of known variance.

2 Decision Analysis as Data Analytics

Jeffrey M. Keisler, University of Massachusetts-Boston, Boston, MA, Contact: jeff.keisler@umb.edu

Data analytics gathers, synthesizes aggregate and manipulates data, to then identify, summarize relationships and patterns with an eye toward application. Instead of gathering raw data, decision analysis instead gathers more structured inputs from various sources and from these calculates artificial data, e.g., endpoint values, decision tree probabilities, and utility function parameters. After this, decision analysis follows a process that resembles a special instance of data analytics. Casting decision analysis in this way can enrich the incorporation of data analytics methods within decision analysis and decision analysis methods within data analytics.

3 Scale Dependence & Preference Reversals with Multicriteria Methods

Andrea Hupman[1], Ali E. Abbas[2], [1]University of Missouri - St. Louis, Saint Louis, MO, [2]University of Southern California, Los Angeles, CA

This talk examines the effects of constructed scales used to evaluate criteria, and monotonic perturbations of those scales, on the ranking of decision alternatives when using multicriteria decision methods. Within real-life applications, we illustrate how monotonic transformations of rating scales can change the preference ordering. We use simulation to characterize the sensitivity of ranking reversals in general classes of decisions. We present analytic results, analogous to those of stochastic dominance, for the conditions necessary to preserve the ranking of alternatives after a scale transformation. The results show that the ranking of decision alternatives is sensitive to the constructed scale, except in limited cases. The results provide insights for practitioners and highlight the implications of using arbitrarily constructed measurement scales.

4 Improving Large Scale Procurement Practices Using Natural Language Processing and Machine Learning

Onesun Steve Yoo[1], Xingyi Li[2], Viviana Culmone[1], Bert De Reyck[3], [1]UCL School Of Management, University College London, London, United Kingdom; [2]UCL, London, United Kingdom; [3]UCL School of Management, London, United Kingdom. Contact: onesun.yoo@ucl.ac.uk

A primary challenge faced by manufacturers aiming to improve their procurement practice is that the vast amounts of purchase orders records in their system are in the form of unstructured text data. We present our work with a publicly listed food manufacturer in the UK to tackle this issue. We used natural language processing and machine learning to classify the suppliers and products into hierarchical categories. We also developed an accompanying decision support tool that helps identify the inefficiencies in their procurement spend and provides request for quote (RFQ) targets. Methodologically, our work is the first to provide an accurate 5-level hierarchical classification problem. Practically, our solution is the first to provide an accurate assessment of the current state of a large-scale procurement practice using a “soup” of unstructured text data.

1 Differential Game Cybersecurity Model Featuring Attackers, Defenders, and Government Intervention

Leo MacDonald, Jomon A. Paul, Kennesaw State University, Kennesaw, GA, Contact: lmacdon4@kennesaw.edu

We develop a dynamic differential cybersecurity game model between an attacker and defender (firm). The attacker can have multiple methods of attack (controls) each with separate probabilities of success and resultant payoffs. The firm meanwhile impacts the probability of successful attack by allocating resources to both prevention and containment strategies that reduce the probability of a successful attack or the resultant losses (attacker payoffs) respectively. We further consider the actions of a third player, namely government (via it's associated agencies), that can use its resources to detect attacker threats and provide information/guidance to a firm to increase the successful defense/containment strategies. We then solve for the equilibrium strategies for each player in the game.

2 A Model of Fortification: A Bayesian Persuasion Approach

Abhra Roy, Jomon A. Paul, Kennesaw State University, Kennesaw, GA, Contact: aroy1@kennesaw.edu

We analyze a model of fortification involving a firm, a government and an attacker. The attacker aims to disrupt the firm's operations. The government can provide intelligence. With these setup we analyze conditions under which the government can persuade the attacker to refrain and the firm to bolster its defenses.

3 Domestic Extremism Prevention in the United States: A Policy Framework

Jomon A. Paul, Aniruddha Bagchi, Kennesaw State University, Kennesaw, GA, Contact: jpaul17@kennesaw.edu

Absence of a domestic extremism prevention architecture represents a major strategic-policy vulnerability in efforts to counter terrorism within the United States. We focus on policies that mitigate this problem. We evaluate how radicalization occurs due to social media, political polarization, attitudes towards immigration, state of economy, religious freedom, among others.

4 Effectiveness of Covid-19 Policies: A Configurational Approach Through Fsqca

Xinfang Wang[1], Jomon A. Paul[2], Aniruddha Bagchi[2], [1]Georgia Southern University, Statesboro, GA, [2]Kennesaw State University, Kennesaw, GA

This study evaluates the impact of state COVID-19 policies such as closures, quarantine, business restrictions on deaths, hospitalizations, and the economy. We employ fuzzy set qualitative comparative analysis (fsQCA) to determine the most impactful configurations of public policies for mitigating COVID-19 hospitalizations and deaths.

1 Agree to Disagree: Expert Disagreement as a Dynamic Decision Making Problem

Hesam Mahmoudi[1], Navid Ghaffarzadegan[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Falls Church, VA, Contact: hesam@vt.edu

The known causes of expert disagreement have one thing in common: they are static. While we do not refute any of these causes, we seek to offer an alternative dynamic explanation of how the decision making and learning can cause within- and between-cohort disagreements. We build upon the experiential learning theory to investigate how conditional feedback and sensitivity to skill interact to create path dependent and diverging opinions among learning agents. When customers have agency over choosing among experts, their choices contribute to path dependency, yet improves the total practice outcome. This improvement is due to endogenous specialization rather than diverse opinions contributing to innovation in open-ended situations. In contrast, top-down interventions to create consensus end in damaging the total outcome, even though they indeed reduce disagreement.

2 Applications of Data-driven Production Optimization for Heavy Processing Industries

Nianjun Zhou[1], Binny Samuel[2], Pavankumar Murali[3], [1]IBM, Chappaqua, NY, [2]IBM, Detroit, MI, [3]IBM, Yorktown, NY

This talk focuses on real-time recommendations for the operations of manufacturing processes based on production optimization. The solution provides the predicted and optimized production in a future horizon without and with adopting our recommendation. We develop regression models based on the carefully selected control variables and real-time sensors as the current states of operation with the deep learning technique. We choose either non-linear or Mixed-integer linear programming optimization based on the process complexity and response requirement. We apply our data-driven solution to different heavy industrial applications, such as cement and paper production.

3 Maximizing the Expected Value of Experimentation for Rank Aggregation of Top-k Pairwise Comparisons

Courtney J. Burris[1], Himangshu Kumar Paul[2], Alexander Nikolaev[1], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo, Amherst, NY, Contact: cburris2@buffalo.edu

In many applications, the top-K commonly most preferred items can be identified by procuring annotators' pairwise preferences of these items. However, soliciting and aggregating this information for ranking can be costly. We present an active sampling algorithm that, at any stage of this inference problem, selects the most informative next pairwise comparison to solicit, based on maximizing the expected value of experimentation. The algorithm's logic and efficiency are demonstrated on both synthetic and real-world datasets.

4 Sequential Anomaly Detection with Sampling Constraints

Aristomenis Tsopelakos[1], Georgios Fellouris[2], [1]University of Illinois at Urbana Champaign, Urbana, IL, [2]University of Illinois at Urbana Champaign, Urbana, IL, Contact: tsopela2@illinois.edu

We consider the problem of sequential anomaly detection, where we observe multiple data sources in real-time, not all of them simultaneously, and we try to identify which of them exhibit outlying statistical behavior. We design detection procedures that consist of a sampling rule that suggests which sources to sample, a stopping rule which determines when to stop, and a decision rule which indicates which sources to identify as anomalous. A lower and an upper bound are assumed on the number of anomalous sources. The probabilities of at least one false alarm and at least one missed detection are controlled below tolerance levels. The number of sources observed at each instance is limited due to sampling constraints. Under this problem setup, we provide two families of sampling rules: the probabilistic and the ordering family, and we show that they are asymptotically optimal.

AMPL /
Technology Tutorial

1 Advances in Model-Based Optimization with AMPL

Robert Fourer, AMPL Optimization, Indianapolis, IN, Contact: 4er@ampl.com

Optimization has been fundamental to OR and Analytics for as long as there have been computers, yet we are still finding ways to make optimization software more natural to use, faster to run, and easier to integrate with application systems. This presentation offers a quick tour of ways that AMPL's modeling framework has been enhanced to support optimization in today's challenging applications. Topics include:
 Expressing objectives and constraints more directly and understandably
 Exchanging data and results more directly and efficiently, with spreadsheets and with database systems
 Building better interfaces to applications using snapshots, callbacks, and other new features of AMPL's APIs for popular programming languages
 Deploying optimization in cloud environments and containersTo complement these feature advances, the presentation concludes by describing ways that AMPL is making model-based optimization more accessible, through the new Community Edition, a rewritten NEOS Server client, and free Model Colaboratory examples for teaching and learning optimization.

Integration of Prediction and Optimization with Applications in Operations Management
Tutorial Session

Session Chair

Mabel Chou, National University of Singapore, SG, SG, Singapore.

1 **Integration of Prediction and Optimization with Applications in Operations Management**

Meng Qi[1], Zuo-Jun Max Shen[2], [1]Cornell University, Ithaca, NY, [2]University of California Berkeley, Berkeley, CA

Big data provides new opportunities to tackle one of the main difficulties in decision-making systems - uncertain behavior following an unknown probability distribution. Standard data-driven approaches usually consist of two steps. The first step involves predicting or estimating the uncertainty behavior using data. Then the second step requires finding decisions that opti-mize an objective function that depends on the output of the first step. Instead of the classical two-step predict-then-optimize (PTO) procedure, this tutorial examines data-driven solutions that integrate these two steps. We first introduce the problem formulation as a contextual sto-chastic optimization. In this formulation, the objective function depends on the unknown uncer-tainty and the distribution of the uncertainty is associated with some contextual information. Massive data is often available to solve this problem, including historical observations of the uncertainty and contextual information. Therefore, machine learning tools have become an im-portant technique to achieve integrated data-driven solutions. Yet, it is noteworthy that the goal of the integrated data-driven solution is very different from traditional predictive tasks for ma-chine learning. Moreover, different integrated data-driven methods have shown applicability and effectiveness in many real-world decision-making situations, such as inventory manage-ment, COVID-19 pandemic, and power system. To demonstrate the practicality and the real-world impact, we review current achievements of integrated methods in different real-world applications in operations management.

Location Analysis in Architectural and Urban Planning

General Session

Session Chair

Hiroko Watanabe, The University of Tokyo, Tokyo, Japan.

Session Chair

Yudai Honma, The University of Tokyo, Meguro-Ku, Japan.

1 **Cost-benefit Analysis of Degree of Renovation and Construction Costs in Architecture Conservation for Conversion to Profit-making Facilities**

Kaori Isawa[1], Hiroko Watanabe[1], Yudai Honma[2], [1]The University of Tokyo, Tokyo, Japan; [2]The University of Tokyo, Meguro-Ku, Japan.

In Japan, whose mainstream urban development is scrap and build, historic architectures are often demolished, and architecture conservation tends to be difficult. Thus this study aims to explore sustainable architecture conservation mathematically. In this study, we propose a mathematical model to solve the optimal degree of renovation in architecture conservation for Conversion to profit-making facilities. We expect this model to become tools to help decision-making for owners have historical architectures.

2 **Maximum Likelihood Estimation of the Optimal Area Assignment by Delivery Planning Simulation**

Junya Maruyama[1], Yudai Honma[2], Daisuke Hasegawa[3], Soma Toki[4], Naoshi Shiono[5], [1]The University of Tokyo, Tokyo, Japan; [2]The University of Tokyo, Tokyo, Japan; [3]The University of Tokyo, Tokyo, Japan; [4]Tokyo Gas Co., Ltd., Tokyo, Japan; [5]Kanagawa Institute of Technology, Atsugi, Japan. Contact: juntama0826@g.ecc.u-tokyo.ac.jp

In this study, we constructed a maximum likelihood estimation model of the optimal area assignment by delivery planning. The model intended to combine the advantages of two delivery planning methods: the efficiency of the software-based method and the flexibility of the area-in-charge method. We solve a large number of delivery planning problems for each stochastic demand pattern using computers and then assign an optimal delivery area that is globally consistent with this data. We focused on whether the optimal route for each demand pattern was included in the same area, and found the assigned area that maximized the probability. This model was created for daily use by solving the optimization of the circulation problem in advance by computer, and turning it into an area map that is easy to understand.

3 **Spatial Interaction Model for Career-path Selections by High School Graduates**

Suzune Nishiyama[1], Yudai Honma[2], [1]The University of Tokyo, Tokyo, Japan; [2]The University of Tokyo, Meguro-Ku, Japan. Contact: nishiyama-suzune713@g.ecc.u-tokyo.ac.jp

In Japan, both the birthrate declining and the population aging are the critical issues, and they are often discussed in conjunction with the excessive concentration in the metropolitan area. Especially, career-path selections by high school graduates significantly affect population distribution nationwide because they often involve moving across the county. This study, therefore, analyzes the structure of their migrations based on the spatial interaction model. As their major choice is either job hunting or proceeding to higher education, we focus on the differences in decision-making between them. This study will contribute to the evidence-based policy-making from educational and urban planning aspects.

4 Spatial Clustering of Sightseeing Spats Based on Real Tourist Trajectory Data

Yuya Nemoto[1], Hiroyuki Hasada[1], Yudai Honma[2], [1]The University of Tokyo, Bunkyo-Ku, Japan; [2]The University of Tokyo, Meguro-Ku, Japan. Contact: nemoto-yuya0324@g.ecc.u-tokyo.ac.jp

With the spread of smartphones and SNS, it has become easier to find attractive sightseeing spots during trips. Therefore, even foreign tourists do not necessarily have to follow a predetermined route, and they can enjoy any place in any order. In this study, we try to clarify the hidden structure behind such free traveling. By proposing a new clustering method for sightseeing movements, we categorize tourist spots and analyze their connections. The method is applied to the actual tourist trajectory data collected on a state scale over several years. This study contributes to load balancing and proposes better tourist spots.

1 Predictive 3D Printing with IoT

Jing-Sheng Jeannette Song[1], Yue Zhang[2], [1]Duke University, Durham, NC, [2]Pennsylvania State University, University Park, PA, Contact: yue.zhang@psu.edu

We consider the context of a 3D printer supplying a critical part installed in multiple machines embedded with sensors and interconnected via IoT. While it is tempting to perceive that the marriage of 3D printing and IoT would make on-demand printing a reality, our results indicate that the true benefit of the marriage is to enable predictive printing. It is optimal for the 3D printer to print-to-stock predictively in advance of demand, triggered by a system-lifetime-status dependent threshold. Whether it is optimal to print-on-advance-demand to achieve minimum inventory depends crucially on the printing speed. We further quantify the impact of IoT on system cost and inventory by separately assessing the impact of advance demand information from embedded sensors and that of IoT's real-time information fusion from sensor interconnections.

2 Should I Make use of Reservations? The use of Booking Systems for Public Services

Benjamin LEGROS[1], Jan C. Fransoo[2], [1]EM Normandie, PARIS, France; [2]Tilburg University, Tilburg, Netherlands. Contact: jan.fransoo@tilburguniversity.edu

Scarce public resources such as parking facilities or museums increasingly make use of booking systems with reservation slots, with a purpose to provide both better service and a better utilization of the limited resource. Endogenizing the service fee and the duration of the time slot in an Erlang loss queuing game, we identify conditions under which it is beneficial to deploy a booking system, and when it would be better to simply let customers arrive at random.

3 Forewarned is Forearmed? In-transit Monitoring, Contingent Sourcing and Supplier Competition

Tao Lu[1], Brian Tomlin[2], [1]University of Connecticut, Storrs, CT, [2]Tuck School of Business, Hanover, NH, Contact: tao.lu@uconn.edu

Shipment monitoring technologies enable supply chain managers to detect yield-threatening disturbances during transportation of perishable and fragile products and take contingency actions if needed. We examine the implications of in-transit monitoring and contingent sourcing on a buyer purchasing from two competing suppliers. One supplier has a long transportation lead time that is prone to yield loss in transit; the other has a short lead time that is not prone to yield loss. We show that the buyer may or may not benefit from contingent sourcing with in-transit monitoring, as the possibility of contingent sourcing may soften the competition between suppliers. We further discuss the cases when the monitoring technology is imperfect and when a detected disturbance can be corrected (with a certain probability).

4 **Blockchain and Its Applications in the Supply Chain**

Yusen Xia, Georgia State University, Atlanta, GA

In this presentation, we will discuss the blockchain application into supply chains. through several model settings. In particular, various benefits and downfalls are reviewed facing uncertainties of either upstream or downstream or both along the channel.

1 **Optimal Feedback in Contests**

Sina Moghadas Khorasani[1], Jeffrey Ely[2], George Georgiadis[3], Luis Rayo[4], [1]University of California San Diego, Rady School of Management, La Jolla, CA, [2]Northwestern University, Evanston, IL, [3]Northwestern University, Kellogg School of Management, Chicago, IL, [4]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: skhorasani@ucsd.edu

We obtain optimal dynamic contests for environments where the designer monitors effort through coarse, binary signals and aims to elicit maximum effort, ideally in the least amount of time possible. The designer has a vast set of contests to choose from, featuring termination and prize allocation rules together with real-time feedback for the contestants. Every effort-maximizing contest has a history-dependent termination rule, a feedback policy that keeps agents fully apprised of their own success, and a prize allocation rule that grants them, in expectation, a time-invariant share of the prize if they succeed. Any contest that achieves this effort in the shortest possible time must in addition be what we call second chance: once a pre-specified number of successes arrive, the contest enters a countdown phase where contestants are given one last chance to succeed.

2 **Pay with Your Data: Designing Optimal Data-sharing Mechanisms for Artificial Intelligence Services**

Seetharama Chandrasekhar Manchiraju[1], Sameer Mehta[2], Milind Dawande[3], Ganesh Janakiraman[4], [1]University of Texas-Dallas, Richardson, TX, [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]The University of Texas at Dallas, Richardson, TX, [4]University of Texas- Dallas, Richardson, TX, Contact: chandumanchi@gmail.com

Technology companies such as Google, Amazon, and Microsoft offer the speech-to-text Machine Learning (ML) service. In interesting pricing mechanisms found in practice for this service, companies provide a discount to customers for sharing their data to improve the ML models used for the service. In this paper, we analyze two pricing mechanisms used by major technology companies and derive an optimal mechanism over a class of mechanisms inspired by these two mechanisms. We compare the revenue obtained, the improvement in the service, and the consumer surplus across these mechanisms.

3 **Empirical Investigation of Side Effects of Adaptive Pricing**

Ozalp Ozer[1], Inki Sul[2], A. Serdar Simsek[3], [1]Amazon, Richardson, TX, [2]University of Texas at Dallas, Richardson, TX, [3]University of Texas-Dallas, Richardson, TX, Contact: inki.sul@utdallas.edu

We assess the impact of a retailer's frequent price adjustments on customers' long term expenditure. From the observational dataset we obtained from our partner luxury fashion retailer, we study the spillover effects of observing different prices of a product on a customer's overall future expenditure pattern within the retailer. Using propensity score matching and causal learning method, we find negative effects of frequent price changes on long-term expenditure of customers who observed them. By quantifying the long-term effect of price fluctuation on sales, we provide product-level optimal price change budget, i.e., the amount of price change allowed within a certain time period. Using this result, we find conditions in which how adaptive pricing retailer can price lower than competitors and still maintain overall revenue in the long run using simulation.

Patient-centered Healthcare Modeling

General Session

Session Chair

Hossein Piri, University of British Columbia-Sauder School of Business, Vancouver, BC, Canada.

1 Individualized Dynamic Patient Monitoring Under Alarm Fatigue

Hossein Piri[1], Tim Huh[1], Steven Shechter[1], Darren Hudson[2], [1]Sauder School of Business-University of British Columbia, Vancouver, BC, Canada; [2]University of Alberta-Department of Critical Care Medicine, Edmonton, AB, Canada. Contact: hossein.piri@sauder.ubc.ca

Hospitals are rife with alarms, many of which are false. This leads to alarm fatigue, in which clinicians become desensitized and may inadvertently ignore real threats. We develop a partially observable Markov decision process model for recommending dynamic, patient-specific alarms in which we incorporate a cry-wolf feedback loop of repeated false alarms. Our model takes into account patient heterogeneity in safety limits for vital signs and learns a patient's safety limits by performing Bayesian updates during a patient's hospital stay. We develop structural results of the optimal policy and perform a numerical case study based on clinical data from an intensive care unit. We find that compared with current approaches of setting patients' alarms, our dynamic patient-centered model significantly reduces the risk of patient harm.

2 Data-driven Predictive Models for Identifying Risk Factors Leading to Opiate Abuse

Jinha Lee[1], Arthur Yeh[2], Zenan Sun[3], Qizhen Lan[3], Hyojung Kang[4], [1]Bowling Green State University, Bowling Green, OH, [2]Bowling Green State University, Bowling Green, OH, [3]Bowling Green State University, Bowling Green, OH, [4]University of Illinois at Urbana-Champaign, Champaign, IL, Contact: jinhal@bgsu.edu

Although slightly decreasing from 2017 to 2018, opioid-related overdose remains a leading cause of injury-related mortality in the US, with nearly 70% of drug overdoses involving opioids. Chronic opioid therapy guidelines recommend identifying patients with increased risk of problematic opioid use, but the clinical assessment of risks often does not occur on a timely basis. Thus, relying on clinical judgment alone may be inadequate for clinicians to choose the proper course of action for patients with chronic pain. This research aims to provide the knowledge and tools necessary for opiate addiction in Ohio. In particular, this study aims to harness the potential of big-data analytics to identify the patient-level factors associated with opioid dependency and subsequently develop a model to predict the likelihood of opioid addiction.

3 A Patient-centered Solution to the Physician Preferred Item Problem

Renato E. de Matta, University of Iowa, Iowa City, IA, Contact: renato-dematta@uiowa.edu

When making decision for a patient about using an implantable medical device, the physician balances the technology, clinical judgment, and medical evidence to produce good patient outcomes. While the purchase of a broader assortment of the device would accommodate the Physician Preferred Items (PPIs), hospitals have become selective in stocking the PPIs as revenues have been constrained and Medicare reimbursements have decreased. We shall find the tradeoff between cost savings from discounts offered by a device manufacturer and reduced patient utility if the patient does not receive the PPI. We formulate the problem with uncertain demand as a two-stage stochastic program with recourse decisions. With industry data, we show that stocking each PPI coupled with the physician's flexibility to use a lesser preferred device can produce good patient outcomes at lower cost.

4 Unlocking Cost Savings Hidden in Hospital Tier Contracts

Willow Yang[1], James Campbell[2], Mitchell Millstein[2], [1]Sam Houston Sate University, Huntsville, TX, [2]University of Missouri - St. Louis, Saint Louis, MO, Contact: willowyang@shsu.edu

Medical supply costs account for up to 40% of a hospital's expenses and continue to grow. We present a new and practice-oriented approach to combatting high medical supply costs by exploiting cost-saving opportunities hidden in complex hospital procurement contracts. We formulate a MILP model to validate and optimize procurement decisions while taking into account real-world complexities, including complicated tier pricing schemes, physician preference items (PPIs), and asymmetric product substitutability. The application of our approach to regional and nationwide health systems shows significant cost-saving opportunities in hospital procurement and the ability to quantity the impact of PPIs. PPIs have been highly criticized for inflating medical supply costs. We show only a few may be "critical" for reducing costs and require the focus of management resources.

1 Fighting Imperfect Produce: Grocery Retailing Strategies and the Battle Against Food Waste

Haoran Yu, Burak Kazaz, Fasheng Xu, Syracuse University, Syracuse, NY, Contact: hyu143@syr.edu

We examine a retailer's food ordering process where a random proportion of the order is imperfect. We build a MNL model to determine how to sell fresh and imperfect produce. We consider three prevailing strategies: Discarding, bunching and differentiating. We determine optimal quantity and price under each strategy. We identify the optimal strategy under various factors, including consumers' valuation of imperfect produce, price sensitivity, and retailer's limited shelf space.

2 Portfolio Approach to Cash Flow Variability

Nikolay Osadchiy[1], William Schmidt[2], Jing Wu[3], [1]Emory University, Atlanta, GA, [2]Cornell University, Ithaca, NY, [3]Chinese University of Hong Kong, Hong Kong, Hong Kong.

Firms with high cash flow variability are more likely to experience cash flow shortfalls that disrupt budget plans, capital expenditures, and research and development investments. We document how cash flow variability changes within firms and over a supply chain network, and find that the variability of inbound cash flows is on average greater than variability of demand, and variability of outbound cash flows is greater than variability of production. We then show that an operational hedge (customer portfolio management) can be a viable alternative to financial hedging to smooth cash flow variability.

3 VinTech: Robo-Advising Using Wine Analytics

Mert Hakan Hekimoglu[1], Burak Kazaz[2], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Syracuse University, Syracuse, NY, Contact: hekimm@rpi.edu

This paper examines a comprehensive path regarding how analytics can be employed for automated trading of wine. We coin this as VinTech. The paper highlights the essential components of data analytics necessary for robo-advising. We first develop a pricing algorithm to represent the realistic value of a wine. Using this algorithm, we then compare the price evolution of underpriced wines to overpriced wines. Last, our robo-advising algorithm constructs wine portfolios for different investment goals and risk preferences. We demonstrate the performance of our algorithm using out-of-sample testing. This paper aims to convert an opaque market into a transparent and efficient investment market.

CC - Room 142
Economics of Retail Distribution Services
General Session

Session Chair
Stanley Lim, Michigan State University, East Lansing, MI

1 The Point of No Return? Restrictive Changes to Lenient Return Policies and Resulting Consumer Reactions

James Duane Abbey[1], Huseyn Abdulla[2], Michael Ketzenberg[3], [1]Texas A&M University, College Station, TX, [2]Mays Business School, Texas A&M University, College Station, TX, [3]Texas A&M University, College Station, TX

Retailers face a challenging trade-off in maintaining versus restricting long-established lenient return policies. Lenient return policies have become an important part of retailers' value proposition. Yet, lenient return policies increase volume of product returns, which hurts profitability. Motivated by observing an increase in restrictive changes to long-established lenient return policies, we investigate consumer reactions to such changes and their managerial implications. Through a series of randomized online experiments with diverse consumer samples, we find that restrictive changes decrease consumer trust in retailers and lead to lowered favorable behavioral intentions. We also find that providing managerial transparency, in the form of communicating the rationale for restrictive changes, can attenuate the negative consumer reactions.

2 Inventory and Supply Chain Management with Auto-delivery Subscription

Junfei Lei, University of Washington, Seattle, WA

Auto-delivery subscription is widely employed in supply chains whereby a supplier delivers products to buyers based on the buyer's choice of shipping quantity. The buyer enjoys a discount for the auto-delivery orders and other benefits, including free subscription and cancellation. Since those benefits seem to all accrue to the buyer at the supplier's expense, it is an intriguing question about the rationale for

the supplier's decision to offer auto-delivery and its impact on the profitability of both parties. We first develop a model consisting of a supplier and a single buyer, whereby the supplier offers a discount for the auto-delivery orders and the buyer chooses the auto-delivery quantity with the flexibility of canceling the subscription. Later, we extend the model to a setting with multiple buyers, whereby the supplier sets a public discount for all the buyers.

3 The Value of Home Delivery Subscription Services: Evidence from an Omnichannel Retailer

Stanley Lim[1], Sungho Park[2,3], Elliot Rabinovich[2], Rui Sousa[4], [1]Michigan State University, East Lansing, MI, [2]Arizona State University, Tempe, AZ, [3]Seoul National University, Seoul, Korea, Republic of; [4]Catholic University-Portugal, Porto, Portugal. Contact: slim@msu.edu

We examine the value of delivery subscription programs in an omnichannel context. Using order transactions data from an an omnichannel retailer before and after the introduction of a subscription program, we find that subscribers increase their online product spending after joining the program. However, the online product sales contribution is offset by changes in consumers' behaviors intended to extract economic benefits from joining the program, with negative impacts on fulfillment operations. We discuss the implications of these findings for the design of subscription programs and fulfillment operations.

4 Modeling Drivers' Choices in a Crowdsourced Delivery System

Hyunsuk Baek[1], Stanley Lim[2], Elliot Rabinovich[3], Lina Wang[4], Rui Yin[3], [1]Arizona State University, Tempe, AZ, [2]Michigan State University, East Lansing, MI, [3]Arizona State University, Tempe, AZ, [4]Georgia Southern University, Statesboro, GA, Contact: hbaek9@asu.edu

We model the choices crowdsourced drivers make when selecting order bundles for last-mile delivery. We apply the model empirically to the operations of a crowdsourced delivery platform during a four-month period to identify how crowdsourced drivers build their delivery workloads as a function of (cumulative) pay, delivery locations of the bundles, and distances between the bundles for density. We then show the insights on improvements to the assembly of bundles.

Sustainability Considerations in Supply Chains

General Session

Session Chair

Olga Perdikaki, University of South Carolina, Columbia, SC

Session Chair

Aditya Balaram, University of South Carolina

1 A Comparison of the Fast-fashion and Traditional Approaches to Apparel Retail: Profits and Environmental Impact

Aditya Balaram, Mark Ferguson, Olga Perdikaki, University of South Carolina, Columbia, SC, Contact: aditya.balaram@grad.moore.sc.edu

Apparel retailers have typically followed either the traditional (long lead times and more durable products) or fast-fashion approach (shorter lead times and less durable products). We compare these two approaches in terms of profitability and environmental impact, identifying win-win (more profitable and lower environmental impact) outcomes for both approaches. We also provide prescriptions to policy makers on which phase of a product's life-cycle to focus their sustainability efforts on.

2 Environmental Regulation Design: Motivating Firms' Clean Technology Investments with Penalties and Consumer Subsidies

Mina Mohammadi[1], H. Sebastian Heese[2], Tim Kraft[3], [1]North Carolina State University, Raleigh, NC, [2]NC State University, Raleigh, NC, [3]NC State - Poole College of Management, Raleigh, NC, Contact: mmohamm6@ncsu.edu

We study a regulator's choice of firm penalty and consumer subsidy for motivating firms to invest in clean technologies. Using an asymmetric duopoly, we examine the effect of competition and development uncertainty on a regulator's optimal decisions. We find that once the penalty and/or subsidy are sufficient to induce firms' investments, the use of a subsidy is always beneficial to the environment, firms, and consumers. Conversely, although penalizing firms for selling harmful products always benefits the environment, whether the penalty increases or decreases firm profitability and consumer welfare depend on the level of competition between the firms. Our findings provide insight into a regulator's policy decisions for motivating firms' environmental investments and how these decisions should be adapted based on the level of competition within an industry.

3 **Role of Traceability and Government Inspections on Deterring Adulteration in Competing Farming Supply Chains**

Weihua Zhou[1], Jinxin Yang[1], Zhong Chen[2], Retsef Levi[3], [1]Zhejiang University, Hangzhou, China; [2]East China Normal University, Shanghai, China; [3]MIT, Cambridge, MA, Contact: jinxin21@mit.edu

Food adulteration poses a serious threat to public health. This paper theoretically and empirically examines whether supply chain traceability can help the government effectively deter adulteration when a traceable supply chain and an untraceable supply chain compete in the market. Our results show that supply chain traceability may inadvertently induce the farmer to adulterate when the traceable supply chain has a competitive advantage over the untraceable one.

Sunday, 5 PM–6:15 PM

Research in Sustainable Operations and Supply Chain Management

General Session

Session Chair

Jason Nguyen, Ivey Business School, Western University, London, ON, Canada.

1 **Pride or Guilt? Impacts of Consumers' Socially Influenced Recycling Behaviors on Closed-loop Supply Chains**

Wenjie Huang[1], Chung-Li Tseng[1], Jason Nguyen[2], Samuel Nathan Kirshner[1], Wenlin Chen[3], [1]UNSW Business School, Sydney, Australia; [2]Ivey Business School, Western University, London, ON, Canada; [3]University of Electronic Science and Technology of China, Chengdu, China. Contact: wenjie.huang1@unsw.edu.au

The Operations Management (OM) and Environmental Psychology literature have examined consumer recycling behavior to address the growing sustainability crisis. Although Environmental Psychology research establishes that social influence substantially impacts recycling behavior, it has been mostly overlooked in OM research. In contrast, Environmental Psychology literature often ignores firms' operational decisions, which also significantly affects consumers' recycling decisions. This article examines how consumers' recycling behaviors are influenced by both the socially influenced emotions of pride and guilt and the firm's optimal decisions. This helps establish a better understanding of the motivations driving consumers' recycling behaviors, which is essential to unlocking the full potential of remanufacturing.

4 **Cosmetic Quality Standard and Its Impact on Food Waste**

Pascale Crama[1], Yangfang (Helen) Zhou[2], Manman Wang[3], [1]Singapore Management University, Singapore, Singapore; [2]Lee Kong Chian School of Business, Singapore Management University, Singapore, Singapore; [3]University of Science and Technology of China, He Fei, China. Contact: helenzhou@smu.edu.sg

A significant amount of fresh produce is wasted in the upstream of food supply chain due to the high cosmetic standard---regarding the appearance of the produce---which are set by retailers. We examine the economic incentives for retailers to adopt such high standards and their impact on food loss. A high minimum cosmetic standard of the produce enables the produce to be sold at a premium, which decreases the proportion of the produce that satisfies such standards. We show how the retailer's decision of cosmetic standard as well as food loss are affected by rejection rate due to high cosmetic standards and consumers' willing-to-pay for cosmetic-pleasing products.

Sunday, 5 PM–6:15 PM

Supply Chains and Sustainability

Contributed Session

Session Chair

Sarah Damberg, EBS University

1 **How Controversies in Supply Chain Help to Achieve Better Sustainability Practices? The Moderating Effect of R&D and Advertising**

Amir Naderpour, Gregory V. Frazier, University of Texas-Arlington, Arlington, TX, Contact: amir.naderpour@mavs.uta.edu

We focus on the effect of sustainable supply chain management (SSCM) controversies on implementing environmental, social, and governance sustainability practices. We study the relationship between SSCM controversies and different dimensions of sustainability practices, and the influence of investments in R&D and advertising on this relationship. Using a longitudinal sample of 610 firms observed from 2009 to 2019 and collected from three archival sources (Sustainalytics, ASSET4, COMPUSTAT) we posit that the relationship between SSCM controversies and sustainability practices would be influenced by the levels of the firm's investments in value-creating (e.g., R&D) and value-appropriating (e.g., advertising) resources.

2 Co_2 Conversion to Fuels Supply Chain Network Optimization

Rui Zhou[1], Mingzhou Jin[2], [1]University of Tennessee, Knoxville, knoxville, TN, [2]University of Tennessee-Knoxville, Knoxville, TN, Contact: rzhou7@vols.utk.edu

CO_2 conversion to fuels has great potential in CO_2 reduction, carbon-based resources alternative, and renewable energy storage. We evaluate the economic performance of three CO_2 conversion pathways and develop a mix-integer linear programming model to incorporate spatial and techno-economical data for the renewable fuels supply chain network optimization. The model is applied to the aviation jet fuel consumption in the major U.S. airports.

3 Who Cares More? An Empirical Study of US Companies on Negative News and Sustainable Supply Chain Management

Sarah Damberg[1], Julia Hartmann[2], [1]EBS Universität für Wirtschaft und Recht, Oestrich, Germany; [2]EBS Universität für Wirtschaft und Recht, Wiesbaden, Germany.

Negative news gains more and more attention in our world and are paramount in current times. Consequences of negative news have to be handled by decision makers, even if the news controversies origin is based among the supply chain. In the current literature we see that negative news influence companies SSCM practices and affects their management. Thus, we know little about the different companies' characteristics. In this research, we empirically ascertain characteristics of a company by using panel regression in form of a split-sample analysis. Among other things, we find that B2C companies react more to negative news by implementing SSCM prcatices than B2B companies do. With our research we contribute to the sparse literature in this research field and provide interesting information for decision makers.

Advances in Algorithms for Nonsmooth Optimization

General Session

Session Chair

Jiaming Liang, Georgia Institute of Technology, Atlanta, GA

1 A Single Cut Proximal Bundle Method for Stochastic Convex Composite Optimization

Jiaming Liang[1], Vincent Guigues[2], Renato D C Monteiro[3], [1]Yale University, New Haven, CT, [2]Fundação Getulio Vargas, Rio de Janeiro, Brazil; [3]ISyE Georgia Tech, Atlanta, GA

We present a stochastic composite proximal bundle (SCPB) method for solving convex composite stochastic optimization problems. Our approach is based on a novel one-cut model instead of the conventional cutting-plane model. The SCPB method includes the stochastic subgradient method as a special instance. To the best of our knowledge, this is the first proximal bundle method for stochastic programming able to deal with continuous distributions. To better illustrate the SCPB method, we study its performance on two-stage stochastic programming problems.

2 Scalable, Projection-Free Optimization Methods

Benjamin Grimmer, Johns Hopkins University, Baltimore, MD

We will discuss a newly developed approach to constrained optimization replacing orthogonal projections with much cheaper radial ones. This machinery only requires one-dimension line-searches while applying to a wide family of nonconvex functions and constraints. This construction gives rise to a duality relating optimization problems to radially dual problems. From this, we develop new projection-free first-order methods that avoid any Lipschitz continuity assumptions while benefiting from smoothness and growth conditions in the objective function. Moreover, we identify benefits from smoothness and strong convexity of constraint sets.

3 Survey Descent: A Multipoint Generalization of Gradient Descent for Nonsmooth Optimization

X.Y. Han, Adrian S. Lewis, Cornell University, Ithaca, NY, Contact: xh332@cornell.edu

For strongly convex objectives that are smooth, the classical theory of gradient descent ensures linear convergence relative to the number of gradient evaluations. An analogous nonsmooth theory is challenging: even when the objective is smooth at every iterate, the corresponding local models are unstable, and traditional remedies need unpredictably many cutting planes. We instead propose a multipoint generalization of the gradient descent iteration for local optimization. While designed with general objectives in mind, we are motivated by a "max-of-smooth" model that captures the subdifferential dimension at optimality. We prove linear convergence when the objective is itself max-of-smooth, and experiments suggest a more general phenomenon.

4 Optimal Methods for Convex Risk Averse Distributed Optimization

Zhe Zhang[1], George Lan[2], [1]Georgia Tech, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: zzhang724@gatech.edu

We study convex risk-averse optimization over a network. The problem generalizes the well-studied risk-neutral distributed optimization, but its communication and computation complexities are unknown. We propose two distributed algorithms, namely the distributed risk-averse optimization (DRAO) method and the distributed risk-averse optimization with sliding (DRAO-S) method, with tight complexities. The DRAO method achieves the optimal communication complexity, but it needs to assume a certain saddle point subproblem to be easily solvable. The DRAO-S method removes the strong assumption by introducing a novel saddle point sliding subroutine. Its computation complexity, characterized by the number of projection steps and gradient evaluations, is optimal. Matching lower communication complexity bounds for both DRAO and DRAO-S are also presented.

Hyoeun Lee, UIUC, Champaign, IL

1 Does Enforcing Fairness Mitigate Biases Caused by Sub-population Shift?

Subha Maity[1], Debarghya Mukherjee[1], Mikhail Yurochkin[2], Yuekai Sun[1], [1]University of Michigan, Ann Arbor, MI, [2]IBM Research, Cambridge, MA, Contact: smaity@umich.edu

Many instances of algorithmic bias are caused by subpopulation shifts. For example, ML models often perform worse on demographic groups that are underrepresented in the training data. In this paper, we study whether enforcing algorithmic fairness during training improves the performance of the trained model in the target domain. On one hand, we conceive scenarios in which enforcing fairness does not improve performance in the target domain. On the other hand, we derive necessary and sufficient conditions under which enforcing algorithmic fairness leads to the Bayes model in the target domain. We also illustrate the practical implications of our theoretical results in simulations and on real data.

2 Optimal Transport Problems for Capacities

David Saunders, University of Waterloo, Waterloo, ON, Canada. Contact: dsaunders@uwaterloo.ca

We consider the problem of finding a capacity on a product space that minimizes the Choquet integral of a cost function among all joint capacities with given marginals. The problem can be reformulated as a linear optimization problem, for which an explicit solution exists. Relations to other optimization problems and applications in finance and economics will be discussed.

3 A Stochastic Conjugate Subgradient Method for Large-scale Convex Optimization Problems

Di Zhang, University of Southern California, Los Angeles, CA

We present a stochastic extension of Wolfe's non-smooth conjugate subgradient algorithm which was originally designed to solve large-scale convex optimization problems using approximations that go beyond standard first order methods. The convergence of the algorithm is outlined, together with compelling computational evidence of the effectiveness using a variety of data sets associated with applications of Kernelized SVM.

4 Dynamic Assortment Planning: Online Demand Learning with Limited Inventory

Omid Arhami[1], Shirin Aslani[2], Masoud Talebian[3], [1]University of Georgia, Athens, GA, [2]Sharif University of Technology, Tehran, Iran, Islamic Republic of; [3]Columbia University, New York, NY, Contact: Omid.Arhami@uga.edu

We explore a simultaneous dynamic assortment planning and inventory allocation problem spanning multiple replenishment periods, in which the store learns demand online and actively based on sales data. To optimize revenue, the store must make two decisions jointly: product assortment and inventory allocation quota. The demand censoring induced by stock-outs and substitution is addressed by our algorithm, which continuously recognizes and filters out the truncated demand data. In various cases, numerical results show that our algorithm has a sublinear regret. Our findings also reveal that an inventory constraint has a major impact on a retailer's both learning and profit.

5 **A Dimension-insensitive Algorithm for Stochastic Zeroth-order Optimization**

Hongcheng Liu, Yu Yang, University of Florida, Gainesville, FL

We consider convex, stochastic zeroth-order optimization (S-ZOO). For this problem, we propose a sparsity-inducing stochastic gradient-free (SI-SGF) algorithm, which provably yields a dimension-free (up to a logarithmic term) query complexity in both convex and strongly convex cases. Such insensitivity to the dimensionality growth is proven, perhaps for the first time, to be achievable when neither gradient sparsity nor gradient compressibility is satisfied.

6 **Insights on the Theory of Robust Games**

Giovanni P. Crespi[1], Davide Radi[2], Matteo Rocca[3], [1]Università Cattaneo LIUC, Castellanza, Italy; [2]Università di Pisa, Pisa, Italy; [3]Universita' degli studi dell'Insubria, Varese, Italy. Contact: pcrespi@liuc.it

We consider aversion to payoff uncertainty in static games. Assuming the robust-optimization approach to uncertainty, we obtain a distribution-free model to handle ambiguity. We introduce opportunity cost of uncertainty and we prove relations between robust-optimization equilibria and \epsilon-Nash equilibria of the nominal counterpart game. Under some regularity conditions, robust-optimization equilibria converge towards a Nash equilibrium of the nominal counterpart game, when the level of uncertainty vanishes. Application to Cournot duopoly is also discussed.

7 **Mitigating the Impacts of Uncertain Geomagnetic Disturbances on Electric Grids**

Minseok Ryu[1], Harsha Nagarajan[2], Russell Bent[3], [1]Argonne National Lab, Tempe, AZ, [2]Los Alamos National Laboratory, Los Alamos, NM, [3]Los Alamos National Laboratory, Los Alamos, NM, Contact: harsha@lanl.gov

Geomagnetic disturbances increase the magnitude of the electric field on the Earth's surface (E-field) and drive geomagnetically-induced currents (GICs) along the transmission lines in electric grids. GICs can pose severe risks, like current distortions, transformer saturation and increased reactive power losses, leading to system unreliability. Further, GIC modeling is challenging because E-field's magnitude and direction are uncertain and non-stationary. In this work, we model uncertain E-fields using the distributionally robust optimization approach (DRO) that determines optimal transmission grid operations such that the worst-case expectation of the cost is minimized. We develop an accelerated CCG algorithm by exploiting a special structure of the support set and present extensive numerical experiments based on GIC-specific test systems.

Leveraging Structure of Uncertainty in Dynamic Optimization

General Session

Session Chair

Eojin Han, Southern Methodist University, Dallas, TX

1 **Dynamic Capacity Management for Deferred Surgeries**

Eojin Han[1], Kartikey Sharma[2], Kristian Singh[3], Omid Nohadani[4], [1]Southern Methodist University, Dallas, TX, [2]Zuse Institute Berlin, Berlin, Germany; [3]Benefits Science Technologies, Arlington, TX, [4]Benefits Science Technologies, Arlington, MA, Contact: eojinh@smu.edu

The COVID-19 pandemic has necessitated widespread deferrals of elective surgeries, which non only increase the cost from deterioration of patients' conditions but also decrease the revenue. However, the endogeneity of the uncertainty to hospital operations renders existing capacity management approaches inapplicable. To this end, we develop a robust optimization framework for the dynamic surgical capacity management problem. Uncertain parameters and their endogenous nature are modeled via multilinear functions, and the concept of tree of uncertainty products is proposed to for tractable approximations under various decision rules. Our Implementation for more than 15,000 hernia patients in the United States demonstrates sizable improvements over alternative methods by up to 10% with multiple practical insights on optimal expansion strategy.

2 **A Decision Rule Approach for Two-stage Data-driven Distributionally Robust Optimization Problems with Random Recourse**

Xiangyi Fan[1], Grani Adiwena Hanasusanto[2], [1]The University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, Contact: fxy@utexas.edu

We study two-stage stochastic optimization problems with random recourse, where the adaptive decisions are multiplied with the uncertain parameters. To mitigate the computational intractability of infinite-dimensional optimization, we propose a scalable approximation scheme via piecewise decision rules. We then develop a data-driven distributionally robust framework with two layers of robustness to address distributionally uncertainty. The optimization problem can be reformulated as an exact copositive program, which admits tractable approximations in semidefinite programming. We design a decomposition algorithm where smaller-size semidefinite programs can be solved in parallel, which further reduces the runtime. Lastly, we establish the performance guarantees of the proposed scheme and demonstrate its effectiveness through numerical examples.

3 Presenter

Karthik Natarajan[1], Louis Chen[2], Divya Padmanabhan[3], Chee Chin Lim[4], [1]Singapore University of Technology and Design, Singapore, Singapore; [2]Naval Postgraduate School, california, CA, [3]IIT Goa, Goa, India; [4]National University of Singapore, Singapore, Singapore.

In this paper, we introduce a correlation robust model for the influence maximization problem. We evaluate a seed set's expected influence under all possible correlations - specifically, the one that presents the worst-case. We show that any seed set's worst-case expected influence can be efficiently computed, and though optimizing the worst-case (over seed sets) is NP-hard, a (1 − 1/e) approximation algorithm can be obtained. We provide structural insights from the model and contrast it with the independent cascade model. We discuss how the proposed model can be extended to optimize other objectives by controlling for conservatism using a mixture of the independent and the worst-case distribution or by incorporating risk criterion in choosing the seed set. Finally we provide insights from numerical experiments to illustrate the usefulness of the model.

4 Supermodularity in Two-stage Distributionally Robust Optimization

Daniel Zhuoyu LONG[1], Jin Qi[2], Aiqi ZHANG[3], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]University of Toronto, Toronto, ON, Canada. Contact: jinqi@ust.hk

We solve a class of two-stage distributionally robust optimization problems which have the property of supermodularity. We exploit the explicit worst-case expectation of supermodular functions and derive the worst-case distribution for the robust counterpart. This enables us to develop an efficient method to obtain an exact optimal solution. We also show that the optimal segregated affine decision rule returns the same optimal value in our setting. Further, we provide a necessary and sufficient condition for checking whether any given two-stage optimization problem has the supermodularity property. We apply this framework to several classic problems, including the multi-item newsvendor problem, the facility location design problem, the lot-sizing problem on a network, the appointment scheduling problem and the assemble-to-order problem.

Modeling for Stochastic Programming

General Session

Session Chair

Alan J. King, IBM Research, Yorktown Heights, NY

1 An End-to-end Automated AI System for Reinforcement Learning

Long Vu[1], Todd Mummert[1], Radu Marinescu[2], Dharmashankar Subramanian[1], Peter KIRCHNER[1], Paulito Palmes[2], Nhan Pham[1], Tejaswini Pedapati[1], [1]IBM TJ Watson Research Center, Yorktown Heights, NY, [2]IBM Research, Dublin, Ireland.

Deep Reinforcement Learning (RL) has emerged as a promising technique for solving sequential decision-making problems under uncertainty in many real-world applications. However, it is known to be highly sensitive to internal hyperparameters and requires significant expert manual effort for tuning an intractably large number of configurations. We present an Automated AI system for RL, combining both open source and proprietary algorithms in a unified framework and enabling rapid algorithm selection and hyperparameter optimization, thus allowing non-experts to benefit from SOTA RL solutions. Our system supports online and offline RL algorithms, achieving optimal solutions for a large set of benchmark RL environments. The system also provides hosted service on IBM API Hub where users can make REST API requests to train RL agents.

2 Continuous Deep Reinforcement Learning for Non-stationary Stochastic Inventory Optimization

Henri Dehaybe[1], Daniele Catanzaro[2], Philippe Chevalier[3], [1]Universite Catholique de Louvain, Louvain-la-Neuve, Belgium; [2]Universite Catholique de Louvain, Mons, Belgium; [3]UCLouvain, Louvain La Neuve, Belgium. Contact: henri.dehaybe@uclouvain.be

The deep Reinforcement Learning (RL) approach to Inventory Control has recently been the subject of increasing research interest as it holds the promise of autonomously learning complex replenishment policies. Yet, prior publications face a major scalability issue due to the need of discretizing the action-space of the problems. We propose to use continuous deep RL to address this issue by approximating continuous policies to backorder and lost sales versions of the single-item lot sizing problem in the most general setting of non-stationary stochastic demand and fixed order cost. We show that, after an appropriate training in randomly generated environments, our approach can interpolate near-optimal dynamic policies in real-time on instances with a rolling-horizon given a previously unseen demand forecast, without the need to periodically resolve the problem.

3 Behaviorally-enriched Learning Mechanism for Road Network Restoration After Disasters

Maryam Babaee, Namrata Saha, Shabnam Rezapour, Florida International University, Miami, FL, Contact: mbaba005@fiu.edu

This study proposes a reinforcement learning-based mechanism for scheduling the restoration of disrupted road infrastructure. Considering post-disruption evolutions in the routing behavior of travelers, the objective of the mechanism is to maximize the traffic acceleration. The mechanism is tested on the road network of Sioux Falls in South Dakota for several tornado scenarios that are developed based on the historical report of the National Oceanic and Atmospheric Administration.

4 Solution Path Algorithm for Distributionally Robust Support Vector Machine

Guangrui Tang, Neng Fan, University of Arizona, Tucson, AZ

Distributionally robust optimization minimizes the worst-case expected loss function under an ambiguity set. This theory inspired new interpretations of regularization in machine learning. In this talk, we derived a support vector machine model with squared loss function based on distributionally robust optimization theory. The regularization term is Lasso penalty. A solution path algorithm is proposed to speed up the tuning of the regularization hyperparameter in this model. We implement numerical experiments to validate the performance of the new model and the computational efficiency of the solution path algorithm.

Session Chair

Ehsan Mahyari, The University of Alabama, Tuscaloosa, AL

1 Stochastic Mixed Model Sequencing with Failures

Ibrahim Ozan Yilmazlar, Mary Beth Kurz, Hamed Rahimian, Clemson University, Clemson, SC, Contact: iyilmaz@g.clemson.edu

In the automotive industry, the sequence of vehicles to be produced is determined ahead of the production day. However, there are some failed vehicles that cannot be produced due to some reasons such as material shortage and paint failure. These vehicles are pulled out of the sequence and the vehicles in the succeeding positions are moved forward which potentially results in an increased work overload. In this study, we predict the failure probability of each model based on the historical data and we develop a sample average approximation model to generate robust mixed-model sequences. To solve the model, we design a customized Benders' decomposition algorithm and exploit several computational enhancement techniques. Numerical results show the computational efficiency of our algorithm over off-the-shelf solvers.

2 How to Safely Move from Periodic Maintenance to Predictive Maintenance

Ragnar Eggertsson[1], Rob Basten[2], Geert-Jan Van Houtum[2], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: r.h.eggertsson@tue.nl

Periodic maintenance is a traditional form of maintenance that is performed after operating a capital good for a predetermined amount of time, irrespective of the capital good's health. In contrast, predictive maintenance is a modern maintenance paradigm that performs maintenance based on the capital good's health, such as maintaining when the capital good's health indicates failure is imminent.
We study how to go from periodic to predictive maintenance for identical critical systems. The degradation process of the critical systems must be learned to implement predictive maintenance. To achieve this, we suggest a method combining safe reinforcement learning with deliberate exploration to learn the degradation process while keeping losses due to failures to a minimum.

3 Optimizing Unmanned Aerial Vehicle Delivery on Last-mile Logistics Under Stochastic Environment

Ali Tolooie, Ashesh Kumar Sinha, Kansas State University, Manhattan, KS, Contact: alit@ksu.edu

We propose a two-stage stochastic mixed-integer programming model to design a reliable and efficient supply chain network using logistics infrastructure. The proposed network includes charging stations to extend the delivery coverage of drones. We handle stochasticity in the problem by developing Markov decision process models that evaluate tradeoffs between the number of batteries and drones in the last-mile logistics system. To overcome difficulties computationally, we propose novel decomposition-based approaches for each problem to provide an exact analysis for our logistics network. In terms of the accuracy of the decomposition technique in our model, we consider the impact of the charging rate, flight rate, and demand arrival rate of each subsystem.

4 Electric Vehicle Fleet Charging Management at a Depot with Multi-connector Chargers

Ehsan Mahyari, Nickolas Freeman, The University of Alabama, Tuscaloosa, AL, Contact: emahyari@crimson.ua.edu

We consider the electric vehicle (EV) fleet charging problem from the standpoint of a Charging as a Service (CaaS) company. Agencies that operate EV fleets can rely on a CaaS company to provide a complete charging solution including services spanning the design of the charging depot to the operation of the charging process to meet an agreed upon service level offered for a contracted rate, thus, the profitability of the CaaS company is dictated by how efficiently they provide the service. Although lower power price periods are more attractive, uncertainties in arrival times and charge needs, and time-varying electricity costs result in a trade-off between charging costs and service levels. Our approach utilizes an Approximate Dynamic Programming approach to minimize the total charging costs of a depot composed of non-homogeneous chargers with multi-connector support.

Novel Algorithms for Faster Optimization and Machine Learning

General Session

Session Chair

Hassan Mortagy, Georgia Institute of Technology, Atlanta, GA

1 Conditional Gradients for the Approximately Vanishing Ideal

Sebastian Pokutta, Elias Wirth, Zuse Institute Berlin (ZIB), Berlin, Germany.

The vanishing ideal of a set of points X is the set of polynomials that evaluate to 0 over all points x in X and admits an efficient representation by a finite set of polynomials called generators. To accommodate the noise in the data set, we introduce the Conditional Gradients Approximately Vanishing Ideal algorithm (CGAVI) for the construction of the set of generators of the approximately vanishing ideal. The constructed set of generators captures polynomial structures in data and gives rise to a feature map that can, for example, be used in combination with a linear classifier for supervised learning. In CGAVI, we construct the set of generators by solving specific instances of (constrained) convex optimization problems with the Pairwise Frank-Wolfe algorithm (PFW).
(joint work with Elias Wirth)

2 A Superlinearly Convergent Subgradient Method for Sharp Semismooth Problems

Vasilis Charisopoulos[1], Damek Davis[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, ITHACA, NY, Contact: vc333@cornell.edu

Subgradient methods comprise a fundamental class of nonsmooth optimization algorithms. Classical results show that certain subgradient methods converge sublinearly for general Lipschitz convex functions and converge linearly for convex functions that grow sharply away from solutions. Recent work has moreover extended these results to certain nonconvex problems.
In this talk, we ask: is it possible to design a superlinearly convergent subgradient method? We provide a positive answer to this question for a broad class of sharp semismooth functions.

3 Reusing Combinatorial Structure: Faster Iterative Projections over Submodular Base Polytopes

Hassan Mortagy[1], Jai Moondra[1], Swati Gupta[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: hmortagy@gatech.edu

Optimization algorithms such as mirror descent enjoy near-optimal convergence rates but suffer from a computational bottleneck of computing projections in each iteration. On the other hand, conditional gradient variants solve a linear optimization but result in suboptimal rates. Motivated by this trade-off in runtime v/s convergence rates, we consider iterative projections of close-by points over submodular base polytopes. We develop a toolkit to speed up the computation of projections using both discrete and continuous perspectives. We strengthen the away-step Frank-Wolfe (AFW) algorithm using this toolkit. For the special case of cardinality based polytopes, we improve the runtime of computing projections by a factor of Ω(n/log n). Our results show orders of magnitude in speed-ups in computational experiments. This is joint work with Jai Moondra and Swati Gupta.

4 Bayesian Optimization with Expensive Kernel Evaluations

Jiayue Wan, Cornell University, Ithaca, NY, Contact: jw2529@cornell.edu

Bayesian optimization is an efficient method for global optimization of expensive-to-evaluate black-box functions. Traditional Bayesian optimization methods use surrogate models such as Gaussian processes whose kernels can be cheaply computed the Euclidean distance between two input points. We consider problems where kernel evaluations are also expensive, which arise in areas such as peptide optimization and chemical design. To solve such problems, we design a novel Bayesian optimization algorithm that leverages cheap features when optimizing the acquisition function. We demonstrate the use case of our approach in various scenarios.

Market Design for Power System Uncertainties

General Session

Session Chair

Cheng Guo, 1</sup

1 Evaluating the Resiliency of Decarbonized Power-Gas Infrastructure

Saurabh Amin[1], Rahman Khorramfar[1], Dharik Sanchan Mallapragada[2], [1]MIT, Cambridge, MA, [2]MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, Contact: amins@mit.edu

Electricity and natural gas are two main energy vectors whose interdependency is expected to grow by mid-century. This interdependency necessitates careful planning to ensure a sustainable and reliable future energy system in the face of numerous uncertainties and extreme events. As such, long-term planning of energy systems has to guarantee efficient and reliable operation of critical infrastructure, and account for timely recovery from disruption. We consider generation and transmission expansion problem of joint power-gas systems and explore both tradeoff and complementarities between decarbonization targets and resiliency through strategic investment and recovery plans.

2 Investment Planning of Multi-region Power Systems with Uncertainty Using Stabilised Benders Decomposition with Adaptive Oracles

Hongyu Zhang[1], Asgeir Tomasgard[1], Ken McKinnon[2], Nicolò Mazzi[3], Rodrigo Garcia Nava[4], [1]Norwegian University of Science and Technology, Trondheim, Norway; [2]The University of Edinburgh, Edinburgh, United Kingdom; [3]aHead-research, Roma, Italy; [4]The University of Edinburgh, Edinburgh, United Kingdom. Contact: hongyu.zhang@ntnu.no

Benders decomposition with adaptive oracles has reduced computational effort significantly by iteratively building inexact cutting planes and valid upper and lower bounds. Adaptive Benders and standard Benders may suffer serious oscillation when solving a multi-region planning problem. Therefore, we propose to stabilise adaptive Benders with level set method to overcome the oscillation. We compare stabilised adaptive Benders with the unstabilised versions of adaptive Benders and standard Benders on a multi-region long-term power system investment planning problem with short-term and long-term uncertainty. The computational results show that for a 1.00% convergence tolerance, the proposed stabilised method is up to 17.5 times faster than standard Benders decomposition and 5.6 times faster than adaptive Benders decomposition without stabilisation.

3 A Statistical Model for the Unit Commitment Problem Under the Presence of Renewable Energy

Carlos Olivos[1,2], Jorge F. Valenzuela[1], [1]Auburn University, Auburn, AL, [2]Universidad Catolica del Norte, Antofagasta, Chile. Contact: cro0010@auburn.edu

The high penetration of renewable energy sources requires complex decision modeling methods that consider high levels of uncertainty. In the Unit Commitment Problem, this issue is usually solved using the two-stage stochastic programming method with a scenario-based approach. Scenarios are sampled and used as realizations of the random variables, thus increasing the computational complexity. We propose a statistical model that does not require scenarios and models the expected dispatch and commitment cost from the probability distribution function of the random residual demand. The expected cost is linearized using a piece-wise approximation, resulting in a Mixed Integer Linear Program. We present experiments up to 400 units and a comparison to a scenario-based approach.

Optimization Problems in Transportation Electrification and Decarbonization

General Session

Session Chair

Juliette Ugirumurera, 1</sup

Session Chair

Zhaocai Liu, 1</sup

1 Developing Hydrogen-fueling Infrastructure for Heavy-duty Transportation

Katherine Hurst, National Renewable Energy Laboratory, Golden, CO, Contact: katherine.hurst@nrel.gov

The use of hydrogen is a promising route to mitigate the greenhouse emissions associated with heavy-duty transportation. Here, we consider the current status for light-duty and heavy-duty hydrogen fueling capabilities and their projected growth and impact. We will describe the development of our fast-fueling capabilities at the National Renewable Energy Laboratory. Computational and thermodynamic modeling of hydrogen fueling system dynamics to optimize system capacity and filling rates will be discussed and further verified with experimental data. Developing hydrogen infrastructure with high-efficiency, reliability and a high standard of safety will provide a strong foundation to enable the decarbonization of transportation.

2 Solving Unit Commitment Problems with Demand Responsive Loads

Devon Sigler, National Renewable Energy Laboratory, Denver, CO, Contact: devon.sigler@nrel.gov

Large scale electrification of the transportation sector has the potential to stress the electric grid by increasing demand and changing energy consumption patterns. Yet, additional load added from vehicle electrification can act in a demand responsive manner to support grid operations. We present work focused on using variations of the Frank-Wolfe algorithm to solve unit commitment problems with high volumes of demand responsive loads. Such algorithms work towards enabling large scale grid simulations that can bench mark the potential impact of demand responsive electric vehicle charging. Through reformulation and relaxation of the problem we enable variations of the Frank-Wolfe algorithm to find time series decisions for demand responsive loads. Computational experiments on the IEEE Reliability Test System show our approach provides near optimal solutions.

3 Optimal Planning and Charging Scheduling for a Fast-charging Battery Electric Bus System Considering Distributed Solar PV

Yiming Zhang, Ziqi Song, Yi He, Utah State University, Logan, UT, Contact: yiming.zhang@usu.edu

A battery electric bus (BEB) is considered a promising alternative to conventional diesel buses. However, the high charging power induced by fast charging may impose an extra burden on the power grid and incur a high demand charge cost. In this study, we address the optimal planning and charging scheduling problem for a BEB system considering energy storage system (ESS) and distributed solar photovoltaic (PV). Based on different settings, three configurations are proposed to analyze the impact of the distributed solar PV on the total system cost. For each configuration, a mathematical model is developed to optimize the planning and charging scheduling. A numerical study is conducted to demonstrate the effectiveness of the proposed models. The results show that the utilization of the integration of ESS and distributed PV can effectively reduce the total system cost.

4 Integrated Charging Infrastructure Planning and Charging Scheduling of Battery Electric Bus Systems

Zhaocai Liu[1], Yi He[2], Ziqi Song[3], [1]National Renewable Energy Laboratory, Lakewood, CO, [2]Beijing University of Technology, Beijing, China; [3]Utah State University, Logan, UT, Contact: zhaocai.liu@nrel.gov

Considering the interdependence of system design and operational strategies, this study proposes a two-phase optimization framework for charging infrastructure planning and charging scheduling for battery electric bus systems. An integrated optimization model is developed in the first phase to simultaneously optimize charger deployment, onboard battery capacity, and charging schedules. A charging scheduling model is further proposed and a rolling horizon approach is utilized in the second phase to optimize the real-time charging scheduling of electric buses. Compared to existing electric bus system planning methods, the proposed integrated optimization model can reduce the total system cost by 19.5%. In addition, compared to uncontrolled charging, the proposed rolling horizon-based charging strategy can reduce the total charging cost by 68.3%.

1 New Results on the Trust Region Subproblem with Extra Second-order-cone Constraints

Samuel Burer, University of Iowa, Iowa City, IA

We study semidefinite relaxations of the Extended Trust Region Subproblem (ETRS), i.e., minimization of a nonconvex quadratic objective over the intersection of the unit ball with additional constraints. These "additional constraints" can include, for example, extra linear, second-order-cone, and ellipsoidal constraints. The ETRS appears in numerous applications and is also a basic substructure found within many mixed-integer nonlinear programs. By focusing on the case of extra second-order-cone constraints, we derive a new, strong relaxation, which enjoys computational advantages over existing relaxations. By the time of the conference, we also hope to have theoretical results supporting our empirical results. Fingers crossed!

2 Fantastic Lifts and Where to Find Them: Using Smooth Parametrizations for Non-smooth Optimization

Eitan Levin[1], Joe Kileel[2], Nicolas Boumal[3], [1]Caltech, Pasadena, CA, [2]University of Texas at Austin, Austin, TX, [3]École polytechnique fédérale de Lausanne, Lausanne, Switzerland.

Many optimization problems are reformulated via a smooth parametrization, or lift, of their domains. Examples include optimization over low rank matrices and tensors by optimizing over a factorization, the Burer--Monteiro approach to low rank semidefinite programs, and training neural networks by optimizing over their weights and biases. Such lifts give rise to two optimization problems, one optimizing a smooth cost function over a nonsmooth domain, and the other minimizing the composition of that cost with a lift map over a smooth manifold. The latter problem is smooth, and can be tackled with standard algorithms which may find various desirable points, like local minima or stationary points. In this talk, we prove when these points map to desirable points for the nonsmooth problem, and discuss the implications for the above examples.

3 Worst-case Complexity of an SQP Method for Nonlinear Equality Constrained Stochastic Optimization

Frank E. Curtis[1], Michael J. O'Neill[2], Daniel Robinson[3], [1]lehigh university, Bethlehem, PA, [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]Lehigh University, Bethlehem, PA

A worst-case complexity bound is proved for a sequential quadratic optimization (commonly known as SQP) algorithm that has been designed for solving optimization problems involving a stochastic objective function and deterministic nonlinear equality constraints. Barring additional terms that arise due to the adaptivity of the monotonically nonincreasing merit parameter sequence, the proved complexity bound is comparable to that known for the stochastic gradient algorithm for unconstrained nonconvex optimization. The overall complexity bound, which accounts for the adaptivity of the merit parameter sequence, shows that a result comparable to the unconstrained setting (with additional logarithmic factors) holds with high probability.

4 Preconditioned Gradient Descent for Overparameterized Nonconvex Burer-monteiro Factorization with Global Optimality Certification

Gavin Zhang, University of Illinois at Urbana-Champaign, IL

We consider using gradient descent to minimize the nonconvex function \$f(X)=\phi(XX^{T})\$ over an \$n\ times r\$ factor matrix \$X\$, where \$\phi\$ is a convex cost function. While only a second-order stationary point \$X\$ can be provably found in reasonable time, if \$X\$ is rank deficient, then its rank deficiency certifies it as being globally optimal. This way of certifying global optimality necessarily requires the search rank r of the current iterate X to be overparameterized with respect to the rank $r^{\star}$ of the global minimizer $X^{\star}$. Unfortunately, overparameterization significantly slows down the convergence of gradient descent. In this paper, we propose an inexpensive preconditioner that restores the convergence rate of gradient descent back to linear in the overparameterized case, while also making it agnostic to possible ill-conditioning.

1 Models, Covariate Frameworks & Optimization Schemes for the Prediction of Song Performance and the Curation of Listener Communities

Kobi Abayomi[1], Paul Beata[2], Mathias DeJounge[2], Julien DeMori[2], Camille Taltas[2], Arash Haddadan[2], Moin Haque[1], Kevin Liu[2], Nakul Sathaye[2], Midigeshi Soumya[2], Arash Parnia[2], Jiajun Song[2], Guannan Zhao[2], Chaoyung Zheng[2], Daniel Lee[1], [1]Warner Music Group, New York, NJ, [2]Warner Music Group, New York, NY, Contact: abayomko@shu.edu

Music rights holders receive voluminous - though limited - tranches of data from their distribution partners: Spotify, AppleMusic, Amazon, Deezer, etc. We - the Data Science team at Warner Music Group - endeavor to extract meaning from a "*Schmutzdecke*" (a coinage from Biology suggesting a layer of mediation) that WMG receives from its D2C distribution partners, via carefully tuned models. Our unique instantiations of topological and semantic similarity on aural and demand data within a Bayesian hierarchical prediction framework yields actionable comprehension, illustration and programmatic advice to WMG on the curation and acceleration of listener demand.

2 Keyword Co-occurrence Network Methodology and Graph Data Science Algorithms for Systematic Pain Research Literature Review

Burcu Ozek, Zhenyuan Lu, Fatemeh Pouromran, Sagar Kamarthi, Northeastern University, Boston, MA, Contact: ozek.b@northeastern.edu

Pain research is expanding rapidly, making the traditional manual literature review process increasingly complex. This study develops an automated, systematic knowledge mapping and highlights future directions for the pain literature to help researchers. Network and graph data science algorithms provide a promising approach for systematic literature reviews. They discover the connections between articles and reveal hidden insights from large-scale and highly interconnected data. This study extracts keywords from 264,560 pain research papers, creates a keyword co-occurrence network (KCN) by these keywords, and analyzes KCN with data science algorithms. Our key findings demonstrate i) the number of new keywords in articles has grown by twenty times in the last two decades; and ii) main emerging concepts are machine learning, acute pain, and pain management.

3 Learn to Decompose Multi-objective Optimization Models for Large-scale Networks

Babak Aslani[1], Shima Mohebbi[2], [1]George Mason University, Fairfax, VA, [2]George mason university, Fairfax, VA, Contact: baslani@gmu.edu

Providing timely restoration plans for interdependent infrastructures facing disruptions has been a challenge for decision-makers. we defined three objective functions in three pillars of sustainability: a) economic, b) social, and c) environmental for the restoration problem. To solve the multi-objective optimization model, we develop a Learn to Decompose (LTD) framework, consisting of a multi-objective evolutionary algorithm based on decomposition (MOEA/D) and a Gaussian Process Regression (GPR) to periodically learn from the obtained Pareto Front and guide the search direction. We applied the proposed framework to benchmark problems and interdependent water and transportation networks in the City of Tampa, FL. The result demonstrates the proposed framework is feasible and applicable for large-scale networks.

1 **Second-order Conic and Polyhedral Approximations of the Exponential Cone: Application to Mixed-integer Exponential Conic Programs**
Weijun Xie, Qing Ye, Virginia Tech, Blacksburg, VA, Contact: wxie@vt.edu
Exponents and logarithms are fundamental components in many important applications such as logistic regression, maximum likelihood, relative entropy, and so on. Since the exponential cone can be viewed as the epigraph of perspective of the natural exponential function or the hypograph of perspective of the natural logarithm function, many mixed-integer convex programs involving exponential or logarithm functions can be recast as mixed-integer exponential conic programs (MIECPs). To harvest the past efforts on MILPs and MISOCPs, this paper presents second-order conic (SOC) and polyhedral approximation schemes for the exponential cone with application to MIECPs. Our numerical study shows that the proposed methods show speed-ups over solver MOSEK for MIECPs, and the scaling, shifting, and polyhedral outer approximation methods work very well.

2 **Absolute and Relative MIP Gap Functions and Their Properties**
Rachael M. Alfant[1], Temitayo Ajayi[2], Andrew J. Schaefer[3], [1]Rice University, Houston, TX, [2]Nature Source Improved Plants, Ithaca, NY, [3]Rice University, Houston, TX, Contact: rma10@rice.edu
A critical measure of model quality for a mixed integer program (MIP) is the difference, or gap, between its optimal objective value and that of its linear programming relaxation. In many contexts, only an approximation of the right-hand side(s) is available - yet, there is no consensus on appropriate measures for MIP model quality over multiple right-hand sides. In this talk, we provide a framework by which to determine a MIP model's quality over multiple right-hand sides by formulating the expectation and extrema of absolute and relative MIP gap functions over finite discrete sets.

3 **A Closest Benders Cut Selection Scheme for the Benders Decomposition**
Chungmok Lee[1], Kiho Seo[2], Seulgi Joung[3], Sungsoo Park[4], [1]Hankuk University of Foreign Studies, Yongin-si, Korea, Republic of; [2]KAIST, Daejeon, Korea, Republic of; [3]Chonnam National University, Gwangju, Korea, Republic of; [4]Korea Advanced Institute of Science & Technology, Daejeon, Korea, Republic of. Contact: chungmok@hufs.ac.kr
This talk presents a novel Benders cut selection scheme based on geometric intuition, called closest Benders cuts. Classical Benders decomposition often shows very slow convergence because many "weak" Benders cuts are generated. Several criteria for selecting "stronger" Benders cuts have been proposed. The proposed closest Benders cut selection scheme can be seen as a generalization of the previous methods while providing the additional possibility of even stronger Benders cuts identification such as facets. The computational study comparing the existing state-of-the-art Benders cut selection methods shows that the proposed method outperforms the others.

Auyon Siddiq, University of California-Los Angrles, Los Angeles, CA

1 **A Dynamic Model for Airline Fleeting and Scheduling**
Chiwei Yan[1], Archis Ghate[2], [1]University of Washington Seattle, Seattle, WA, [2]University of Washington, Seattle, WA, Contact: yan.cw08@gmail.com
COVID-19 has reshaped the global airline industry. Travel demands are volatile, and passengers have more flexibility in bookings and cancellations. More than ever, airlines have to be agile and adaptive in terms of their operational decisions. In this talk, we introduce a new dynamic model for airlines to make adaptive scheduling and fleeting decisions, based on evolving demand and booking signals. We derive theoretical, algorithmic, and managerial insights from this model. We present computational experiments based on real-world scenarios to demonstrate potential benefits of this approach.

2 **Planning Bike Lanes with Data: Ridership, Congestion, and Path Selection**
Jingwei Zhang[1], Sheng Liu[2], Auyon Siddiq[3], [1]UCLA

Anderson School of Management, Los Angeles, CA, [2]University of Toronto, Toronto, ON, Canada; [3]University of California-Los Angrles, Los Angeles, CA, Contact: jingwei.zhang.phd@anderson.ucla.edu

Urban bike lane expansion promotes cycling and reduces vehicle traffic, but narrows vehicle lanes and amplifies congestion. We study the bike lane planning problem while accounting for the conflicting effects. In an extensive case study on the City of Chicago with data collected from 8 sources, we first present a consistent estimator for travel-time parameters and then optimize new bike lane locations while enforcing traffic equilibrium. As a result, we estimate that adding 25 miles of bike lanes as prescribed by our model can lift ridership from 3.9% to 6.9%, with at most an 8% increase in driving times.

3 Drone Network Design for Multimodal Delivery

Ruijiu Mao[1], Long He[1,2], [1]National University of Singapore, Singapore, Singapore; [2]George Washington University, Washington, DC, Contact: maoruijiu@u.nus.edu

We aim to design a collaborative land-air network to help courier firms improve service performance and resolve the issue of long-tail distribution of delivery time. Specifically, we formulate an optimization problem that minimizes the cost of investment in drone systems to achieve a target in delivery time. By conducting a case study on order data from an e-commerce platform, we develop a drone network design that reduces the system average of the long-tail delivery time. We also discuss managerial insights about infrastructure design and drone technology.

4 Expanding Scheduled Transit with On-demand Mobility

Partha S. Mishra[1], Sebastien Martin[2], Sunil Chopra[3], Karen Smilowitz[3], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Cambridge, MA, [3]Northwestern University, Evanston, IL, Contact: partha.mishra@kellogg.northwestern.edu

The use of mobility-on-demand (MOD) to complement conventional shuttle transit has gained much traction in recent times. Such a hybrid transit mode has been studied in several contexts, like the first mile and last mile connectivity problems. We consider a stylized setup where a platform evaluates its options of transit for its customers at a single terminal based on its cost of operation and the average waiting time of the customers. It could deploy fixed frequency shuttles looping around the terminal, request MODs at the terminal, or use some hybrid combination of the two. We show that there is value to using a hybrid mode of operation for platforms that can accept a moderate range of average waiting time for their customers. Further, we show how this range is affected by variability.

Session Chair
Jeremiah Dirnberger, Wabtec Freight, Jacksonville, FL

1 Yard Automation Beyond Power Switches and Remote Control Locomotives

Jeremiah Dirnberger, Wabtec Freight, Jacksonville, FL, Contact: jeremiah.dirnberger@wabtec.com

As freight volume continues to grow, reliable yard operations will be critical for the railroads to attract more volume. Until now, the limited yard automation efforts have typically focused on power switches and Remote Control Locomotives (RCL). The barriers to achieving higher levels of automation are lower than mainline automation. Automation in Intermodal Terminals is more widespread. In the near term, combining visual inspection and monitoring technologies with remote-control train operations, drones and planning tools will provide significant variability reduction and productivity improvements in classification yards and intermodal terminals. This session will review an overall strategy, examples with the implications for OR practitioners and potential synergies between technologies deployed in Classification Yards and Intermodal Terminals.

2 Intermodal Railcar Network Analysis Utilizing ML

Muhannad H. Ramahi, TTX Company, Chicago, IL, Contact: muhannad.ramahi@ttx.com

We present a study/results of exploring a new technique for forecasting railroad operational metric(s) such as cycle time and railcars network mileage. The goal is to explore the new emerging techniques of machine learning against classical methods in predicting cycle time and railcar mileage for various fleets. Cycle time is an essential part of the business planning process that partly determines how many railcars are potentially needed for satisfying the network demand. Moreover, mileage prediction is critical in deciding how equipment maintenance is planned and budgeted.

3 **Railcar Network Analysis Using GPS**

Joseph Melchiors, TTX

As GPS becomes more prevalent within the railcar fleet, how can the rail industry leverage that information to improve Customer Service and car use efficiency? True GPS integration into the existing tracking and messaging infrastructure must recognize and handle uncertainties and timing issues from both GPS and railroad event reporting. TTX will present information on how they are combining GPS, EDI/TRAIN messaging, internal system reporting, and the North American Rail Network map to understand if and how they can work together to provide seamless railcar tracking and tracing.

Session Chair

Lluvia (Weijia) Jing, Northeastern University, Boston, MA

1 **Post-disaster Restoration Scheduling and Community Function**

Bahar Shahverdi, Elise Miller-Hooks, George Mason University, FAIRFAX, VA, Contact: bshahver@masonlive.gmu.edu

Hazardous events can induce service loss in infrastructure lifelines, such as power, water, and transportation. These lifelines are critical to community function, supporting hospitals, schools, nursing homes, government buildings, and much more. This presentation proposes mathematical modeling and solution methods to optimize the scheduling of post-disaster restoration actions on these infrastructures for improved critical community function.

2 **Multi-criteria Path Planning for Teams of Unmanned Ground Vehicles in Unstructured Environments**

Sachet Khatiwada, Emmanuel Adjei, Pamela Murray-Tuite, Clemson University, Clemson, SC, Contact: sachetk@clemson.edu

Teams of unmanned ground vehicles (UGVs) may be used to deliver items (humanitarian relief, fire-fighting materials, troops) to dangerous or hard-to-reach areas that do not contain a formal transportation network and where information is imperfect. We provide an overview of a framework for routing teams of UGVs through an unstructured environment using multiple paths such that all the UGVs arrive at the destination at the same time. Using a priori information about the environment and other information, such as risk and travel time, a cost-to-go map is generated which is subsequently used as input to goal-directed, planning level, path algorithms. We present the results of the approach in different scenarios. DISTRIBUTION STATEMENT A. Approved for public release: distribution unlimited.(OPSEC # 6037)

3 **Enhancing Cost Effectiveness and Efficiency of USAID's Food Aid Supply Chain: A Supply Chain Optimization Tool for Both On-going and Sudden-onset Demand Response**

Lluvia (Weijia) Jing, Ozlem Ergun, Northeastern University, Boston, MA, Contact: jing.we@northeastern.edu

Millions of tons of food aid are distributed each year by the U.S. Agency for International Development's (USAID) Office of Food for Peace (FFP). Yet, needs always exceed the food aid resources available to meet them. Efficiency gains in existing supply chains offer the potential for closing this gap. We developed a supply chain optimization tool (SCOT) to optimize the decision-making process for procurement, prepositioning, and shipping decisions under a merged supply chain with both on-going demand and sudden-onset demand, while assessing the range of potential efficiency/effectiveness gains and on-time delivery associated with alternative investments in and management of the food aid supply chain.

Routing and Consolidation Issues in Logistics

General Session

Session Chair

Abhay Sobhanan, University of South Florida, Tampa, FL

1 Middle Mile Consolidation Network Design: Maximizing Profit Through Flexible Lead Times

Lacy Greening, Jisoo Park, Mathieu Dahan, Alan Erera, Benoit Montreuil, ISyE Georgia Tech, Atlanta, GA

In this work, we propose an approach for designing a middle-mile consolidation network that aims to maximize the profit of large e-commerce retailers. We embed lead-time dependent sales volumes predictions into a new mixed-integer program (MIP) that determines shipment lead times and consolidation plans to maximize sales revenue net logistics cost. We propose a solution approach that uses an IP-based local search and dynamic lead time selection to find excellent consolidation plans for large, practically-sized instances. Preliminary results are illustrated using data from a U.S.-based e-commerce partner.

2 Hyperconnected Logistics Networks: Parcel Consolidation in Modular Handling Containers

Nidhima Grover[1], Benoit Montreuil[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: ngrover9@gatech.edu

In Physical Internet-based hyperconnected logistics, packages are routed through a multi-tier meshed network of logistic hubs, proven to be more efficient, sustainable, and resilient than traditional networks in literature. Packages are consolidated in modular containers to travel together for a long portion of their multi-hub journey, which reduces handling time in intermediate hubs. This research focuses on the dynamic optimization of parcel consolidation, considering each parcel's sequence of hubs in the path, service level, and dimensions. We develop an optimization model that minimizes handling costs while ensuring delivery time, consolidation targets, and other operational constraints are best met. We present computational results that demonstrate the increase in performance induced by effective consolidation.

3 Equitable Workload Allocation in Vehicle Routing Problem with Heterogeneous Drivers

Iman Dayarian[1], Vahid Mahmoodian[2], Hadi Charkhgard[2], [1]University of Alabama, Tuscaloosa, AL, [2]University of South Florida, Tampa, FL, Contact: idayarian@cba.ua.edu

Efficient solutions are not necessarily equitable. Maximizing the sum of utilities of all the players might not result in a sufficiently fair distribution of resources, responsibilities, and benefits among different stakeholders. Fairness considerations in the private logistics service sector are new and growing due to public or governmental pressures to improve equity in workload allocation among drivers or other personnel providing the service. This is more crucial when employing crowdsourced workforce considering their inherent heterogeneity in terms of skills, availability, and productivity levels. This research aims at creating a decision-support tool to strike a balance between efficiency and equitable workload allocation that ensures acceptance of operational plans, maintains employee satisfaction, and reduces bottlenecks in resource utilization.

4 Solving the Multi-depot Vehicle Routing Problem by a Genetic Algorithm with Learning to Evaluate Individuals

Abhay Sobhanan[1], Junyoung Park[2], Jinkyoo Park[3], Changhyun Kwon[4], [1]University of South Florida, Tamp, FL, [2]KAIST, Daejeon, Korea, Republic of; [3]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of; [4]University of South Florida, Tampa, FL, Contact: sobhanan@usf.edu

In the Multi-Depot Vehicle Routing Problem (MDVRP), we can separate the decisions into two phases: assigning customers to a depot and then routing vehicles from each depot. The latter becomes a Capacitated Vehicle Routing Problem (CVRP) on its own. In this paper, we propose a simplified genetic algorithm that only determines the customer-depot assignments. We train a neural network to learn the objective function value generated by a CVRP solver and evaluate each customer-depot assignment decision by predicting the result of a CVRP for each depot. We show that such a simplified approach is effective via numerical experiments.

1 Are Your Customers Paying Attention? Mobile Advertising in a Multiscreen Viewing Environment?

Siddharth Bhattacharya, George Mason University, Fairfax, VA

It is increasingly common for consumers to use an additional device like smartphone while watching TV, a phenomenon known as multiscreen viewing. While this additional device (or second screen) provides an extra advertising channel, little is known about how consumers respond to ads on second screen during a multiscreen viewing experience. Thus, in this research, we seek to understand how firms can optimize advertising on a second screen in light of how primary screen content influences consumer behavior on second screen. Our results indicate an inverse relationship between primary and second screen viewing. We also show that ad recognition is higher for ads appearing on second screen when supplemental content is displayed on primary screen, as opposed to when core content is displayed. Results of the research contribute to the literature on advertising in Marketing and IS.

2 Content and Style of Marketer Generated Content on Social Media: A Study of User Engagement on Hedonic and Utilitarian Product Pages on Facebook

Scott Schanke[1], Gautam Ray[2], Gedas Adomavicius[3], Mihir Wagle[3], [1]University of Wisconsin Milwaukee, Milwaukee, WI, [2]University of Minnesota, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN, Contact: schanke@uwm.edu

Digital platforms are playing an important role in customers' sales journey, but there is limited research on how product characteristics influence firm behavior on these platforms. This paper examines the relationship between firm-generated content and user engagement on product pages, and how characteristics moderate this relationship. Analyzing Fortune 1000 firm posts on Facebook, we study the relationship between content and style of a given post and the level of user engagement. The key finding is that content not traditionally expected for a product of a given type, generate more favorable engagement. Interestingly, irrespective of the type of the product, informal style achieves more favorable engagement.

Scheduling and Logistics Problems against Pandemics

General Session

Session Chair

Xiangtong Qi, Hong Kong University of Science & Technology, Hong Kong.

1 The Seating Assignment Problem with Social Distancing

Zikang Li[1], Xiangtong Qi[2], Qian Liu[3], [1]HKUST, Kowloon, Hong Kong; [2]Hong Kong Univ of Science & Technology (HKUST), Kowloon, Hong Kong; [3]Hong Kong University of Science and Technology-HKUST, Hong Kong, Hong Kong.

Social distancing, a non-pharmaceutical way to contain the spread of infectious disease, has been broadly recognized and practiced. In this paper, we consider the seat assignment problem with social distancing when encountering deterministic and stochastic demands. In a pandemic, the government may issue a minimum physical distance between people, which must be respected in the seating assignment. The problem is further complicated by the existence of groups of guests who will be seated together. To achieve such a goal, we provide an optimal assignment based on the column generation algorithm with given rows of seats and the demands of groups. We also develop a column-and-cut method to obtain an assignment with stochastic demands of groups under scenarios. With these results, we can provide a guideline for policies related to seat utilization rate.

3 Strategies for Using Rapid Antigen Tests (RAT) in Workplaces and Schools Under Uncertain Sensitivity

Ho Yin Wan[1], Xiangtong Qi[2], Jin Qi[3], [1]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]Hong Kong University of Science & Technology (HKUST), Hong Kong, Hong Kong; [3]Hong Kong University of Science and Technology, Hong Kong, Hong Kong. Contact: hywanae@connect.ust.hk

Rapid Antigen Testing kits enable easy and quick assessment for identifying COVID-19. When compared to PCR Tests, their accuracy is yet to be certified. Literatures show there is a time-dependency on returning false negative result by using the RAT. There is an unidentified period for each patient even when they exercise frequent rapid testing. Longer unidentified period leads to higher risk to infect others. Risk models are therefore essential for one to assess the potential impacts. We collect individual-level data from COVID-19 in Hong Kong to quantify the time-dependent impacts for not identifying a patient. For given uncertainties, we propose an assessment model that quantify the safe of using RAT. We aim to apply the model in contextual setting such that the decision makers can decide for testing frequency and operation strategies to guarantee the level of safety.

1 Why Platform Algorithms Shape What You Think

Sarah H. Cen[1], James Siderius[2], Asuman Ozdaglar[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: shcen@mit.edu

Social media platforms employ algorithms that simultaneously recommend content from friends and from news outlets. While some of these recommendations are anchored by the existing social network of users, outlet recommendations may be chosen by the platform to shape users' beliefs over time (e.g., nudging users toward political extremes to increase engagement). In this work, we model belief shaping as a linear dynamical system, in which each user's belief is influenced by their social network and content that the platform injects into their feed. We examine three questions: (i) how a platform should inject content from external outlets, (ii) how this content affects the short-term beliefs of exposed users, and (iii) how this content affects users' long-term beliefs through the social network. We explore these questions through both analytical results and simulations.

2 Exploring Fair, Stable and Optimal Income Pools in Volatile Industries

Timothy Chan[1], Ningyuan Chen[2], Craig Fernandes[1], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Mississauga, ON, Canada. Contact: craig.fernandes@mail.utoronto.ca

An income pool involves individuals coming together to sign a contract which stipulates that if any individual earns more than a salary threshold, that a portion of their earnings above this threshold will be shared amongst all pool members. We investigate income pools within professional baseball where even the best players must compete in the Minor league before they are eligible for the Major league. The average annual salary in the Minors is $8000, grossly incomparable to the $4.4 million in the Majors. The average probability of transferring from the Minors to the Majors is only 14%. As such, income pools involve Minor league players signing a contract that pledges a share of future potential Major league earnings. We explore the decision problem of which pools a player should join to maximize their expected utility, as well as define notions of fair, stable, and optimal pools.

Invited Lecture: QPLEX - A Modeling and Computational Methodology for Transient Analysis of a Class of Stochastic Systems

General Session

Session Chair

Ton Dieker, Columbia University, New York, NY

Session Chair
Steve Hackman, 1</sup

1 QPLEX - a Modeling and Computational Methodology for Transient Analysis of a Class of Stochastic Systems
Ton Dieker[1], Steve Hackman[2], [1]Columbia University, New York, NY, [2]Georgia Institute of Technology, Atlanta, GA

This work was motivated by problems of managing stochastic networks featuring temporary overloads, small to moderate time-varying number of servers, non-homogeneous service-time distributions and complex routing of entities. Such problems require prediction of future system behavior over time so that appropriate adjustments can be made today.
In this tutorial, we present a methodology to predict transient distributions of key performance metrics over time, e.g., distributions of the number of customers or the virtual wait times in a queueing network. Our methodology is fundamentally non-parametric and non-Markovian. It includes a modeling framework capable of representing the characteristics described above, and a computational approach that quickly generates results by relying on approximate deterministic calculations. A key feature of our methodology is that no advanced knowledge of applied probability is required to understand the key ideas.
The primitives of our modeling framework are relatively few. In simple models, they might be scalars or probability mass functions. In more elaborate models, they can be specified as code fragments. The resulting model defines the dynamics from which the desired performance metrics can be computed exactly, but this is not practical due to the sheer size of the number of calculations required. Our computational approach introduces a vastly lower dimensional space where a much smaller number of calculations suffice. Experiments on a diverse and challenging testbed yield remarkably accurate results and the time to generate thousands of distributions is on the order of seconds. For several classical queueing systems our computational approach generates exact results.
Throughout this presentation, we illustrate our modeling framework and computational approach with many stochastic network examples. We conclude this tutorial with a brief discussion of future directions.

1 Learning to Personalize Treatments when Agents are Strategic
Evan Munro, Stanford University, Stanford, CA, Contact: munro@stanford.edu

There is increasing interest in allocating treatments based on observed individual characteristics: examples include targeted marketing, and individualized credit offers. We use a non-parametric model to show that treatment personalization introduces incentives for individuals to modify their behavior to obtain a better treatment. This shifts the distribution of covariates, which means the Conditional Average Treatment Effect (CATE) now depends on how treatments are allocated. The optimal rule without strategic behavior allocates treatments only to those with a positive CATE. With strategic behavior, we show that the optimal rule can involve randomization, which incentivizes distributions of CATEs that lead to more effective targeting. We propose a sequential experiment that converges to the optimal treatment allocation function.

2 A Spectral View of Thompson Sampling
Mohsen Bayati, Yuwei Luo, Stanford University, Stanford, CA

Recently, it has been shown that Linear Thompson Sampling (LinTS) can have a poor worst-case performance in stochastic linear bandit setting. This problem with LinTS is rooted in the geometry of the posterior covariance matrix. Motivated by this observation, we focus on spectral distribution of the posterior covariance matrix and study its connections with performance of LinTS.

3 Adaptivity and Counfounding in Multiarmed Bandit Experiments
Daniel Russo, Columbia University, New York, NY

Bandit algorithms offer efficiency benefits when learning to make effective decisions requires experimentation. They achieve this through adaptivity: early feedback is used to identify competitive parts of the decision space and future effort is focused there. Unfortunately, due to this adaptivity, these algorithms risk confounding in problems where nonstationary contexts influence performance. As a result, many practitioners resort to non-adaptive randomized experimentation, providing robustness but foregoing efficiency benefits. We develop a new model to study this issue and propose deconfounded Thompson sampling. We argue that this method strikes a delicate balance, allowing one to build in robustness to nonstationarity while, when possible, preserving the efficiency benefits of adaptivity.

4 Synthetically Controlled Bandits

Andrew T. Zheng, Massachusetts Institute of Technology, Boston, MA

We present a new dynamic approach to experiment design in settings where, due to interference or other concerns, experimental units are coarse. `Region-split' experiments on online platforms are one example of such a setting. The cost, or regret, of experimentation is a natural concern here. Our new design, dubbed Synthetically Controlled Thompson Sampling (SCTS), minimizes the regret associated with experimentation at no practically meaningful loss to inferential ability. We provide theoretical guarantees characterizing the near-optimal regret of our approach, and the error rates achieved by the corresponding treatment effect estimator. Experiments on synthetic and real world data highlight the merits of our approach relative to both fixed and `switchback' designs common to such experimental settings.

E-commerce/Omni-channel Fulfillment and Operations

General Session

Session Chair

Linwei Xin, University of Chicago, Chicago, IL

1 Assortment Optimization Under a Two-category Choice Model

Tiancheng Zhao[1], Menglong Li[2], Xin Chen[1], Yuan Zhou[3], Jiachun Li[3], [1]UIUC, Urbana, IL, [2]City University of Hong Kong, Hong Kong, Hong Kong; [3]Tsinghua University, Beijing, China. Contact: tz14@illinois.edu

In this paper, we study an assortment optimization problem in which an assortment consists of products from two categories, and customers are allowed to choose a bundle of at most one product from each category. We allow arbitrary product interaction that determines the utility of each bundle. We show that the problem is NP-hard. Motivated by this, we design a 0.74-approximation algorithm based on an LP relaxation of the problem. This algorithm almost closes the integrality gap of the LP relaxation which is shown to be at most 0.75. Numerical experiments are conducted to demonstrate the quality and efficiency of our proposed algorithm.

2 Simple and Order-optimal Correlated Rounding Schemes for Multi-item E-commerce Order Fulfillment

Will Ma, Columbia University, Cambridge, MA

A fundamental problem faced in e-commerce is---how can we satisfy a multi-item order using a small number of fulfillment centers (FC's), while also respecting long-term constraints on how frequently each item should be using inventory from each FC? In a seminal paper, Jasin/Sinha (2015) identify and formalize this as a correlated rounding problem, and propose a scheme for randomly assigning an FC to each item according to the frequency constraints, so that the assignments are positively correlated and not many FC's end up used. Their scheme pays at most n/4 times the optimal cost on a n-item order. In this paper we provide the first substantial improvement of their scheme, paying only 1+\ln(n) times the optimal cost, which is tight. We also derive other schemes, all based on an intuitive new idea: items wait for FC's to "open" at random times but observe them on "dilated" time scales.

3 Assortment Planning Considering Split Orders

Duygu Soylemez[1], Oya Ekin Karasan[2], Alper Sen[2], [1]University of Chicago Booth School of Business, Chicago, IL, [2]Bilkent University, Ankara, Turkey. Contact: dsoyleme@chicagobooth.edu

When multi item orders cannot be satisfied through a single shipment due to not having all the items in an order in the same depot, packaging and transportation costs increase and the deliveries can be delayed. To minimize order splitting, it is crucial to determine the allocation of the limited capacities of the depots to items or to reduce the transportation costs by consolidation. In this study, heuristic algorithms based on the LP relaxation of a model in the literature are offered to solve this NP hard assortment planning problem. The analytical characterization of the optimal solution of this LP problem is revealed and an algorithm is suggested to find this solution. Also, the assortment allocation and consolidation problems are modeled together. An extensive numerical study is conducted to evaluate the quality of the solutions provided by offered methodologies.

4 Effective Online Order Acceptance Policies for Omni-channel Fulfillment

Su Jia[1], Jeremy Karp[2], R. Ravi[3], Sridhar R. Tayur[3], [1]CMU, Pittsburgh, PA, [2]Lyft, San Francisco, CA, [3]Carnegie Mellon University, Pittsburgh, PA

Omni-channel retailing has led to the use of traditional stores as fulfillment centers for online orders. Omni-channel fulfillment problems have two components: (1) accepting a certain number of on-line orders prior to seeing store demands, and (2) satisfying (or filling) some of these accepted on-line demands as efficiently as possible with any leftover inventory after store demands have been met. Hence, there is a fundamental trade-off between store cancellations of accepted online orders and potentially increased profits due to more acceptances of online orders. We study this joint problem of online order acceptance and fulfillment (including cancellations) to minimize total costs, including shipping charges and cancellation penalties in single-period and limited multi-period settings.

1 Gaussian Process Covariance Prediction via Separable Transformation

Ruda Zhang, University of Houston, Houston, TX, Contact: ruda.zhang@duke.edu

We propose GP[illegible], a Gaussian process (GP) model that approximates functions that output positive semi-definite matrices or multivariate Gaussian distributions. The GP is used to encode positive-definite matrices as covariances of Gaussian random vectors. We obtain a posterior process by matching the marginal posterior distributions at sample points to those in the data, using separable affine transformations. In particular, it allows both the mean and the covariance of the outcome to vary with the predictors. We examine the accuracy of this model in a simulation study, and apply it to the emulation of stochastic simulators. Preliminary results show several times better accuracy than existing methods.

2 Compositional Multifidelity Models for Uncertainty Quantification via Directed Graphs

Alex Gorodetsky, University of Michigan

We present an approach for constructing a multifidelity surrogate from ensembles of information sources of varying cost and accuracy. In this talk, information sources correspond to partial differential equations of varying fidelity: including multiple physics models and numerical discretization levels. The proposed approach encodes connections between information sources as function compositions structured as directed acyclic graphs. The framework generalizes the typical autoregressive hierarchical modeling that is prevalent in multifidelity uncertainty quantification. We show that this approach can lead to greater data efficiency and applicability to the common situation where information sources do not admit a strict hierarchy on several applications. Both maximum likelihood and Bayesian training are described.

3 A Graphical Multi-fidelity Gaussian Process Model, with Application to Emulation of Expensive Computer Simulations

Yi (Irene) Ji, Duke University

We present a novel Graphical Multi-fidelity Gaussian Process (GMGP) model that uses a directed acyclic graph to model dependencies between multi-fidelity simulation codes. It is an extension to the Kennedy-O'Hagan model for problems where different codes cannot be ranked in a sequence from lowest to highest fidelity. We also present a scalable recursive formulation and a non-linear extension to the GMGP model. The advantages of the GMGP model over existing methods are demonstrated via an application to heavy-ion collisions emulation, which shed light on the origins of the Universe shortly after the Big Bang.

4 Non-parametric Ridge Recovery of Image Time Series Given Temporal Parameterization

David Matteson, Yuchen Xu, Cornell University, Ithaca, NY

As a classical tool to extract curvilinear features in image processing framework, ridge detection has its straightforward application in material science problems, especially when filtering relatively stable atom-shaped objects in image series such as Transmission Electron Microscope (TEM). Other than implementing frame-by-frame object recognition, this work borrows strength of temporal correlatedness by inputting the (spatial-plus-temporal) image tensor, and adapts the ridge detection algorithm non-parametrically to extract explicit trajectories of object locations as a continuous function of time. The method demonstrates both effectiveness and efficiency with simulations, and delivers visible outperformance in a real TEM application compared to other material science benchmarks.

1 Droplet Evolution Prediction in Material Jetting via Tensor Time Series Analysis

Luis Javier Segura[1], Zebin Li[2], Chi Zhou[2], Hongyue Sun[3], [1]University of Louisville, Louisville, KY, [2]University at Buffalo, Buffalo, NY, [3]University at Buffalo, Buffalo, NY, Contact: ljsegu01@louisville.edu

Droplet morphology and behavior substantially determine the quality of the Material Jetting (MJ) printed parts. However, obtaining consistent and stable droplet morphology and behavior is difficult because the droplets are very sensitive to different material and process parameters. This work investigates the droplet evolution prediction via Tensor Time Series (TTS) analysis. The cross-linked (i.e., underlying relationships shared across droplet evolution behaviors with diverse material and process parameters) and spatial-temporal relationships of the TTS are captured via Tensor Graph Convolutional Network (TGCN) and Tensor Recurrent Neural Network (TRNN), respectively. The method is tested in experimental and simulated droplet evolution data in the MJ process.

2 Multi-class Reinforced Active Learning for Droplet Pinch-off Behaviors Identification in Inkjet Printing

Zebin Li[1], Luis Javier Segura[2], Yifu Li[3], Chi Zhou[1], Hongyue Sun[1], [1]University at Buffalo, Buffalo, NY, [2]University of Louisville, Louisville, KY, [3]University of Oklahoma, Norman, OK, Contact: zebinli@buffalo.edu

Inkjet printing is an additive manufacturing technique that yields many innovations. The quality of the products is affected by the droplet pinch-off behaviors, which results in the importance of identifying them. However, annotating these behaviors is heavy since a large amount of images can be collected easily. Active learning (AL) is a machine learning method that incorporates human knowledge. However, it suffers from rigid handcrafted query strategies, which cannot handle the dynamics of the varying most informative data. To address this limitation, we propose a multi-class reinforced active learning (MCRAL) method in which the conventional AL is combined with reinforcement learning (RL). An intrinsic reward is designed to improve the model capacity. A graph convolutional network (GCN) is used for droplet feature extraction. The results show that MCRAL excels AL.

3 Computer Model Calibration with Multi-source Auxiliary Observations in Material Jetting

Christian Santiago Zuniga[1], Luis Javier Segura[1], Chi Zhou[2], Hongyue Sun[2], [1]University of Louisville, Louisville, KY, [2]University at Buffalo, Buffalo, NY, Contact: cszuni01@louisville.edu

Material Jetting (MJ) process is capable to produce intricate functional structures. The MJ process performance and quality of the printed products are largely affected by the deposited droplet volumes. However, obtaining consistent droplet volumes during the process is difficult to achieve because the droplets characteristics are very sensitive to material and process parameters. This work investigates a Bayesian model calibration and prediction method that captures the volume variations (i.e., discrepancy) and measurement error (i.e., measurement bias) of the jetted droplets using multi-source material (i.e., water and glycerol). The method is tested using simulated data and experimental observations in the MJ process.

4 Analysis of Upper-body Fatigue During Warehouse Worker Material Handling

Setareh Kazemi Kheiri[1], Zahra Vahedi[1], Sahand Hajifar[1], Saeb Ragani Lamooki[1], Fadel Mounir Megahed[2], Lora Cavuoto[1], Hongyue Sun[1], [1]University at Buffalo, Buffalo, NY, [2]Miami University, Oxford, OH, Contact: skazemik@buffalo.edu

Musculoskeletal disorders are among the most prevalent injuries in warehouses and distribution centers. It is important to detect the underlying causes of such disorders and take preventive measures to reduce them. In this study, a lab experiment was conducted to simulate a dynamic overhead order-picking task, under four different combinations of load and pace. During the task, wearable sensors were mounted on upper-body muscles of participants, and rated

perceived exertion (RPE) scores were reported every five minutes. To understand the impact of different task loads and paces on the accumulated fatigue in participants' upper extremities, functional ANOVA was conducted on RPEs. The results indicate there is a significant difference between task conditions on the RPEs. It was also found that the effect of task pace was more significant than task loads on the RPEs.

Big Data Analytics for System Prediction and Quality Control

General Session

Session Chair

Honghan Ye, 1</sup

1 A Dynamic Recurrent Framework for Diagnostics and Predictive Analytics for Switching Behavior State Space Models

Md Tanzin Farhat[1], Ramin Moghaddass[2], [1]University of Miami, Coral Gables, FL, [2]University of Miami, Coral Gables, FL, Contact: tanzinfarhat@miami.edu

Any large-scale sensor-driven complex system with single or multiple latent states can have switching behavior that creates variable system dynamics, making it difficult to model with traditional approaches. Previous works have mainly focused on the use of deterministic relation or distribution assumptions to model dynamics to capture switching stages. Another concern in the literature is to predict the time to an event of interest keeping the dynamics variable into consideration. For this, a dynamic recurrent framework to perform predictive analytics and diagnostics for complex systems with switching behavior latent states is proposed. The proposed approach utilizes recurrent neural networks and Bayesian networks with a state-space structure to capture the switching effect along with a prediction for events of interest like remaining useful life.

2 A Sample-weighting Algorithm for Classification of Overlapped and Imbalanced Data with Mixed Numerical and Categorical Features

Henry J. Johnston[1], Dongping Du[2], [1]Texas Tech University, Lubbock, TX, [2]Texas Tech University, Lubbock, TX, Contact: henry.johnston@ttu.edu

Electronic Health Records (EHR) contain patient samples consisting of mixed numerical and categorical features, class overlap and imbalanced data. These problems pose great challenges to EHR data analysis and classification. Motivated by these problems, this study explores a Density Peaks Clustering (DPC) algorithm to detect class overlap in samples consisting of both numerical and categorical features. A suitable metric for mixed data is used to calculate distances between each pair of samples. Clusters are used to calculate weights that represent importance of samples in each class and reduce the influence of overlapped samples. The sample weights are then used to enhance classification performance of overlapped and imbalanced data. Classifiers are trained using the sample weights and the effectiveness of the technique is tested in a case study.

3 Optimal Test Design for Reliability Demonstration Under Multistage Acceptance Uncertainties

Bingjie Wang[1], Suiyao Chen[2], Lu Lu[3], Mingyang Li[4], [1]UNIVERSITY OF SOUTH FLORIDA, Tampa, FL, [2]Amazon, San Diego, CA, [3]University of South Florida, Wesley Chapel, FL, [4]University of South Florida, Tampa, FL, Contact: bingjiew@usf.edu

While designing a reliability demonstration test (RDT), the actual testing results are random, making the test acceptance decision highly uncertain. If a test is rejected, the product reliability will be improved and then re-assured by the next round of RDT. Such reliability growth and re-assurance will be repeated in a multi-stage fashion until an RDT is accepted. The conventional RDT design often has a limited planning horizon without anticipating the acceptance uncertainties of sub-sequent re-assuring RDTs. We expand the planning horizon by proposing an optimal RDT design under multi-stage acceptance uncertainties to minimize the overall anticipated costs of RDTs, reliability growth and warranty service. A case study is provided to illustrate the proposed work and demonstrate its cost efficiency over conventional designs.

4 Online Monitoring of High-dimensional Asynchronous and Heterogeneous Data Streams for Shifts in Location and Scale

Honghan Ye, University of Wisconsin- Madison, Woodbury, MN

In this paper, we propose a generic nonparametric monitoring framework to online monitor high-dimensional asynchronous and heterogeneous data streams, where sampling intervals of data streams are different from each other and measurements of each data stream follow arbitrary distributions. In particular, we first propose a quantile-based nonparametric CUSUM scheme to monitor each data stream locally for possible changes in both location and scale. Then, for unsampled data streams, a compensation method based on the Bayesian approach is introduced. Furthermore, we develop a global monitoring scheme of using the sum of top-*r* local statistics, which is able to quickly detect a wide range of possible shifts in location and scale in all directions. Simulations and a case study are conducted to evaluate the performance of the proposed method.

Learning and Inference for Designing Policies in Stochastic Systems

General Session

Session Chair

Weina Wang, Carnegie Mellon University, Pittsburgh, PA

1 On Improving Model-free Reinforcement Learning Algorithms for Average-reward MDPs

Qiaomin Xie, University of Wisconsin-Madison, Madison, WI

We develop model-free algorithms for learning infinite-horizon average-reward MDPs. In the online setting, our algorithms, based on reference-advantage decomposition, provably achieve an $\tilde O(\sqrt{T} \mathrm{poly}(S,A,\mathrm{sp}(h^*)))$ regret after T steps, where $\mathrm{sp}(h^*)$ is the span of the optimal bias function. Our results firstly achieves the near-optimal order in T, and improves the best existing result with $\tilde O(T^{2/3})$ regret. In the setting with simulator, we propose an algorithm that finds an ϵ-optimal policy using $\tilde{O} \left(\frac{SA\mathrm{sp}^2(h^*)}{\epsilon^2}+\frac{S^2A\mathrm{sp}(h^*)}{\epsilon} \right)$ samples, while the corresponding lower bound is $\Omega\left(\frac{SA\mathrm{sp}(h^*)}{\epsilon^2}\right)$.

2 Efficient Decentralized Multi-agent Learning in Asymmetric Queuing Systems

Daniel Freund[1], Thodoris Lykouris[1], Wentao Weng[2], [1]MIT, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: wweng@mit.edu

We study decentralized multi-agent learning in bipartite queuing systems, a standard model for service systems. In particular, N agents request service from K servers in a fully decentralized way, i.e, by running the same algorithm without communication. Previous decentralized algorithms are restricted to symmetric systems, have performance that is degrading exponentially in the number of servers, require communication through shared randomness and unique agent identities, and are computationally demanding. In contrast, we provide a simple learning algorithm that, when run decentrally by each agent, leads the queuing system to have efficient performance in general asymmetric bipartite queuing systems while also having additional robustness properties. Along the way, we provide the first UCB-based algorithm for the centralized case of the problem.

3 Learning and Balancing Unknown Loads in Large-scale Systems

Diego Goldsztajn[1], Sem C. Borst[1], Johan van Leeuwaarden[2], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Tilburg University, Eindhoven, Netherlands. Contact: d.e.goldsztajn@tue.nl

Threshold-based policies provide powerful mechanisms for balancing loads in a scalable manner, but crucially rely on knowledge of load patterns which are typically uncertain and time-varying. We consider a system of identical server pools where an admission threshold is used in an inner control loop to dispatch the incoming tasks. In an outer control loop, a learning scheme adjusts the threshold over time to keep it aligned with the unknown and time-varying offered load. We prove that, in a large-scale regime, the threshold remains constant along intervals of time where the offered load is suitably bounded, and that this results in a balanced distribution of the load. In fact, we examine a family of learning schemes which trade off stability of the threshold with the degree of load balance that can be attained.

4 Federated Minimax Optimization: Improved Convergence Analyses and Algorithms

Pranay Sharma, Carnegie Mellon University, Pittsburgh, PA, Contact: pranaysh@andrew.cmu.edu

In this work, we consider nonconvex minimax optimization, which is gaining prominence in many modern machine learning applications such as GANs. We analyze Local stochastic gradient descent ascent (SGDA), the local-update version of the SGDA algorithm. We prove that Local SGDA has order-optimal sample complexity for several classes of nonconvex-concave and nonconvex-nonconcave minimax problems, and also enjoys linear speed-up with respect to the number of clients. We provide a novel and tighter analysis, which improves the convergence and communication guarantees in the existing literature. For nonconvex-PL and nonconvex-one-point-concave functions, we improve the existing complexity results for single-node minimax problems.

Grid Optimization GO Competition: Goals, Formulation and Analysis
General Session

Session Chair
Richard Paul O'Neill, ARPA-E, Silver Spring, MD

1 **Grid Optimization Go Competition: Goals and Formulation**
Jesse Holzer, Pacific Northwest National Laboratory, Richland, WA
The Grid Optimization (GO) Competition Challenge 3 has launched. This talk gives an overview of the model formulation and the questions we are aiming to address with it. The model includes multi-period unit commitment; AC bus/branch modeling; scheduling of energy and reserves; flexible loads; storage; and combined cycle generators. The model can be configured for use in an ISO/RTO context for applications of real-time (RT) look ahead, day ahead (DA) market clearing, and week ahead (WA) advisory. The model combines features that are considered in isolation in a sequence of models in current electricity industry practice, for example solving a DA unit commitment model with little regard for AC considerations, then solving an ACOPF with fixed commitments closer to RT. With this combined model and the solvers that competition entrants will develop, we want to ask and answer: Can the combined model be solved to high accuracy in a reasonable amount of time on practical instances? What are the incremental benefits to society of the combined solution, relative to the sequential approach? How will various industry trends, including increasing capacity of variable and uncertain generation resources, distributed energy resources, price sensitive load, and storage, affect the value of advanced computational tools for grid optimization?

2 **Go Competition Challenge 2: Analysis and Lessons Learned**
Brent Eldridge, Pacific Northwest National Laboratory, Baltimore, MD
The Grid Optimization (GO) Competition Challenge 2 is nearly finished. This competition focused on a security constrained AC optimal power flow problem with fast start unit commitment, transmission switching, and a detailed post-contingency model. The Final Event trial finished in September 2021, and the Monarch of the Mountain ongoing trial will finish in October 2022. This talk reviews the results so far and presents some lessons learned regarding the impact of solver time limits, the value and computational difficulty of model features like transmission switching and flexible load, the challenges of working with confidential industry data, and other outcomes of the competition.

3 **Grid Optimization (GO) Competition Challenge 2 Case Studies**
Farnaz Safdarian, Texas A&M University, College Station, TX
The case studies used in Grid Optimization (GO) Competition Challenge 2 include 16 synthetic grids with 84 scenarios created by three data teams, and six industry (actual) datasets composed of 36 scenarios that cannot be made publicly available. The synthetic grids are created based on publicly available data such as census data and load per capita and generator data and do not include any confidential information. Scenarios are created based on changes in the load and the availability of renewable energy resources. All power flow network configuration data files are provided in specific formats as an input for competitors. The input data is validated based on actual grids. The difficulty of each grid is assessed and the existence of a feasible solution for each grid is verified. The results achieved by different teams are analyzed and their performance on synthetic grids and actual industry grids are compared.

4 **Make It Real. Exploring the Gaps Between Power System Optimization Problems and Reality**
Scott Greene, University of Wisconsin Madison, Madison, WI, Contact: sgreene1@wisc.edu
For decades, the electric power industry has been the source of demanding scheduling and allocation problems. The availability of computational tools has affected how power system engineers operate and model the grid while the heuristics and approximations exploited in practice in turn influence the evolution of software. This presentation examines the problems created for ARPA-E's Grid Optimization Competition and their association with current and future power grid and electricity market operations. Topics addressed include voltage control, demand aggregations, congestion management, security, reliability, and risk management. The formulations of the GO Competition problems are compared to typical industry practice and available software solutions.

Electric Vehicle Management in Coupled Power-transportation Systems

General Session

Session Chair

Yunhe Hou, University of Hong Kong, Hong Kong, Hong Kong.

Session Chair

Yue Chen, The Chinese University of Hong Kong, Sha Tin

1 Power and Transport Nexus - Autonomous Electric Vehicle Fleet Operation and Optimization

Hongcai Zhang, University of Macau

Autonomous vehicles (AVs) that transport passengers or goods without human intervention will not only free human drivers from burdensome driving labor, but also promote transportation accessibility, cut down mobility costs, enhance energy efficiency, and reduce green-house gas emission. When AVs are electrified, which we refer to as autonomous electric vehicles (AEVs), then the last two aforementioned advantages will be further enhanced, particularly if the electricity is supplied from clean energy. The adoption of AEVs will significanty strengthen the power transportaiton nexus. To enhance the synergy between smart power grid & intelligent tranpsortation, this talk discusses some primary operation and optimization strategies of AEV systems on coupled power & transportation networks.

2 Modeling of Electric Vehicle Load in the Wireless Charging Scenario and Its Impact on the Distribution Network

Xin Cui[1], Liang Liang[2], Yunhe Hou[1], [1]the University of Hong Kong, Hong Kong, China; [2]Harbin Institute of Technology, Shenzhen, Shenzhen, China. Contact: cuixin@eee.hku.hk

Wireless charging of EVs on the power track is influenced by the traffic flow and has a certain impact on the power grid. In order to ensure the stable and reliable operation of the distribution network and reasonably schedule such EV load resources, it is necessary to analyze the EV charging load in combination with wireless charging characteristics and transportation information. Based on a general lithium battery model and vehicle motion equation influenced by the traffic flow, the static and dynamic charging load model of a single EV on a power track is given. Combined with the probability distribution of the initial state of charge, transportation network, and user travel habits, the charging load model of multiple EVs on the power track is presented. Finally, the influence of EV load on the distribution network is analyzed based on an example simulation.

3 Impact of COVID-19 on Learning-based Electric Vehicle Charging: Challenges and Solutions

Tongxin Li, Zachary Lee, Steven Low, Caltech, Pasadena, CA

The rapid growth of electric vehicles (EVs) in the last decade reduces carbon emissions of the transportation sector. We first introduce a large-scale adaptive charging network (ACN) infrastructure with a public dataset (ACN-Data). We showcase some applications of ACN-Data in control and learning-based EV research. With EV charging data collected in the past 3 years, we analyze the impact of COVID-19 on users' charging behavior, which poses challenges to existing control and learning-based charging algorithms. Finally, we highlight an MPC-regularized policy gradient charging method, which trusts user inputs in lieu of historical data records if they are biased because of pandemic-related policy shifts or human behaviors; and trusts data if user inputs are adversarial.

4 Online Distributed Routing Problem of Electric Vehicles

Zaiyue Yang, Southern University of Science and Technology, Shenzhen, China. Contact: yangzy3@sustech.edu.cn

Considering the penetration of numerous electric vehicles (EV) into the transportation sector, the EV routing problem that jointly optimizes the charging and routing of EVs becomes increasingly important. First, we start with an offline EVs routing and charging (EVRP) problem which is a large-scale mixed integer nonlinear program. A method is proposed to decompose the offline EVRP into a master problem and a set of sub-problems. To further speed up the computation, we relax the mixed integer master problem to a linear program, and a novel valid cut is added to reduce the number of iterations. In order to adapt to the online setting, we introduce the virtual depot and utilize the rolling-horizon framework to tackle uncertain future information. Numerical results validate that the speed of proposed algorithm is faster than current algorithms by several orders of magnitude.

Environment, Sustainability and Urban Infrastructure
General Session

Session Chair
Wei Qi, McGill University

Session Chair
Aiqi Zhang, Hong Kong, Hong Kong.

Session Chair
Ronald McGarvey, University of Missouri, IMSE and TSPA, Columbia, MO

1 **Urban Infrastructure Planning to Manage Stormwater**
Sheng Liu[1], Wei Qi[2], Aiqi Zhang[3], [1]University of Toronto, Toronto, ON, Canada; [2]McGill University, Montreal, QC, Canada; [3]Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: aq.zhang@rotman.utoronto.ca
We propose an urban water infrastructure planning problem that integrates the sewage systems and retention basins as control methods. Leveraging the traditional Intensity-duration-frequency (IDF) Curve to characterize rainfall scenarios, we analyze the flooding cost of each scenario and show that even the scenarios with same return periods on the IDF Curve can result in entirely different flooding costs, providing a perspective of operations management for the planning. Applying robust optimization techniques, we provide tractable infrastructure solutions that hedge against worst-case rainfall scenarios. Finally, we extend our model to the case of capacitated sewage systems and multiple catchments.

2 **Mitigating Climate-induced Floods via Real-time Operation of Urban Stormwater Systems: The Case for Model Predictive Control**
Marcus Nobrega Gomes Jr[1], Ahmad Taha[2], Marcio Giacomoni[1], Eduardo Mario Mendiondo[3], [1]University of Texas at San Antonio, San Antonio, TX, [2]Vanderbilt University, Nashville, TN, [3]University of Sao Paulo, Sao Carlos, Brazil.
Urban stormwater systems face tremendous challenges due to the climate change, which will increase the frequency and severity of storms, resulting in more flooding. Due to advances in sensing and actuating technology, computation power, weather/climate forecast, and control theory, there are great opportunities to mitigate climate-induced flooding via real-time operation of urban stormwater systems. To this end, we develop a novel non-linear state-space model of hydrologic and hydrodynamic processes in watersheds, reservoirs, and channels. We tested reactive controls and compared them to a model predictive control (MPC) using a synthetic case study. MPC outperforms the reactive controls not only for design and rare storms but also for continuous simulations. The tested MPC approach is flexible and performed well even under relatively short prediction horizons.

3 **Exploring Social Dimension for Sustainable Solid Waste Management Optimization**
Jenny Gutierrez-Lopez[1,2], Ron McGarvey[1], [1]University of Missouri, Columbia, MO, [2]Escuela Superior Politecnica del Litoral (ESPOL), Guayaquil, Ecuador. Contact: jgutierrezlopez@mail.missouri.edu
The goal of this study is to present a sustainable and engaged solid waste management multi-objective optimization framework to recommend waste treatment strategies. The objective functions consider the three pillars of sustainability attempting to (1) minimize total costs, (2) minimize environmental impacts, and (3) maximize service quality. The novel feature of this study is that it also incorporates a social score threshold as a constraint such that the framework reflects not only expert's perspectives at local government and organizations in solid waste management but also considers views of residents of the city. Results are expected to illustrate complexities in solid waste management decisions, provide suggestions to manage conflicting criteria and demystify trade-offs of different waste treatment strategies.

New Algorithmic Concerns in Market Revenue Management
General Session

Session Chair
Vijay Kamble, University of Illinois at Chicago, Chicago, IL

Session Chair
Swati Gupta, ISyE Georgia Tech, Atlanta, GA

1 **Markdown Pricing Under Unknown Parametric Demand Models**
Su Jia, Andrew A. Li, R. Ravi, Carnegie Mellon University,

Pittsburgh, PA, Contact: aali1@cmu.edu
Consider the problem of pricing a single product under unknown demand, with the objective of maximizing expected revenue over T rounds, subject to a markdown pricing constraint. Previous work has shown a tight $T^{3/4}$ regret bound under minimal, non-parametric assumptions on the demand curve (whereas the same problem without markdown constraint admits $T^{2/3}$ regret).
We investigate this same problem assuming the demand curve comes from a known parametric family. Specifically, we ask: (1) Can the $T^{3/4}$ regret bound be improved with extra assumptions on the functional form of the demand function? (2) Is markdown pricing still harder than unconstrained pricing under these additional assumptions? To answer these, we introduce a concept called markdown dimension that measures the complexity of the given parametric family, and present tight regret bounds under this framework.

2 Bayesian-Nash-Incentive-Compatible Mechanism for Blockchain Transaction Fee Allocation

Zishuo Zhao[1], Xi Chen[2], Yuan Zhou[3], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]New York University, New York, NY, [3]Tsinghua University, Beijing, China. Contact: zishuoz2@illinois.edu
In blockchain systems, the design of transaction fee mechanisms is essential for stability and satisfactory for both miner and users. A recent work has proven the impossibility of collusion proof mechanisms with non-zero miner revenue which is DSIC for users. In our work, we relax the DSIC requirement for users to BNIC, and designed a so-called soft second-price mechanism to ensure a form of collusion-proofness with a positive miner revenue, breaking the zero-revenue barrier while preserving reasonable truthfulness.

3 Fair Assortment Planning

Qinyi Chen[1], Negin Golrezaei[2], Fransisca Susan[1], Edy Baskoro[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, [3]Institut Teknologi Bandung, Bandung, Indonesia. Contact: qinyic@mit.edu
Assortment planning decisions of online platforms have a significant impact on customers' choices, and many platforms employ algorithms that feature items with the highest popularities. This, however, can lead to too little visibility for the rest of the items, making them leave the platform, which in turn hurts the platform's long-term goals. Motivated by that, we introduce and study a fair assortment planning problem, which requires any two items with similar merits to be offered similar visibility. We propose a framework to find near-optimal solutions to this problem, using the Ellipsoid method and a separation oracle to its dual. We then develop two approximate separation oracles, which result in a polynomial-time 1/2-approx. algorithm and an FPTAS for our problem. Finally, we conduct a case study on the MovieLens dataset, demonstrating the efficacy of our algorithms.

4 Ensuring Comparative Fairness at the Time of Purchase in Demand Learning

Vijay Kamble, University of Illinois at Chicago, Chicago, IL
A multi-segment pricing strategy satisfies comparative fairness at the time of purchase if the price received by a segment isn't much worse (up to a certain degree of publicly allowable disparity) than that received by any segment in the past. We design novel algorithmic approaches to satisfy this notion of fairness in the process of demand learning for the case where the revenue functions are known to be smooth and strongly concave. These approaches ultimately achieve the same optimal regret guarantees (up to logarithmic factors) as those achievable without the fairness constraint. This algorithmic framework can help firms address the rising concerns of inequitable treatment in dynamic pricing.

Sunday, 5 PM–6:15 PM

1 Do Irrelevant Alternatives Influence Choices in Environmental Decisions?

Mirel Yavuz[1], Guia Bianchi[2], Charles J. Corbett[3], Tayler Bergstrom[3], Aimee Drolet[3], Timothy F. Malloy[4], Deepak Rajagopal[5], Rakesh Kumar Sarin[3], Francesco Testa[2], [1]University of California, Los Angeles, Los Angeles, CA, [2]Sant'Anna School of Advanced Studies, Pisa, Italy; [3]University of California, Los Angeles, Los Angeles, CA, [4]University of California, Los Angeles School of Law, Los Angeles, CA, [5]UCLA Institute of Environment and Sustainability, Los Angeles, CA, Contact: mirel.yavuz.phd@anderson.ucla.edu
Although several tools exist to collect environmental information, there is minimal guidance on making decisions based on such information. Decision-makers are subject to a wide range of context effects in other

domains. This experimental study finds that attraction and compromise effects occur in the context of sustainability-related decision-making.

2 Race and Facility Emissions

Abhinav Shubham, Ravi Subramanian, Georgia Institute of Technology, Atlanta, GA, Contact: ashubham3@gatech.edu

Environmental justice researchers have found evidence of racial minorities bearing disproportionate environmental burdens. However, it is unclear how facility level operational choices contribute to this disparity. We conduct an empirical investigation into the environmental and operational choices of facilities in host communities with substantial presence of racial minority populations.

3 Evaluating Small Business Preference Programs in Public Procurement: Evidence from U.S. Federal Government R&D Contracts

Dwaipayan Roy[1], Anant Mishra[2], Kingshuk K. Sinha[3], [1]University of Virginia Darden School of Business, Charlottesville, VA, [2]Carlson School of Management, University of Minnesota, Minneapolis, MN, [3]University of Minnesota SCO, Minneapolis, MN, Contact: royd@darden.virginia.edu

We examine whether the performance of R&D contracts awarded through the Set-Aside program differs from those awarded through open competition and, if so, in what way. Furthermore, we examine how characteristics of the contracting environment—namely, contractor firm experience (i.e., the number of R&D contracts executed by a contractor firm for the federal government) and contract award timing (i.e., awarded *early* in a federal fiscal year)—interact with the set-aside status of an R&D contract to affect its performance.

4 Does Leader Disability Influence the Productivity Performance of Teams with Workers with Disabilities? An Empirical Study in the Apparel Industry

Dustin Cole[1], Sriram Narayanan[2], Shawnee Vickery[2], [1]Auburn University, Auburn, AL, [2]Michigan State University, East Lansing, MI

This research examines the impact of a direct supervisor with a disability on the productivity of workers with disabilities through the lens of Leader-Member Exchange Theory (LMX). Through both quantitative analysis and a qualitative study we find that a supervisor with a disability mitigates the potential productivity decline as the number of workers with a disability increases. A potential mechanism for this is greater task stability of supervisors with disabilities which came out as a major theme of the qualitative study.

1 Optimizing Decommissioning Strategy for Thermal Power Plants in the Climate Resilient Power System -- Case Study of Decommissioning Plan in China

Ziting Huang, Johns Hopkins University, MD

To comply with more stringent carbon emissions goals, old thermal power plants now face challenges of being forced to decommission earlier than the scheduled retirement year. The study aims to explore the optimized decommissioning strategy for existing thermal plants using the economic dispatch in the power system considering the extreme climatic events and renewables uncertainty. Four strategies are available to thermal plants regarding such a decision: to retire as scheduled, to retrofit with carbon capture and storage devices, to decommission early, and to redevelop into new renewable energy site. The study will focus on the coal power industry in China.

2 Data-driven Operations for a Smart Vehicle-grid System

Ziliang Jin[1], Jianqiang Cheng[2], Kai Pan[3], Zuo-Jun Max Shen[4], Yulan Amanda Wang[1], [1]The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]University of Arizona, Tucson, AZ, [3]Hong Kong Polytechnic University, Hung Hom, Hong Kong; [4]University of California Berkeley, Berkeley, CA, Contact: ziliang-lms.jin@connect.polyu.hk

We consider a vehicle-grid integration system, which is supported by vehicle-to-grid (V2G) technology. Our goal is to identify the potential of V2G in such synergy. To address this problem, we propose a two-stage robust mixed-integer linear programming (MILP) model which jointly optimizes grid's planning and EV sharing company's operations under uncertainties. Due to its large-scale computational difficulty, we propose three different approaches (new strong valid inequalities, ADMM, and hybridization of machine learning and optimization) that are applicable in different sample sizes to boost the solving efficiency. Finally, we show the potential of V2G by numerical results.

3 Two-stage Robust Optimization with Decision-dependent Uncertainties

Yunfan Zhang, Feng Liu, Tsinghua University, Beijing, China. Contact: zhang-yf18@mails.tsinghua.edu.cn

Decision-dependent uncertainties impose great challenges to the current robust optimization (RO) framework. We investigate the two-stage RO problems that involve two classes of decision-dependent uncertainty sets (DDUS) including 1) polyhedral DDUS whose right-hand-side vector has a dependency on the here-and-now decisions; and 2) transformable DDUS that comprises a coupling function concerning certain exogenous uncertain parameters. A novel iterative algorithm based on the Benders dual decomposition and a variant of C&CG method based on scenario mapping are proposed, where advanced optimality and feasibility cuts are applied to incorporate the uncertainty-decision coupling.

4 Robust Generation Dispatch with Strategic Renewable Power Curtailment and Decision-dependent Uncertainty

Yue Chen, The Chinese University of Hong Kong, Sha Tin, Hong Kong. Contact: yuechen@mae.cuhk.edu.hk

This talk introduces a novel two-stage robust generation dispatch (RGD) model, where the curtailment strategy is optimized in the pre-dispatch stage. Therefore, the problem casts down to a robust optimization under decision-dependent uncertainty (DDU). To overcome the difficulty in solving the RGD with DDU, an adaptive column-and-constraint generation (AC&CG) algorithm is developed. We prove that the proposed algorithm can generate the optimal strategy in finite iterations. Numerical examples validate the practicability and scalability of the proposed model and algorithm.

5 Two Bird, One Stone: Modeling Time-based Energy Attribute Certificates for 24/7 Carbon-free Electricity Procurement and Carbon-optimized Procurement

Qingyu Xu, Neha Patankar, Aneesha Manocha, Jesse D. Jenkins, Princeton University, Princeton, NJ, Contact: xuqingyu0610@gmail.com

We enhance a capacity expansion planning model, GenX, to model a Time-based Energy Attribute Certificate (TEAC) system, with which we model two voluntary clean-energy-procurement schemes: 24/7 carbon-free electricity (24/7 CFE) procurement and carbon-optimized (CO) procurement. 24/7 CFE participating consumers procure TEACs from CFE generated in each hour to match their hourly demand, while carbon-optimized procurement aims to maximize the system-level CO2 emissions reduction using hourly marginal emission rates. We analyze the two schemes by showing their procured portfolios, cost premiums, and emission impacts on the California electricity system in 2030.

6 Using Geographic Load Shifting to Reduce Carbon Emissions

Line Roald[1], Julia Lindberg[1], Bernard Lesieutre[2], [1]University of Wisconsin - Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, Contact: roald@wisc.edu

Two rapidly increasing categories of electric load, namely electric vehicle charging or operation of hyperscale data centers, exhibit flexibility in either when or where electricity is consumed. We discuss how these loads can interact with the electricity market to minimize the carbon emissions of their electricity consumption, even as the market operator targets cost minimization. We propose to locational marginal carbon emissions as a new metric to guide load shifting, and discuss how this metric can be defined using tools from sensitivity analysis and multi-parametric programming. We then demonstrate its efficacy compared to existing metrics on a standard test case.

7 Routing and charging facility location for EVs under nodal pricing of electricity: A bilevel model solved using special ordered set

Felipe Feijoo, 1</sup

8 Integrated Prediction and Optimization for Power Grid Resilience Planning

Erhan Kutanoglu, University of Texas-Austin, Austin, TX

We analyze the resilience planning problem for the power grid and make the case for integrating prediction and optimization. We focus on two extreme weather events (flood causing heavy rain events and cold snaps). We propose models to enhance the grid resilience by significantly improving mitigation and adaptation planning, rather than focusing on recovery. We propose a comprehensive modeling and methodological framework for the integration of scenario generation, impact predictions and optimization-based resilience planning. We demonstrate the overall approach and present results using a synthetic but realistic Texas-size power grid. We finally tie the overall analysis to our latest work on equitable resilience planning and climate change adaptation of the power grid.

1 Simple Policies for Joint Pricing and Inventory Management
Adam Elmachtoub[1], Harsh Sheth[2], Yeqing Zhou[3], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY, [3]Eindhoven University of Technology, Eindhoven, Netherlands.
In this paper, we study the fundamental joint pricing and inventory control problem where the customers are price sensitive, and the demand rate can be controlled by the price. In this setting, an optimal policy is highly dynamic, with price varying over time to leverage supply and demand. We analyze the effectiveness of simpler policies, where only a small number of prices are offered throughout, and offer insights of how these policies compare to their dynamic counterparts. We find that when there is no backlogging, a single price can be used to be a *log(S)* factor away for holding costs while doing just as good on revenue and ordering costs under exponential demand. This factor can be improved to 1.5 when the demand is linear. When there is backlogging, using three prices instead of one gives us similar performance guarantees.

2 Optimal Feature-based Market Segmentation and Pricing
Titing Cui, Michael L. Hamilton, University of Pittsburgh, Pittsburgh, PA, Contact: mhamilton@katz.pitt.edu
In this work, we study semi-personalized pricing strategies where a seller uses features about their customers to segment the market, and where customers are offered segment specific prices. Specifically, we study market segmentation and pricing under the assumption that the seller has trained a (noisy) regression model mapping features to valuations. We establish novel hardness and approximation results for when model noise is independent. In the common case when the noise in the model is log-concave, we show the joint segmentation and pricing problem can be efficiently solved and characterize a number of attractive structural properties about the optimal feature-based market segmentation and pricing.

3 Speed Service with Spotlight Products: Assortment Optimization and Pricing with Service Rate Consideration
Zhe Liu[1], Shixin Wang[2], [1]Imperial College Business School, London, United Kingdom; [2]CUHK Business School, Hong Kong, Hong Kong. Contact: zhe.liu@imperial.ac.uk
Quick-service restaurants, such as fast-food franchises and coffeehouse chains, recommend items with spotlight menu that may shorten customers' decision time and hence speed up the service, but with a trade-off of possibly lower profit margin. We study such assortment optimization problems when service rate is affected by the recommendation and plays a role in the revenue rate objective. Formulated as a sequential recommendation problem in a queueing setting under the multinomial logit model, we obtain structural properties of the impact of arrival rate and system capacity on optimal assortment, and find optimality conditions for attractiveness-ordered or fare-ordered nested policies. We also characterize the optimal joint assortment and pricing under common price sensitivity.

4 Uncertain Search with Knowledge Transfer
Woonghee Tim Huh, Michael Jong Kim, Meichun Lin, University of British Columbia, Vancouver, BC, Canada. Contact: meichun.lin@sauder.ubc.ca
We study a problem of sequential learning and choosing from a group of similar alternatives. The unknown payoff of accepting an alternative depends on a set of common features that enables knowledge transfer across the group. There is also an idiosyncratic value for each alternative that needs to be learned by sampling over time. The problem is whether to accept the current alternative, continue sampling, or switch to the next one. We model it as a Bayesian dynamic program and analyze structural properties.

1 The Effect of Privacy Policy on Pricing and Revenue
Ningyuan Chen[1], Ming Hu[2], Jialin Li[3], Sheng Liu[4], [1]University of Toronto, Mississauga, ON, Canada; [2]University of Toronto, Minneapolis, MN, [3]University of Toronto, Toronto, ON, Canada; [4]University of Toronto,

Toronto, ON, Canada. Contact: jln.li@rotman.utoronto.ca
Retailer(s) may collect or purchase historical data to build demand model that can be used to give optimal pricing at the current stage. However as what is becoming prevailing, user information would be hided in such data as required by regulators to protect users' privacy. This policy will have an impact on the so-believed optimal price and revenue when users' features have correlation with prices in history, which is often observable in data. We show that in cases of monopoly, the retailer will suffer revenue loss under privacy policy when sample size is large; whereas for duopoly the difference on equilibrium revenue is closely related to the coefficient(s) of users' feature(s) in the model. Our analysis also shows what kind of features, when hided, will be most harmful to revenue.

2 Policy Optimization Using Semi-parametric Models for Dynamic Pricing

Mengxin Yu, Yongyi Guo, Jianqing Fan, Princeton University, Princeton, NJ, Contact: mengxiny@princeton.edu
In this paper, we study the contextual dynamic pricing problem where the market value of a product is linear in some observed features plus some market noise (with unknown distribution). Products are sold one at a time, and only a binary response indicating the success or failure of a sale is observed. We propose a dynamic statistical learning and decision-making policy that combines semi-parametric estimation and online decision-making to minimize regret (maximize revenue). Under mild conditions, we show that for a market noise c.d.f. F with m-th order derivative, our policy achieves a sublinear regret. The upper bound is further reduced to sqrt root of T if F is super smooth whose Fourier transform decays exponentially. These upper bounds are close to the lower bound where F belongs to a parametric class.

3 Linear Contextual Dynamic Pricing

Jianyu Xu, University of California Santa Barbara, Santa Barbara, CA, Contact: xu_jy15@ucsb.edu
Feature-based dynamic pricing are formally studied as an online learning problem where a seller sets appropriate prices for a sequence of products (described by their features) on the fly and learns from the binary feedbacks ("Sold" if valuation >= price and "Not Sold" otherwise). We study this problem by making a linear use of these features. In specific, we consider the following two models: (a) a "linear valuation" problem where customers' valuations are a linear mapping of features adding iid noises, and (b) a "linear policy" problem where we are agnostic of the valuation mechanism and only aim at competing with the best linear pricing policy. For both of these two problems, we design algorithms with provable regret upper bounds and propose information-theoretic lower bounds under a variety of assumptions.

4 Network Revenue Management: A PAC-Bayesian Approach

N. Bora Keskin[1], David Simchi-Levi[2], Prem Talwai[3], [1]Duke University, Durham, NC, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]MIT, Cambridge, MA, Contact: talwai@mit.edu
We consider a seller offering a large network of N products over a horizon of T periods. The seller is unaware of the parameters of the products' linear demand model, and can dynamically adjust product prices to learn the the model based on sales observations. The seller aims to minimize their revenue loss relative to a clairvoyant who knows the underlying demand model. We consider a sparse set of demand relationships between products and focus particularly on two different sparsity frameworks: (1) L_0 sparsity, which constrains the number of connections in the network, and (2) off-diagonal sparsity, which constrains the magnitude of cross-product price sensitivities. We propose a dynamic pricing-and-learning policy that combines PAC-Bayesian and OFUL approaches, and achieves asymptotically optimal performance in terms of N and T.

1 Trading Safety Stock for Service Response Time in Inventory Positioning

Hanzhang Qin[1], David Simchi-Levi[2], Ryan Ferer[3], Jonathan Mays[4], Ken Merriam[4], Megan Forrester[5], Alex Hamrick[5], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Accenture, Atlanta, GA, [4]Accenture, Atlanda, GA, [5]The Home Depot, Atlanda, GA, Contact: hqin@mit.edu
We study the inventory placement optimization problem, where demand is sensitive to service response time, under the online retailing setting. The main challenge is to achieve the optimal trade-off between revenue benefits from shorter delivery time and inventory operation costs. To predict the

effects of modified demand under service response time variations, we introduce a demand prediction and elasticity model to quantify the sensitivity in demand for particular product categories. We also propose a novel data-driven two-stage stochastic programming approach complementing the demand prediction and elasticity model, which optimally trades safety stock for service response time. We then illustrate the efficiency of our approach through data provided by an e-commerce retailer in North America.

2 Leveraging Consensus Effect to Optimize Feed Ranking in Online Discussion Boards

Joseph Carlstein[1], Gad Allon[1], Yonatan Gur[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Stanford University, Stanford, CA, Contact: jc95@wharton.upenn.edu

Online discussion boards are designed for facilitating discussions between groups of users. To stimulate engagement, these platforms suggest arriving users a recommended "feed" of comments made by other users. In this study we collaborate with Ment.io, an online discussion board catering to groups in business and education settings. From their data, we identify and empirically validate a new engagement driver capturing the level of discussion *consensus*. This driver suggests that, when designing the recommended feed, the platform should consider not only comments that would yield present engagement, but also ones that would maximize *future* engagement by managing the desired discussion consensus level. Based on this, we propose a new dynamic model and a practical class of algorithms that integrate both considerations to maximize engagement along the discussion path.

3 Designing Layouts for Sequential Experiences: Application to Cultural Institutions

Ali Aouad[1], Abhishek Deshmane[2], Victor Martinez de Albeniz[3], [1]London Business School, London, United Kingdom; [2]IESE Business School, Barcelona, Spain; [3]IESE Business School, Barcelona, Spain. Contact: adeshmane@iese.edu

Experience providers - ranging from retail platforms to cultural institutions - need to decide on how to display an assortment of items for physical and digital interactions. In this paper, we develop a data-driven analytics framework to optimize these layout-related decisions for maximum user engagement. We develop a new dynamic choice model, called Pathway MNL, that represents visitor activity as a sequence of conditional logit experiments. Through an ongoing collaboration with the Van Gogh Museum, we validate the model on large-scale logs of visitor activity recorded through audio guides. We uncover significant relationships between visitors' choices and layout-related factors, among others. Finally, we analyze the resulting mathematical program for layout optimization and identify simple layout interventions that can significantly lift visitor engagement.

4 Regret Minimization with Dynamic Benchmarks in Repeated Games

Ludovico Crippa[1], Yonatan Gur[1], Bar Light[2], [1]Stanford University, Stanford, CA, [2]Microsoft Research, New York, NY

In repeated games, the dynamics arising when all players deploy strategies with no-regret relative to a static benchmark have been extensively studied. However, static benchmarks are limited and can perform poorly in natural dynamic scenarios. In this work we study the dynamics that emerge when players adopt strategies with guarantees relative to dynamic benchmarks. Our main result shows that the empirical distribution of plays still converges to the Hannan set. Our results imply that, despite being more stringent than static comparators, these different classes of strategies drive comparable game dynamics. This characterization allows one to adopt analyses from settings that consider a static benchmark, which we demonstrate by extending results on the Price of Anarchy to our setting.

1 How Many Pooled Covid Tests are Enough?

Ilias Zadik, Massachusetts Institute of Technology, Cambridge, MA

The problem of pooled or group testing, which was of paramount importance over the recent COVID-19 pandemic, tests on parallel subsets of a population of individuals with the goal to detect a subset of infected ones. The perhaps simplest, yet mathematically optimal in terms of number of required tests, such testing procedure is to choose the individuals participating in each test independently at random. Yet, identifying the infected individuals using this testing procedure seems to require a large (exponential) time. We will discuss recent work on trying to understand whether such a number of tests vs time trade-off is actually fundamental or not.

2 Patterns and Predictors of Urban Emissions in the United States: A Typology Approach

Alexa Weinman, Jimi Oke, University of Massachusetts Amherst, Amherst, MA, Contact: aweinman@umass.edu

Notably, 4.25% of the global population resides in the US, which contributed 11% of global greenhouse gas emissions in 2019. Furthermore, cities accounted for 63% of total US emissions in 2012 (Gately et al., 2015). Yet, their patterns and predictors have been relatively understudied. To address these gaps, we first analyze multivariate emissions patterns in over 300 US urban areas to develop novel typologies. Second, we estimate models to predict these typologies based on explanatory variables from mobility, socioeconomic, geographic, urban form, environmental, and public health categories. This approach provides deeper insights into the drivers of urban emissions and can facilitate future analyses of climate change mitigation strategies.

3 A Scientific Mapping on Polymer Nanoparticles in Cancer Drugs Through Global Publications

Xindan Kang[1], Mohammadhossein Amini[1], Majid Jaberi-Douraki[2], [1]Washington University in St.Louis, St. Louis, MO, [2]Kansas State University, Manhattan, KS, Contact: k.xindan@wustl.edu

In this study, we mine published studies in various reputed journals across different countries in the area of anticancer drugs. We mainly focus on the studies where anticancer drugs are carried by functionalized polymer nanoparticles in different types of cancers. Our dataset contains 240000 publications indexed through the Scopus database from 1980 to the present, where the number of publications peaked after 2010. We apply various text mining and data-analytic techniques to find current trends, core objectives, distinguished scientists, and the most prominent research groups in this field. Our findings show the potential patterns underlying the changes in cancer treatment to provide references for polymer nanoparticles' future development.

4 Hurricane Forecasting: A Novel Multimodal Machine Learning Framework

Cynthia Zeng, Massachusetts Institute of Technology, Cambridge, MA

This work describes a novel machine learning (ML) framework for tropical cyclone intensity and track forecasting, combining multiple ML techniques and utilizing diverse data sources. Our multimodal framework, called Hurricast, efficiently combines spatial-temporal data with statistical data by extracting features with deep-learning encoder-decoder architectures and predicting with gradient-boosted trees. We evaluate our models in the North Atlantic and Eastern Pacific basins on 2016-2019 for 24-hour lead time track and intensity forecasts and show they achieve comparable mean average error and skill to current operational forecast models while computing in seconds. Furthermore, the inclusion of Hurricast into an operational forecast consensus model could improve over the National Hurricane Center's official forecast, thus highlighting the complementary properties with existing approaches. In summary, our work demonstrates that utilizing machine learning techniques to combine different data sources can lead to new opportunities in tropical cyclone forecasting.

Data Protection and Privacy in Redistricting

General Session

Session Chair

Soraya Ezazipour, Oklahoma State University, Stillwater, OK

1 Presenter

Christopher T. Kenny[1], Shiro Kuriwaki[2], Cory McCartan[3], Evan Rosenman[4], Tyler Simko[1], Kosuke Imai[5], [1]Harvard University, Cambridge, MA, [2]Stanford University, Cambridge, MA, [3]Harvard University, Cambridge, MA, [4]Harvard University, Cambridge, MA, [5]Harvard University, Cambridge, MA, Contact: christopherkenny@fas.harvard.edu

Census statistics play a key role in public policy decisions and research. However, given the risk of revealing individual information, many statistical agencies are considering disclosure control methods based on differential privacy, which add noise to tabulated data. Unlike other applications of differential privacy, however, census statistics must be postprocessed after noise injection to be usable. We study the impact of the U.S. Census Bureau's latest disclosure avoidance system (DAS) on a major application of census

statistics, the redrawing of electoral districts. We find that the DAS systematically undercounts the population in mixed-race and mixed-partisan precincts, yielding unpredictable racial and partisan biases. While the DAS leads to a likely violation of the “One Person, One Vote” standard, it does not prevent accurate predictions of race.

2 Redrawing Attendance Boundaries to Promote Racial and Ethnic Diversity in Elementary Schools

Keyu Zhu[1], Nabeel Gillani[2,3], Pascal Van Hentenryck[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Northeastern University, Boston, MA, [4]Georgia Institute of Technology, Atlanta, GA

Most US school districts assign children to schools based on where they live, drawing “attendance boundaries” to define catchment areas that often recapitulate neighborhood demographic segregation in schools. Focusing on elementary schools, we ask: how much might we reduce school segregation by redrawing attendance boundaries? We simulate alternative boundaries for 98 US school districts serving over 3 million students, minimizing White/non-White segregation while imposing constraints on travel times and school sizes. Across districts, we observe a median 12% relative decrease in segregation requiring nearly 20% of students to switch schools and, surprisingly, a slight reduction in travel times. We explore the sensitivity of these results under different privacy-preservation strategies to inform practicable desegregation efforts across school districts.

3 Casual Inference in Redistricting

Zachary Schutzman, MIT, Cambridge, MA, Contact: zis@mit.edu

Drawing districts to achieve a purpose, whether a positive one like equitable and effective representation or a nefarious one like locking in a partisan advantage is an exercise in using data to infer demographic attributes and predict the voting behavior of living in a jurisdiction. In a formal sense, these inferences about identity and voting patterns erodes their privacy, yet these privacy concerns are given little attention. On the other side, analysts seeking to uncover the motives and impacts of a districting plan have to perform similar privacy-violating analyses. This sets up a tension between privacy and effective representation, though we generally consider both to be desirable. We’ll discuss the data analysis domain experts perform in the redistricting setting, how that analysis chips away at privacy, and highlight points of conflict between those two values.

4 What is the “Real” Population of My District? The Worst-case Effects of Differential Privacy

Soraya Ezazipour, Austin Buchanan, Oklahoma State University, Stillwater, OK

To protect the privacy of respondents, the US Census Bureau added random noise to the 2020 Census data, including to the population counts. This has led to concerns that districts that are reported to be equally populous may actually deviate beyond what is legally acceptable. In this presentation, we aim to understand the worst-case impacts of noising on district populations. We build single districts with maximum actual population such that their census-reported population is legal. To solve this optimization problem, we use integer programming techniques. For our data, we use the actual 2010 population counts and the noised 2010 population counts. We apply the approach to county-level, tract-level, and block-level instances of congressional redistricting.

Social Media Analytics in Operations and Supply Chain Management

Joint Session

Session Chair

jiayuan Zhang, University of Rhode Island, kingston, RI

1 Embeddedness and Complexity of Nexus Supplier in Multitier Supply Chains from Information-communication Technology (ICT) Industry

Kara Li Liu, Koray Ozpolat, Seung Kyoon Shin, University of Rhode Island, Kingston, RI, Contact: karaliliu@uri.edu

Nexus supplier in multitier supply chains (MSCs) has drawn attention from industry due to disruptions and risk through the pandemic. It is challenging for firms to map extended supply chains, gain insights into current industry trends, and adapt to rapid changes in the business environment. Our study addresses recent issues related to ICT nexus supplier through its embeddedness and complexity in supply networks. Using the latent Dirichlet allocation (LDA) topic modeling approach and unstructured data of SEC filings, we demonstrate how to identify the emerging issues and investigate the effects of nexus supplier in MSCs for the ICT industry.

2 Using Social Media Data to Explore Supply Chain Vaccine Challenges

jiayuan Zhang, University of Rhode Island, kingston, RI

This study uses social media data to explore supply chain vaccine challenges. We find that product, production, allocation, distribution, and global procurement are the main supply chain challenges in the vaccination process. Actionable insights based on the findings are provided.

3 Learning when Reading: Evidence from an Online Mobile Reading Platform

Yuchen Liu, University of Washington, Seattle, WA

Online reading platforms offer a by-chapter purchase method and implement a novel in-chapter online review function. However, how such intervention would affect consumer purchase decisions remains to be uncovered. In this study, we build a structural model on the data from a leading China online reading platform to unveil the consumer learning process enabled by the by-chapter purchase method and the impact of in-chapter review content on consumer decisions. We found evidence that consumers learn the quality of different book genres at a different pace. In addition, our analysis reveals that the in-consumption reviews of different topics have heterogeneous effects on consumers' sequential purchase decisions. Meanwhile, the current reading spot of consumers out of the whole book and the informativeness of chapter names also affect consumer purchase intention.

4 Maximizing Propagation Times in Networks Using First Passage Times

Niloufar Daemi, Juan Sebastian Borrero, Baski Balasundaram, Oklahoma State University, Stillwater, OK

In a Markov chain, the minimum first passage times are defined as the first time the chain reaches a given state starting from some other state. In this work, we apply this concept in social network analysis where we define the minimum first passage time as the first time a user in a social network is exposed to a rumor or an offensive post. We propose an interdiction model where the goal is to interdict vertices to maximize the minimum first passage time. Interdicting a user decreases the probability of sharing the information with other users and results in longer first passage times. We formulate the problem as a mixed integer linear programming and solve it using decomposition algorithms.

Emerging Topics in Service Operations

General Session

Session Chair

Jiding Zhang, 1</sup

1 Estimating The Effects of Online Food Delivery on Small-Business Restaurants During Covid-19 in California

Hailong Cui[1], Xin Tong[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Southern California, Los Angeles, CA, Contact: hailongc@umn.edu

We use econometric methods to study the impact of online food delivery on small-business restaurants in California during COVID-19. To do this, we collect and analyze two types of data (proprietary data from a food distributor supplying to these restaurants and restaurant-level data via surveys and web-crawling).

2 Causal Bandits: Online Decision-making in Endogeneous Settings

Yifang Chen[1], Jingwen Zhang[1], Amandeep Singh[2], [1]University of Washington, Seattle, WA, [2]Wharton School, Philadelphia, PA, Contact: yifangc@cs.washington.edu

The deployment of multi-armed bandits has become commonplace in many marketing applications. However, regret guarantees for state-of-the-art linear bandit algorithms such as Optimism in the Face of Uncertainty Linear bandit (OFUL) make strong exogeneity assumptions wrt arm covariates. This assumption is very often violated in many economic contexts and using such algorithms can lead to biased decisions. In this paper, we consider the problem of online learning in linear stochastic multi-arm bandit problems with endogeneous covariates. We propose an algorithm we term \textit{BanditIV}, that uses instrumental variables to correct for this bias and prove strong regret guarantees for the algorithm. We carry out extensive Monte Carlo simulations to demonstrate the performance of our algorithm compared to other recently developed methods.

3 A Hybrid Machine Learning-optimization Framework to Distinguish Positive-agers from Cognitive-decliners using Resting-state Functional MRI Data

Mohammad Fili, Luning Bi, Guiping Hu, Iowa State University, Ames, IA

Classification models rely on the class labels to learn and estimate the boundaries between different classes. Sometimes the labels are not available, or the labeling procedure is complicated. In this study, we proposed a hybrid machine learning-optimization framework to optimally assign the class labels to the observations. The proposed algorithm incorporates the information from a separate dataset called shadow dataset to find the class labels. The algorithm utilizes Bayesian Optimization to optimize the decision variables pertinent to the labeling procedure.

1 Bitcoin Mining and Electricity Consumption
Ling Qin[1], Min Dai[2], Steven Kou[3], Shuaijie Qian[2], [1]The Hong Kong university of Science and Technology, Hong Kong, Hong Kong; [2]National University of Singapore, Singapore, Singapore; [3]Boston University, Boston, MA
We propose a dynamic industry equilibrium model for Bitcoin electricity consumption in a general framework, including Bitcoin miners' optimal entry and exit with technology innovation. Using average operating costs to approximate the true operating costs, we overcome the difficulty of strong path-dependency incurred by the interaction among entry, exit, and technology innovation. The model can capture the upside and downside co-movements of miners' computing power, electricity consumption, and mining revenue. Our model predicts that the Bitcoin electricity consumption will not grow indefinitely and the ratio of Bitcoin electricity consumption to the miners' revenue must fluctuate within a certain range.

2 Efficient Simulation of Polyhedral Expectations with Applications to Finance
Lewen Zheng[1], Dohyun Ahn[2], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Chinese University of Hong Kong, Shatin, Hong Kong.
We consider the problem of estimating the expectation over a convex polyhedron specified by a set of linear inequalities. This problem encompasses a multitude of financial applications including systemic risk quantification, portfolio management, and exotic option pricing. We particularly focus on the case where the target event is rare, which corresponds to extreme systemic failures, large portfolio losses, and deep out-of-the-money options in the aforementioned applications, respectively. This rare-event setting renders the naive Monte Carlo method inefficient and requires variance reduction techniques. To address this issue, we develop a novel and strongly efficient method for the computation of the said expectation in a general rare-event setting by exploiting the geometry of the target polyhedron and concentrating the sampling density almost within the polyhedron. The proposed method significantly outperforms the existing approaches in various numerical experiments in terms of accuracy and computational burden.

3 Scalable Reinforcement-Learning Trading Framework with Dynamic Financial Data Embedding
Jinghai He, Cheng Hua, Zeyu Zheng, University of California, Berkeley, Berkeley, CA
We develop a scalable reinforcement learning (RL) framework for generic trading, where a trader wishes to maximize expected cumulative discounted returns by learning an effective policy to map her specified streaming financial data to trading orders. To handle the high dimensionality of financial data and its associated computational challenges, our proposed framework utilizes an embedding projection from the original space to a lower-dimensional embedding space. The algorithm employs a policy training procedure in the embedding space and dynamically adjusts the embedding projection by backpropogating the updated policy performance in an online meta-learning manner. Our algorithm is scalable due to embedding and dynamic embedding adjustment. We implement our framework to learn trading policies and backtest on stock index constituents (Standard & Poor's 500 Index and China Security Index 500). The learned trading policies obtain an annualized return of 50.72% when trading S&P 500 constituents, outperforming widely used benchmarks, including passive (23.94%) and active investment strategies such as mean-variance (21.24%) and reinforcement learning with raw state inputs (26.84%).

Recent Advances in Asset Pricing and Market Microstructure

General Session

Session Chair

Scott Robertson, Boston University Questrom School of Business, Saint Louis

1 Activism Trading and Monge-Kantorovich Duality

Ibrahim Ekren[1], Eunjung Noh[2], Reda Chhaibi[3], [1]Florida State University, Tallahassee, FL, [2]Florida State University, Tallahassee, FL, [3]Université Toulouse Paul Sabatier, Toulouse, France.

Motivated by activism trading, we solve a generalized Kyle's model type problem using the theory of optimal transport and backward stochastic partial differential equations. Our problem can be recast into a terminal utility maximization problem with distributional constraints, and hence the theory of optimal transport between spaces of unequal dimension becomes a natural tool. The pricing rule is established using the structure of Monge-Kantorovich duality, and the optimal trading strategy is obtained by analyzing a backward version of the filtering problem from the market maker's point of view. In the special case of the classical Kyle's model, the optimal trading strategy we find is distinct from the classical bridge based construction.

2 Consistency of MLE for Partially Observed Diffusions, with Application in Market Microstructure Modeling

Sergey Nadtochiy, Illinois Institute of Technology, Chicago, IL

In this talk, I will present a tractable sufficient condition for the consistency of maximum likelihood estimators (MLEs) in partially observed diffusion models, stated explicitly via the stationary distribution of the fully observed system. This result is then applied to a model of market microstructure with latent (unobserved) price process, for which the estimation is performed using real market data for liquid NASDAQ stocks. In particular, we obtain an estimate of the price impact coefficient, as well as the micro-level volatility and the drift of the latent price process (the latter is responsible for the concavity of expected price impact of a large meta-order). Joint work with Y. Yin.

3 Rational Expectations Equilibrium with Heterogeneous Information Flows

Scott Robertson, Boston University Questrom School of Business, Saint Louis

In this talk, we consider equilibria in the presence of dynamically evolving asymmetric information. "Insiders" obtain private signals about the terminal value of an asset at intermediate times, and at each signal time, the "uninformed" agent receives a noisy version of the respective insider's signal. Both the filtration and asset price process jump at each signal time, and markets are in general incomplete. After establishing existence of a dynamic noisy rational expectations equilibrium for a finite set of signal times, we pass to the continuous time limit where the fundamental filtration is enlarged by a continuous signal flow process. Results are valid for constant absolute risk aversion investors, and where the factor process follows a multi-dimensional OU process. After presenting OU results, we will discuss extending to general factor processes.

1 Can Machines Learn to be Human? Can Humans Learn to Leverage Machines? Integrating Artificial Intelligence and Behavioral Science in Operations Management

Andrew M. Davis[1], Charles J. Corbett[2], Elena Katok[3], Shawn Mankad[1], [1]Cornell University, Ithaca, NY, [2]University of California-Los Angeles, Los Angeles, CA, [3]University of Texas at Dallas, Richardson, TX, Contact: adavis@cornell.edu

The use of Artificial Intelligence ("AI") in operations management research, focuses on how to utilize large amounts of data to improve predictions. These techniques offer a great deal of promise, but are not without drawbacks (e.g., fairness concerns). One remedy for addressing some of these drawbacks is to employ Behavioral Science methodologies. Conversely, Behavioral Science seeks to better understand how individuals make decisions in various environments. But, the availability of large data sets means that AI techniques can be used to understand behavior in certain settings which were previously intractable for Behavioral Science. In this article, we aim to explore how AI and Behavioral Science can be employed together to solve a wide range of problems within operations management.

2 Algorithmic Assistance with Recommendation Dependent Preferences

Bryce Mclaughlin, Jann Spiess, Stanford Graduate School of Business, Stanford, CA, Contact: brycem@stanford.edu

When algorithms provide recommendations, we typically think of them as information about which choices will lead to beneficial outcomes.But when a decision-maker obtains a recommendation, they may not only react to the information. The decision-maker may view the recommendation as a default action, making it costly for them to deviate, such as when a judge is reluctant to overrule a high-risk assessment or a doctor fears the consequences of deviating from recommended procedures. We consider the effect and design of recommendations when they affect choices not just by shifting beliefs, but also by imposing a cost on the decision-maker whenever they deviate from the recommended action.

3 The Impact of Forced Intervention on AI Adoption

Dennis Zhang[1], Xinyu Cao[2], [1]Washington University in St Louis, ST LOUIS, MO, [2]NYU, NYC, NY

This paper studies whether and how forced external interventions can catalyze long-term behavioral change, with a focus on the adoption of artificial intelligence (AI) technologies. Specifically, we investigate whether forcing people to use or not to use AI for a period of time can change their post-intervention AI usage, making use of a field experiment among salespeople in a major online education platform in China.

4 Improving Human-Algorithm Collaboration: Causes and Mitigation of Over- and Under-Adherence

Maya Balakrishnan[1], Kris Johnson Ferreira[2], Jordan D. Tong[3], [1]Harvard Business School, Boston, MA, [2]Harvard Business School, Boston, MA, [3]University of Wisconsin Madison, Madison, WI, Contact: mbalakrishnan@hbs.edu

Even if algorithms make better forecasts than human decision-makers (HDMs) on average, HDMs may have private information which the algorithm does not have access to that can improve algorithmic forecasts. How can we help HDMs effectively use and adjust algorithmic recommendations in such situations? We propose a mathematical model that captures how an HDM combines information they directly observe with an algorithmic prediction to make a final demand forecast. HDMs take a weighted average between their own forecast and the algorithm's where the weights depend only on aggregate relative historical performances. We validate our model with a lab experiment where participants make demand forecasts while having access to an algorithm's recommendations. In a follow up experiment, we design algorithmic transparency to help HDMs use private information more effectively.

Incorporating Consumer Preferences in Behavioral OM

General Session

Session Chair

Xiaoyang Long, University of Wisconsin-Madison, Madison, WI

1 Effects of Consumers' Context-dependent Preferences on Product Bundling

Qianbo Yin[1], Baojun Jiang[2], Sean Zhou[3], [1]Shanghai University of Finance and Economics, Shanghai, China; [2]Washington University in St. Louis, Saint Louis, MO, [3]Chinese University of Hong Kong, New Territories, Hong Kong. Contact: baojunjiang@wustl.edu

Bundling can change the consumers' choice set and affect their purchase decision. It is well-documented that consumers' preferences depend on the bundling context. This paper investigates the effects of consumers' context-dependent preferences on the firm's optimal bundling strategy in various competitive situations. We show that context-dependent preferences can change the firm's optimal bundling strategy.

2 Choice Overload with Search Cost and Anticipated Regret: Theoretical Framework and Field Evidence

Xiaoyang Long[1], Jiankun Sun[2], Hengchen Dai[3], Dennis

Zhang[4], [1]University of Wisconsin-Madison, Madison, WI, [2]Imperial College London, London, United Kingdom; [3]UCLA Anderson School of Management, Los Angeles, CA, [4]Washington University in St Louis, ST LOUIS, MO, Contact: xiaoyang.long@wisc.edu

An important but under-studied problem in the design of recommendation systems in online retail is how many products to offer in a recommendation set. In this work, we conduct a large-scale field experiment involving 1.6 million consumers on an online retail platform to causally examine how consumer behavior changes as the number of products in a recommendation set increases. Our field experiment results show that the consumers' likelihood of making a purchase first increase and then decrease as the number of options increases, thus providing evidence of the choice overload effect. Moreover, we find that a large proportion of the decrease in purchase rate can be attributed to a decrease in consumers' likelihood to start a search. We demonstrate that our empirical results are consistent with the predictions of a model that incorporates consumers' anticipated regret.

3 Consumer Attitudes on Corporate Workforce Diversity Disclosure

Jimin Nam[1], Maya Balakrishnan[2], Ryan Buell[3], [1]Harvard Business School, Boston, MA, [2]Harvard Business School, Boston, MA, [3]Harvard Business School, Boston, Contact: jnam@hbs.edu

Firms are facing increased pressure to take more action on diversity, equity, and inclusion (DEI). In this research, we examine how consumers perceive the strategic decision by firms to engage in the disclosure of diversity information regarding their workforce, more specifically the EEO-1 report. In terms of attitudes and perceived commitment to DEI initiatives, we find that there is no negative consequence for firms to disclose EEO-1 reports—even if that information reflects a non-diverse workforce. Furthermore, we find that consumers perceive firms with greater attitudes and perceive the firm to be more committed to DEI when the firm discloses their EEO-1 report as compared to when they learn that the firm chooses not to disclose. This result holds regardless of what that information reflects in terms of workforce diversity.

4 Pricing and Inventory Management when Consumers' Emotions Run High

Ozalp Ozer[1], Arun Kumar Rout[2], A. Serdar Simsek[3], [1]Amazon, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas-Dallas, Richardson, TX

We derive demand distributions for a product for which consumers have uncertain valuation. Due to this uncertainty, consumers may experience disappointment-elation or regret-rejoice after their decision. Hence, we develop a novel consumers' choice model that accounts for the impact of anticipated disappointment-elation or regret-rejoice on consumer behavior. We show that the anticipation of disappointment-elation decreases product demand when consumers are disappointment averse. However, the anticipation of regret-rejoice has no impact on product demand even when consumers are regret averse. We also utilize these demand functions to characterize (both analytically and numerically) a firm's optimal pricing and inventory strategies for a product with uncertain consumer valuation.

Machine Learning and Online Platforms

General Session

Session Chair

Mochen Yang, University of Minnesota, Minneapolis, MN

1 The Effect of Peer-to-peer Tangible Donation on Donors and Receivers' Participation in Online Charity Platform

Sojung Yoon[1], Gauri Subramani[2], Mani R. Subramani[1], Mochen Yang[1], [1]University of Minnesota, Minneapolis, MN, [2]Lehigh University, Bethlehem, PA, Contact: yoon0180@umn.edu

Despite the prevalence of charity platforms, several problems remain to be addressed; Platforms that allow tangible donation are underexplored, the role of donation on engagement behavior of givers and receivers is not understood well, and receivers' behavior is undermined. In this research, we focus on a crowdfunding charity platform that facilitates peer-to-peer tangible donation and examine such donation on users' engagement in an online charity platform. We find that, after giving (receiving) donation, givers increase (receivers reduce) their engagement behavior by writing more (fewer) posts and comments than non-givers (non-receivers). Overall, our additional analyses ensure robustness of our findings and explore underlying mechanisms.

2 **Predicting Ad Recall Using Consumer Psychophysiological Data**

Ramin Zandvakili[1], William Hedgcock[2], Mochen Yang[3], Jason Chan[3], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN, Contact: zandv003@umn.edu

Psychophysiological measures are increasingly being used in both academia and commercially to assess consumer responses to marketing. However, little is known about the effectiveness of these tools to measure memory and recall compared to self-reported measures. In a study, we tracked psychophysiological signals from the eyes, face, and heart of each participant while they were watching movie trailers. In addition, we recorded their self-reported level of affective measures and their interest in the trailer, movie, and its genre. Using the data, we built machine learning models and compared the predictive power of psychophysiological and self-reported data for recalling trailers reported one week after the experiment. Our results show that psychophysiological signals significantly outperform self-reported data in predicting trailer recalls.

3 **Countering State-Sponsored Media Through Labeling: Evidence from Facebook**

Patricia Moravec, Nicholas Wolczynski, Avinash Collis, University of Texas at Austin, Austin, TX, Contact: nicholas@mccombs.utexas.edu

While attention has been turned toward disinformation, social media pages controlled by governments have been able to share information to encourage social media users toward beliefs without sharing content that may be clearly labeled as false. In an effort to combat the effect of foreign government persuasion attempts, Facebook debuted a 'state-controlled media' label in June 2020 in order to alert users that a post originates from a Page associated with the government of China, Iran, or Russia. We conduct an online randomized experiment to better understand the causal impact of these labels on intentions to engage with content on Facebook and augment our experiment by analyzing field data from Facebook. We find that labels are effective in reducing engagement on social media, but could be far more effective if Facebook clearly alerted users to the presence of the new label.

4 **User Profiling and Vulnerability Introduction Prediction in Social Coding Repositories: A Dynamic Graph Embedding Approach**

Agrim Sachdeva, Indiana University

Social coding repositories such as GitHub host open-source code that is mission-critical to the world's economy. Open-source code is especially vulnerable, and most vulnerabilities are introduced by human error. An important mitigation strategy is "shifting left" or preventing the introduction of vulnerabilities. One of the ways this can be achieved is targeted security strategy, such as conducting targeted security software development trainings. This requires the identification of high-risk actors, and prediction of the introduction of vulnerabilities. By adapting a continuous dynamic graph embedding approach and introducing a novelty that takes into account unique characteristics of vulnerability introduction, our proposed method can help predict of the introduction of the type and severity vulnerabilities in social coding repositories.

Innovative Product Development and Production

General Session

Session Chair

Panos Kouvelis, Washington University in St. Louis, Clayton, MO

Session Chair

Iva Rashkova, Washington University-St Louis, St Louis, MO

1 **Evaluating the Environmental Impact of Government Subsidy on the Adoption of Resource Efficient Durable Products**

Haoying Sun[1], Stephen M. Gilbert[2], [1]University of Kentucky, Lexington, KY, [2]University of Texas-Austin, Austin, TX, Contact: haoying.sun@uky.edu

We use a durable goods framework to study how the government subsidy on energy-efficient products shifts demand and subsequently affects the manufacturer's incentive of investing in quality improvement measures. Then, we show how these changes in turn influence the total life cycle energy consumption.

2 **Crowdsourced Drug Discovery**

Brian Lee, Hui Zhao, Pennsylvania State University, University Park, PA

Crowdsourced drug discovery (CDD) platforms have emerged recently to fill the development void of commercially challenging drugs such as antibiotics by synthesizing compounds to test for their drug properties and effectiveness. Such platforms allow scientists to submit their designs for drug compounds and observe other scientists' ideas. The openness creates an opportunity for remixing (i.e., incorporating others' ideas into their designs), potentially improving the collective effort for drug discovery. This study aims to explore the relationship between the performance of crowdsourced drug discovery and remixing activities.

3 Behavioral Aspects in The Design of Procurement Auctions: The Capacity to Bid

Ivan Lugovoi[1], Jurgen Mihm[2], [1]KLU, Hamburg, Germany; [2]Insead, Fontainebleau, France. Contact: ivan.lugovoi@hec.edu

Practical experience and academic research have shown that the design of a tender may have a substantial impact on its outcome. A recent focus on behavioral biases has complemented our understanding of rational aspects in auction design. But while extant work has focused mainly on individual behavioral biases, we focus on organizational biases afflicting entire organizations. Particularly, we are interested in understanding how a buyer should consider the bidders "capacity to bid". We conduct an empirical investigation of large-scale tenders of pharmaceutical products performed by German health insurance companie in order to study which tender designs influence the number of participants. We thus hope to give tender designers practical advice based on rigorous analysis.

4 Drug Shortages and New Drug Approvals: An Empirical Investigation

Iva Rashkova[1], Panos Kouvelis[2], [1]Washington University-St Louis, St Louis, MO, [2]Washington University in St. Louis, Clayton, MO, Contact: irashkova@wustl.edu

We leverage a combination of publicly available data sources to study the link between new drug approvals and drug shortages. Specifically, we classify drug approvals by therapeutic class of the drug as well as by type - brand name, generic with or without market exclusivity. We observe that the event of a new drug shortage reported by the FDA is correlated with a subsequent drug approval for the same firm. Interestingly, the time lag between these events is increasing in the attractiveness of the drug approval's type. With the time lag identified based on the drug approval type, we also find a positive correlation between the time-to-recovery for an individual drug-shortage event and the associated drug approval. Our results potentially offer healthcare providers and policymakers insights into industry-wide capacity and resource allocation trends.

Group Decision and Negotiation

General Session

Session Chair

Rodrigo Ulloa, Arizona State University, Tempe, AZ

1 Incorporating Agency into the Fair Allocation of Pennsylvania's Opioid Settlement Funds

Robert A. Newton[1], Paul Griffin[2], Qiushi Chen[2], [1]Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, University Park, PA

Recent settlements with opioid distributors and manufacturers differ from the 1998 settlement with "Big Tobacco" as the amount of funds received by a state from the opioid settlement is contingent upon substate entities (counties, municipalities) also dropping their lawsuits. A major critique of the 1998 tobacco settlement was how little of the settlement flowed to the substate level, driving a need for assurances from the states for more local distributions in order for substate entities to participate. Informed by the determination of a "fair allocation" in Pennsylvania, we present an optimization model with constraints for both fairness and participation, incorporating substate agency into the state allocation process.

2 An Experimental Study of Career Concerns in Groups

Chen Wei, Washington University in St.Louis, St Louis, MO, Contact: chen.wei@wustl.edu

Workers usually work in groups and may face trade-offs between working on their own tasks and supporting other group members. When workers have career concerns, their decisions may be driven by the desire to influence external perceptions of their abilities. This paper studies career concerns in groups using a laboratory experiment where workers can allocate effort between their own tasks and other group members' tasks. Under this framework, we first investigate how workers allocate effort when they have career concerns. Then, given these workers have career concerns, we study their decisions when their performance is measured aggregately (i.e., group performance) rather than separately.

Our experimental results are consistent with the theoretical predictions. We discuss implications for managers and firms that are trying to build supportive working environments.

1 Ml Approximations of Operational Subproblems in Strategic Planning

Chun Ye, Zhikun Gao, Amazon.com, Seattle, WA, Contact: ychun@amazon.com

We consider a two-stage stochastic program used to capture last mile capital investment decisions for a large e-tailer. In the first stage, the decision on where to add incremental last mile delivery capacity for the e-tailer's internal carrier is made. Given the planned capacity and realized demand, the second stage problem decides how to optimally allocate packages between the internal carrier vs an external carrier in order to minimize variable cost. To mitigate problem scalability, we outline an approach to use ML to "summarize" the optimal second stage package allocation decisions as a function of different problem parameters that can be used as a surrogate model for first stage problem.

2 Fleet Planning with Demand Fluctuation, Reliability, Overhead, and Growth Considerations

Yaniv Mordecai, [1</sup]

The number of machines, vehicles, or servers that satisfies demand depends on more than the ratio between total demand and unit capacity. Service providing units (SPUs) exhibit partial reliability, availability, and autonomy. Demand fluctuates, projected growth is likely, and service level may be tracked. We present an algorithm to determine the minimal SPU fleet size that satisfies demand and guarantees the service level probability (SLP), under multiple realistic factors. The algorithm relies on the cumulative binomial distribution. We present the algorithm, its python-based implementation, and its application to delivery vehicle fleets and cloud servers. We discuss problem scales, demand peaks, and degraded performance options.

3 End-to-end Strategic Fulfillment Network Design at Wayfair

Ryo Kimura, Wayfair, Boston, MA, Contact: rkimura@wayfair.com

Wayfair's fulfillment network is one of our most important assets for enabling fast, reliable, and cost efficient deliveries across our vast catalog of home goods. However, its size and complexity makes it difficult to determine the end-to-end effects of various strategic investments to the network. We present a nonlinear multi-commodity network design approach to tackle this problem, and discuss some of the innovations we have made particularly related to modeling expected duration in the network which is critical to optimizing and scaling up Wayfair's outbound fulfillment capabilities.

4 An MINLP Model for the Optimal Management of Carbon Intensity Along Sustainable Supply Chains

Ignacio E. Grossmann[1], Demian Presser[2], Diego Cafaro[3], Pratik Misra[4], Sanjay Mehta[5], [1]Carnegie Mellon University, Pittsburgh, PA, [2]INTEC (UNL-CONICET), Santa Fe, Argentina; [3]INTEC(UNL-CONICET), Santa Fe, Argentina; [4]Air Products and Chemicals, Allentown, PA, [5]Air Products, Allentown, PA, Contact: grossmann@cmu.edu

Carbon intensity is an indicator of greenhouse gas emissions per unit of product processed, stored and transported along a supply chain. It represents a measure of carbon environmental impact. Supply chains must develop rigorous techniques to track carbon intensity and meet market regulations. We present an MINLP model for the optimal planning of production operations, overseas shipping and onshore transportation. We address the modeling and optimization of global supply chains under carbon intensity constraints. We assess the impacts of this indicator on the optimal solutions and how to optimally determine carbon intensity targets.

5 On the Philosophy of Management Science

Stephen E. Garrett, Entos Consulting International, Dayton, OH, Contact: garrettste@aol.com

One of the subdivisions of TIMS (a predecessor Institute to INFORMS) was the College on the Philosophy of Management Science. The College may no longer exist, but questions around the nature and practice of management science continue. These include the proper domain of management science, its methods of inquiry, the development of the discipline, and the training and preparation of management scientists. While some aspects of these issues are addressed in the natural pursuit of management science, there is no central focus to these efforts. This presentation will argue that INFORMS consider re-establishing a subdivision on the Philosophy of Management Science. It will also seek to remind the membership that Management Science gives INFORMS the last two letters of its name.

6 Empirical Analysis of What Improves the Careers of Heads of Procurement and Supply Chain Management

Thorsten Makowski, Skema, lille, France. Contact: thorsten.makowski@skema.edu

The aim of this paper is to identify which attributes help people working in procurement and supply chain management early and later in their career to be successful. For that the data of a global study with 1000+ participants, plus online available data from LinkedIn career profiles plus additional interviews of especially successful executives were analyzed. The study tries to answer whether a career is influenced by factors like age, transfer between different industry functions, changing frequency of employees etc. Also attributes like academic developments, language skills or certifications etc. are analyzed. Because of its empiric character the study is significantly restricted to an analysis of correlations between attributes and success, while it is based on the used methodology not possible to come to a certain causality.

1 Unveiling Hidden Energy Poverty Using the Energy Equity Gap

Destenie S. Nock[1], Shuchen Cong[2], Lucy Yueming Qiu[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Stanford, Contact: scong@andrew.cmu.edu

Income-based energy poverty metrics miss people's behavior patterns, particularly those who reduce their energy consumption to limit financial stress. Using a residential electricity consumption dataset, we determine the outdoor temperature at which households start using home cooling systems. We calculate the relative energy poverty within a region, defined as the energy equity gap. The energy equity gap between low and high-income groups ranges from 4.7°F to 7.5°F. In 2015-2016, out of 4,577 households, we found 86 energy-poor and 214 energy-insecure, meaning they are at risk of heat-related illness and death. Surprisingly, 83 of these households were missed by traditional income based measures of energy poverty.

2 Distributionally Robust Optimization Approaches for a Stochastic Mobile Facility Fleet Sizing, Routing, and Scheduling Problem

Karmel S. Shehadeh, Lehigh University, Bethlehem, PA

A mobile facility is a facility-like vehicle that can serve customers in manners similar to static facilities but can also move from one place to another to bring services closer to otherwise-underserved communities. In this paper, we propose two distributionally robust optimization (DRO) models for a mobile facility fleet-sizing, routing, and scheduling problem (MFRSP) with time-dependent and random demand, as well as computationally efficient methodologies for solving these models. We present extensive computational experiments comparing the operational and computational performance of the proposed models and a stochastic programming model, demonstrating when significant performance improvements could be gained and illustrating the potential for impact in practice.

3 Trying and Failing: Biases in Donor Aversion to Rejection

Kaitlin Daniels[1], Leon Valdes[2], [1]Washington University in St. Louis, Olin Business School, Saint Louis, MO, [2]University of Pittsburgh, Pittsburgh, PA

Non-profit organizations (NPOs) play a key role in advancing the UN Sustainable Development Goals. To achieve this, they rely on donations of physical goods - which are not always wanted or needed. We explore how donors respond to rejection using a controlled experiment: subjects choose whether to complete a task to generate a donation, which is accepted with a fixed (but unknown) probability. We measure donation decisions and beliefs about this probability and compare these measures against a for-profit condition where the subject, not an NPO, may benefit from the task. Our results identify a mechanism by which rejections affect donations: via a reduction in beliefs of future success. We also find evidence of self-serving bias: when high effort is needed, beliefs respond more negatively to rejection in the donation condition. We propose ways for NPOs to alleviate this bias.

Eli Olinick, Southern Methodist University, Dallas, TX

1 **Web Scraping Social Media Data as a Proxy for Player Popularity in European Football Leagues**
Nicholas F. Parham, Colorado School of Mines, Golden, CO
Social media data serves as a powerful proxy for an influential entity's popularity; however, social media indices are either unreliable or incomplete. By implementing various web scraping techniques in Python, a reliable and complete solution can be constructed. Using this, professional European football player and club popularity can be introduced into machine learning models aimed at predicting player market values.

2 **Predicting English Premier League Player Transfer Fees**
Garrett Miyaoka, Colorado School of Mines, Goulden, CO
During the 2021 summer transfer window, English Premier League teams signed 103 different players to 20 different teams at a total cost of $1.36 billion. We implement neural network regression to predict fair and expected transfer fees.

3 **Integer-linear Programs in Sports Applications**
Mark Husted, Colorado School of Mines, Golden, CO
Modern sports fans are in constant search for the latest and most accurate information about their favorite teams. By using mixed integer-linear programs with advanced solvers, such as CPLEX and Gurobi, complex season standings models are able to be solved. We present some of the logic and math on some of the more complicated instances posted on RIOTSports.net.

4 **Show Me the Money: Explaining MIP-Generated Magic Numbers**
Eli Olinick[1], Alexandra Newman[2], [1]Southern Methodist University, Dallas, TX, [2]Colorado School of Mines, Golden, CO
So-called magic numbers capture the attention of fans across a variety of professional sports, and provide information regarding when a team has clinched or been eliminated from a playoff spot, and, additionally, when a team has captured or lost the opportunity for a first-place final standing prior to post-season play. Mixed integer programming (MIP) models for determining magic numbers for a variety of professional sports have been proposed in the literature and implemented in practice. Often the proof that a magic number is correct relies on showing that a MIP model is infeasible. So, although fans enjoy tracking these numbers, most must take them on faith. We discuss strategies for and challenges of automating the process of justifying magic numbers to sports fans in plain English.

Advances in Input Uncertainty
General Session

Session Chair
Sara Shashaani, North Carolina State University, Raleigh, NC

Session Chair
Kimia Vahdat, North Carolina State University, raleigh, NC

1 **Distributionally Robust Optimization for Input Model Uncertainty in Simulation-based Decision Making**
Soumyadip Ghosh[1], Mark S. Squillante[2], [1]IBM TJ Watson Research Center, Yorktown Heights, NY, [2]IBM Research, Yorktown Heights, NY, Contact: ghoshs@us.ibm.com
We consider a new approach to solve distributionally robust optimization formulations that address nonparametric input model uncertainty in simulation-based decision making problems. Our approach for the minimax formulations applies stochastic gradient descent to the outer minimization problem and efficiently estimates the gradient of the inner maximization problem through multi-level Monte Carlo randomization. Using theoretical results that shed light on why standard gradient estimators fail, we establish the optimal parametrization of the gradient estimators of our approach that trades off between computation time and statistical variance. We apply our approach to nonconvex portfolio choice modeling under cumulative prospect theory, where numerical experiments demonstrate the significant benefits of this approach over previous related work.

2 **Distributionally Robust Stratified Sampling for Stochastic Simulations with Time-varying Input Models**

Seung Min Baik[1], Eunshin Byon[2], Young Myoung Ko[1], [1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]University of Michigan, Ann Arbor, MI, Contact: gshs27@postech.ac.kr

Our study proposes a robust version of the stratified sampling method under input uncertainty due to changes in the probability distribution over time. The conventional stratified sampling method induces a unique sampling strategy for a fixed input model. However, we often encounter situations where the nature of the input model, e.g., wind speed of a specific location or inter-arrival time of the customer, changes over time. Since we have a limited budget insufficient to run a simulation every time with a different input model, we need an efficient sampling strategy accounting for uncertainty caused by input model changes. We, therefore, propose a procedure for constructing and solving an optimization problem to minimize the worst-case estimator variance among uncertain future input models using the distributionally robust optimization framework.

3 Robust Machine Learning with Monte Carlo Methodology

Kimia Vahdat, Sara Shashaani, North Carolina State University, Raleigh, NC, Contact: kvahdat@ncsu.edu

Prediction error estimation in machine learning (ML) models has three prominent roles: estimating the model's performance on unseen data, optimizing for the best model hyper-parameters, and comparing multiple algorithms. The quality of an estimator is measured by its bias and variance. A correct variance estimate of the prediction error is crucial for accurate inference and comparison between models. Quantifying bias can also capture the sensitivity of the error estimator to the data on hand. This talk aims to estimate the prediction error of ML models using a novel sampling scheme that enables the user to quantify the bias and variance estimations correctly with non-parametric methods. We redefine the ML model as a Monte Carlo (MC) simulation model, utilizing established uncertainty quantification methods in the MC literature.

4 Resampling Stochastic Gradient Descent for Robust Inference

Zitong Wang, Henry Lam, Columbia University, New York, NY, Contact: zw2690@columbia.edu

Stochastic gradient descent (SGD) or stochastic approximation is widely used in model training and stochastic optimization thanks to its computational advantages and robustness. While there is a huge literature on analyzing its convergence, inference on the obtained solutions from SGD has only been recently studied, yet is of importance due to the growing need of uncertainty quantification. We propose a novel resampling-based method to construct confidence intervals for SGD solutions, by running multiple, but few, SGDs in parallel via resampling with replacement from the data. Our inference approach that allows minimal SGD runs, yet bypassing the intricate mixing conditions in existing batching-type methods, is built upon a new simple result on the asymptotic independence between resampled and original SGDs using a recently developed Berry-Esseen-type bound.

1 Representing Random Utility Choice Models with Neural Networks

Ali Aouad[1], Ali Désir[2], [1]London Business School, London, United Kingdom; [2]INSEAD, Fontainebleau, France.

Motivated by the successes of deep learning, we propose a class of neural network-based discrete choice models, called RUMnets, which is inspired by the random utility maximization (RUM) framework. This model formulates the agents' random utility function using the sample average approximation (SAA) method. We show that RUMnets sharply approximate the class of RUM discrete choice models: any model derived from random utility maximization has choice probabilities that can be approximated arbitrarily closely by a RUMnet. Reciprocally, any RUMnet is consistent with the RUM principle. We derive an upper bound on the generalization error of RUMnets fitted on choice data, and gain theoretical insights on their ability to predict choices on new, unseen data depending on critical parameters of the dataset and architecture. By leveraging open-source libraries for neural networks, we find that RUMnets outperform other state-of-the-art choice modeling and machine learning methods by a significant margin on two real-world datas

2 A Decomposition Algorithm for Two-Stage Stochastic Programs with Nonconvex Recourse

Cui Ying, Hanyang Li, University of Minnesota, Minneapolis, MN

We consider a decomposition method for solving a class of nonconvex two-stage stochastic programs, where both the objective and constraints of the second-stage problem are nonlinearly parameterized by the first-stage variables. Due to the failure of the Clarke regularity of the resulting nonconvex recourse function, classical decomposition approaches such as Benders decomposition and (augmented) Lagrangian-based algorithms cannot be directly generalized to solve such models. By exploring an implicitly convex-concave structure of the recourse function, we introduce a novel decomposition framework based on the so-called partial Moreau envelope. The algorithm successively generates strongly convex quadratic approximations of the recourse function based on the solutions of the second-stage convex subproblems and adds them to the first-stage master problem. Convergence under both fixed scenarios and interior samplings is established. Numerical experiments are conducted to demonstrate the effectiveness of the proposed algorithm.

3 Adjustability in Linear Robust Optimization

Peter Zhang[1], Ningji Wei[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Texas Tech University, Lubbock, TX

We investigate the concept of adjustability - the difference in objective values between two types of dynamic robust optimization formulations: one where (static) decisions are made before uncertainty realization, and one where uncertainty is resolved before (adjustable) decisions. This difference reflects the value of information and decision timing in optimization under uncertainty, and is related to several other concepts such as interchangeability in games and optimality of decision rules in robust optimization. We develop a theoretical framework to quantify adjustability based on the input data of a robust optimization problem with linear objective, linear constraints, and fixed recourse. We make very few additional assumptions. In particular, we do not assume constraintwise separability or parameter nonnegativity that are commonly imposed in the literature for the study of adjustability. This allows us to study important but previously underinvestigated problems, such as formulations with equality constraints and problems with both upper and lower bound constraints. Based on the discovery of an interesting connection between the reformulations of the static and fully adjustable problems, our analysis gives a necessary and sufficient condition - in the form of a theorem-of-the-alternatives - for adjustability to be zero when the uncertainty set is polyhedral. Based on this sharp characterization, we provide a mixed-integer optimization formulation as a certificate of zero adjustability. Then, we develop a constructive approach to quantify adjustability when the uncertainty set is general, which results in an efficient and tight algorithm to bound adjustability. We demonstrate the efficiency and tightness via both theoretical and numerical analyses.

Airport Planning and Operations

General Session

Session Chair

Nuno Antunes Ribeiro, Singapore University of Technology and Design, Singapore, Singapore.

1 Strategic Model to Optimize Terminal Airspace Operations

Wayne Ng, Nuno Ribeiro, Singapore University of Technology and Design, Singapore, Singapore. Contact: wayne_ng@mymail.sutd.edu.sg

The Terminal Maneuvering Area (TMA) of congested airports are a critical region to be managed effectively, as they are a key bottleneck of the air traffic management system. This research aims to help air traffic managers evaluate different airspace design and planning scenarios through an optimization modeling approach. We combine linear programming optimization and metaheuristic approaches to develop an efficient modelling approach to solve the TMA optimization problem. The model optimizes decisions related to runway sequencing, aircraft speeds, and utilization of holding stacks and vectoring to minimize air traffic delays.

2 Bottleneck Analysis of Pre-Pandemic ASEAN Commercial Air Traffic Network

Peter Jackson, Benjamin Tan, Gengling Dai, Singapore University of Technology and Design, Singapore, Singapore. Contact: peter_jackson@sutd.edu.sg

In anticipation of a return to pre-COVID-19 traffic levels, we report on the anticipated sensitivity of network-wide air traffic delays to isolated service interruptions at perceived bottlenecks in the ASEAN (plus Hong Kong, China) air traffic network. We focus on six airports (SIN, KUL, HKG, CGK, BKK, MNL) and four routes (L644+M722, G579+B470, M758, L642+M771) and explore the impact of a temporary service interruption at peak times at or along each of these capacity constrained components. We employ an optimization-based air traffic flow management model with the objective of both minimizing fight arrival delays and maximizing the success rate of passenger hub connections by delaying, rerouting, and/or cancelling fights at the aircraft trajectory level.

3 Airport Slot Allocation with Social Considerations

Suresh Kumar Jakhar, Indian Institute of Management Lucknow, Lucknow, India. Contact: skj@iiml.ac.in

We propose a mechanism to allocate slots at congested airports. Our slot allocation mechanism satisfies the following goals: (a) It incorporates the valuations of the slots by the airlines, (b) It provides opportunities for the flights connecting remote cities to the congested airport, and (c) It incorporates congestion cost and controls the number of allocated slots to minimize congestion. The allocation function provides the resulting slot allocations, and the payment function provides the payments to be made by each flight movement as a function of slot valuations, congestion level, and city-type connected.

4 A Modelling Approach to Optimize Airport Scheduling Limits in Airport Demand Management

Xie Peining[1], Nuno Antunes Ribeiro[1], Sebastian Birolini[2], [1]Singapore University of Technology and Design, Singapore, Singapore; [2]University of Bergamo, Dalmine (BG), Italy. Contact: nuno_ribeiro@sutd.edu.sg

In today's overcrowded aviation industry, congestion mitigation is a key priority as it allows to implement smooth and regular air traffic operations. Airport demand management mechanisms aim to mitigate air traffic congestion by restricting the imbalances between demand and capacity through scheduling limits. This research proposes an optimization modeling approach to examine typical airport demand patterns and estimate optimal scheduling limits that approximate the Pareto-frontier of three conflicting objectives: slot rejections, slot displacement and expected flight delays.

Session Chair

Adiel Teixeira De Almeida, Universidade Federal de Pernambuco, Recife PE, Brazil.

1 Divide and Conquer? Experimental Evidence from Interdependent Operational Tasks

Yun Shin Lee[1], YoungSoo Park[1], Enno Siemsen[2], [1]Korea Advanced Institute of Science and Technology, Seoul, Korea, Republic of; [2]University of Wisconsin-Madison, Madison, WI

We examine when and how task division improves operational performance when sub-tasks are highly interdependent. Specifically, we divide the newsvendor ordering task into two interdependent sub-tasks: preparing a forecast and setting a service level. Using a behavioral experiment, we demonstrate that the level of cognitive burden is a moderator for the relationship between task division and performance. The effect of task division on performance is greater when the cognitive burden is high; performance improves through a reduction in random judgment errors in the final decision through more effective synchronization between sub-tasks. Specifically, under task division, we observe counteracting behavior, which describes an individual's tendency to make decisions that can counteract their partner's mistake.

2 Supporting The Expansion Program of An Educational Institute in Brazil: Ranking States with The Fitradeoff Method

Eduarda Asfora Frej, Pedro Henrique Albuquerque, Universidade Federal de Pernambuco, Recife, Brazil. Contact: eafrej@cdsid.org.br

This work addresses a multicriteria group decision problem of ranking states in Brazil in order to support the expansion program of an education institute in the country. The FITradeoff multicriteria method is applied to conduct the elicitation with the decision makers. The combination of two preference modeling paradigms - elicitation by decomposition and holistic evaluation - is explored in a flexible way. Throughout this application, it is possible to analyze several benefits that the combination of these two preference modeling types can bring improvements to the decision process, including the possibility of shortening the elicitation process. Insights on how to deal with group decision making problems with the new features of the FITradeoff method are also presented.

3 Group Decision Model to Reduce Unauthorized Water Consumption

Ana Clara Cachina Saraiva[1], Danielle Costa Morais[1], PASCALE ZARATE[2], [1]Universidade Federal de Pernambuco, Recife, Brazil; [2]University Toulouse Capitole 1 - IRIT, TOULOUSE, France. Contact: anaclaracsaraiva@gmail.com

Unauthorized Water Consumption (UWC) is the misuse of water by theft or clandestineness. It reflects a system with technical, economic, social, and environmental problems that significantly impact society and need quick solutions for its combat. A Group Decision Support Model to evaluate alternatives developed to combat UWC becomes necessary. FITradeoff is highly appreciated, and with a voting procedure, the individual rankings obtained in FITradeoff can be condensed into a single result. This article presents a case study applied to a concessionaire in Brazil; 3 Decision-Makers evaluated 34 alternatives. Borda Count aggregated the 3 rankings to obtain a representative result for all. As a result, a final ranking was obtained to assist the concessionaire in the fight against UWC, taking into account the achievement of social, environmental, and economic benefits.

4 Secure Group Decision-Making in AHP

Konrad Kulakowski, Jacek Szybowski, Sebastian Ernst, AGH University of Science and Technology, Krakow, Poland. Contact: konrad@kulakowski.org

At the core of the Analytic Hierarchy Process (AHP) is a common belief that experts are honest, that is, that their opinions reflect theirinner views. But unfortunately, this may not always be true.Hence, like sometimes voters during elections, people involved in decision-making may try to manipulate the ranking result. For example, they may evaluate alternatives strategically to strengthen their preferred candidate and weaken another. In the presented paper, we propose heuristics that can help identify potentially dishonest experts. We also show how these heuristics can be used to aggregate results in group decision-making using the AHP.

1 Asymptotically Optimal Sequential Multiple Testing

Jay Bartroff, University of Texas at Austin, Austin, TX, Contact: bartroff@austin.utexas.edu

I will discuss asymptotically optimal multiple testing procedures for sequential data for controlling FDR/FNR and other metrics. For FDR/FNR and related metrics, the procedures are closely related to those proposed and shown by Song & Fellouris (2017, Electron. J. Statist.) to be asymptotically optimal for controlling type 1 and 2 familywise error rates (FWEs). By appropriately adjusting the critical values of the Song-Fellouris procedures, they can be made asymptotically optimal for controlling any error metric that is bounded between multiples of FWE in a certain sense. Not fitting into this category are the generalized error metrics gamma-FDP and k-FWER, and more complex procedures can be constructed that are asymptotically optimal for these metrics. Our analysis includes regimes in which the number of null hypotheses approaches infinity.

2 Active Sequential Change-point Detection Under Sampling Control

Yajun Mei, ISyE Georgia Tech, Atlanta, GA

Active sequential change-point detection problem occurs in many real-world problems such smart manufacturing or biosurveillance when one monitors multi-dimensional data streams under the sampling control due to limited capacity in data acquisition, transmission or processing. In such a scenario, one needs decide how to smartly observe which local components or features at each and every time, and then uses the observed data to quickly raise an alarm once a change has occurred subject to the false alarm constraint. In this talk, we develop efficient active change-point detection algorithms through bandit sampling policies. Numerical simulations and case studies will be presented to demonstrate the usefulness of our proposed algorithms, and future potential research directions will also be discussed.

3 Sequential Change Diagnosis

Austin Warner[1], Georgios Fellouris[2], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]University of Illinois at Urbana-Champaign, Champaign, IL, Contact: fellouri@illinois.edu

We will discuss the problem of sequential change diagnosis, where the goal is to detect a change in a monitored process and to accurately identify the type of the change, while controlling the false alarm rate. We will highlight a drawback of many methods in the literature: the implicit, heavy use of pre-change data in order to determine the post-change regime. Moreover, we will propose a recursive algorithm that resolves this issue without the use of tuning parameters and without sacrificing the worst-case delay in detection.

4 Quickest Detection of The Change of Community Via Stochastic Block Models

Ruizhi Zhang, University of Georgia, Athens, GA

Community detection is a fundamental problem in network analysis and has important applications. In many cases, the community structure of the network may change at some unknown time and thus it is desirable to come up with efficient monitoring procedures that can detect the change as quickly as possible. In this work, we use the Erd\H{o}s-R\'{e}nyi model and the bisection stochastic block model (SBM) to model the pre-change and post-change distributions of the network, respectively. We then propose an efficient monitoring procedure by using the number of k-cycles in the graph. The asymptotic detection properties of our proposed procedure are derived when all parameters are known. A generalized likelihood ratio (GLR) type detection procedure and an adaptive CUSUM type detection procedure are constructed to address the problem when parameters are unknown.

1 Representations of Songs and Artists from Audio Features & Consumption Patterns for Modeling Music Demand

Julien De Mori, Guannan Zhao, Paul Beata, Arash Haddadan, Kevin Liu, Philip Watson, Kobi Abayomi, Warner Music Group, New York, NY

Forecasting listener demand for music, in particular streaming demand, requires understanding of demand patterns for similar music. Music listening has shifted to nearly completely digital: this generates a wealth of data on user streaming patterns. We can further extract insights from measurable audio characteristics of musical content. This yields a contextual and flexible notion of similarity, without depending on pre-defined categorical labels such as genres or demographics but augmented by listener demand preferences. We present various approaches to modeling song and artist representations for music similarity estimation, and evaluate them on relevant downstream tasks, including demand forecasting.

2 Temporal Peak-managing and Clustering for Continual Learning from Manufacturing Data

Minseok Han, Jong-Seok Lee, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: sasack3218@skku.edu

Process data collected from manufacturing sites generally varies with time due to environmental changes such as facility maintenance and equipment aging. A predictive model accordingly tends to perform worse as time goes apart from its learning timepoint. To ensure the long-term validity of a prediction model, re-learning strategy has emerged as a critical issue in manufacturing analytics. This research proposes a continual learning framework that tracks temporal changes of data and incorporates those into re-learning decisions. The proposed method trains several local prediction models based on a temporal clustering system. By detecting structural changes over time for each cluster, it determines in real time whether the corresponding model requires re-learning. The effectiveness of the proposed method is demonstrated based on real manufacturing data.

3 SMRT: A Structural Model of Latent Ratings and Topics in Text

Desheng Ma[1], Shawn Mankad[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, Contact: dm852@cornell.edu

We propose a structural model of latent ratings and topics (SMRT), a data driven statistical approach that incorporates ratings, the review text, and review-specific covariates. Specifically, we construct a hierarchical mixed membership model to infer topics and latent topic ratings from reviews by parameterizing the topics, their prevalence, and their contribution to the overall rating with a generalized linear model on document-level covariates. Our empirical study on Yelp online reviews during 2020 provides evidence that the lockdowns and reopening are significantly associated with the discussion and sentiment around the topics of responsiveness and wait time: key service quality metrics of managerial significance, which highlights how SMRT can extract meaningful insights and help answer business questions from user-generated data on digital platforms.

1 An Optimization-based Learning for Decision Making in Mechanical Ventilation Management

Maryam Alimohammadi, Shengfan Zhang, University of Arkansas, Fayetteville, AR

Learning and decision-making using electronic health records are challenging due to the complex temporal data's heterogeneity, noisiness, and irregularity. We proposed a framework to find the optimal time window sizes to reduce the missingness and noisiness of data. By aggregating data and using descriptive statistics over the optimal time windows, we show improvement in performance for mechanical ventilation outcome prediction in ICU, in comparison to the traditional classification methods. Additionally, the time to stop mechanical ventilation in ICU is a critical decision to ensure intervention success while considering resource utilization. We demonstrate how the improved prediction of ventilation outcome before the start of ventilation or at the beginning of the ventilation can facilitate decision-making on weaning from mechanical ventilation in the ICU.

2 An Interpretable Two-stage Modeling Approach for Lung Cancer Survivability Prediction

Zahra Sedighi Maman[1], Jonathan Heath[2], [1]Adelphi University, Garden City, NY, [2]Georgetown University, Washington, DC

We propose a two-stage data analytic framework that is capable of classifying survival status for 0.5-, 1-,1.5-, 2-, 2.5- and 3-year time-points (Stage I) and predicting the number of survival months within 3-years(Stage II) using recent SEER data from 2010 to 2017. By implementing a comprehensive data preparation phase, we demonstrate that a statistical and interpretable approach like GLM performs comparable to more complex models at a considerably lower computational cost. We quantify/visualize the effect of individual features on survival status using the Odds Ratio in Stage I and the effect of individual features on survival length using coefficient values in Stage II. Our proposed two-stage approach, which exploits GLM, may assist physicians in their decision-making process by prioritizing the most important factors related to lung cancer survivability.

3 Distributionally Robust Dataset Selection for Learning Models

Utku Tarik Bilgic[1], Bo Zeng[2], Xiaoning Qian[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Texas A&M University, Pittsburgh, PA, Contact: utb3@pitt.edu

While training a model, there may be insignificant points in the dataset. Also, the dataset can contain outliers and/or noisy points, which may lead to poor training. In this study, we present our distributionally robust dataset selection model for training regression (and classification) models. We unveil the relation of these robust models with machine learning models and present new interpretations. We developed an efficient online learning algorithm with theoretical guarantees for large datasets. Numerical results will be presented to demonstrate the performance of our proposed models and online algorithm.

1 Non-Dominated Sequential Experimental Designs

Peter Norwood, North Carolina State University

Many online learning problems seek to optimize reward and information gain simultaneously. We can estimate the reward and information gain associated with each action at each decision point. We propose a sampling method that only considers actions that maximize some convex combination of these two -- the non-dominated set of actions. By defining information gain with optimal experimental design criteria, we can sample from only the non-dominated set while maintaining consistency and asymptotic normality. Extensive simulation experiments show bandit algorithms run on only the non-dominated set perform favorably compared to their unrestricted counterparts.

2 **Randomization Tests for Adaptively Collected Data**

Yash Nair, Lucas Janson, Harvard University, Cambridge, MA, Contact: yashnair@college.harvard.edu

Randomization testing enables a range of inferential tasks, such as testing independence of random variables and constructing conformal prediction intervals, but its use is generally restricted to exchangeable data. Yet in many applications, data is collected adaptively, e.g., via a bandit algorithm. We present a general framework for randomization testing on adaptively collected data, encompassing the few existing results in this area as well as many other important settings. The key to our framework is the ability to resample the data and compute likelihood ratios between the resampled data and the original data based purely on the known adaptive assignment algorithm. We present novel resampling algorithms for a range of popular adaptive assignment algorithms and data-generating environments, and demonstrate our framework's power and efficiency via simulations.

3 **Bandits with Priors**

Timothy Keaton, Arman Sabbaghi, Purdue University, West Lafayette, IN, Contact: keatont@purdue.edu

Bayesian Multi-Armed Bandit (MAB) algorithms, most prominently Thompson sampling, are effective at sequentially assigning treatments to experimental units to identify the best treatment(s) while controlling the regret, or opportunity cost, of exploration. However, they have traditionally been viewed as less flexible than existing non-Bayesian MAB algorithms due to their supposed lack of design in terms of tuning parameters. We demonstrate via simulation studies that the prior distribution in a Bayesian MAB algorithm does indeed serve an important role as a tuning parameter, affecting both the expected regret and the algorithm replication variance of regret obtained from Thompson sampling. Ultimately, our consideration of Bayesian prior specifications can help researchers design MAB algorithms with different and desirable properties.

1 **Mitigating The Bias of Data Collection Used in Machine Learning Through Instances**

Aida Khosh Raftar Nouri, Memorial University of Newfoundland, St Johns, NL, Canada. Contact: akhoshraftar@mun.ca

An important challenge in machine learning is *bias* in data - wherein states represented in a dataset are distorted with respect to the real world state data. Biased data used to train machine learning models can result in compromised decisions for organizations, and society. This research will examine the proposition that a source of bias in data is *class-based data collection (CBDC)*, in which data about entities is collected on the assumption that these entities will be assigned to predetermined CBDC collect specific attributes of entities relevant to a certain classification of those entities, resulting in an unrepresentative data. I propose that an instance-based data collection (IBDC) model provides a detailed representation of the data that mitigate bias. An experiment will be performed using both a CBDC and proposed IBDC to measure level of bias and ML performance.

2 Gnss Data Analysis, Positioning, and Attitude Determination Using Neural Networks

Raul de Celis, Luis Cadarso, Rey Juan Carlos University, Fuenlabrada, Spain. Contact: raul.decelis@urjc.es

Position and attitude measurements are intimately connected to accurate navigation and control of aerial Vehicles. By monitoring two vectors in two different reference frameworks, such as the inertial and body reference frames, the rotation of an aircraft can be approximated. With a GNSS sensor-based matrix with at least three sensors and calculating their position to fix these pairs of vectors may be done using GNSS carrier phase measurements only resolving carrier phase ambiguity. Multipath, frequent lock loss, cycle slips, and significant clock drifts make precise integer ambiguity resolution difficult, especially with low-cost GNSS receivers. This innovative neural network-based technique improve the reliability of carrier phase ambiguity resolution and optimize the management of large amounts of data.

3 Dynamic Object Detection with Labeling Images Applying Domain Knowledge

Donghwan Shin[1], Taesu Cheong[1], Jangmook Kang[2], [1]School of Industrial Management Engineering, Korea University, Seoul, Korea, Republic of; [2]Department of Hacking & Security, Far East University, Eumseong-gun, Chungcheongbuk-do,, Korea, Republic of. Contact: ppuya1212@korea.ac.kr

A wildfire is an unpredicted fire that occurs in wildlands such as forests, or grasslands. Due to climate change, and an increase in the population living in proximity to high wildfire hazard areas, wildfires have become increasingly destructive in recent years. It could destroy not only an ecosystem but also human life. In related research, optical flow and pattern-based algorithms or convolution neural network-based models are used for fire detection. Our research focuses on fire, smoke, and smog data which is applied to a detection system that is embeddable into a security camera. We show the importance of deep learning models such as YOLOv5 or EfficientDet for fast and accurate dynamic object detection.

4 Differentially Private Synthetic Minority Oversampling Technique

Yuliia Lut[1], Ethan Z. Turok[2], Rachel Cummings[1], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY, Contact: yl4737@columbia.edu

The problem of learning from imbalance datasets, in which the classes are not equally represented, arises often in practice. A widely used method to combat imbalanced learning is resampling from the minority class. However, when confidential or sensitive attributes are present, data replication can lead to privacy leakage that has a disproportionally larger effect on the minority class. Therefore, privacy-preserving preprocessing techniques are needed. Differential privacy has been a powerful tool for machine learning models when the training data is sensitive. In this work, we present a differentially private synthetic minority oversampling technique (DP-SMOTE). Our algorithm guarantees privacy to the minority samples as the minority class is often more sensitive. We demonstrate how our preprocessing technique decreases privacy leakage in a empirical study.

1 Analysis of Rare Events Using Multidimensional Liquidity Measures Based on High-frequency Trade and Quote (taq) and Limit Order Book (lob) Market Data

Margarita Zaika, Dragos Bozdog, Ionut Florescu, Stevens Institute of Technology, Hoboken, NJ, Contact: dbozdog@stevens.edu

In this work, we develop methodologies for detection and analysis of rare events in high-frequency financial data. Multidimensional liquidity measures based on Trade and Quote (TAQ) and Limit Order Book (LOB) are investigated, analyzed, and transformed though dimensionality reduction techniques. Several methods for rare events detection are applied to the liquidity measures dataset such as Isolation Forest, Local Outlier Factor and Mahalanobis Distance and they are compared based on their relative performance. The rare events methodology is reviewed and compared based on trading data during the beginning of COVID-19 outbreak. A new intensity measure is introduced to assess the occurrence of the rare events clusters.

2 High-frequency Liquidity in The Chinese Stock Market: Measurements, Patterns, and Determinants

Ruixun Zhang[1], Chaoyi Zhao[1], Yufan Chen[1], Lintong Wu[1], Yuehao Dai[1], Ermo Chen[1], Zhiwei Yao[1], Yihao Zhou[1], Lan Wu[2], [1]Peking University, Beijing, China; [2]Peking University, BEIJING, China.

We explore a broad range of high-frequency liquidity measures for the Chinese stock market, based on a comprehensive tick-level dataset for stocks with approximately 16.7 billion events in 2020. We summarize their liquidity levels and key distributional properties. Order interarrival times follow Weibull distributions, implying that Poisson flow is not an appropriate model for order flow in the Chinese stock market. We conduct extensive analysis for the intraday and cross-sectional patterns of liquidity. In particular, spectral analysis reveals novel intraday periodicities in liquidity at whole-minute frequencies. Finally, we propose the *aggressive-passive imbalance* analogous to the order flow imbalance, and develop an order-based model of the change in bid-ask spread that sheds light on the universal mechanism of spread formation with respect to order flows.

3 A Continue Bubble Detection Mechanism for Cryptocurrencies

Jing-Rung Yu[1], Wei-Ting Chen[1], WenYi Lee[2], [1]National Chi-Nan University, Nantou, Taiwan; [2]National Taipei University of Business, Taipei City, Taiwan.

Cryptocurrency market uncertainty is a significant factor causing the price bubbles in the NFT and Defi markets. We develop an early digital financial bubble detection mechanism for cryptocurrencies and provide real-time monitoring of fluctuations of cryptocurrencies using the method developed by Phillips and Shi. We have examined a period from 2017 to the first quarter of 2022, which includes the rise of the COVID-19 pandemic, the Ukraine-Russian war, and the US rate rise.

1 Psychological Reactions to Artificial Intelligence in The Workplace: A State-of-the-art Review

Yuan Cheng, Renmin University of China, Beijing, China.

With the growing prevalence of artificial intelligence (AI) in the workplace, more and more scholars and practitioners have shown interest in understanding how employees react to AI. However, despite the increasingly prominent of research, scholars from a wide array of disciplines have utilized a wide range of theoretical and methodological perspectives, resulting in fragmented and disconnected literature. What we need is a synthesis of existing research to gain a more comprehensive and holistic view of the field. This study provides an integrative review and synthesis by organizing the literature into several dominant themes. For each theme, this study summarizes and discusses the theoretical arguments, research methods, and major findings. Finally, this study proposes promising theoretical and methodological opportunities for future research.

2 Prediction of Tool Wear Based on Machine Learning Methods for Cutting Process

koo ho-geun[1], Soomin Lee[1], Wonkeun Jo[1], hyein kim[2], Jeongin Koo[3], Juheon Kwak[1], Dongil Kim[1], [1]Chungnam National University, Daejeon, Korea, Republic of; [2]Korea Institute of Industrial Technology, Cheonan-si, Korea, Republic of; [3]Korea Institute of Industrial Technology, Cheonan, Korea, Republic of.

Predicting tool wear in cutting processes is important. As the cutting process progresses, the tool wear increases; it affects the product quality. Since the actual measurement of the tool wear during cutting process is expensive, another approach to predict the tool wear is required. We predict the tool wear by using time-series data collected from sensors during the cutting process and cutting force predicted through a neural network. Features are extracted from the collected time series data and predicted cutting force data. Then a subset of feature that has a high correlation with tool wear is selected. We employed various machine learning models to predict the tool wear with the selected features. Experimental results involving a real-world cutting process data showed that the proposed method showed an excellent performance.

3 Generalist Agentive Ai and The Power of Multimodal Foundation Models

Ross Gruetzemacher, Wichita State University, Wichita, KS, Contact: ross.gruetzemacher@wichita.edu

Language models have taken the world of natural language processing by storm over the past few years. Powered by the transformer architecture, these simple foundation models are capable of very impressive feats such as programming and domain-specific reasoning. However, foundation models are not limited to language, and multimodal foundation models—trained on different types of data, such as images and text—are poised to have a tremendous impact on all aspects of business and society. For example, earlier this year Google's DeepMind demonstrated the first generalist agentive AI, Gato. This presentation will discuss these recent advances and their implications for industry over the remainder of the decade.

4 Smart Prognostics and Health Management: A Smart Manufacturing Framework Enabled by Artificial Intelligence and Digital Twins

Sarvesh Sundaram, Northeastern University, Boston, MA, Contact: sundaram.s@northeastern.edu

The manufacturing shop-floor is undergoing a rapid transformation with of Internet of Things (IoT) capable wireless sensors and field devices that generate large volumes of data. Prognostics and Health Management (PHM) deals with monitoring of system health and maintenance activities of shop-floor devices. Component level prognostics at large manufacturing facilities can be complex due to the heterogeneity in the underlying technology of the machinery. Forecasting of tool conditions can be expedited using Artificial Intelligence (AI) and other data-driven methods. We propose Smart Prognostics and Health Management (SPHM), a framework for Smart Manufacturing enabled by AI and Digital Twins. As a use-case, we demonstrate Fault Detection and Remaining Useful Life (RUL) estimation on data from a milling machine experiment.

1 Explainable Ai for Employees: Loan Officer Preferences and Profitability Implications for Firms

Stephanie Kelley[1], Anton Ovchinnikov[2,3], Adrienne Heinrich[4], [1]Ivey Business School, University of Western Ontario, London, ON, Canada; [2]Queen's University, Smith School of Business, Kingston, ON, Canada; [3]INSEAD, Fontainebleau, France; [4]The Union Bank of the Philippines, Aboitiz Data Innovation, Pasig, Philippines.

Little is known about what forms of explainability build confidence and trust in AI models for "non-AI people" in organizations. We generate machine learning models to predict loan customer default data from an Asian lender. We then generate post-hoc explanations (e.g., importance, SHAP) for both positive and negative lending outcomes, and conduct a choice-based conjoint survey to explore the explainability preferences of lending officers. We evaluate the results with Hierarchical Bayes to estimate employee preferences and study the impact of employee heterogeneity on the results. The study uncovers the explainability preferences for employees, including individual versus global explanations, and feature counts. The findings help firms to build trust in AI-based algorithms amongst bank employees using explainable AI methods, whilst balancing profitability.

2 Human-AI Complementarity: The Role of Explainable AI

Max Schemmer, Karlsruhe Institute of Technology, Karlsruhe, Germany. Contact: max.schemmer@kit.edu

In many application areas, Artificial intelligence (AI) can improve human decision-making. Teaming between AI and humans may even lead to complementary team performance (CTP), i.e., a level of performance beyond the one that can be reached by AI or humans individually. Interestingly enough, CTP does not often materialize in previous research. This may be due to the fact that previous work did not focus on the presence of a fundamental prerequisite for CTP—the existence of complementarity potential between humans and AI. We focus on the existence and exploitation of such potential for effective human-AI decision-making. To provide common ground, we identify possible sources of complementarity potential and derive a classification for human-AI decision integration mechanisms to exploit this potential.

3 Trust Repair in Human-Robot Interaction

Connor Esterwood, University of Michigan, Ann Arbor, MI, Contact: cte@umich.edu

Humans and robots must work together to function as an effective team. Teamwork requires trust which changes over time. Specifically, trust increases when robots perform successfully but decreases when robots inevitably make mistakes. The latter of these can be especially challenging as repairing trust is often more difficult than damaging it. Fortunately, a handful of trust repair strategies have emerged which have the potential to repair trust. Unfortunately, these strategies seem to produce unpredictable and variable results with some proving effective at certain times but not at others. One explanation for this variability may be individual differences and in particular one's positive attitudes towards robots. This presentation will focus on a study examining this phenomenon and its corresponding results along with possible future research directions.

4 Understanding Human-AI Decision-making in The Real-world: From Observational Studies to Theoretical Models

Anna Kawakami[1], Luke Guerdan[1], Zhiwei Steven Wu[2], Haiyi Zhu[1], Kenneth Holstein[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: akawakam@andrew.cmu.edu

Organizations are increasingly leveraging AI-based decision support tools (ADS) to improve human decisions. A growing body of work has examined human-AI decision-making in simplified contexts through online experimental studies. However, much less is known about the opportunities and pitfalls of introducing ADS tools in complex, real world contexts. In this talk, we discuss findings from observational studies in the context of AI-augmented child welfare decision-making, examining how organizational structures and incentives, amongst other factors, influence workers' reliance on ADS. Building on these findings, we develop a framework based on structural causal modeling which brings clarity to key challenges in the design and evaluation of ADS. We discuss how this framework can guide the design of more robust experimental studies on human-AI decision-making.

Recent Advances in Multi-level Network Optimization and Their Applications

General Session

Session Chair

Ningji Wei, Carnegie Mellon University, Philadelphia, PA

1 Supervalid Inequalities in Binary Interdiction Games and Applications in Greedoid Interdiction

Ningji Wei[1], Jose L. Walteros[2], [1]Carnegie Mellon University, Philadelphia, PA, [2]University at Buffalo, Buffalo, NY, Contact: ningjiwei@cmu.edu

Binary interdiction games (BIGs) are Stackelberg games where a leader's strategy either interacts or not with the follower's structure, and if it does, then the structure becomes unavailable for the follower. Every binary interdiction game adopts a set-covering-like integer programming (IP) formulation. In this work, We derive a general class of supervalid inequalities, inequalities that can remove non-trivial suboptimal solutions, to improve the performance of the general IP formulation. Such supervalid inequalities are induced by a certain bipartition of the leader's strategy space. We prove the existence of these inequalities in all BIGs and develop a partial verifier to identify them. Finally, we demonstrate the effectiveness of this framework in the class of Greedoid interdiction games, where the follower's structures form a basis of a Greedoid.

2 Adjusting Customers' Utility Functions Via Bilevel Optimization

Svetlana Riabova, Jose L. Walteros, University at Buffalo, Buffalo, NY, Contact: sriabova@buffalo.edu

We investigate the leader's ability to slightly shift the follower's preference in a way that favors the leader while guaranteeing that the follower's objective is not damaged. By doing that, the leader usually incurs a cost associated with the effort they make to change the follower's problem. The goal of our analysis is to evaluate incentive mechanisms designed to affect the follower's utility function alongside the cost of employing such mechanisms. We illustrate our work with an example application in online retail, where the leader introduces variable pricing to shift delivery preferences to reduce the routing cost. The lower level problem is modeled using a structure that allows us to exploit strong duality and work with a single-level reformulation of the relaxed problem while employing delayed constraint generation.

3 Maximizing Node Activation Network Flow Problems Under Nonsimultaneous Flow Assumptions

Robert Curry, United States Naval Academy

In this work, we study a nonsimultaneous network flow problem, in which resources are transported through a network of nodes via arcs in order to maximize the value of activated nodes. A node is defined as activated whenever some positive number of resources are allocated or transported to that node during some time period. We assume the network consumes some nonnegative units of a finite budget for moving such resources through the network. These problems have applications in disaster relief, wireless sensor network optimization, and defense settings. We present two mixed integer programs (MIPs) for solving this problem as well as computationally effective Branch And Price algorithm for its solution. Furthermore, we present a series of preliminary results to display the efficacy of our approach compared to the MIPs.

4 Designing Network Inspection Operations: A Mean-variance Formulation with Bayesian Learning

Bastián Bahamondes[1], Mathieu Dahan[1], Saurabh Amin[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Massachusetts Institute of Technology, Cambridge, MA

Motivated by the challenge of efficient identification of failures in infrastructure networks, we design inspection schedules conducted by resource-constrained ground crews equipped with unmanned aircraft systems (UASs). We formulate an optimization problem to maximize a weighted sum of the expected value and variance of the most recent failure distribution in inspected regions of a network. After each inspection epoch, the information on identified failures is used to perform a Bayesian update on the failure distribution, which impacts the subsequent inspection schedules. We derive a mixed-integer program to obtain coordinated crew-UAS inspection schedules over tree networks. The resulting strategies capture the tradeoff between prioritizing the full exploration of a region versus reducing the uncertainty in failure locations using partial explorations.

Models and Algorithms for Smart Fleet Operations

General Session

Session Chair

Michael Hyland, University of California, Irvine, Irvine, CA

1 Competition and Cooperation of Autonomous Ridepooling Services: Game-based Simulation of a Broker Concept

Roman Engelhardt, Patrick Malcolm, Florian Dandl, Klaus Bogenberger, Technical University of Munich, Munich, Germany. Contact: roman.engelhardt@tum.de

Autonomous ridepooling services can improve future transport efficiency by offering shared rides. Nevertheless, because a sufficient user base is required for pooling to take effect, their performance can suffer if multiple operators split demand. A simulation framework is presented to evaluate the impact of competition and cooperation among ridepooling providers. Two different kinds of interaction via a broker platform are compared. In the first, the broker forwards trip offers from operators to customers, who can then freely choose an operator. In the second, a regulated broker platform manipulates operator offers to shift the system towards a system optimum. Results show that all stakeholder can benefit from a regulated broker: operators increase profit, customers experience higher service rates and cities benefit from increased pooling efficiency.

2 Fast and Scalable Shared Fleet Algorithms for Large-scale Applications

Krishna Murthy Gurumurthy[1], Akhil Vakayil[2], Felipe de Souza[1], Taner Cokyasar[3], Jeffrey Larson[4], [1]Argonne National Laboratory, Lemont, IL, [2]Georgia Institute of Technology, Atlanta, GA, [3]Argonne National Laboratory, Darien, IL, [4]Argonne National Laboratory, Argonne, IL, Contact: kgurumurthy@anl.gov

Dynamic ride-sharing offered by shared fleets has been proven to be useful in improving the network state and boosting the fleet's efficiency. Solving this in a fast and scalable manner, while doing so in an integrated manner compliant with travel behavior has been missing in recent literature. An iterative algorithm is proposed with objectives to minimize fleet hours and traveler hours and is implemented for large regional demand through the agent-based POLARIS framework. This presentation will highlight the algorithm, compare and contrast it with a greedy heuristic counterpart that does just as well, and provide motivation for moving toward large-scale solution settings.

3 MODELINg and OPTIMIZING MOBILITY-ON-DEMAND SHARED-RIDE SERVICEs with WALKING LEGS

Zifan Wang[1], Michael Hyland[2], Navjyoth J. S. Sarma[2], [1]RMSI North America Inc, New York, NY, [2]University of California, Irvine, Irvine, CA

Most mobility-on-demand (MOD) shared-ride services are door-to-door. However, in the past few years, several studies and real-world MOD services start introducing walking legs to the shared-ride trips so that travelers may be asked to walk for a short distance to the prescribed pickup locations and/or to their final destinations. Compared to the conventional door-to-door shared-ride services, shared-ride with walking legs services may bring benefits such as reduced system vehicle-distance-traveled. Yet, critical analysis on the trade-offs among various service-related metrics such as walking time, traveler total trip time, vehicle travel distance of MOD share-ride services with walking legs is still rare. This presentation aims to provide more insights on such trade-offs using our recent simulation results.

4 Mixed-service Operation and Pricing of Shared-use Autonomous Mobility Systems

Hoseb S. Abkarian[1], Hani S. Mahmassani[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: masmah@northwestern.edu

We study a new mixed-service (mixed-purpose) operation of shared-use autonomous mobility systems (SAMS) where customers can request rides either immediately or through reservations and use the vehicle for a point-to-point service or a time-slot-based rental service, respectively. An optimization-based strategy for assignment is presented for vehicle-to-customer matching with a dynamic pricing problem formulated as a Markov Decision Process and subsequently solved through a reinforcement learning algorithm. We also adopt a learning method of estimated time of arrival (ETA) of vehicles to customers (i.e. customers' wait times) to be accurately reflected in customer's choice process. Insights from fixed fleet operation of an autonomous mixed-service operation are presented.

Monday, 8AM–9:15AM

Innovation in Healthcare Delivery

General Session

Session Chair

Kamalini Ramdas, London Business School, London, United Kingdom.

Session Chair

Nazli Sonmez, Bilkent University, London, United Kingdom.

1 Identifying The Bottleneck Unit: Impact of Congestion Spillover in Hospital Inpatient Unit Network

Song-Hee Kim[1], Fanyin Zheng[2], Joan Brown[3], [1]Seoul National University, Seoul, Korea, Republic of; [2]Columbia University, New York, NY, [3]Keck Medicine of USC, Los Angeles, CA, Contact: songheekim@snu.ac.kr

We use 5-year data from a hospital with 16 inpatient units to empirically examine whether and how much congestion propagates through the network of inpatient units. We find that the magnitude of the congestion spillover is substantial in our study hospital. We then use counterfactual analyses to empirically identify the bottleneck unit---the unit that has the biggest impact on system performance when an intervention is applied to increase its capacity.

2 Uniformly Conservative Exploration in Reinforcement Learning

Wanqiao Xu[1], Jason Yecheng Ma[2], Kan Xu[3], Hamsa Sridhar Bastani[4], Osbert Bastani[2], [1]Stanford University, Stanford, CA, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]Wharton School, Philadelphia, PA, Contact: wanqiaox@stanford.edu

A key challenge to deploying reinforcement learning in practice is avoiding excessive (harmful) exploration in individual episodes. We propose a natural constraint on exploration---*uniformly* outperforming a conservative policy (adaptively estimated from all data observed thus far), up to a per-episode exploration budget. We design an algorithm that uses a UCB reinforcement learning policy for exploration, but overrides it as needed to satisfy our exploration constraint with high probability. We prove that our approach remains conservative while minimizing regret in the tabular setting. We experimentally validate our results on a sepsis treatment task and an HIV treatment task, demonstrating that our algorithm can learn while ensuring good performance compared to the baseline policy for every patient.

3 Artificial Intelligence on Call: The Physician'S Decision of Whether to use Ai in Clinical Practice

Tinglong Dai[1], Shubhranshu Singh[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, Contact: dai@jhu.edu

Physicians are increasingly able to use AI systems to aid their medical decision-making. This paper examines a physician's decision regarding whether to use an assistive AI system when prescribing a treatment plan for a patient. Using AI helps the physician generate an informative signal that lessens clinical uncertainty. It can also change the physician's legal liability in the event of patient harm. We analyze two patient-protection schemes that determine physician liability when using AI and show that in both schemes, the physician has an incentive to use AI in low-uncertainty scenarios, even if AI provides little value. Furthermore, the physician may avoid using AI in higher-uncertainty scenarios where AI could have aided in better decision-making. As AI becomes more precise, the physician may become more hesitant to use it on certain patients.

4 Improving Group Testing in a Pandemic

Tong Wang, Kamalini Ramdas, S. Alex Yang, London Business School, London, United Kingdom. Contact: tongw@london.edu

In a pandemic, we rely on accurate tests to identify positive cases and reduce infection, yet large scale tests can be costly to run and subject to capacity constraints. Group testing can efficiently test populations and significantly save testing capacities. In a group test, samples are first pooled and tested. If the result is negative, every individual in the group is healthy. Otherwise, individual tests are conducted to detect the infected individuals. The appropriate group size depends on the underlying risk level of individuals. In this study, we examine different approaches that health policy makers or health administrators can use to improve group formation for the pooling stage of the testing procedure in the presence of heterogeneous risk levels among individuals.

Modeling for Screening or Treatment Policies in Healthcare

General Session

Session Chair

Qiushi Chen, Penn State University, University Park

Session Chair

Yu-Hsin Chen, State College

1 Developing Personalized Diabetic Retinopathy Screening Recommendations

Poria Dorali[1], Zahed Shahmoradi[2], Christina Weng[3,4], Taewoo Lee[5], [1]University of Houston, Houston, TX, [2]Norfolk Southern Corporation, Atlanta, GA, [3]Baylor College of Medicine, Houston, TX, [4]Ben Taub Hospital, Houston, TX, [5]University of Pittsburgh, Pittsburgh, PA, Contact: pdorali@uh.edu

Diabetic retinopathy (DR) is the leading cause of blindness among working-age Americans. While regular screening can help prevent up to 98% of DR-related vision loss, currently only 30-60% of patients adhere to annual screening guidelines due to inconvenience and limited access to eye care. Teleretinal imaging (TRI) is emerging as an affordable tool that has the potential to increase screening rates, yet little is known how TRI-based screening should be recommended in conjunction with traditional screening exams. We develop a POMDP model that determines personalized screening policies that take into account patient-specific characteristics such as age, A1C level, cost savings preferences, and adherence behavior. We also analyze the cost-effectiveness of the personalized policies against current standardized guidelines.

2 Tuberculosis Treatment Modeling Using Laboratory Test Results

Maryam Kheirandish Borujeni, Shengfan Zhang, University of Arkansas, Fayetteville, AR, Contact: mkheiran@uark.edu

In this research, a sequential decision model is developed for effective tuberculosis (TB) treatment planning. Patients may develop acquired drug resistance during the course of treatment. However, there are no biomarkers to predict severity of the disease or predict the progression of interventions. Some laboratory tests are available to detect the existence or drug-resistance of TB bacteria in human's body. Although these tests are time-consuming, expensive, and not perfect, they are the only tests available for decision-making. We use these test results to develop a mathematical model to help physicians decide if they should continue the current regimen and/or administer a new test in each follow-up session.

3 A Tool to Inform Global Hepatitis C Elimination in Developing Countries

Huaiyang Zhong[1], Alec Donovan Aaron[2], Lindsey Hiebert[3], John Ward[3], Jagpreet Chhatwal[1], [1]Harvard Medical School, Mass General Hospital, Boston, MA, [2]Mass General Hospital, Boston, MA, [3]The Task Force for Global Health, Atlanta, GA, Contact: hzhong2@mgh.harvard.edu

The World Health Organization (WHO) recently launched a global campaign for eliminating hepatitis C virus (HCV) as a public health threat by the year 2030. However, most countries do not have a national strategy for HCV screening and treatment that can lead to HCV elimination. We developed a microsimulation model to assess various combinations of screening and treatment strategies, and built an online, publicly accessible tool to help policy makers identify a path to HCV elimination.

4 Optimize Risk-based Autism Screening Under Limited Diagnostic Service Capacity

Yu-Hsin Chen, Qiushi Chen, Pennsylvania State University, University Park, PA

Autism Spectrum Disorder (ASD) is a developmental disorder that affects 1 in 44 children in the US. The current diagnosis process for ASD experiences a long delay due to insufficient accuracy in screening tools and limited diagnostic service capacity. To improve the early diagnosis of ASD children, we developed a mathematical programming model to optimize the diagnostic referral decisions based on individuals' risk at different ages and the length of diagnostic waitlist during the screening process. Using a detailed individual-level simulation model, we found that compared with the fixed policies which have the same risk threshold across all ages, optimal policies with risk threshold adapted to the waitlist length achieved a lower average diagnosis age and a higher early diagnosis rate below age 4.

1 Predicting Disease Severity in Patients Hospitalized with COVID-19

Mina Ostovari, Claudine Jurkovitz, Keshab Subedi, Bayo M. Gbadebo, Mia Papas, ChristianaCare Health Services Inc., Wilmington, DE

The study aimed to identify risk factors for severe illness in patients with COVID-19. The outcome was the WHO Clinical Progression Scale (WHO-CPS) measured after hospital admission. We used electronic health records data to predict the WHO-CPS from patient demographic and clinical characteristics. The study period was from March 2020 to August 2022. The predictors included patient age, sex, race, ethnicity, insurance, Elixhauser comorbidity count, BMI, flags for hypertension, diabetes, chronic pulmonary disease, heart failure, renal failure, and a variable that indicated the time from the onset of the pandemic. The study population included 8852 patients with an average age of 60±18. The variable importance feature of random forest identified age, BMI, and time from the onset of the pandemic as the most significant predictors of the outcome.

2 Solving The Two Population Sir Model to Provide Early Estimates of Peak and Duration of a Covid-19 Wave

Louis Luangkesorn, HIghmark Health, Pittsburgh, PA, Contact: kiatikunlouis.luangkesorn@highmarkhealth.org

During the COVID-19 pandemic, new variants of the virus created waves of cases as the virus has increased virulence. In addition, with variants that are immune evasive prior infection to an earlier variant does not confer immunity and prior vaccination only protects a portion of the vaccinated population. Healthcare organizations need to be able to estimate the impact of a new wave in order to assess and manage resources needed to manage future caseloads. This work solves the initial value problem for an infectious disease model that accounts for partial vaccine effectiveness applied to a metropolitan area using insurance claims. The goal is to have a model that effectively provides early estimates of the peak and duration of an epidemic wave in its initial stages. The results from the model will be used to inform healthcare provider interventions and policy.

3 Designing High Quality, Efficient, and Accessible Provider Networks for Healthcare

Bishal Karki, Kiran Jambhale, Highmark Health, Pittsburgh, PA

As a health insurance company, Highmark Health has to review multiple providers on attributes such as quality of care, accessibility to membership, cost of care, etc. At Highmark, we have built a tool that does this optimization exercise algorithmically using internal and publicly available data. This talk will be a quick description of the problem we're trying to solve, our approach, and the value of such solutions to organizations like ours.

Monday, 8AM–9:15AM

Machine Learning in Healthcare

Flash Session

Session Chair

Agni Orfanoudaki, Saïd Business School, University of Oxford, Oxford, United Kingdom.

1 Analytics for Public Impact: Research Activities at The Public Impact Analytics Science Lab at Harvard

Soroush Saghafian, Harvard Univeristy, Cambridge, MA, Contact: soroush_saghafian@hks.harvard.edu

In this flash talk, we briefly overview various projects and research activities at the Public Impact Analytics Science Lab (PIAS Lab) at Harvard. We discuss our close collaboration with various stakeholders, the analytics science approaches used, and the data collection methods employed. We also shed light on the potential impact of these research activities as well as the broader lessons learned in conducting analytics-driven research that can have public impact.

2 Contextual Learning with Online Convex Optimization with Applications to Medical Decision-making

Esmaeil Keyvanshokooh[1], Mohammad Zhalechian[2], Cong Shi[2], Mark P. Van Oyen[2], Pooyan Kazemian[3], [1]Mays Business School, Texas A&M University, College Station, TX, [2]University of Michigan, Ann Arbor, MI, [3]Case Western Reserve University, Cleveland, OH, Contact: keyvan@tamu.edu

We formulate a new contextual multi-armed bandit model under a two-dimensional nested control in the context of medical decision-making. We develop a new contextual learning and optimization algorithm for this model and prove its regret. We illustrate the effectiveness of our methodology by using a case study on type-2 diabetes patients.

3 Quantifying The Benefits of Targeting for Pandemic Response

Sergio Camelo[1], Dragos Florin Ciocan[2], Dan Andrei Iancu[1], Xavier Warnes[3], Spyros Zoumpoulis[2], [1]Stanford University, Stanford, CA, [2]INSEAD, Fontainebleau, France; [3]Stanford University Graduate School of Business, Stanford, CA, Contact: spyros.zoumpoulis@insead.edu

We propose and implement a rigorous framework and algorithms to quantify the merits of targeted confinement interventions for pandemic response, and demonstrate them in a case study of COVID-19 in Île-de-France. We find that optimized interventions that differentiate based on both population groups and activities are interpretable, and achieve significantly better health and economic outcomes, while also reducing confinement time for each group, compared to less targeted interventions. Our framework highlights the significant benefits in explicitly and transparently modelling targeting and identifying the interventions that rigorously optimize overall societal welfare.

4 Managing The Risk of Readmission for Solid Organ Transplant Patients

Agni Orfanoudaki[1], Soroush Saghafian[2], [1]Saïd Business School, University of Oxford, Oxford, United Kingdom; [2]Harvard Univeristy, Cambridge, MA, Contact: agni.orfanoudaki@sbs.ox.ac.uk

Solid organ transplant patients are associated with a wide range of complications. In this study, we investigate the impact of routinely recorded risk factors and use machine learning to predict the 30-day risk of readmission. In addition, we present a reinforcement learning approach to derive interpretable prescriptive policies that account for unobserved confounding. We demonstrate that the proposed models lead to improved operational and patient outcomes compared to the standard of care. Our analysis includes real-world data from an online survey of human experts and the electronic health records of a major academic medical center based in the United States.

5 Deciphering Inpatient Procedure Heterogeneity with Multivariate Point Process Modeling

Fenglian Pan[1], Jian Liu[1], You Zhou[2], Nan Kong[2], [1]University of Arizona, Tucson, AZ, [2]Purdue University, West Lafayette, IN, Contact: nkong@purdue.edu

To improve the delivery of precision health, it is critical to decipher the heterogeneity among patients and further detect temporal associations for each type of patients. This research develops a multivariate point process model for discovering patients' latent temporal inpatient procedure patterns, which are represented as mutual-influencing mechanisms. An algorithm is developed to estimate the model parameters, based on which patients with different latent patterns are clustered. The proposed model can be used to predict the timing of procedures more accurately. The performance of proposed model is demonstrated by a read-world case study on opioid use disorder treatment with claims data.

6 Flash Paper

Kyra Gan, Carnegie Mellon University, Pittsburgh, PA

Will talk about the intersection of causal inference and reinforcement learning and its application in healthcare

7 Flash Paper

Model the Demand and Distribution of Vaccinations and Vaccine Hesitancy

Contributed Session

Session Chair

Marta J Ventura, Penn State, State College, PA

1 **Vaccine Demand Forecast Using Machine Learning Technique**

Abhijeet Kumar, Janeth Gabaldon, M A SHARIFUL AMIN, Javier RubioHerrero, Victor R. Prybutok, University of North Texas, Denton, TX, Contact: abhijeet.kumar@unt.edu

The demand for vaccines has significantly increased due to the occurrence of new infectious diseases. The recent outbreaks of coronavirus have added to the overall demand for vaccines. However, the growth in demand for vaccines has resulted in challenges related to the planning and management of the complex immunization supply chain. One of the key challenges is an accurate demand forecast for vaccines. While under-estimation of vaccine demand can lead to stock-outs, overestimation can lead to vaccine wastage. Therefore, this study aims to find a suitable model using machine learning techniques to forecast an appropriate demand for vaccines to avoid shortage and over-supply.

2 **Machine Learning Algorithms to Analyze Covid-19 Vaccine Hesitancy Behavior at The County Level in The U.S**

Hieu T. Bui, University of Arkansas, Fayetteville, AR

COVID-19 vaccine hesitancy (VH) has hindered the effectiveness of vaccination campaigns. We use open-access databases, and machine learning to (1) develop an effective measure of VH behavior; (2) determine the main factors contributing to changes in VH behavior at the county level over time; (3) explain the differences in VH of rural versus urban areas. The model identified political affiliation, Google search, and income per capita as some of the factors that impact VH behavior. These findings can help public health officials develop tailored strategies to address specific challenges leading to VH.

3 **Economic Impact of COVID-19 Vaccination on Healthcare Facilities**

Marta Ventura[1], Jose Antonio Ventura[2], Hui Yang[1], Adhithya Padmanabhan[1], [1]Penn State, State College, PA, [2]Pennsylvania State University, University Park, PA, Contact: mxv176@psu.edu

When vaccines became available, however, health officials had to face the challenging question of who should be vaccinated first and how to distribute the limited production of vaccines within their countries and all over the world. In addition, the limited logistics available to manage the manufacturing and distribution of vaccines led to new challenges. In this paper, we propose a mixed integer linear programming model to determine an optimal allocation of limited COVID-19 vaccines to reach herd immunity in a geographical area in an orderly manner while minimizing the overall cost, including the cost of building temporary medical facilities, travel cost of population to medical facilities, purchasing cost of vaccines, and inventory holding cost.

1 **Disease Progression in Alzheimer'S Disease Among US Veteran Population**

Ying Wang, Bentley University, Waltham, MA

Mild cognitive impairment (MCI) has become particularly attractive as it is considered to be the transitional state between normal aging and early Alzheimer's disease. However, not all MCI cases will progress to dementia or Alzheimer's. Some reverse to normal or near-normal conditions, some remain stable at MCI. Previous studies regarding the transitioning from MCI to AD relied on limited samples yield a wide range of estimations. This study described the disease progression from MCI to AD to death in a multistate framework from a large population of US veterans. The transition rates and probabilities between different disease phases were presented using the Markov multi-state modeling.

2 **Precision Public Health as a Strategy for Transforming Data into Actionable Information**

Ryan B. Simpson[1], Elena N. Naumova[2], [1]Tufts University Friedman School of Nutrition Science and Policy, Boston,

MA, [2]Tufts University, Boston, MA, Contact: ryan.simpson@tufts.edu

The recent paradigm shift towards Precision Public Health (PPH) aims to improve decision-making through evidence-based data-driven individualized health promotion, prevention, and control strategies. With the use of complex data, machine learning and artificial intelligence (AI), we are expanding PPH beyond a collection of tools for enhancing public health surveillance to a strategy for transforming data into actionable information. By examining global surveillance systems for infections with high pandemic potential, like WHO FluNET, we developed a framework for assessing time series records based on 5 principles (ACTOR: Availability, Capacity, Timeliness, Operability, and Reliability) accompanied by 25 standardized quantitative metrics.

3 Global Nutrition and Health Atlas: A Tool of Scientific Discovery

Bingjie Zhou, Elena N. Naumova, Tufts University Friedman School of Nutrition Science and Policy, Boston, MA, Contact: bingjie.zhou@tufts.edu

Public health and nutrition data are rapidly increasing in volume and complexity. Novel data visualization techniques offer a way to ease the user's cognitive load and improve comprehension, research reproducibility, and transparency. Using 4E principles: Evidence, Efficiency, Emphasis, and Ethics, we reviewed 13 highly utilized dashboards to examine their properties from users' perspectives. We created an open access data platform: Global Nutrition and Health Atlas (https://sites.tufts.edu/gnha/) to power innovation and research discovery with global data repositories with 26 themes and 500+ indicators from 190+ countries up to 30 years. We applied 'best practices in developing data portals, tutorials, and interactive visualization galleries.

4 Self-selecting No-pay Service Delivery Strategies: A Rising Tide that Lifts All Boats?

Omkar D. Palsule-Desai[1], Vikrant Vaze[2], Gang Li[3], Srinagesh Gavirneni[4], [1]Indian Institute of Management Indore, Indore, India; [2]Dartmouth College, Hanover, NH, [3]Bentley University, Waltham, MA, [4]Cornell University, Montreal, Canada. Contact: omkardpd@iimidr.ac.in

Services such as housing, food, and healthcare are expected to be universally accessible and affordable. Under rapidly increasing cost structures and income inequality, some organizations are implementing schemes under which customers can choose not to pay the required fees. We develop a mathematical model to characterize conditions under which service providers should adopt these strategies in a competitive environment. We show that the strategy of offering free services to the needy can, in addition to benefiting the firm, the consumer, and the society, also benefit the competitor. The underlying reasons are philanthropic amplification of paying customers' willingness to pay, non-paying customers' restriction-induced utility reduction, a faster transition of service professionals up the learning curve, and their appreciation for the societal contribution.

1 Reward Structure Design for Socially Optimal Ambulance Diversion Strategy

Hyun-Rok Lee[1], Taesik Lee[2], [1]Inha University, Incheon, Korea, Republic of; [2]KAIST, Daejeon, Korea, Republic of. Contact: hyunrok.lee@inha.ac.kr

To reduce overcrowding, an Emergency department (ED) may declare ambulance diversion (AD) status and divert arrivals of ambulances to other EDs. While AD is a logical strategy to pooling resources in an emergency medical service system, negative consequences, i.e. limited access to EDs for emergency patients, arise if excessively used by individual EDs. We model an ED network as a stochastic game and propose a reward structure design method to induce EDs to follow socially optimal AD strategies. This method guarantees that an equilibrium status is achieved under socially optimal operation. Numerical experiments are conducted to analyze the reward structure for socially optimal AD strategy.

2 A Subsidized One-Leader-Multiple-Follower Trauma Network Redesign Problem

Fangyuan Li, Purdue University

Ineffective emergency care for trauma injuries has been a serious healthcare problem in the U.S., which is partially caused by geographic maldistribution of trauma centers in the care network. We formulate this network redesign problem with a bilevel mixed-integer program, where the government as the leader allocates subsidies to each hospital system and each hospital system then follows to decide which hospital to downgrade and which to upgrade, and how to zone the potential trauma injury incidents. We apply a branch-and-bound solution technique and propose a multiway-branching method. We test the solution technique with a case study based on the US state of Indiana, and generate policy insights.

3 Sequential Allocation of Vaccine to Control An Infectious Disease

Isabelle J. Rao[1], Margaret L. Brandeau[2], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA, Contact: isarao@stanford.edu

The vaccine allocation problem has broad applications in public health and has received renewed attention during the COVID-19 pandemic. We consider an SIR model with interacting population groups, an allocation over multiple time periods of limited vaccines and four objectives: minimize new infections, deaths, life years lost and quality-adjusted life years lost due to death. We develop intuitive and practical analytical conditions characterizing the optimal solution. We calibrate the model to the COVID-19 epidemic in New York and show that our method achieves near-optimal results. Our method highlights the need for more interpretable models over black-box models to aid in decision making.

4 Challenges in Diagnosing Staff Shortages in Healthcare Personnel Scheduling Problems

Daiwen Zhang, Amy Cohn, William Pozehl, Maocui Mu, University of Michigan, Ann Arbor, MI, Contact: dwzhang@umich.edu

Infeasibility is a common issue when solving personnel scheduling problems in healthcare. Most of those cases are caused by shortages of workforce in some sense. In particular, this means the current staffing supply cannot cover the needs of all time periods. In practice, it will be helpful to the decision maker if more information on the infeasibility can be diagnosed, e.g., which shifts cannot be covered at the same time, and how much the shortages are. We present algorithmic approaches to detecting the source and extent of infeasibility.

5 Utilizing a Systematic Approach to Predict Resource Allocation and Improve Intervention Success

Aparna Reddy, Makayla Roma, Emily Lindblad, Amy Cohn, Nithya Ramnath, University of Michigan, Ann Arbor, MI, Contact: aparnakr@umich.edu

Studies show lack of accurate resource allocation increases the likelihood of intervention failure. This study aims to improve intervention success by predicting accurate staffing and resource needs through a systematic method. Using a Lung Cancer Screening Program at the *VA Ann Arbor Health Care System* as a model, resource needs were determined from a predictive method. Utilizing process mapping, resource availability, and program goals, we developed a systematic method to calculate resource allocation. We outlined a systematic method to be applied in various contexts to promote efficient resource allocation, preempt future problems, and improve intervention success.

6 Using Simulations as Inputs

Sze-chuan Suen, University of Southern California, Los Angeles, CA

Markov decision processes (MDPs) rely on accurate state transition probabilities, stage rewards, and terminal rewards, but these values may be difficult to measure in health applications, where they may need to capture residual lifetime outcomes. Microsimulation models, stratified by demographic factors, may provide a good way to estimate these MDP inputs. I provide several examples of this process and discuss challenges and potential solutions.

7 Optimally Designing Cybersecurity Insurance Contracts to Encourage The Sharing of Medical Data

Yoon Lee[1], Anil Aswani[2], [1]UC Berkeley, Bellevue, WA, [2]UC Berkeley, Berkeley, CA

Though the sharing of medical data has the potential to lead to breakthroughs in health care, the sharing process itself exposes patients and health care providers to various risks. Patients face risks due to the possible loss in privacy or livelihood that can occur when medical data is stolen or used in non-permitted ways, whereas health care providers face risks due to the associated liability. As a result, health care providers are hesitant to share medical data. One possible solution to encourage health care providers to responsibly share data is through the use of cybersecurity insurance contracts. This paper studies the problem of designing optimal cybersecurity insurance contracts, with the goal of encouraging the sharing of the medical data.

8 Strategies for Efficient Funding of HIV Prevention Interventions to Achieve The Incidence Goals of The Ending The HIV Epidemic in The U.S. (EHE) Initiative

Evin Jacobson[1], Katherine A. Hicks[2], Justin Carrico[2], Paul Farnham[1], [1]CDC, Atlanta, GA, [2]RTI International, Durham, NC, Contact: wqm4@cdc.gov

We considered multiple strategies for efficiently funding HIV prevention interventions to meet 5-year and 10-year EHE annual incidence goals. Our results showed that these goals could be reached by proportionally scaling up current funding to all interventions by an additional 130%. We also used optimization methods to identify funding strategies that met EHE incidence goals with minimized annual funding across the interventions. Even when we required that 75% of current funding to each of the interventions be continued, optimizing the funding meant that the EHE incidence goals could be met with less total funding than was currently spent.

9 A Linear Model to Identify Optimal Hiv Prevention Funds Allocation Policy for Local Health Jurisdictions in The United States

Md Hafizul Islam, Centers for Disease Control and Prevention, Atlanta, GA, Contact: qla0@cdc.gov

Local U.S. health jurisdictions receive funds from different sources to implement HIV prevention interventions for appropriate populations at risk. We developed a linear programming model to identify the optimal allocation of the Centers for Disease Control and Prevention's HIV prevention funding for local health jurisdictions. The model allocates a given budget among prevention interventions and populations stratified by gender and risk groups to maximize the number of cases prevented. Inputs to the model include available budget and data on the costs and efficacy of HIV prevention programs for different subpopulations. Model solutions report the number of new cases prevented and the corresponding funding allocation to each prevention intervention for different subpopulations.

Supply Chain Resilience: Impact of Stakeholder Behavior and Trustworthy Information Sharing with a Case Study on Pharmaceutical Supply Chains

Tutorial Session

Session Chair

Mabel Chou, National University of Singapore, SG, SG, Singapore.

1 Supply Chain Resilience: Impact of Stakeholder Behavior and Trustworthy Information Sharing with a Case Study on Pharmaceutical Supply Chains

Ozlem Ergun, Jacqueline Griffin, Northeastern University, Boston, MA

Recent disruptions in many different supply chains have brought the critical issues of supply chain resilience into focus. Despite the notion that most economic markets should adjust to shifts in supply and demand through entry and exit of competitors, we have seen that even sectors that are not as heavily regulated, as the pharmaceutical sector, are vulnerable and prone to severe shortages. Although there are many aspect of a supply chain from design to last-mile logistics that impact resilience, in this chapter we highlight and focus on the importance of incorporating the concepts of (i) stakeholder behaviors and (ii) information availability in the future of OR/MS models focused on addressing supply chain resiliency. We present how the pharmaceutical industry, which has been plagued by supply chain shortages, is a strong case study for exploring these concepts. Further, within this context we present a research framework that incorporates these elements. Informed by the initial results with this framework we highlight important new research directions.

Addressing Facility Workload Balancing in Coverage Problems

Jing Xu, University of California, Santa Barbara, Santa Barbara, CA

Coverage problems have been important location models and have been widely applied in practice. A major limitation of simple coverage problems is that they do not control allocation, which might lead to unreasonable facility workloads and workload imbalance. Previous studies have been dealt with facility workload related issues in coverage problems, with one of the most popular approach is to impose capacities and/or thresholds. However, capacities and thresholds cannot guarantee facility workload balance and have associated issues in application. This work seeks to evaluate existing approaches that consider workload balance in coverage problems and study alternative approaches to better address facility workload balance. The primary contribution of this research includes: better understanding and systematic evaluation of existing capacitated coverage approaches including their solution characteristics and commercial GIS performance, new modeling approaches explicitly considering facility workload balance in coverage problems that might be applied to other types of location problems, and efficient solution techniques for proposed multi-objective spatial optimization models.

A Discrete-continuous Approximation Model for Optimal Facility Location in Disaster Response Logistics

Diana Gineth Ramirez-Rios, University at Buffalo, Buffalo, NY

This work proposes a discrete-continuous facility location model that focuses on the identification of the optimal location of the points of distribution (PODs) in a continuous geographical region and the size of the districts served by the various PODs. Given the location of a distribution center where relief supplies are stored, the optimization model produces a districting plan for each POD that includes the POD's location inside each district and a post-disaster delivery strategy. The model computes the optimal location, number of PODs, and shapes of the districts, delivery frequencies and shipment sizes such that the total social costs, i.e., the summation of the logistics costs and the deprivation costs, are minimized. A set of continuous approximation functions that compute the total deprivation costs of typical districting shapes are integrated into the model.

Interesting Topics in Retail Operations

General Session

Session Chair

Santiago Gallino, University of Pennsylvania, Philadelphia, PA

1 Inequity in Disaster Operations Management

Xabier Barriola[1], William Schmidt[2], [1]INSEAD, Fontainebleau, France; [2]Cornell University, Ithaca, NY, Contact: xabier.barriola@insead.edu

Responding to natural disasters requires a large and rapid deployment of resources to relieve the needs of the victims. Using a triple difference regression, we isolate the percentage change in prices paid by low-income versus high-income areas in disaster-affected versus unaffected areas, before and after a set of disasters. We show that affected low-income areas endure higher average percentage price increases within grocery categories compared to high-income areas. We find that low-income areas see a larger drop in price promotions, higher unit percent price increases, a larger decrease in offer sets of low-priced products, and a larger increase in substitution from low-priced items to high-priced items. Our results highlight how companies and agencies can use data to facilitate more targeted and equitable operational interventions in the aftermath of a disaster.

2 Order-based Trade Credits and Operational Performance in The Nanostore Retail Channel

Rafael Escamilla[1,2], Jan C. Fransoo[1], Santiago Gallino[3], [1]Tilburg University, Tilburg, Netherlands; [2]Kuehne Logistics University, Hamburg, Germany; [3]University of Pennsylvania, Philadelphia, PA, Contact: R.Escamilla@tilburguniversity.edu

Millions of nanostores sell basic items to bottom of the pyramid consumers in emerging markets. However, their suppliers struggle with high operational costs due to shopkeepers' cash constraints. In this setting, we empirically investigate whether order-based trade credits help improve operational performance in the supply chain. On the one hand, these credits can create efficiency gains in selling and distributing products to the nanostores. On the other hand, they are a risky endeavor, as shopkeepers might default on their credit lines. Using a difference-in-differences approach with nearest neighbor matching, we find that trade credits lead to substantial efficiency gains, while resolving important operational challenges for the supplier. We further investigate under what circumstances suppliers stand to gain from extending trade credits.

3 Monitoring Government Purchases to Reduce Public Spending: A Large Scale Field Experiment

Marcelo Olivares, Universidad de Chile, Santiago, Chile.

In most organizations, procurement decisions are typically delegated to local purchasing units who have a better understanding of actual needs. However, there can be misaligned incentives between these purchase units and the central organization, which leads to principal/agent problem that may increase procurement costs. This paper conducts a large field experiment using government purchases in Chile, implementing a novel monitoring system to track overspending of thousands of purchasing units, testing alternative informational designs to reduce public spending. Our results show that monitoring overspending coupled with informative feedback to buyers can significantly reduce overspending.

4 Inventory Record Inaccuracy Explains Price Rigidity Inperishable Groceries

Ioannis Stamatopoulos[1], Robert E. Sanders[2], Naveed Chehrazi[3], [1]The University of Texas at Austin, McCombs School of Business, Austin, TX, [2]UC, San Diego, Beverly Hills, CA, [3]Olin Business School, SAINT LOUIS, MO, Contact: yannis.stamos@mccombs.utexas.edu

Grocery retailers cannot engage in inventory-based pricing without physically auditing their shelves, because their inventory records are inaccurate and incomplete. We argue that this informational friction, known in the literature as inventory record inaccuracy (IRI), is much more powerful than physical menu costs in explaining price rigidity in perishable groceries.

Balancing Supply & Demand in Retail Electricity Markets

General Session

Session Chair

Saed Alizamir, Yale University, New Haven, CT

Session Chair

Michael Blair, Yale University, New Haven, CT

1 Data-driven Clustering and Feature-based Retail Electricity Pricing with Smart Meters

N. Bora Keskin[1], Yuexing Li[2], Nur Sunar[3], [1]Duke University, Durham, NC, [2]Duke University, Durham, NC, [3]UNC, Chapel Hill, NC, Contact: bora.keskin@duke.edu

We consider an electric utility company that serves N customers over T periods. In each period, the company observes the customers' consumption and high-dimensional features on customer characteristics and exogenous factors. The space of features is partitioned into clusters based on similarity, and in each cluster, there is a distinct relationship between consumption and features. The company knows neither the underlying cluster structure nor the corresponding consumption models. We design a data-driven clustering-and-pricing policy to learn these elements on the fly and prove that our policy achieves near-optimal performance in terms of N and T. Through a case study on a real-life data set, we show that our policy significantly outperforms the historical decisions of the utility company.

2 When Should The Off-grid Sun Shine at Night? Optimum Renewable Generation and Energy Storage Investments

Christian Kaps[1], Simone Marinesi[2], Serguei Netessine[1], [1]The Wharton School, Philadelphia, PA, [2]WHARTON, Philadelphia, PA, Contact: ckaps@upenn.edu

Globally, 1.5 billion people live off the grid, their only access to electricity often limited to operationally-expensive fossil fuel generators. Solar power has risen as a sustainable and less expensive option, but its generation is variable during the day and non-existent at night. Thanks to recent technological advances, which have made large-scale electricity storage economically viable, a combination of solar generation and storage holds the promise of cheaper, greener, and more reliable off-grid power in the future. Still, it is not yet well-understood how to jointly determine optimal capacity levels for renewable generation and storage.

3 Electric Vehicles' Managed Home-Charging Programs

Ali Fattahi, Johns Hopkins University, Baltimore, MD

Experts estimate 20 million electric vehicles (EVs) will be on U.S. roads by 2030, and the majority (around 80%) of EV owners will perform home charging. Many utilities are designing managed charging programs to effectively integrate and manage the total EV load. We study a general case of an active managed home-charging program, in which a large number of non-homogeneous participants plug in their EVs at different times and indicate their required loads and charging windows. The utility is obligated to satisfy these requirements. We present a large-scale non-linear optimization model and an effective approximation method. We present the following managerial insights that are contrary to the utilities' common beliefs: a) increasing participation in managed charging programs may not be a cost-saving strategy, and b) higher charging frequency may increase the total cost.

4 Estimating The Impact of Climate Change: An Empirical Analysis of Smart Thermostat Data

Michael Blair[1], Saed Alizamir[1], Shouqiang Wang[2], [1]Yale University, New Haven, CT, [2]The University of Texas at Dallas, Richardson, TX, Contact: michael.blair@yale.edu

Using a rich micro-level dataset, we empirically analyze smart thermostat data to understand the relationship between households' thermostat settings and their ambient environment. We combine a variety of methodological tools including Dynamic Linear Models, random effects, and Bayesian Statistics, to develop models for short- and long-term behavior. Using established models we create realistic estimates of future weather conditions under a variety of climate change scenarios. We combine these scenarios with our statistical model to estimate the impact of climate change. Specifically, we predict future household behavior and investigate the resulting changes in consumption. The insights derived from our research provide a valuable framework to evaluate and design interventions such as smart nudging or demand response management programs.

Optimizing Trials and Healthcare Operations

General Session

Session Chair

Aadhaar Chaturvedi, University of Auckland, AUCKLAND, New Zealand.

Session Chair

Philippe Chevalier, UCLouvain, Louvain La Neuve, Belgium.

1 Network Inventory Management for Clinical Trials

Philippe Chevalier[1], Alejandro Lamas[2], [1]UCLouvain, Louvain La Neuve, Belgium; [2]NEOMA Business School, Levallois-Perret, France. Contact: philippe.chevalier@uclouvain.be

Clinical trials are a critical step for the development of new drugs, both in cost (often in the order of billions of dollars) and in terms of elapsed time to bring the potential drug to the market. Since clinical trials are increasingly going global, optimizing the supply chain can bring huge benefits, in this research we model the inventory management problem between the central depot and the regional depots that will then supply the investigation sites. The main decision is when to resupply and how much inventory to send to each regional depot and as a consequence how much inventory will be left in the central depot for potential resupplies of other regional depots. The global network view is very important given that for regulatory reasons it is impossible to send products back to the central depot or between regional depots.

2 Learning Personalized Treatment Strategies with Predictive and Prognostic Covariates

Andres Alban[1], Stephen E. Chick[2], Spyros Zoumpoulis[2], [1]MGH Institute for Technology Assessment, Boston, MA, [2]INSEAD, Fontainebleau, France.

We consider the problem of sequentially allocating sample observations to learn personalized treatment strategies, motivated by the design of adaptive clinical trials that aim to learn the best treatment as a function of patient covariates. In such clinical settings, there may be knowledge of which covariates are predictive (they may interact with the treatment choice), and which are prognostic (they influence the outcome independent of treatment choice). We show how Bayesian sequential optimization techniques can be adapted to take advantage of such structural knowledge. We illustrate that such knowledge can improve the rate of inference relative to some existing approaches to adaptive contextual learning with a numerical experiment motivated by an application of clinical trial design to assess potential treatments of sepsis.

3 Emergency Care Access Vs. Quality: Uncovering Hidden Consequences of Fast-track Routing Decisions

Shuai Hao[1], Zhankun Sun[2], Yuqian Xu[3], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]City University of Hong Kong, Kowloon, Hong Kong; [3]UNC-Chapel Hill Kenan-Flagler Business School, Durham, NC, Contact: shuaih2@illinois.edu

Many hospitals have established a separate fast-track (FT) service line dedicated to patients with less urgent care needs to improve emergency department (ED) operational efficiency. However, so far, hospitals have not yet established consistent guidelines for determining which patients should be routed to the FT, possibly due to the lack of a comprehensive understanding of how FT routing decisions impact patient outcomes. Using data from two Canadian hospitals, we show that better-informed FT routing decisions can put the right patient in the right place at the right time, improving both the access to and the quality of emergency care.

4 Optimal Vaccine Allocation

Justin Goodson, Stephen Scroggins, Enbal Shacham, Tasnova Afroze, Saint Louis University, Saint Louis, MO, Contact: goodson@slu.edu

Allocation of limited vaccine supplies faces two main obstacles. First, classical models of disease spread struggle to incorporate the spatio-temporal factors that drive the person-to-person transmission of respiratory infection. Second, because these predictive models are difficult to integrate within a prescriptive optimization framework, the resulting allocation policies typically carry no guarantee of optimality. We show how to model disease spread that captures a population's mobility and location across time and space and that results in a tractable optimization model. We demonstrate how optimal allocation policies could have averted infections, deaths, and hospital costs during the first half of 2021, a period when vaccine supplies were low and COVID-19 was rampant. Our framework is a template for response to future outbreaks.

iFORM: Risk Behaviors

General Session

Session Chair

Rong Li, Syracuse University, Syracuse, NY

Session Chair

Meng Li, University of Houston, Houston, TX

Session Chair

Rong Li, Syracuse University, Syracuse, NY

1 Risk Management Under Cognitive Bias: Overconfidence as a Psychological Hedge

Rong Li[1], Meng Li[2], Shuxiao Sun[3], [1]Syracuse University, Syracuse, NY, [2]University of Houston, Houston, TX, [3]Peking University, Beijing, China. Contact: rli138@syr.edu

Overconfidence (OC) and risk aversion (RA) are found as the most prevailing uncorrelated biases in managers. In the risk management literature, while RA is extensively examined, OC has never been studied. This paper is the first to study how OC affects risk management. Interestingly, we find that OC reduces RA in a linear fashion and thus can serves as a psychological hedge.

2 Managing Service Systems with Overconfident Customers

Na Zhang[1], Anand Paul[2], Xu Sun[2], [1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL

We study a service system where true service times are unknown and customers exhibit the cognitive bias of being overconfident (in particular, overprecise) in their beliefs about service times—customers underestimate the variability of service times. We examine the implications of overconfidence in both an unobservable queue and an observable queue. We further investigate the impact of queue length information in this setting and obtain qualitatively different results from the classical models.

3 Sell Now or Later? Regret with Price Volatility

Jingjing Weng[1], Yiwei Chen[1], Meng Li[2], [1]Temple University, Philadelphia, PA, [2]University of Houston, Houston, TX, Contact: jingjing.weng@temple.edu

Selling is of paramount significance in the trade, of which the most important aspect for a firm is to determine when to sell and how many quantities to sell. This is especially crucial under the dynamics of everchanging markets with price volatility, because firms often experience regret by both selling too soon and selling too late. In this paper, we employ dynamic programming to investigate a regret minimization firm's problem of allocating a fixed amount of capacity in a dynamic multi-period setting with price volatility.

4 Dynamic Moral Hazard with Adverse Selection

Feifan Zhang, Durham

We study the optimal incentive scheme for a long-term project with both moral hazard and adverse selection. The moral hazard issue is due to the fact that the agent's effort, which increases the arrival rate of a Poisson process, is not observable by the principal. In addition, the agent's effort cost, which needs to be reimbursed by the principal, is also the agent's private information.

1 Increasing Charity Donations: A Bandit Learning Approach

Divya Singhvi[1], Somya Singhvi[2], [1]NYU Stern School of Business, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA

We consider the problem of maximizing charity donations with personalized recommendations on crowd-sourcing platforms, when donor preferences are unknown. One salient feature of these platforms is that campaign recommendations do not always result in a donation. A donation is observed only when the campaign is selected and an eventual donation is made. We show that not accounting for this selection bias leads to sub-optimal recommendations. Hence, we propose the SSB algorithm to resolve the sample selection bias issue. We show that the SSB algorithm achieves near optimal rate of regret and considerably outperforms state-of-the-art learning algorithms in numerical experiments on synthetic as well as real world data sets.

2 Closing The Supply-demand Gap: Scheduling Policies for Volunteer Organizations

Mariana Escallon-Barrios, Karen Smilowitz, Northwestern University, Evanston, IL, Contact: marianaescallon2023@u.northwestern.edu

Recent research in volunteer management has explored how online scheduling platforms can be used to balance volunteer preferences with organizational needs. Strategically removing some scheduling options has been shown to improve supply/demand balance. In this talk, we explore how best to select those slots from the perspective of the staff or volunteers assigned. We proposed a max-min column generation solution approach and present a case study motivated by a disaster response volunteer-based organization to address the current coverage imbalances.

3 Combinatorial Exchange for Resource Sharing Among Nonprofits

Weixiao Huang[1], Jennifer A. Pazour[2], Alex Teytelboym[3], Andrew C. Trapp[1], [1]Worcester Polytechnic Institute, Worcester, MA, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]University of Oxford, Austin, Contact: whuang2@wpi.edu

Nonprofit organizations (NPOs) often serve marginalized communities and resolve societal challenges, yet face a key barrier of severe resource limitations. We introduce a new auction-based mechanism that uses combinatorial optimization to catalyze resource exchanges among NPOs. We discuss rules of engagement, bidding languages, and nonprofit feedback toward facilitating collaboration.

4 Modeling Volunteer Response to Out-of-hospital Cardiac Arrest Cases

Pieter van den Berg[1], Shane Henderson[2], Caroline Jagtenberg[3], Hemeng Li[2], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Cornell University, Ithaca, NY, [3]Vrije Universiteit Amsterdam, Amsterdam, Netherlands. Contact: hl2359@cornell.edu

Out of hospital cardiac arrest (OHCA) requires immediate treatment and patient survival can be improved by combining traditional ambulance response with the dispatch of volunteers alerted via an app. In this talk, we explore volunteer dispatch strategies that use real-time information to determine which volunteers to alert and when, to maximize the survival rates while minimizing the total number of alerts. If time permits, we will also discuss how we model the presence of volunteers throughout a region as a Poisson point process and how we use the optimal volunteer location distribution that maximizes survival rates to guide the recruitment of volunteers.

Monday, 8AM–9:15AM

Sourcing, Production, and Distribution in Supply Chains

General Session

Session Chair

Sammi Tang, University of Miami, Coral Gables, FL

1 A Socio-technical Analysis of Blood Supply Chain Challenges in Nigeria

Temidayo Akenroye[1], Jamal El Baz[2], Femi Ogunremi[3], Olusola Olowoselu[4], [1]Liverpool Business School, Liverpool, United Kingdom; [2]Ibn Zohr University, Agadir, Morocco; [3]Monitor Healthcare Limited Nigeria, Laos, Nigeria; [4]University of Lagos, Lagos, Nigeria. Contact: T.O.Akenroye@ljmu.ac.uk

This paper examines Nigeria's blood supply chain challenges using socio-technical theory. Blood and blood products are scarce commodities in Nigeria because the demand for transfusion often exceeds supply availability. This unmet demand has contributed to increased mortality rates. Semi-structured interviews and consultation workshops were conducted to collect qualitative data from multiple stakeholders in Nigeria to examine the challenges associated with key operational activities. Different themes emerged from the thematic data analysis, which were further sub-categorized, to show the socio-technical challenges facing the blood supply chain.

2 Agricultural Subsidy Programs Under Decentralized Procurement and Deliberate Quality Degradation

Aysajan Eziz[1], Omkar D. Palsule-Desai[2], Srinagesh Gavirneni[3], [1]Ivey Business School, London, ON, Canada; [2]Indian Institute of Management Indore, Indore, India; [3]Cornell University, Ithaca, NY, Contact: aeziz@ivey.ca

The purpose of this study is to analyze two different types of farmer subsidies in India: price support scheme and price deficiency payment scheme. Given the guaranteed support price from the government under both subsidy programs, farmers are likely to engage in quality degradation behaviour to increase farm produce quantity, thus total revenue, by adding foreign particles or low-quality leftovers from previous years. We explicitly model such a degradation activity by the farmer. We systematically discuss under what conditions farmers decide to degrade and to what level. The factors considered include minimum support price, market price premium for high quality crops, farmer size, etc. We strive to gain insights for improvising/redesigning current farmer subsidy programs in India to improve the overall quality of crops while maintaining farmer support.

3 The Dynamcis of Distribution to Financially Constrained Nanostores

Zheyu Jiang[1], Harihara Prasad Natarajan[2], Nan Yang[2], [1]University of Miami, Coral Gables, FL, [2]University of Miami, Coral Gables, FL, Contact: zxj144@miami.edu

Nanostores, which account for a significant portion of fast-moving consumer goods (FMCG) market in developing countries, rely on regional distributors to replenish inventory. Take into consideration nanostores' financial constraints, we address the distribution problem for a regional distributor to supply multiple stores in a two-stage decision process. We characterize each nanostore's inventory decisions and the distributor's optimal delivery decision, which naturally decompose all stores into three mutually exclusive sets. The classification helps us to further investigate the impacts of two common levers, financial credits and retail pricing flexibility, on the distribution dynamics and all parties' profits in the supply chain.

4 Reshoring Under Tariff Uncertainty and Competition

Panos Kouvelis[1], Xiao Tan[2], Sammi Tang[3], [1]Washington University in St. Louis, St Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]University of Miami, Coral Gables, FL, Contact: ytang@miami.edu

Recent development in the U.S. tariff policies has forced companies to rethink their global operational strategies, particularly whether to add a domestic production location that is immune to tariffs. This paper formulates a three-stage model to analyze the global firm's reshoring capacity, output quantity, and production decisions. We examine how reshoring capacity investment is affacted by domestic competition and by tariff uncertainty at both the raw-material and finished-goods level.

Monday, 8AM–9:15AM

CC - Room 144

Socially Responsible and Sustainable Operations

General Session

Session Chair

Wei Wei, Isenberg School of Management, University of Massachusetts Amherst, Hadley, MA

1 Allocation of Funds in Bilevel Subsidy Welfare Programs

Wei Wei[1], Priyank Arora[2], Senay Solak[1], [1]University of Massachusetts Amherst, Amherst, MA, [2]University of South Carolina, Columbia, SC, Contact: wwei0@umass.edu

We analyze funds allocation problem in the subsidy welfare program (e.g., child care subsidy programs), wherein a funding agency allocates funds to multiple service agencies that make investments to enhance the quantity and quality of services received by beneficiaries at local service providers. We develop a bilevel, one-to-many, and forward-looking optimization model for the distribution of funds by taking into account: asymmetry of information (between entities at the two levels), equity consideration (by the funding agency), and service focus (of these programs). Our analysis reveals and explains how the funding agency can use funds allocation as a strategic lever to ensure the equitable social impact is generated by different agencies.

2 Examining The Impact of Leniency Bias on Supplier Audits

Tim Kraft[1], Xiaojin Liu[2], Robert Handfield[1], H. Sebastian

Heese[1], Balaji Soundararajan[1], [1]NC State - Poole College of Management, Raleigh, NC, [2]Virginia Commonwealth University, Richmond, VA, Contact: xliu22@vcu.edu

Auditing is a critical governance instrument that enables buyers to monitor suppliers and thus reduce corporate social responsibility (CSR) risk. However, auditing is not an exact science: audits are subject to potential biases that can impact their accuracy. In this study, we examine the impact of monitor leniency on facility CSR risk. Using a unique dataset consisting of historical, facility-level audits for a large global apparel brand, we find that monitor leniency in the current audit helps to reduce CSR risk. Further, we find that an increase in monitor leniency has a greater effect on facilities with low compliance ability, on facilities in developing countries, on facilities that have been audited a fewer number of times, and on facilities that experienced a greater positive change in leniency since their previous audit.

3 Delivery Terms for Voluntary Carbon Offsets

Vishal Agrawal[1], Gokce Esenduran[2], Safak Yucel[3], [1]Georgetown University, Washington, [2]Purdue University, West Lafayette, IN, [3]Georgetown University, Washington, DC, Contact: safak.yucel@georgetown.edu

A carbon offset represents one unit of reduction in greenhouse gas emissions that can be used to compensate for emissions that occur elsewhere. Companies purchase carbon offsets under two delivery terms: The first is prompt delivery, where a buyer orders offsets from a seller who has already invested in a project and generated offsets. The second is forward delivery, where a buyer orders offsets from a seller who has not yet invested. Given that the emissions reduction from the investment is uncertain, under forward delivery there is quantity risk---the seller may not generate sufficient offsets to fulfill the buyer’s order. In contrast, there is no quantity risk under prompt delivery. In this paper, we ask a fundamentally important question: Which delivery term should a buyer prefer and which one leads to a higher environmental benefit by leading to a higher investment?

Roundoff-Error Free Matrix Factorization Algorithms

General Session

Session Chair

Christopher Lourenco, US Naval Academy, Annapolis, MD

1 History and Background of Roundoff-error Free Factorization Algorithms

Erick Moreno-Centeno, Texas A&M University, College Station, TX

Solving sparse linear systems has a central role in solving linear programs and other optimization problems. Moreover, exactly solving linear programs and systems is necessary for some applications (e.g., theoretical results, feasibility problems, military applications, applications with hefty costs, ill-conditioned issues, etc.). To address this, we are developing the Sparse Exact (SPEX) Factorization Framework: a high-performance, well-documented, and extremely robust software package. This talk will focus on the history and the theoretical foundations of the package and companion talks on the recent developments.

2 Algorithms and Software to Solve Square Sparse Linear Systems Via Roundoff-error-free Lu and Cholesky Factorization

Christopher Lourenco, US Naval Academy, Annapolis, MD, Contact: lourenco@usna.edu

Square sparse linear systems are ubiquitous in optimization problems. For example, when solving linear programs, unsymmetric (simplex) or symmetric positive definite (interior point) linear systems must be solved. In this talk, we present algorithms and software which can exactly solve these sparse linear systems. Specifically, we present three factorizations which exactly solve the sparse linear system Ax=b in time proportional to arithmetic work---to date the only exact algorithms with this property. On the software front, we present a published software package which was shown to outperform competitor exact rational and exact iterative approaches. This software can be accessed either in C or via easy to use MATLAB and Python interfaces.

3 Roundoff-error-free QR Factorization

Lorena Mejia Domenzain, Texas A&M University, College Station, TX

QR factorization is a widely used tool in mathematics, computer science, and engineering. For example, QR factorization is regularly used to solve least squares problems. The QR factorization of matrix A is given by A=QR, where Q is an orthogonal matrix, and R is an upper triangular matrix. For some matrices, the round-off errors incurred when factorizing can lead to a loss in orthogonality. Thus, it is crucial to reduce or eliminate roundoff errors to reach the correct solution. This talk presents a roundoff-error-free (REF) QR factorization framework and algorithm. The REF QR factorization factors matrix A as A=QDR, where Q is a left orthogonal matrix, R is an upper triangular matrix, and D is a diagonal matrix. Every operation used to compute these factors is integral; thus, REF QR is guaranteed to be an exact orthogonal decomposition.

4 Exact Factorization Updates for Nonlinear Programming

Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ

This talk introduces a novel approach for solving sequences of closely related systems of linear equations (SLEs) encountered in nonlinear programming efficiently and without roundoff errors. Specifically, it introduces rank-one update algorithms for the roundoff-error-free (REF) factorization framework, a toolset built on integer-preserving arithmetic that has led to the development and implementation of fail-proof SLE solution subroutines for linear programming (LP). Formal guarantees are established through the derivation of theoretical insights. Their advantages are supported with computational experiments, which demonstrate upwards of 75x-improvements over exact factorization run-times on fully dense matrices with over one million entries. An additional use of the featured algorithms for performing LP-related updates is also discussed.

Fair Learning and Optimization

General Session

Session Chair

Qing Ye, Blacksburg, VA

Session Chair

Weijun Xie, Virginia Tech, Blacksburg, VA

1 An Algorithmic Framework for Bias Bounties

Ira Globus-Harris, 1</sup

I will propose and analyze an algorithmic framework for "bias bounties": events in which external participants are invited to propose improvements to a trained model, akin to bug bounty events in software and security. This framework allows participants to submit arbitrary subgroup improvements, which are then algorithmically incorporated into an updated model. The algorithm has the property that there is no tension between overall and subgroup accuracies, nor between different subgroup accuracies, and it enjoys provable convergence to either the Bayes optimal model or a state in which no further improvements can be found by the participants. I will discuss the algorithm's analysis, experimental evaluation, and findings from a preliminary bias bounty event.

2 Strategic Manipulation Disparities in Fair Classification

Vijay Keswani, Yale University, New Haven, CT, Contact: vijay.keswani@yale.edu

In real-world classification settings, individuals respond to classifier predictions by updating their features to increase their likelihood of receiving positive decisions (at a certain cost), for instance, by opening multiple credit lines to improve credit scores. Yet, these kinds of strategic manipulations favor historically-advantaged groups and provide relatively fewer opportunities for socioeconomic minorities. Fair classification aims to address such disparities by constraining the classifiers to satisfy statistical fairness properties. However, we find that standard fair classifiers do not always eliminate strategic manipulation disparities. Addressing such biases requires novel analyses of connections between strategic cost functions and standard fairness metrics, and is necessary to construct models that provide equal opportunities.

3 Feamoe: Fair, Explainable, and Adaptive Mixture of Experts

Shubham Sharma[1,2], [1]University of Texas at Austin, Austin, TX, [2]University of Texas at Austin, Austin, TX, Contact: shubham_sharma@utexas.edu

Three key properties that are desired of trustworthy machine learning models deployed in high-stakes environments are fairness, explainability, and an ability to account for drift. While drift with respect to the accuracy of a model has been widely investigated, drift in regard to fairness metrics remains largely unexplored. We propose FEAMOE, a mixture of experts framework aimed at learning fairer, more interpretable models that can also rapidly adjust to drifts in both the accuracy and fairness of a classifier. We illustrate our framework for three popular fairness measures and demonstrate how drift can be handled with respect to these fairness constraints, while producing a more interpretable model. We also show that models trained on the large-scale HMDA dataset demonstrate drift with respect to both accuracy and fairness, and show that FEAMOE can handle these drifts.

4 Fermi: Fair Empirical Risk Minimization Via Exponential Renyi Mutual Information

Sina Baharlouei, University of Southern California, Los Angeles, CA, Contact: baharlou@usc.edu

Despite the success of large-scale empirical risk minimization (ERM) at achieving high accuracy across a variety of machine learning tasks, fair ERM is hindered by the incompatibility of fairness constraints with stochastic optimization. In this talk, we propose fair empirical risk minimization via the exponential R\'enyi mutual information (FERMI) framework. FERMI is built on a stochastic estimator for exponential R\'enyi mutual information (ERMI), an information divergence measuring the degree of the dependence of predictions on sensitive attributes. Theoretically, we show that ERMI upper bounds existing popular fairness violation metrics, thus controlling ERMI provides guarantees on other commonly used violations. Empirically, we show that FERMI is amenable to large-scale problems with multiple (non-binary) sensitive attributes and non-binary targets.

Recent Advances in Distributionally Risk-Receptive and Risk-Averse Programs

General Session

Session Chair

Sumin Kang, Virginia Polytechnic Institute and State University, Blacksburg, VA

Session Chair

Manish Bansal, Virginia Tech., Blacksburg, VA

1 Solution Approaches for Distributionally Robust Mixed-integer Programs

Sumin Kang[1], Manish Bansal[2], [1]Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Virginia Tech., Blacksburg, VA, Contact: suminkang@vt.edu

We introduce cutting-planes based solution approaches for solving distributionally robust mixed-integer programs with general ambiguity sets. We also present results of our computational experiments to showcase the effectiveness of these approaches.

2 TTRrisk: Tensor Train Decomposition Algorithm for Risk Averse Optimization

Akwum Onwunta, Lehigh University, Bethlehem, PA, Contact: ako221@lehigh.edu

We present a new algorithm to solve high-dimensional risk-averse optimization problems governed by differential equations under uncertainty. We focus on Conditional Value at Risk (CVaR), but the approach is equally applicable to other coherent risk measures. The algorithm is based on low rank tensor approximations of random fields discretized using stochastic collocation. We propose an adaptive strategy to select the width parameter of smoothed CVaR to balance the smoothing and tensor approximation errors. Moreover, unbiased Monte Carlo CVaR estimate can be computed by using the smoothed CVaR as a control variate. We introduce an efficient preconditioner for the optimality system in a full space formulation. The numerical experiments demonstrate that the proposed method enables accurate CVaR optimization constrained by large-scale discretized systems.

3 Bayesian Decision Models for Adversarial Forecasting Under Incomplete Information and Uncertainty

Tahir Ekin[1], William Nicholas Caballero[2], Roi Naveiro[3], [1]Texas State University, San Marcos, TX, [2]US Air Force Academy, Colorado Springs, CO, [3]Institute of Mathematical Sciences (ICMAT-CSIC), Madrid, Spain. Contact: t_e18@txstate.edu

Forecasting methods typically assume clean and legitimate data streams. However, adversaries may attempt to influence data and alter forecasts, which in turn may impact decisions. This talk presents a Bayesian decision theoretic approach for adversarial forecasting. Proposed adversarial risk analysis based framework allows incomplete information and adversarial perturbations on the forecasting output. We solve the adversary's poisoning decision problem where he manipulates batch data being fed into forecasting methods. Adversarial autoregressive and hidden Markov models are demonstrated with examples using real world data. The findings show the vulnerability of forecasting models under adversarial activity. We discuss potential defender strategies to improve the security of existing decision frameworks that use forecasting method outputs.

4 Distributionally Risk-receptive and Risk-averse Network Interdiction Problems with General Ambiguity Set

Manish Bansal[1], Sumin Kang[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, Contact: bansal@vt.edu

We consider a distributionally risk-receptive network interdiction problem (DRR-NIP) where a leader maximizes a follower's minimal expected objective value for the best-case probability distribution belonging to a given set of distributions (referred to as ambiguity set). The DRR-NIP is applicable for network vulnerability analysis where a network user (or follower) seeks to identify vulnerabilities in the network against potential disruptions by an adversary (or leader) who is receptive to risk for improving the expected objective values. We present exact and approximation algorithms for solving DRR-NIP and distributionally robust NIP with a general ambiguity set. We also provide conditions for which these approaches are finitely convergent along with our computational results.

Applications and Theory of Robust and Stochastic Programs

General Session

Session Chair

Nan Jiang, Virginia Tech, Blacksburg, VA

Session Chair

Weijun Xie, Virginia Tech, Blacksburg, VA

1 The Analytics of Robust Satisficing

Melvyn Sim[1], Qinshen Tang[2], Minglong Zhou[1], Taozeng Zhu[3], [1]National University of Singapore, Singapore, Singapore; [2]Nanyang Techonological University, Singapore, Singapore; [3]Institute of Supply Chain Analytics, Dongbei University of Finance and Economics,, Dalian, China. Contact: qinshen.tang@ntu.edu.sg

We propose a new prescriptive analytics model based on robust satisficing that incorporates a prediction model to determine the here-and-now decision that would achieve a target expected reward as well as possible under both risk ambiguity and estimation uncertainty. The reward function of the decision model depends on some observable parameters whose future realizations are uncertain, and their outcomes may be influenced by some observable factors or the decision made. We feature two applications and use real data in their case studies and elucidate the benefits of our robust satisficing model over the predict-then-optimize approach; when evaluated on the true distribution, the robust satisficing models yield solutions with lower risks, and with suitably chosen targets, they could also achieve higher expected reward.

2 Data-driven Distributionally Robust Optimization with Multiple Datasets: Applications to The Optimal Power Flow Problem

Adrián Esteban-Pérez[1], Yves Rychener[2], Juan M. Morales[1], Daniel Kuhn[3], [1]University of Málaga, Malaga, Spain; [2]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland; [3]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland, Switzerland. Contact: adrianesteban@uma.es

We study data-driven distributionally robust optimization (DRO) problems where multiple datasets are available to the decision maker. Under standard assumptions on the cost function, we show that these problems can be reformulated as convex optimization problems in a DRO framework. We argue that these reformulations are useful in the Optimal Power Flow problem under ambiguity about the probability distribution of the wind power forecast error.

3 Two-stage Stochastic Program with Mixed Integer Recourse for Relay-based Network Design

Onkar Kulkarni, Mathieu Dahan, Benoit Montreuil, ISyE Georgia Tech, Atlanta, GA, Contact: onkar.kulkarni@gatech.edu

In this work, we study a two-stage stochastic program to design relay-based transportation networks. We position and size relay hubs in the first stage, while we schedule trucks for transporting commodities upon realization of commodity demand uncertainty in the second stage. Due to commodity consolidation considerations, the second stage contains integer decision variables, which makes the problem challenging to solve. To alleviate the issue, we propose algorithm(s) based on Benders-decomposition to provide good quality solutions. In order to test our approach, we apply the developed methodology to design a relay-hub network for a major car manufacturing company to be used for car deliveries.

4 An Active-set Method for Two-stage Stochastic Quadratic Programming

Niloofar Fadavi, Harsha Gangammanavar, Southern Methodist University, Dallas, TX

In this talk, we examine two-stage stochastic quadratic programming problems. The first and second stage problems are convex programs with quadratic objective functions and affine constraints. We model the uncertainty that affects the right-hand sides and variable bounds in the second stage using random variables with finite support. We provide exact and inexact proximal bundle algorithms to deal with these problems. In the inexact variation of the algorithm, we use approximate second-stage solutions to alleviate the computational difficulties associated with the exact approach. Using the relationship between the partitions generated from a primal-dual active-set method and observations of random variables, we compute approximate solutions by solving (reduced) linear systems. We present the convergence and numerical analysis of these algorithms.

Shreyas Subramanian, Amazon Web Services, Herndon, VA

1 **Using Genetic Algorithms to Optimize Scheduling**
Greg Sommerville, AWS, New York, NY
Genetic algorithms are an efficient way to find optimal solutions within a large solution space. GAs use concepts from nature like genetic crossover, genetic mutation, and survival of the fittest to evolve a solution to a problem. In this talk, we'll introduce genetic algorithms, discuss how they work, and apply them to solve an example scheduling problem that runs with AWS SageMaker.

2 **Optimization of Robot Trajectory Planning with Nature-inspired Algorithms**
Martin Schuetz[1], Kyle Brubaker[1], Mauricio C. Resende[2], Helmut Katzgraber[3], [1]Amazon, Bellevue, WA, [2]Amazon.com, Inc., Bellevue, WA, [3]Amazon Web Services, Kirkland, WA
We solve robot trajectory planning problems at industry-relevant scales. Our end-to-end solution integrates highly versatile random-key algorithms with model stacking and ensemble techniques, as well as path relinking for solution refinement. Through a distinct separation of problem-independent and problem-dependent modules, we achieve an efficient problem representation, with a native encoding of constraints. The core optimization module consists of a biased random-key genetic algorithm. We show that generalizations to alternative algorithmic paradigms such as dual annealing are straightforward. We provide numerical benchmark results for industry-scale data sets. Our approach is found to consistently outperform greedy baseline results.

3 **Efficient Global Optimization Algorithm Using Neural Network-based Prediction and Uncertainty**
Laurel Barnet[1], Leifur Leifsson[2], Kenneth Bryden[1], [1]Iowa State University, Ames, IA, [2]Purdue University, West Lafayette, IN, Contact: labarnet@iastate.edu
Surrogates are important for global modeling and search in large engineering and science data sets. The efficient global optimization (EGO) algorithm uses the surrogate uncertainty estimator to guide the selection of the next sampling point. Gaussian process regression (or Kriging) provides an uncertainty estimate and is widely used in EGO or EGO-like algorithms. Here, an EGO-like algorithm, called the efficient global optimization with neural network-based prediction and uncertainty (EGONN), is described which uses two neural networks, one for prediction and the other modeling the prediction uncertainty. Given a set of initial data, one for each neural network, the algorithm proceeds in cycles and selects the next sampling point based on the expected improvement. EGONN is demonstrated on analytical functions and physics-based problems.

4 **How to Optimize for Emerging Mobility Solutions at Scale?**
Apoorv Maheshwari, Ernst & Young, Glenmont, NY
Several emerging mobility concepts such as flying cars, autonomous vehicles, and electric vehicles, are envisioned to be ubiquitous in future mobility ecosystem. Realizing the vision of large-scale adoption requires efficiently solving complex optimization problems, for example, placement of EV charging stations. These optimization formulations need not only account for a diverse set of data layers but also need to have somewhat explainable solutions to inform policy decisions. Additionally, given the wider applicability, the framework needs to be scalable. In this presentation, we will discuss application of a scalable optimization framework to some of these emerging transportation problems.

1 Improving QAOa with Various Warm-Start Strategies

Bryan Gard[1], Swati Gupta[2], Creston Herold[1], Greg Mohler[1], Jai Moondra[3], Reuben Tate[3], [1]Georgia Tech Research Institute, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, [3]Georgia Institute of Technology, Atlanta, GA, Contact: rtate30@gatech.edu

We discuss a warm-started variant of Quantum Approximate Optimization Algorithm (QAOA), i.e., the initial quantum state is an arbitrary separable state. In addition to changing the initial state, we change the mixing Hamiltonian in a way that aligns with adiabatic principles. Experiments suggest that even at low circuit depth, this approach is robust against noise and yields superior cuts compared to Goemans-Williamson and standard QAOA. This talk is joint work with Bryan Gard, Swati Gupta, Creston Herold, Greg Mohler, and Jai Moondra.

2 Error Mitigation for Quantum Optimization by Leveraging Problem Symmetries

Ruslan Shaydulin, JPMorgan Chase & Co., New York, NY

Hardware errors are the central obstacle to the success of the Quantum Approximate Optimization Algorithm (QAOA). We introduce an application-specific approach for mitigating the errors in QAOA evolution by performing parity checks that leverage the symmetries of the objective function to be optimized. We develop a theoretical framework for analyzing this approach under local noise and derive explicit formulas for fidelity improvements on problems with global $_2$ symmetry. We numerically investigate the symmetry verification on the MaxCut problem and identify the error regimes in which this approach improves the QAOA objective, which align well with the error rates present in near-term hardware. We further demonstrate the efficacy of symmetry verification on an IonQ trapped ion and IBM Quantum superconducting quantum processors.

3 How to Improve The Performance of The QAOA

Ramin Fakhimi[1], Hamidreza Validi[2], Illya V. Hicks[2], Tamás Terlaky[1], Luis F. Zuluaga[1], [1]Lehigh University, Bethlehem, PA, [2]Rice University, Houston, TX, Contact: raf318@lehigh.edu

QAOA is one of the promising quantum algorithms for solving combinatorial optimization problems. We investigate different derivative-free optimization algorithms for finding optimal parameters. We also examine the impact of quadratic unconstrained binary optimization (QUBO) models on the associated QAOA in this study. Notably, we explore the effect of the penalty coefficients. We propose two QUBO models with tight penalty coefficients for the max k-cut problem. We show how different models affect the quality of solutions concerning the feasibility and the objective value. For at least 60% of test instances, the computational experiments show the superiority of the tight models over naive ones in terms of the quality of feasible solutions. Finally, we investigate how tight penalty coefficients can mitigate the effect of intrinsic noise of quantum computers.

4 Solving The Semidefinite Relaxation of QUBOs in Matrix Multiplication Time, and Faster with a Quantum Computer

Brandon Augustino, Lehigh University, Landing, NJ

Recent works on quantum algorithms for solving semidefinite optimization problems have leveraged a quantum-mechanical interpretation of positive semidefinite matrices to obtain quantum speedups with respect to the dimension n and sparsity measure s. While their dependence on other parameters suggests no overall speedup, some quantum SDO solvers provide speedups in the low-precision regime. We present an iterative refinement scheme for the Hamiltonian Updates algorithm of Brandão et al. (Quantum 6, 625 (2022)) to exponentially improve the dependence of their algorithm on precision. As a result, we obtain a classical algorithm to solve the semidefinite relaxation of Quadratically Unconstrained Binary Optimization problems in matrix multiplication time, and in time $\tilde{\Ocal} (n^{1.5} s^{0.5 + o(1)})$ with a quantum computer.

1 Non-convex Optimization in Unsupervised Learning

Kaizheng Wang, Columbia University, New York, NY

This talk concerns non-convex optimization in unsupervised learning.

2 Comparing Solution Paths of Sparse Quadratic Minimization with a Stieltjes Matrix

Ziyu He[1], Shaoning Han[2], Andres Gomez[2], YING CUI[3], Jong-Shi Pang[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, [3]University of Minnesota, Minneapolis, MN, Contact: ziyuhe@usc.edu

This paper studies several solution paths of sparse quadratic minimization problems as a function of the weighing parameter of sparse regularizer. Three such paths are considered: the “ℓ_0-path” which is exact but computationally expensive; the “ℓ_1-path” where the ℓ_1-function provides a convex surrogate; and the “capped ℓ_1-path” where the capped ℓ_1-function aims to enhance the convex approximation. Our study of the capped ℓ_1-path is the first of its kind as the path pertains to computable directionally stationary solutions of a parametric nonconvex nondifferentiable problem. A major conclusion of this paper is that a capped ℓ_1 directional stationary path offers interesting theoretical properties and practical compromise between the ℓ_0 and the ℓ_1-paths.

3 Presenter

Rahul Mazumder, Massachusetts Institute of Technology, Cambridge, MA

4 Rational Generalized Nash Equilibrium Problems

Jiawang Nie[1], Xindong Tang[2], Suhan Zhong[1], [1]UCSD, San Diego, CA, [2]The Hong Kong Polytechnic University, Hong Kong, Hong Kong.

This talk discusses generalized Nash equilibrium problems that are given by rational functions. Rational expressions for Lagrange multipliers and feasible extensions of KKT points are introduced to compute generalized Nash equilibria (GNEs). We give a hierarchy of rational optimization problems to solve rational generalized Nash equilibrium problems. The existence and computation of feasible extensions are studied. The Moment-SOS relaxations are applied to solve the rational optimization problems. Under some general assumptions, we show that the proposed hierarchy can compute a GNE if it exists or detect its nonexistence. Numerical experiments are given to show the efficiency of the proposed method.

1 Continuous-time Analysis of AGM Via Conservation Laws in Dilated Coordinate Systems

Jaewook J. Suh, Gyumin Roh, Ernest Ryu, Seoul National University, Department of Mathematical Sciences, Seoul, Korea, Republic of. Contact: jacksuhkr@snu.ac.kr

We analyze continuous-time models of accelerated gradient methods through deriving conservation laws in dilated coordinate systems. Namely, instead of analyzing the dynamics of $X(t)$, we analyze the dynamics of $W(t)=t^\alpha(X(t)-X_c)$ for some α and X_c and derive a conserved quantity in this dilated coordinate system. Through this methodology, we recover many known continuous-time analyses in a streamlined manner and obtain novel continuous-time analyses for OGM-G, an acceleration mechanism for efficiently reducing gradient magnitude that is distinct from that of Nesterov. Finally, we show that a semi-second-order symplectic Euler discretization in the dilated coordinate system leads to an $\mathcal{O}(1/k^2)$ rate on the standard setup of smooth convex minimization, without any further assumptions such as infinite differentiability.

2 An ADMM-Based Interior-Point Method for Conic Optimization

Joachim Dahl, Cardinal Operations, Denmark.

We consider an ADMM-based interior-point method conic optimization. We consider both symmetric and non-symmetric cones, and we give preliminary computational results for a selection of large-scale problems.

3 From An Interior Point to a Corner Point: Smart Crossover

Chengwenjian Wang, ETH Zurich, Zurich, Switzerland.

The crossover in solving linear programs is a procedure to recover an optimal corner/extreme point from an approximately optimal inner point generated by classical interior-point methods or emerging first-order methods. Unfortunately, the computation time of this procedure can be much longer than the time of the former stage. Our work shows that this bottleneck can be significantly improved if the procedure smartly takes advantage of the problem characteristics and implements customized strategies. Specifically, we design smart crossover algorithms for the problem with the network structure and the problem with a large optimal face. The comparison experiments with state-of-art commercial LP solvers on classical linear programming problem benchmarks, network flow problem benchmarks, and MINST datasets exhibit their considerable advantages in practice.

4 DRSOM: A Dimension-Reduced Second-Order Method

Chuwen Zhang, Shanghai University of Finance and Economics, Shanghai, China. Contact: chuwen@shanshu.ai

We introduce a Dimension-Reduced Second-Order Method (DRSOM) for convex and nonconvex unconstrained optimization. Under a trust-region-like framework our method preserves the convergence of the second-order method while only using Hessian-vector products in two directions. Moreover, the computational overhead remains comparable to the gradient descent method. We show that the method has a complexity of $O(\square^{-3/2})$ to satisfy the first-order and second-order conditions in the subspace. The applicability of DRSOM is exhibited by various computational experiments in logistic regression, L_2-L_p minimization, sensor network localization, and neural networks. For neural networks, our method gains computational advantages in terms of iteration complexity over state-of-the-art first-order stochastic methods, such as ADAM.

1 Using Weighted Behavioral Co-expression Networks for Deception Detection

Xinran Wang[1], Steven Pentland[2], [1]University of Arizona, Tucson, AZ, [2]Boise State University, Boise, ID, Contact: xinranwang@arizona.edu

Human behavior involves the simultaneous coordination of multiple channels (e.g., face, voice). Most deception research treats these separately, failing to capture the interactions between channels. We view the human body as a coordinated system and apply network science methodologies to deception detection tasks. Specifically, we construct weighted behavioral co-expression networks (CoNets) which represent patterns of correlation among nonverbal behaviors. We test the hypothesis that deceivers and truthtellers differ in their behavioral coordination and that these differences manifest as different network properties. We employ node embeddings to represent CoNets for predicting deception. Preliminary results show that deception detection performance using CoNets node embeddings outperforms methods that aggregate features independently.

2 Distributed and Asynchronous Multi-task Learning

Lingzhou Hong, Alfredo Garcia, Texas A&M University, College Station, TX

The ever-growing size and complexity of data create scalability challenges for storage and processing. In certain application domains, data streams are spatially distributed and their underlying models are not necessarily the same. We consider a distributed asynchronous Multi-Task Learning scheme that accounts for heterogeneous and correlated data streams. We assume that nodes can be partitioned into groups corresponding to different learning tasks and are connected in a directed network. Each node estimates a linear model asynchronously and is subject to local (within-group) regularization and global (across groups) regularization terms targeting noise reduction and generalization performance improvement. We provide a finite-time characterization of convergence and illustrate the scheme's general applicability in real-world examples.

3 Design and Operations for Complex Site Product Network Integration Under Uncertainty

Yixin Ye[1], Lingxun Kong[1], Scott Bury[2], [1]The Dow Chemical Company, Lake Jackson, TX, [2]The Dow Chemical Company, Midland, MI, Contact: lkong1@dow.com

Unplanned events, such as equipment failures or raw material shortages, are major challenges faced by highly integrated chemical manufacturing sites due to the large number of critical points and the propagation effect on the manufacturing network. At Dow, we built a web-based application to provide algorithmic traversing of such manufacturing network graphs for impact analyses of the unplanned events. In addition, a MILP model was developed to generate optimal inventory reallocation solutions. With minimal adaption effort, this app also allows decision makers to proactively study the impact of planned events (e.g., maintenance) and adjust inventory and production plans. On the design level, we use an AI agent-based approach to establish a bottleneck identification procedure for the site considering asset reliability as well as supply/demand scenarios.

Kayhan Behdin, Massachusetts Institute of Technology, Cambridge, MA

1 Rank-Constrained Optimization Problem

Yongchun Li, Weijun Xie, Virginia Tech, Blacksburg, VA, Contact: liyc@vt.edu

We study the rank-constrained convex optimization problem. We prove necessary and sufficient conditions under which a convex relaxation is equal to the convex hull of the feasible region.

2 PARS-Push: Personalized, Asynchronous and Robust Decentralized Optimization

Mohammad Taha Toghani[1], Soomin Lee[2], Cesar A. A. Uribe[3], [1]Rice University, Houston, TX, [2]Yahoo! Research, Sunnyvale, CA, [3]Rice University, Houston, TX, Contact: mttoghani@rice.edu

We study the multi-step Model-Agnostic Meta-Learning (MAML) framework where a group of n agents seeks to find a common point that enables "few-shot" learning (personalization) via local stochastic gradient steps on their local functions. We formulate the personalized optimization problem under the MAML framework and propose PARS-Push, a decentralized asynchronous algorithm robust to message failures, communication delays, and directed message sharing. We characterize the convergence rate of PARS-Push for smooth and strongly convex and smooth and non-convex functions under arbitrary multi-step personalization. Moreover, we provide numerical experiments showing its performance under heterogeneous data setups.

3 Integer Programming for Subspace Clustering with Missing Data

Akhilesh Soni, Jeff T. Linderoth, Jim R. Luedtke, Daniel Pimentel Alarcon, University of Wisconsin-Madison, Madison, WI, Contact: soni6@wisc.edu

In the Subspace Clustering with Missing Data (SCMD) problem, we are given a collection of points where each of the points is observed partially, and the points are assumed to lie in the union of a small number of low-dimensional subspaces. The goal is to identify clusters of vectors belonging to the same subspace and learn the corresponding basis.
We propose a mixed-integer nonlinear programming framework that is based on dynamically determining a set of candidate subspaces and optimally assigning points to selected subspaces. We propose a Benders' decomposition approach for solving the LP relaxation and integrate it with a column-generation approach for generating new subspaces. An empirical study shows that our framework achieves better clustering accuracy than state-of-the-art methods when the data is high rank or the percentage of missing data is high.

4 On Distributed Exact Sparse Linear Regression over Networks

Tu Nguyen[1], Cesar A. Uribe[2], [1]Rice University, Houston, TX, [2]Rice University, Houston, TX, Contact: tan5@rice.edu

In this work, we propose an algorithm for solving exact sparse linear regression problems over a network in a distributed manner. Particularly, we consider the problem where data is stored among different computers or agents that seek to collaboratively find a common regressor with a specified sparsity k. The main novelty in our proposal lies in showing a problem formulation with zero duality gap for which we adopt a dual approach to solve the problem in a decentralized way. This sets a foundational approach for the study of distributed optimization with explicit sparsity constraints. We show theoretically and empirically that, under appropriate assumptions, where each agent solves smaller and local integer programming problems, all agents will eventually reach a consensus on a sparse optimal regressor.

1 Dynamic Pricing Under a Ridesharing Network: A Tighter Upper Bound than Fluid Approximation

Yiming Jiang[1,2], [12]Georgia Institute of Technology, Atlanta, GA

Motivated by ridesharing platforms like Uber, we study dynamic pricing problem under a closed queuing network. Due to the exponentially large state space, fluid approximation was proposed to deal with the computational intractability. Different from fluid approximation which generates static pricing policy, we propose a dynamic pricing policy which utilizes both the information from origin and destination in each trip. We prove that our model yields a tighter upper bound than fluid approximation. And the gap between these two upper bounds is provided. Moreover, we demonstrate how to use value function approximation to reduce problem size. Computational experiments with synthetic data show that our dynamic pricing policy outperforms static policy generated by fluid approximation.

2 Gamifying Learning in Mathematical Optimization: The Burrito Optimization Game

Lawrence V. Snyder, Lehigh University, Bethlehem, PA

The Gurobi Burrito Optimization Game is a new educational game designed to introduce learners to the power of optimization. Players choose locations for burrito trucks on a city map to maximize their revenue. The free web-based game can be used in OR, data science, or other courses, or as a standalone app. The game teaches users why optimization is valuable and important, why it's difficult, and why solvers and other optimization algorithms are. In this talk, I will introduce the game and discuss learning outcomes that can emerge, including teachable moments such as the tradeoff between fixed costs and variable revenues, directional changes in the optimal solution as the data change, and why enumeration is not a practical approach.

3 Two-echelon Prize-collecting Vehicle Routing with Time Windows and Vehicle Synchronization: A Branch-and-price Approach

I. Edhem SAKARYA[1], Milad Elyasi[2], Sonja Rohmer[3], Örsan Özener[2], Ali Ekici[2], Tom Van Woensel[4], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Ozyegin University, Istanbul, Turkey; [3]HEC Montreal, Montreal, QC, Canada; [4]Eindhoven University of Technology, Mb Eindhoven, Netherlands. Contact: i.e.sakarya@tue.nl

Traffic congestion and air and noise pollution in urban areas are aggravating due to the increasing rate of urbanization and the resulting tendency toward utilizing e-commerce in grocery delivery in cities. Adverse health effects linked to this pollution demand the implementation of appropriate countermeasures that reduce the number of vehicles and mitigate the environmental impact of logistics within cities. One possible solution is the use of cargo bikes and large vehicles simultaneously. An integrated planning approach presents opportunities by allowing to replenish the cargo bikes from the inventory of the larger-sized vehicles without having to return to a depot location. In this context, we propose a branch-and-price algorithm to solve 2E-PC-VRP with Time Windows and Vehicle Synchronization and obtain promising results in comprehensive numerical studies.

4 Courier Coordination Policies for Crowdsourced Delivery with a Hybrid Fleet of Couriers

Adam Behrendt, Georgia Tech, Atlanta, GA

Crowdsourced delivery platforms operate as an intermediary between consumers who place orders and couriers who make deliveries; both of which are uncertain. Crowdsourced delivery platforms have begun to utilize multiple courier types (i.e., a hybrid system) with the hope of reaping the advantages of each. In this paper, we address the challenge of managing two types of couriers at both the planning and operational level. We present fluid models for fleet sizing and order pricing that establish the superiority of a hybrid system over each system individually. Furthermore, we study order allocation policies between the two systems and study order pooling and splitting policies in depth. In our online experiments we find that a look ahead splitting policy outperforms pooling and batching policies by 2.4% while being more robust uncertainty.

1 EVALUATING PEAK VOLUME RECOVERy in HUMP YARDs with ANYLOGIC SIMULATION

Jiaxi Zhao[1], Tyler Dick[2], [1]University of Illinois at Urbana Champaign, Urbana, IL, [2]U of Illinois at Urbana-Champaign, Urbana, IL, Contact: jiaxiz3@illinois.edu

As freight transportation demand continues to increase worldwide, great stress has been given to the classification yards to ensure accurate and efficient operations to sort freight to their destinations. Seasonal and unplanned surges in freight demand and disruptions from incidents and maintenance activities add to congestion in yards and even affect the mainline network. Quantifying the influence and recovery patterns of peak demands has been challenging due to the limitation to implement experiments in the field. This research developed a novel hump yard simulation model using AnyLogic software and conducted various experiments to study the impact of the extents of volume increment and the duration of volume peak on the recovery pattern of hump yards in terms of the change in railcar average dwell time.

2 ANALYTICAL MODELs on YARD CAPACITY

V. Varadarajan, Norfolk Southern, Suwanee, GA

A review of analytical models on yard capacity will be presented and potential variations will be discussed along with the insight we gain for congestion modeling using analytical approaches.

3 An Integrated Approach for Social Distancing and Revenue Optimization in Long Distance Passenger Trains

MD Tabish Haque, Faiz Hamid, Indian Institute of Technology Kanpur, Kanpur, India. Contact: tabish@iitk.ac.in

The present study aims to develop an integrated model that minimizes the spread of COVID-19 through multi-dimensional social distancing rules and maximizes train operator revenue via a quantity-based revenue strategy in a post-pandemic world. The seating plan incorporates a group seat reservation policy where social distancing rules are relaxed within the same group. This is due to a shallow risk of virus spread within a group and increased capacity utilization. A mixed-integer linear program (MILP) is proposed to build a seating plan. Several classes of valid inequalities are also employed to strengthen the MILP model. The validity of the model and the efficacy of valid inequalities have been tested on real-life instances. The computational results illustrate a significant improvement in both the objectives compared to the present practice observed by operators.

4 Tools for Predicting Decarbonization Impacts for the Rail Freight Industry

George F. List, NC State, Raleigh, NC

Identifying low cost decarbonization pathways for the rail freight industry is critical to achieve goals of net zero carbon emissions. The industry is a major consumer of diesel fuel. However, freight railroad operations are complex, the power demands are significant for individual trains, and the distances between refueling locations are long. For technologies like battery power and hydrogen fuel cells, there are also challenges about tying recharging stations to the power distribution grid. This presentation describes a set of tools being developed to allow analysts to explore ways in which the rail freight industry's use of diesel fuel can be reduced or eliminated. Included are modules for identifying decarbonization pathways, future rail freight demand, energy consumption by national region, supporting recharging technology, interfaces with the power grid, and costs.

1 Learning The Max Pressure Control for Urban Traffic Networks Considering The Phase Switching Loss

Xingmin Wang[1], Yafeng Yin[1], Yiheng Feng[2], Henry Liu[3], [1]University of Michigan, Ann Arbor, MI, [2]Purdue University, West Lafayette, IN, [3]University of Michigan, Ann, MI, Contact: xingminw@umich.edu

This work proposes a novel framework that utilizes reinforcement learning algorithms to optimize a max pressure controller considering the phase switching loss. We extend the max pressure control by introducing a switching curve and prove that the proposed control method is throughput-optimal in a store-and-forward network. Then the theoretical control policy is extended by using a distributed approximation and position-weighted pressure so that the policy-gradient reinforcement learning algorithms can be utilized to optimize the parameters in the policy network. The proposed framework combines the strengths of the data-driven method and the theoretical control model; it is also of great significance for real-world implementations because the proposed control policy can be generated in a distributed fashion based on local observations.

2 Cvlight: Decentralized Learning for Adaptive Traffic Signal Control with Connected Vehicles

Wangzhi Li[1], Zhaobin Mo[2], Yongjie Fu[3], Kangrui Ruan[2], Sharon Di[2], [1]Purdue University, West Lafayette, IN, [2]Columbia University, New York, NY, [3]Columbia University, New york, NY, Contact: li4444@purdue.edu

This paper develops a decentralized reinforcement learning (RL) scheme for multi-intersection adaptive traffic signal control (TSC), called "CVLight", that leverages data collected from connected vehicles (CVs). A novel algorithm, Asymmetric Advantage Actor-critic (Asym-A2C), is proposed where both CV and non-CV information is used to train the critic network, while only CV information is used to execute optimal signal timing. Experiments show the superiority of CVLight over state-of-the-art algorithms under a 2-by-2 synthetic road network with various traffic demand patterns and penetration rates. A case study further demonstrated the effectiveness of CVLight under real-world scenarios. Compared to other baseline models, the trained CVLight agent can efficiently control multiple intersections solely based on CV data and achieve the best performance.

3 Real-time Network-level Signal and Trajectory Optimization in Mixed-autonomy Environments

Ali Hajbabaie, Ramin Niroumand, Leila Hajibabai, North Carolina State University, Raleigh, NC

This study develops a real-time framework for the network-level integrated signal and trajectory optimization in mixed autonomy environments. The network-level problem is decomposed into intersection-level sub-problems and embedded into a coordination scheme via information exchange to push the intersection-level solutions toward the network-level optima. Each intersection uses a bi-level architecture to solve the joint problem. An efficient shooting heuristic is developed to optimize the trajectories of connected-automated vehicles (CAVs) while the trajectories of connected human-driven vehicles (CHVs) are estimated using a customized car-following model with a given set of signal timing plans in the lower level. The upper level enumerates all the feasible signal timing plans and selects the one with the best objective function to be implemented.

1 The Hidden Costs of Not-so-friendly Ghost Lanes

Angela Acocella, Tilburg University, Tilburg, Netherlands. Contact: a.j.acocella@tilburguniversity.edu

Shippers' procurement of truckload transportation is a costly process. Shippers adopt a coverage strategy to secure contracted capacity upfront to reduce potential administrative and search costs later on if and when volume materializes. However, this strategy leads to unnecessary costs and inefficiencies when lanes are procured that do not end up being used. In fact, 70% of shippers' procured lanes are never utilized. These ghost lanes cause network imbalances for carriers. Using a large transaction dataset, we demonstrate that a high rate of ghosting from a shipper in one year contributes to a carrier inflating contract prices the following year for that shipper. We characterize lanes most likely to be ghosted before they occur, demonstrate how these potential ghost lanes tend to underperform, and show ways to reduce the rate - and negative effects - of ghosting.

2 A Statistical Approach for Design of a New Facility Based on Horizontal Collaboration

Dilhani Shalika Marasinghe, Clemson University, Clemson, SC, Contact: dmarasi@g.clemson.edu

This study presents a new type of facility in a future logistics system based on horizontal collaboration. These facilities organize and reroute pallets or similar-sized containers. Freight rerouting decisions are made dynamically based on last-minute information about inbound pallets, and limited storage is available in the facility to temporarily store a few pallets. A pallet assignment model (PAM) is introduced to determine the decisions in a single period that minimizes the penalty. The model is then used to experimentally investigate the impact of the amount of storage. The number of pallets sent to storage across many scenarios is described by a Gamma - Poisson distribution. Further, an experimental approach is taken that centers on parameters critical to the design of these facilities. A factorial design was performed to determine the effect of design parameters.

3 The (s,m,S) Policy: Increasing Truck Efficiency Through Collaborative Shipping

Bram De Moor[1], Robert N. Boute[2,3,4], Stefan Creemers[5], [1]Netherlands; [2]KU Leuven, Leuven, Belgium; [3]Vlerick Business School, Leuven, Belgium; [4]Flanders Make, Leuven, Belgium; [5]IESEG School of Management, Lille, France.

Collaborative shipping can reduce truck usage in today's supply chains. To orchestrate collaborative shipping, ordering policies from the joint replenishment problem can be used. However, these policies often make abstraction of capacity constraints of the shared transport mode. In this paper, we propose a novel joint replenishment policy that takes capacity constraints into account: the *(s,m,S)* policy, with *(s,S)* the traditional reorder point and order-up-to level, and *m* the minimum order quantity for which a company is willing to join a replenishment. We develop an optimization procedure and benchmark our policy against other (capacitated) joint replenishment policies. Furthermore, we demonstrate how our policy can be used to engage with freight sharing platforms, on which companies are offered spare truck capacity at certain moments in time.

1 Device Targeting in Mobile Search Advertising

Sai Soundarya Gorthi[1], Kartik Ganju[2], Alain Pinsonneault[1], [1]McGill University, Montreal, QC, Canada; [2]University of Minnesota, Minneapolis, MN, Contact: sai.gorthi@mail.mcgill.ca

We examine if the paid information search results(ads) received on mobile devices are tailored to the model of the user device. We emulated different models of Apple mobile devices to collect the ads they receive for the search term "buy baby toys." Comparing the average first two and first three ad (maximum number of ads visible on a mobile screen) prices across the devices indicates that the latest models of mobile devices have a significantly higher average ad price compared to older models. Our preliminary analysis also indicates that the latest model receives ads of a higher price more frequently than older models. Our results show that targeting is possible without socio-demographic data about the user, calling into question the efficacy of recent regulations restricting targeting to advertisements based on user characteristics.

2 An Unintended Consequence of Platform Dependence: Empirical Evidence from IT-enabled Food-delivery Platforms

Varun Karamshetty[1], Michael Freeman[2], Sameer Hasija[2], [1]National University of Singapore, Singapore, Singapore; [2]INSEAD, Singapore, Singapore. Contact: varun.karamshetty@nus.edu.sg

Digital food-delivery platforms increase restaurants' catchment area and reduce search costs for customers. Larger catchment area allows restaurants to pool their risks and decreases noise in demand, whereas reduced search costs increases competition and noise. Overall, it is unclear how these competing factors affect restaurants' ability to forecast demand - a critical factor for operational efficiency and profitability. We empirically investigate the impact of food-delivery platforms on demand forecast error in restaurants. We find that a 10 percentage point increase in dependence on delivery platforms leads to a 2.83% increase in overall forecast error. We also find that the majority of increase is due to increase in the error associated with forecasting intra-day demand pattern, and a smaller portion is due to error in forecasting inter-day demand amplitude.

3 Ways to Have Successful Self-improvement Activities: An Empirical Study of Reminder Effects for Different Types of Procrastinators

Kyung Pyo Kang, Jaehong Park, Kyung Hee University, Seoul, Korea, Republic of. Contact: kpkang0646@khu.ac.kr

While many people have self-growth activities, not all people are equally motivated nor do they keep their goal commitment over time. For example, while some people routinely get involving their activities (i.e., non-procrastinators), other people tend to procrastinate their self-growth activities (i.e., procrastinators). To support people's goal achievements, previous studies have investigated various strategies (e.g., providing reminders). However, they overlooked the different effects of such strategies depending on the type of who you are. This study aims to reveal how differently reminders (push-alarm) affect people's goal achievements depending on whether the people procrastinate their activities or not. We expect this paper will expand the understanding of successful self-growth activities associated with people's behavior of procrastination.

4 Where Do You Want to Buy a Game Item? Empirical Study of The Price Fluctuation of a Game Item at Used Market

SeungMin Hong, GaHyeon Jeong, JaeHong Park, Kyung Hee University, Seoul, Korea, Republic of. Contact: seungmin.h9748@gmail.com

Online game users frequently make transactions in the RMT (Real Money Trading) market to strengthen their game characters easily instead of the in-game purchases. Weempirically examine how the shock from the game (e.g., the release of the game update patch) influences the price of game items traded at the RMT market using DID (Difference-In-Differences) methods. In particular, we classify items to the game item categories (e.g., weapons, armors, etc.) as the patch is often related to the game items such as the power balance of weapons. We initially found that the release of game patch raises the average item price at RMT market, and such effect varies depending on game item purposes. Thus, this study will contribute to the game item price design as this finding can provide an understanding of the role of the RMT market in the game economy.

1 AI vs. Human Buyers: A Study of Alibaba's Inventory Replenishment System

Jiaxi Liu[1], Shuyi Lin[1], Linwei Xin[2], Yidong Zhang[1], [1]Alibaba Group, Hangzhou, China; [2]University of Chicago, Chicago, IL

Inventory management is one of the most important components of Alibaba's business. Traditionally, human buyers make replenishment decisions: although AI algorithms make recommendations, human buyers can choose to ignore and make their own decisions. The company has been exploring a new replenishment system in which algorithmic recommendations are final. The algorithms combine state-of-the-art deep reinforcement learning techniques with the framework of fictitious play. By learning the supplier's behavior, we are able to address an important endogeneity issue of lead time and fill rate on order quantity, which has been ignored in the extant literature of stochastic inventory control. We present evidence that our algorithms outperform human buyers in terms of reducing out-of-stock rates and inventory levels. More interestingly, we have seen additional benefits amid the pandemic. Over the last two years, cities in China have (partially) intermittently locked down to mitigate COVID-19 outbreaks. We have observed panic buying from human buyers during lockdowns, leading to the bullwhip effect. By contrast, panic buying and the bullwhip effect can be mitigated under our algorithms, due to their ability to capture the change in the supplier's behavior during lockdowns.

2 Generalized Synthetic Control for TestOps at ABI: Models, Algorithms, and Infrastructure

Tianyi Peng[1], Foncea Patricio[1], Vivek Farias[2], Ivo Montenegro[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT, Cambridge, MA, [3]Portugal. Contact: tianyi@mit.edu

We describe a novel approach to learning from experiments in the world of physical retail, and an associated platform, TestOps, implemented by ABI and MIT. TestOps leverages a recent theoretical breakthrough to learn from experiments when treatment effects are small, the environment is noisy and non-stationary, and adherence problems are commonplace, resulting in ~100x increase of experimental power relative to alternatives. TestOps currently runs experiments impacting ~135M USD in revenue every month and routinely identifies interventions that result in a 1-2% increase in sales volume.

1 A Novel Mixed-integer Linear Programming Model for The Multi-mode Resource-constrained Project Scheduling Problem

Nicklas Klein, Department of Business Administration, Bern, Switzerland. Contact: nicklas.klein@unibe.ch

In many projects, there are tradeoffs between the resource requirements and durations of activities. These tradeoffs can be represented via multiple execution modes of the activities, which is considered in the multi-mode resource-constrained project scheduling problem (MRCPSP). Given are precedence-related activities whose durations and resource requirements depend on the chosen execution mode. Sought are the activities' start times and modes to minimize the project makespan. We present a novel MILP model that uses two kinds of sequencing variables to detect which activities are executed in parallel. A numerical comparison indicates that the novel model outperforms the state-of-the-art models on instances with relatively long activity durations.

2 Multi-site Project Scheduling Under Resource Constraints

Tamara Bigler, Mario Gnaegi, Norbert Trautmann, University of Bern, Bern, Switzerland. Contact: norbert.trautmann@unibe.ch

The execution of a project often requires resources which are distributed among multiple sites, and therefore transportation times must be considered for moving some mobile resource units or the output of some precedence-related activities. Example applications arise in hospital clusters that are sharing pools of medical personnel and medical devices, and in a make-to-order production that is carried out by several partners in a supply chain. We present a MILP-based approach for minimizing the duration of such a project subject to completion-start precedence and renewable-resource constraints.

3 Efficient Algorithms for Project Scheduling with Autonomous Learning

Alessandro Hill[1], Thomas Vossen[2], [1]California Polytechnic State University, San Luis Obispo, CA, [2]University of Colorado-Boulder, Boulder, CO, Contact: ahill29@calpoly.edu

We study a class of novel project scheduling problems that incorporate autonomous learning. In these models, certain jobs can be completed in a reduced amount of time if scheduled after jobs that lead to acquiring relevant experience. We consider single-and multi-predecessor learning and present corresponding learning mechanisms. We discuss the structure and complexity of these combinatorial problems and devise polynomial algorithms to solve them. In a computational analysis, we quantify the potential scheduling benefits that can be obtained when integrating learning compared to classical project scheduling.

4 Further Revisions to The Pert Model with Lognormal Activity Times

Eric Logan Huggins[1], Ivan G. Guardiola[2], [1]Fort Lewis College, Durango, CO, [2]Fort Lewis College, Durango, CO, Contact: huggins_e@fortlewis.edu

We consider the PERT model but with activity times that follow lognormal distributions rather than the traditional PERT-Beta distributions. The lognormal distribution has an infinite right tail which allows for activities to be delayed indefinitely, requiring the project planner to determine how confident they are when estimating pessimistic times. We develop a model for the project completion time using a single lognormal distribution using approximation methods. We also consider a Bayesian model for the project completion time that can be updated while the project is ongoing.

1 Data-driven Condition-based Maintenance for Perpetual Systems

Sandun Perera[1], Varun Gupta[2], Hongwei Long[3], Xiaohang Yue[4], [1]College of Business, University of Nevada, Reno, Reno, NV, [2]Penn State Erie, The Behrend College, Erie, PA, [3]Florida Atlantic University, Boca Raton, FL, [4]University of Wisconsin-Milwaukee, Milwaukee, WI

We consider an IOT-based smart system where the past performance of the system is monitored in real-time and is used to derive the operational control bands to optimize its performance over time. In particular, we show that the optimal maintenance policy for this smart system is to follow a “two-band control” on the current performance level. The smart system autonomously switches to a prearranged backup system when its performance is detected to be unacceptable (not in control) and immediately transmits an IoT-enabled Kanban signal to the maintenance crew. When the maintenance order is completed, the backup system switches back to the original system. This paper not only proves the optimal policy is a two-band control policy but also provides efficient ways to approximate the optimal policy as well as the underlying performance of the system.

2 Multi-product Dynamic Upgrades

Xiao Zhang, Saint Louis University, Saint Louis, MO

Upgrades in travel industry are often static and offered either at the booking time or at the check-in time. In this paper, we study dynamically offered upgrades by a multi-product firm via notifications (e.g., emails) between the booking and the check-in times.

Causal Inference
General Session

Session Chair
Christina Yu, [1]</sup

1 Network Interference in Micro-randomized Trials

Shuangning Li, Stanford University, Stanford, CA, Contact: lsn@stanford.edu

The micro-randomized trial (MRT) is an experimental design that can be used to develop optimal mobile health interventions. Often, mobile health interventions have a social media component; an individual’s outcome could thus depend on other individuals’ treatments and outcomes. In this paper, we study the micro-randomized trial in the presence of such interference. We model the interference with a network interference model. Assuming the dynamics can be represented as a Markov decision process, we analyze the behavior of the outcomes in large sample asymptotics and show that they converge to a mean-field limit when the sample size goes to infinity. We then give characterization results and estimation strategies for various causal estimands including the short-term direct effect of a binary intervention, its long-term direct effect and its long-term total effect.

2 Graph Agnostic Randomized Experimental Design Under Heterogeneous Network Interference

Christina Lee Yu, Cornell University, Ithaca, NY

Randomized experiments are widely used to estimate causal effects across many domains, however classical approaches to experimental design rely on critical independence assumptions that are violated by network interference. We consider heterogeneous linear and polynomial potential outcomes models for network interference, under which we propose simple estimators for the total treatment effect that output unbiased estimates with low variance under simple randomized designs. Our solution and statistical guarantees do not rely on restrictive network properties, allowing for highly connected graph structures. When the network is completely unknown, we provide a simple unbiased and efficient estimator under a staggered rollout randomized design, showing that the flexibility from additional measurements over time can relax requirements of network knowledge.

3 Counterfactual inference in sequential experimental design

Raaz Dwivedi, Harvard and MIT, Cambridge, MA

We consider the problem of counterfactual inference insequentially designed experiments wherein a collection of N units each undergoa sequence of interventions for T time periods, based on policies thatsequentially adapt over time. We introduce a suitable latent factor model wherethe potential outcomes are determined by exogenous unit and time level latentfactors. Under suitable conditions, we show that it is possible to estimate themissing (potential) outcomes using a simple variant of nearest neighbors.First, assuming a bilinear latent factor model and allowing for an arbitraryadaptive sampling policy, we establish a distribution-free non-asymptoticguarantee for estimating the missing outcome of any unit at any time; undersuitable regularity conditions, this guarantee implies that our estimator isconsistent. Second, for a generic non-parametric latent factor model, weestablish that the estimate for the missing outcome of any unit at time Tsatisfies a central limit theorem as T goes to infinity, under suitableregularity conditions. Finally, en route to establishing this central limit theorem,we prove a non-asymptotic mean-squared-error bound for the estimate of themissing outcome of any unit at time T. Our work extends the recently growingliterature on inference with adaptively collected data by allowing for policiesthat pool across units and also compliment the matrix completion literaturewhen the entries are revealed sequentially in an arbitrarily dependent mannerbased on prior observed data.

4 Time Series Versus Cross-Sectional Patterns in Panel Data

Dennis Shen, UC Berkeley, Berkeley, CA

A central goal in social science is to evaluate the causal effect of a policy. One dominant approach is through panel data analysis in which the behaviors of multiple units are observed over time. The information across time and space motivates two general methods: (i) horizontal regression (i.e., unconfounedness), which exploits time series patterns, and (ii) vertical regression (e.g., synthetic controls), which exploits cross-sectional patterns. Although conventional wisdom asserts that the two are fundamentally different, we prove that they yield numerically identical point estimates under several standard settings. Within this regime, we study properties of the estimator from three model-based perspectives with randomness stemming from (i) time series patterns, (ii) cross-sectional patterns, and (iii) both patterns. For each model, we construct corresponding confidence intervals that offer new approaches to inference. The juxtaposition of our results articulates how the choice of randomness relates to the estimand. We show that these insights carry over to the design-based framework as well.

Theory and Applications of Flexible Servers Systems

General Session

Session Chair

Yuan Zhong, 1</sup

1 Stability and Instability of Parameter Agnostic Policies in Parallel Server Systems

Gorkem Unlu, Yuan Zhong, Booth School of Business, Chicago, IL

We consider the X-Model parallel server system and examine its stability properties under parameter agnostic policies. Parameter agnostic policies are attractive because they require only the queue size information. However, they can lead to instability for relatively low system loads. For the X-Model system, we show that switching curve policies, where each server makes the service decision according to a non-decreasing function of queue sizes, can lead to instability. We conjecture that there does not exist a parameter agnostic policy that stabilizes all underloaded parallel server systems.

2 Detecting Service Rate Slowdown in Service Systems

Gal Mendelson, Stanford University, Palo Alto, CA, Contact: galmen@stanford.edu

In this talk I will discuss the interplay between control and statistical analysis in service systems. The choice of the control mechanism is key for obtaining desired performance, and fast, online detection of changes to system parameters such as servers' service rates is key to maintaining desired service quality and availability. I will demonstrate that the choice of control has a substantial impact on the nature of the data that is being generated and consequently changes how it should be used. I will discuss the limitations of using state data (e.g. queue lengths) for detection and present a new statistic, namely action data, and demonstrate that it can be very powerful. This is joint work with Kuang Xu (Stanford).

3 Parallel Server Systems Under An Extended Heavy Traffic Condition

Rami Atar[1], Eyal Castiel[2], Martin I. Reiman[3], [1]Technion, Haifa, Israel; [2]Georgia Tech, Atlanta, GA, [3]Columbia University, Maplewood, NJ, Contact: castieleyal@yahoo.fr

The goal of this presentation is to talk about recent developments in the heavy traffic analysis of parallel server systems. The typical asymptotically optimal policies require an assumption that a static resource allocation linear program has a unique solution giving only one reasonable resource allocation for the system controller. This solution determines the graph of basic activities, which identifies the set of activities that are used. This talk will outline the weakness of this assumption and how to get rid of it by focusing on the simplest non-trivial example. A policy is constructed and proved to be asymptotically optimal in a diffusion scaling. The design of the policy relies on the solution to a non-linear differential equation (HJB equation) and the scaling limit is a controlled diffusion process. Finally, we will see how to generalize this result

4 Size-based Scheduling in Many-server Queues with Impatient Customers and Noisy Service Time Estimates

Jing Dong[1], Rouba Ibrahim[2], [1]Columbia University, New York, NY, [2]University College London, London, United Kingdom.

Size-based scheduling policies, such as shortest-job-first (SJF), have been extensively studied, for decades, yet almost exclusively in single-server queues with infinitely patient jobs and under exact job-size information. Motivated by applications to service systems, we analyze the performance of size-based scheduling in multiserver queues with abandonment and inexact job-size information. We propose appropriate measures of job-size estimation noise and prove that noisy SJF maximizes, asymptotically, the system throughput. We also show that the noisy SJF queue is asymptotically equivalent to a two-class priority queue where customers with short predicted service times (below a threshold) are served without waiting, and customers with long predicted service times (above a threshold) abandon without service.

1 Ergodic Control of Bipartite Matching Queues with Class Change and Matching Failure

Xin Liu[1], Amin Khademi[2], [1]Amazon, Seattle, WA, [2]Clemson University, Clemson, SC, Contact: xinliu@alumni.unc.edu

We study a bipartite matching queue with multi-class customers and multi-type resources. Customers may change their classes or abandon the system while waiting in queue, and they may decline the offered resource units which results in matching failure. We are interested in designing efficient instantaneous matching policies that allocate resources upon arrival to waiting customers. Under a suitable stability condition, we construct a simple linear program (LP) which serves as a lower bound for the original stochastic control problem under any admissible policy. We then propose a randomized matching policy based on the solution of the LP and show that the proposed policy is asymptotically optimal under both the long-run average and ergodic cost criteria.

2 Dynamic Pricing, Matching and Empty Vehicle Relocation Policies in Ride-sourcing Systems

Mojtaba Abdolmaleki, Xiuli Chao, Tara Radvand, Yafeng Yin, University of Michigan, Ann Arbor, MI, Contact: mojtabaa@umich.edu

With the development of shared mobility there is a growing interest in design and optimization, such as pricing and empty vehicle relocation, to maximize system utility. Impatience of passengers during waiting is an important feature of such systems, but it has been neglected due to its complexities. We develop a provably near-optimal dynamic pricing and empty vehicle relocation policy for a ride-sourcing system with limited passenger patience. We solve three open questions: (i) the performance of our dynamic policy converges to that of the true optimal value exponentially fast in time when the market size is large; (ii) the passenger loss of our policy decreases to zero exponentially fast when demand size increases; and (iii) using empty vehicle relocation, our dynamic policy can balance supply utilization and customer waiting times under the Square Root Safety (SRS) rule.

3 Platform Competition in Two-sided Networks

John R. Birge[1], Emin Ozyoruk[2], [1]University of Chicago, Chicago, IL, [2]University of Chicago, CHICAGO, IL

Platforms for ridesharing, contract work, hospitality, entertainment, etc., involve network externalities in matching supply and demand. The form of the externalities has implications for competition among platforms and potential market segmentation. Understanding these interactions can inform market design and policies that encourage efficiency. In this study, we focus on ridesharing platform competition and propose a model for externality effects and equilibrium among platforms. After using queueing theory and heavy traffic approximations to derive the key performance metrics, we analyze relationships among geography, population density, and external market competition in the form of equilibria and overall efficiency.

4 Pricing in On-demand (and One-way) Vehicle Sharing Networks

Xiaobing Shen, Saif Benjaafar, University of Minnesota, Minneapolis, MN, Contact: shen0341@umn.edu

We consider the dynamic pricing problem that arises in the context of an on-demand vehicle sharing system with one-way trips. We provide an alternative approach to bounding the performance of static pricing policies. Our approach is startlingly simple, producing, upon the application of a well-known recursive relationship that relates system availability in a system with K vehicles to one with K-1 vehicles, a sequence of bounds that are increasingly tight. The worst of these bounds is given by K/(N + K - 1 + /μ), where is the total demand rate and 1/ μ is the average trip travel time, implying a convergence rate that is at least of order 1- O(1/K) in the number of vehicles for fixed /μ. The same recursive relationship can be used to obtain a bound that is independent of /μ given by 1-O(1/K^(1/2)).

Machine Learning for Quality Assurance and Decision-making

General Session

Session Chair

Yinan Wang, Virginia Tech, Blacksburg, VA

Session Chair

Wenbo Sun, University of Michigan Transportation Research Institute, Ann Arbor, MI

1 Online Monitoring of Heterogeneous Partially Observable Data Streams Based on Q-learning

Haoqian Li[1], Honghan Ye[2], Kaibo Liu[3], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Woodbury, MN, [3]UW-Madison, Madison, WI, Contact: hli788@wisc.edu

With the rapid advances in Internet of Things (IoT) technology and computational infrastructure, heterogeneous data streams are becoming common in various manufacturing applications. Meanwhile, the resource constraints often restrict the observability of data streams. In this article, diverging from conventional heuristic approaches, we propose a new algorithm based on Q-learning to monitor and quickly detect mean shifts occurring to heterogeneous data streams in the context of limited resources, where only a subset of observations is available at each acquisition time. In particular, we integrate Q-learning with a global threshold learned through a nonparametric cumulative sum (CUSUM) procedure to effectively detect a wide range of possible mean shifts when data streams follow arbitrary distributions.

2 A Bayesian Optimization Framework for Personalized System Design Based on Computer Experiments

Jiacheng Liu[1], Wenbo Sun[2], Jionghua Jin[3], Jingwen Hu[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Transportation Research Institute, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, Contact: liujc@umich.edu

It is increasingly important to consider human variation in optimizing a personalized system design based on individual characteristics. Most available optimization methods for personalized design are only developed for observational and fixed samples, and thus are not directly applicable to the computer-simulation-based optimal design that can sequentially add new computer simulation runs with a flexible selection of sample size and inputs. In this study, we proposed a new Bayesian-Optimization-based method that searches for the optimal personalized design policy to optimize the expected system responses over the whole population by sequentially introducing informative computer simulation runs. Both a numerical example and a case study on the vehicle restraint system will be presented to demonstrate the effectiveness and robustness of the proposed method.

3 Real-time Process Monitoring and Closed-loop Laser Power Control in Powder Bed Fusion

Rongxuan Wang, Blacksburg, VA

Laser powder bed fusion still suffers from the printing accuracy issue, especially for small features such as the tips of a turbocharger compressor. Heat accumulation is the main reason and results from using constant laser power. This work develops a closed-loop control system to regulate the laser power based on real-time thermal monitoring. The desired control target is found by correlating the printing error with the thermal signatures from a set of thin line printing trails. The control system is built upon a self-designed multi-sensing laser powder bed fusion platform. The result shows the laser power can be successfully controlled with 2 kHz, and a significant improvement in small feature printing accuracy has been observed by both microscopic imaging and 3D scanning. The controller can also prevent the lack of fusion and swelling problems due to improper power input.

4 Transfer Learning for Predictive Quality in Laser-based Micro-machining

Mengfei Chen, Weihong Guo, Rutgers, The State University of New Jersey, Piscataway, NJ, Contact: wg152@rutgers.edu

Machine learning methods are increasingly used to provide unprecedented opportunities towards smart manufacturing. However, traditional machine learning models are challenged with data availability and high training effort in the event of changes in the manufacturing process. In this work, we address this challenge by introducing transfer learning (TL) into manufacturing. We demonstrate the potentials and benefits of TL in a case study for predictive quality in laser-based micro-machining processes across different materials (steel and aluminum), different dielectric liquid (water and oil), and different process parameters (laser speed, laser power, and repetition frequency). The proposed TL framework is expected to adapt to such process changes and deliver accurate predictions on the quality of the channels machined without the need to re-train the model.

1 Hierarchical Deep Learning with Generative Adversarial Network for Automatic Diagnosis of ECG Signals

Zekai Wang[1], Bing Yao[2], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Stillwater, OK, Contact: zekai.wang@okstate.edu

Cardiac disease is the leading cause of death in the US. Routine use of electrocardiogram (ECG) is the most common method for physicians to assess the electrical activities of the heart and detect possible abnormal cardiac conditions. In this paper, we propose a two-level hierarchical deep learning framework with Generative Adversarial Network (GAN) for automatic diagnosis of ECG signals. The first-level model is composed of a Memory-Augmented Deep auto-Encoder with GAN (MadeGAN), which aims to differentiate abnormal signals from normal ECGs. The second-level learning aims at robust multi-class classification for different arrhythmias identification, which is achieved by integrating the transfer learning technique to transfer knowledge from the first-level learning with the multi-branching architecture to handle the data-lacking and imbalanced data issue.

2 Collaborative Online Learning for a Heterogeneous Population of Units Under Resource Constraints

Tanapol Kosolwattana[1], Huazheng Wang[2], Ying Lin[3], [1]University of Houston, Houston, TX, [2]Oregon State University, Corvallis, OR, [3]University of Houston, Houston, TX, Contact: tkosolwa@CougarNet.UH.EDU

Adaptive monitoring of a large population of dynamic processes enables cost-effective process control under limited resources. However, existing adaptive monitoring models either ignore the dependency among processes or overlook the uncertainty in process modeling. To design an optimal monitoring strategy that accurately monitors the processes with poor health conditions and actively collects information for uncertainty reduction, a novel combinatorial bandit with a dependent and dynamic arms method is proposed in this study. The efficiency of the proposed method is demonstrated through both theoretical analysis and an empirical study of adaptive monitoring for degrading batteries.

3 A Simulation-optimization Framework for Food Supply Chain Network Design to Ensure Food Accessibility Under Uncertainty

Mengfei Chen[1], Mohamed Kharbeche[2], Mohamed Haouari[2], Weihong Guo[3], [1]Rutgers, The State University of New Jersey, PIscataway, NJ, [2]Qatar University, Doha, Qatar; [3]Rutgers, The State University of New Jersey, Piscataway, NJ

How to ensure accessibility to food and nutrition while the global food supply chain suffers from disruptive forces like COVID and natural disasters is an emerging and critical issue. A food accessibility evaluation index is proposed in this work to quantify how nutrition needs are met. The proposed index is then embedded in a multi-objective optimization problem to determine the optimal supply chain design to maximize food accessibility and minimize cost. Considering uncertainty in demand and supply, the multi-objective optimization problem is solved in a two-stage simulation-optimization framework where Green Field Analysis is used to determine supply chain configuration and then Monte Carlo simulation is used to determine supply chain operations by solving a stochastic programming problem. Model parameters are estimated from historical data and real-time data.

4 Collaborative Discrimination-enabled Generative Adversarial Network (cod-gan) for Data Augmentation in Imbalanced Classification

Ziyang Zhang, Yuxuan Li, Chenang Liu, Oklahoma State University, Stillwater, OK, Contact: jan.zhang@okstate.edu

This study aims to modify GAN to optimize data augmentation when data from two classes is imbalanced. Hence, a creative and effective GAN structure, collaborative discrimination-enabled generative adversarial network (CoD-GAN) is proposed. The main novelty lies in integrating multiple discriminators to improve the robustness of its discrimination and the diversity of the synthetic samples. The effectiveness of the proposed method is validated by simulation data and real-world dataset.

1 Applying Wassestein-based Policy Optimization to Hvac Problems

Chaoyue Zhao, University of Washington, Seattle, WA

Model-free RL methods have been exploited to address HVAC problems, but their performances are not ideal for real-world implementation. One major concern is most of these work limits the policy to a particular parametric distribution class and optimizing over such distributions results in local movements in the action space and thus leads to a sub-optimal solution. This framework will replace the untrustworthy probabilistic assumptions of policy gradient methods with an ambiguity set that covers all permissible distributions. A practical on-policy actor-critic algorithm is proposed. Experiments show that our approach demonstrates the stability and solution optimality.

2 Knowledge-constrained Machine Learning for Modeling and Prediction of Complex Systems

Hao Yan[1], Jiayu Huang[2], Yongming Liu[1], Jing Li[3], Frank Setzer[1], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Chandler, AZ, [3]Georgia Institute of Technology, Tempe, AZ, Contact: haoyan@asu.edu

Incorporating knowledge into machine learning models for uncertainty quantification is an important topic for the modeling of complex systems. Traditionally, the prior regularization method is often used to control the model complexity via specific prior knowledge. However, it is hard to incorporate these prior distributions in the black-box Bayesian machine learning models. Here, we propose two works on incorporating domain knowledge into the black-box Bayesian machine learning models, such as Bayesian neural networks. Case studies such as solar PV plant modeling, trajectory prediction and image segmentation will be used to illustrate the advantage of the proposed methods.

3 The Application of Transfer Learning in Tellurene Manufacturing

Yueyun Zhang, Jorge Loria, Jing Jiang, Wenzhuo Wu, Zachary Hass, Arman Sabbaghi, Purdue University, West Lafayette, IN

As a solution-grown product, tellurene can be manufactured through a scalable process. It is critical to learn the effects of process factors on the production yield and dimensions. We apply transfer learning in the analysis of tellurene manufacturing under new process B based on the established linear regression model under old process A. It is done by incorporating the equivalent effect of a lurking variable in terms of an observed factor into the linear regression model. Process A and process B can be distinguished by different settings of lurking variables. We use a blocked Gibbs sampler to compute the posterior of equivalent effect conditional on direct draws of mean and variance parameters. With the validation data from the proposed experimental design, we model TEA and incorporate the TEA model in the base model to complete the model transfer.

4 GAN-assisted Data Analytics and Modeling to Advance Complex Engineering Systems

Yuxuan Li, Chenang Liu, Oklahoma State University, Stillwater, OK

As many advanced engineering systems become complex, it also becomes common that the collected data have high dimensionality and inherent complexity, leading to more technical challenges in data analytics. Thus, to improve the power of data analytics and further advance the complex engineering systems using data, advanced techniques are critically needed. Inspired by the emerging generative adversarial network (GAN), this talk will present a GAN-assisted methodological framework to thoroughly address these issues, which has been validated under various scenarios.

5 Posterior Regularized Bayesian Neural Network

Jiayu Huang[1], YUTIAN PANG[1], Yongming Liu[1], Hao Yan[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ

Traditional NNs often lack the ability for uncertainty quantification. Bayesian NNs(BNNs) could help measure the confidence level by using distributions in NNs modeling. Besides, knowledge is commonly available and could improve the performance of BNNs if it can be properly incorporated. In this work, we propose a novel Posterior-Regularized BNN(PR-BNN) model by incorporating soft and hard constraints as a posterior regularization term. We also propose an augmented Lagrangian method and stochastic optimization algorithm for efficient updating via Monte Carlo sampling. The simulations and case studies have shown the performance improvement of the proposed model over traditional BNNs.

6 Tensor Dirichlet Process Multinomial Mixture Model with Graphs Clustering for Passenger Trajectory Clustering

Ziyue Li, University of Cologne, Cologne, Germany. Contact: zlibn@wiso.uni-koeln.de

Existing passenger clustering cannot easily cluster the passengers due to the hierarchical structure of the passenger trip information. Furthermore, existing approaches rely on an accurate specification of the clustering number. Finally, existing methods do not consider spatial semantic graphs such as geographical proximity and functional similarity between the locations. In this paper, we propose a tensor Dirichlet Process Multinomial Mixture model with graphs, which can preserve the hierarchical structure of the multi-dimensional trip information and cluster them in a unified one-step manner with the ability to determine the number of clusters automatically. The spatial graphs are utilized in community detection to link the semantic neighbors. We further propose a tensor version of Collapsed Gibbs Sampling method with a minimum cluster size requirement.

7 VLP: A Visual Language Processing Modeling Framework Via An Attention-on-attention Mechanism

Xiaoyu Chen[1], Ran Jin[2], [1]University of Louisville, Louisville, KY, [2]Virginia Tech, Blacksburg, VA, Contact: xiaoyu.chen@louisville.edu

Quantitatively understanding human visual searching process in interactive and intelligent systems will not only advance the knowledge preservation of human expertise, but also enhance the AI modeling performance by imitating the human visual searching process. A general visual language processing (VLP) modeling framework is proposed to provide computational attention on visual attention (AonA) based on eye movements. This VLP modeling framework is expected to explain visual searching decisions via AonA even for counter-intuitive scenarios when cognitive threats bias human decision making.

Abdallah A. Chehade, University of Michigan-Dearborn, Canton, MI

Leveraging AI/ML for scaled assessment of safety and reliability of AI-driven systems in autonomous vehicles

9 Task Allocation and Coordinated Motion Planning for Autonomous Multi-robot Optical Inspection Systems

Yinhua Liu[1], Xiaowei Yue[2], [1]University of Shanghai for Science and Technology, Shanghai, China; [2]Virginia Tech, Blacksburg, VA, Contact: xwy@vt.edu

Numerous methods for path planning and robotic coordination have been developed but they may not work for autonomous multi-robot optical inspection due to fast computation requirements, end-effector orientations, and complex surfaces. This paper proposes a novel method for coordinated motion planning of multi-robot inspection. A local robust task allocation is proposed to achieve efficient and well-balanced measurement assignment among robots; collision-free path planning and coordinated motion planning are developed via dynamic searching. A case study shows that it can mitigate the risk of collisions, resolve conflicts among robots, and reduce the cycle time.

19 Change Detection in Spatio-temporal Processes: Applications in Smart Manufacturing Systems

Satish Bukkapatnam, Texas A&M University, College Station, TX

This flash talk presents an overview of the key challenges in, and the methods employed for tracking changes in spatio-temporal dynamics underlying real world manufacturing processes and systems.

1 Flexibility Management in Economic Dispatch with Dynamic Automatic Generation Control

Lei Fan, University of Houston, Houston, TX

As the installation of renewable energy resources grows rapidly in power systems, system frequency maintenance and control become challenging problems to maintain the system reliability in bulk power systems. As two of the most important frequency control actions in the control centers of independent system operators and utilities, the interaction between Economic Dispatch and Automatic Generation Control attracts more and more attention. In this paper, we propose a robust optimization based framework to measure the system flexibility by considering the interaction between two hierarchical processes. We propose a cutting plane algorithm with the reformulation technique to obtain seven different indices of the system. In addition, we study the impacts of several system factors and show numerically how these factors can influence the system flexibility.

2 Battery bidding under uncertainty considering practical market situations

Weihang Ren, Yongpei Guan, University of Florida, Gainesville, FL, Contact: renw@ufl.edu

Storing off-peak electricity and supplying for peak demand is advantageous in terms of energy production, social impact, and environmental preservation. The potential gain from the bidding spread for the battery owner motivates multiple methods of energy storage. In this paper, we use stochastic programming to investigate optimized bidding methods under market uncertainty. From the standpoint of a battery owner, we create efficient algorithms to create strategies for three common energy market settings. We present one-time validation for our proposed strategies in each market setting, as well as an analysis of the structural feature of each strategy that reveals the underlying logic. We then improve our solution approaches to a rolling horizon method for better fit in practice. We run numerical experiments to demonstrate the empirical performance of our solutions.

3 Electric Grid and Market Impact from Transportation Electrification: A Case Study of Heavy-duty Freight Electrification in The Atlanta-ChattanoogaRegion

Zhi Zhou, Lusha Wang, Vincent Freyermuth, Natalia Zuniga, Olcay Sahin, Monique Stinson, Argonne National Laboratory, Lemont, IL, Contact: zzhou@anl.gov

The decarbonization of the electric grid happens in both generation and demand sides. One of the major sources on the demand side is the shift of fuel from gas to electricity in the transportation sector. This will change the shape of electricity demand profiles, and the change will be different from time and regions. In this study, we investigate the impact of charging demand on grid operations in a day-ahead electricity market clearing context, which is based on a mixed integer program formulated unit commitment and economic dispatch problem. We applies the model to a case study of heady-duty freight electrification in the Atlanta-Chattanooga region, with a number of charging demand profiles from different future electrification scenarios.

4 Climate-Resilient Power System Expansion Planning

Amelia Musselman[1], Jean-Paul Watson[1], Tomas Valencia Zuluaga[2], [1]Lawrence Livermore National Laboratory, Livermore, CA, [2]University of California Berkeley, Berkeley, CA

Climate change, through not only more frequent extreme weather events but also shifts in routine weather patterns, is increasingly impacting power systems. Factors such as increased temperatures, droughts, changing wind patterns, and solar irradiance shifts can impact generator, storage, and transmission efficiencies, production, and lifetimes. We analyze the impact of climate change on power systems via a novel climate-resilient capacity expansion planning model, which seeks to minimize costs while ensuring power system resilience and reliability under a changing climate. We apply our model to a case study of California, initially varying temperature, wind speed, and irradiance. Climate data from the CMIP6 model repository is leveraged.

Modeling Deep Decarbonization in the Power Sector

General Session

Session Chair

Qingyu Xu, Princeton University, Baltimore, MD

1 Incorporating Forward-looking Projections into Present-day Electric Sector Decisions with Long-run Marginal Emission Rates

Pieter Gagnon, National Renewable Energy Laboratory, Golden, CO

Emissions factors are widely used to estimate how various interventions would influence emissions from the electric sector. The ongoing evolution of the electric grid, however, calls into question the usage of retrospective or short-run emissions factors, which do not incorporate how changes in electricity demand can influence the structure of the grid (the building and retiring of capital assets, such as generators). This talk will address how long-run marginal emission rates can, in a modeling environment, outperform other common emissions metrics at comprehensively anticipating the consequences of an intervention, and discuss the implications of this finding for policy and technology evaluation.

2 Informing Energy Storage Solutions to Decarbonize Electricity

Audun Botterud[1], Jonghwan Kwon[2], Neal Mann[1], Zhi Zhou[3], Todd Levin[4], [1]Argonne National Laboratory, Lemont, IL, [2]Argonne National Laboratory, LEMONT, IL, [3]Argonne National Laboratory, Argonne, IL, [4]Argonne National Laboratory, Lemont, IL, Contact: abotterud@anl.gov

We present a detailed capacity expansion model (CEM) for the U.S. power system, accounting for multiple expansion stages and chronological operations. We use the model to compare four pathways for full electricity decarbonization by 2035 with different levels of technology innovation and public acceptance. In particular, we focus on the role of energy storage. We find that the optimal level of energy storage expansion and technology choice differ substantially between the four pathways. We also illustrate the importance of energy storage representation within CEMs for the results of decarbonization analysis.

3 Optimizing Transmission Expansion for Renewable Energy Development Considering Existing Rights-of-Way

Fikri Kucuksayacigil[1], Michael R. Davidson[2], [1]University

of California San Diego, San Diego, CA, [2]University of California, San Diego, La Jolla, CA, Contact: fkucuksayacigil@ucsd.edu

Models of large-scale renewable energy development typically expand transmission infrastructure to accommodate heterogeneous geographic resources. Yet, planning new transmission lines is complicated due to permitting, land use and other constraints. Upgrading existing rights-of-way emerges as a promising alternative due to reduced costs (when accounting for more accurate cost structures) and simplified process of land acquisition and construction. In this study, we develop a capacity expansion model with operational details and integer transmission expansion decisions corresponding to voltage upgrade options for the Western United States. Our research reveals that upgrade significantly substitutes new line building, capacities of proposed lines are insufficient, and lines from wind-dominated zones to major demand centers should be massively upgraded.

4 No-regrets Capacity Expansion Planning Model for New York City Considering Key Uncertainties: Prices & Policies for Natural Gas & Hydrogen

Stephanie Wilcox, Johns Hopkins University, Baltimore, MD

In recent years, a growing number of cities have banned natural gas in new construction. Restrictions directly impact energy reliability, infrastructure investments, electricity and fuel prices, and energy access. However, few studies evaluate the technical, environmental, and economic effects of natural gas legislation at the city-level. The U.S. EPA's City-based Optimization Model for Energy Technologies (COMET) will be extended to analyze the future of natural gas, hydrogen, and distributed energy resources in cities under various natural gas policy scenarios.

1 Dynamic Pricing with Non-stationary Demand Using Reinforcement Learning

Sadegh Kazemi[1], Mahdi Kazemi[2], [1]University of Houston, Houston, TX, [2]Yazd University, Yazd, Iran, Islamic Republic of.

In this study, we investigate how the pricing policy of an online retailer is influenced by customers' time-varying willingness to pay (WTP). We model customers' changing WTP with a linear recursion and use reinforcement learning to enable the retailer to learn the time-varying demand. We show that by using reinforcement learning, the retailer can optimize its pricing strategy. We solve the pricing problem based on fixed and dynamic pricing strategies. We use simulation to make performance comparisons between the two pricing strategies and provide managerial insights.

2 Toward Effective Human-system Integration in Customized Vehicle Automation

Jundi Liu, Linda Boyle, Ashis Banerjee, University of Washington, Seattle, WA, Contact: jundiliu@uw.edu

It is crucial to continuously improve human-system integration to realize human-aware and responsive automation. In this work, we proposed to improve vehicle automation by customizing it to driving styles. Specifically, we adopted an Inverse Reinforcement Learning (IRL) approach for customizing vehicle automation to driving styles identified from naturalistic driving data by using Multivariate Functional Principal Component Analysis (MFPCA) and clustering analysis. As a follow-up, we leveraged real-time trust modeling for further trust calibration considerations. We designed an online driving simulator study to collect trust dynamics data while interacting with vehicle automation and developed a clustering-based State Space Model for real-time trust prediction. Our proposed framework has implications for the design of future vehicle automation.

3 Demand-side Energy Resources as Virtual Batteries: A Learning-based Approach

Junjie Qin, Purdue University, West Lafayette, IN

Diverse demand-side energy resources can provide valuable grid services. Bringing these resources to electricity markets requires an interoperable representation of their dynamics and constraints, which may depend on exogenous stochastic processes like weather and building occupancy. Virtual battery models have been proposed as a standardized representation of dynamic demand-side flexible energy resources. In this work, we propose a learning-based framework for the identification and real-time control of virtual battery models for diverse demand-side flexible resources (eg., building thermostatistic loads and electric vehicle charging loads) while providing performance and reliability guarantees.

Mechanisms for Emerging Forms of Democratic Participation

General Session

Session Chair

Paul Goelz, 1</sup

1 **Auditing and Designing for Equity in Resident Crowdsourcing**

Zhi Liu[1], Nikhil Garg[2], [1]Cornell, New York, NY, [2]Cornell Tech, New York, NY, Contact: ngarg@cornell.edu

Modern governance relies on crowdsourcing to identify problems such as downed trees. A major concern is that residents do not report problems at the same rates, leading to inefficient and inequitable allocation of government resources. However, measuring under-reporting is difficult---we do not observe unreported incidents. Thus, distinguishing between low reporting rates and ground-truth incident rates is challenging. First, we develop a method to identify reporting rates, without using external ground truth data. We apply our method to over 100,000 resident reports made to the NYC Department of Parks and Recreation, finding that there are substantial spatial and socio-economic disparities in reporting rates. Second, I'll overview work in redesigning inspection decisions to improve system efficiency and equity.

2 **Liquid Democracy in Practice: An Empirical Analysis of Its Epistemic Performance**

Manon Revel, Massachusetts Institute of Technology, Cambridge, MA, Contact: mrevel@mit.edu

Increasing distrust in democratic institutions leads scholars to re-think how we make decisions in democracies. Proposals often include involving more lay citizens in decisions to reduce the biases in the compositions of the representative bodies. One idea is to use liquid democracy to allow all to participate in the nomination of representatives through transitive delegations. While liquid democracy promises to identify more competent representatives, little is known about how the system would unfold in practice. Theoretical models have studied the mathematical guarantees under which liquid democracy outperforms direct democracy on closed questions for which there exists a ground truth. Herein, we test these theories through a series of 10 experiments on liquid democracy and find those delegation behaviors are consistent with those identified in theory.

3 **Liquid Democracy with Ranked Delegations**

Ulrike Schmidt-Kraepelin, TU Berlin

Liquid democracy is a novel paradigm for collective decision-making that gives agents the choice between casting a direct vote or delegating their vote to another agent. We consider a generalization of the standard liquid democracy setting by allowing agents to specify multiple potential delegates, together with a preference ranking among them. This generalization increases the number of possible delegation paths and enables higher participation rates because fewer votes are lost due to delegation cycles or abstaining agents. In order to implement this generalization of liquid democracy, we need to find a principled way of choosing between multiple delegation paths. We call such functions delegation rules, and analyze their space from axiomatic, empirical, and algorithmic viewpoints.

4 **Supporting Democratic Innovation: Fairness, Representativeness, and Transparency for Citizens' Assemblies**

Paul Gölz, Harvard University, Boston, MA

One of the most exciting developments in democracy are citizens' assemblies, panels of randomly constituents that contribute to questions of policy. Since panels should be representative of the population, and since each constituent should have a fair chance of being randomly selected to the panel, the selection process poses challenges of fairness, efficiency, and transparency. I describe how we support nonprofit organizations in running citizens' assemblies using algorithms and mathematical modeling.

Innovations in Auction Design

General Session

Session Chair

Benjamin Lubin, Boston University, Boston, MA

Session Chair

Sven Seuken, University of Zurich, Zuerich, Switzerland.

1 **Bidder Feedback in First-Price Video Ad Auctions**

Sébastien Lahaie, Google Research, New York, NY

The display advertising industry has recently moved to first-price auctions as its main mode of ad allocation and pricing. To inform buyers' bidding algorithms, these ad auctions typically send the minimum-bid-to-win as feedback to buyers after the auction: the second-highest bid for the winning bidder, and the highest bid for losing bidders. For ads in video streams, the minimum-bid-to-win concept does not have a clear generalization as the auctions are combinatorial. Buyers can bid to show ads of various lengths and in different positions within the stream. We propose practical generalizations of the minimum-bid-to-win concept to combinatorial auctions, drawing on connections to cost sharing and cooperative game theory, and investigate the bidding dynamics induced by various feedback policies.

2 **Monotone-Value Neural Networks: Exploiting Preference Monotonicity in Combinatorial Assignment**

Jakob Weissteiner, University of Zurich, Zürich, Switzerland.

Many resource allocation problems involve the combinatorial assignment of items, e.g., auctions or course allocation. Because the bundle space grows exponentially in the number of items, preference elicitation is a key challenge. Recently, researchers have proposed ML-based mechanisms that outperform traditional mechanisms while reducing elicitation costs. However, previously used ML algorithms disregard important prior knowledge about agents' preferences. To address this, we introduce monotone-value neural networks (MVNNs), which are designed to capture combinatorial valuations, while enforcing monotonicity and normality. We prove that MVNNs are universal and provide a MILP to make solving MVNN-based WDPs practically feasible. Our results show that MVNNs improve the prediction performance and they yield state-of-the-art allocative efficiency.

3 **Within-Instance Mechanism Design**

Maria Florina Balcan, Siddharth Prasad, Tuomas Sandholm, Carnegie Mellon University, Pittsburgh, PA

There has been significant work on a subfield of automated mechanism design where the designer only has samples from the valuation distribution, initiated by Likhodedov and Sandholm (2004). This has been used to design high-revenue auctions, pricing schemes, and many other mechanisms. We present applications to multi-item, multi-bidder revenue maximization (for limited supply) when such samples are not available. First, we present a learning-within-an-instance mechanism that generalizes and improves upon prior random-sampling mechanisms for unlimited supply, and prove revenue guarantees for it. Second, we show how to design an auction that is robust to market shrinkage and uncertainty: if there is a fixed population of buyers known to the seller, but only some random (unknown) fraction of them participate, how much revenue can the seller guarantee?

1 **Enabling Process-materials Co-optimization Via Surrogate Modeling for Adsorption-based Gas Separations**

Xiangyu Yin[1], Lorenz T. Biegler[2], Chrysanthos E. Gounaris[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: xiangyuy@andrew.cmu.edu

This work proposes methodologies to learn and incorporate MOF surrogate models within PSA process models, making it possible to directly co-optimize the PSA process and the materials for gas separation applications. The first step is to develop an automatic workflow for learning algebraic surrogate models from user-defined MOF structure files. After that, a fidelity-tunable PSA column model is created within the IDAES-PSE framework. The surrogate-integrated process model enables simultaneous simulations and optimizations in both the material and the process design space.

2 Machine Learning Surrogates with OMLt and IDAEs for Improved Design and Analysis of Energy Systems

Bashar L. Ammari[1], Carl Laird[1], Ruth Misener[2], Alexander Thebelt[2], Calvin Tsay[2], Michael Lee Bynum[3], Joshua Haddad[4], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Imperial College London, London, United Kingdom; [3]Purdue University/Sandia National Laboratories, Albuquerque, NM, [4]University of Florida, Gainesville, FL, Contact: bammari@andrew.cmu.edu

Increased interest in integrating machine learning and optimization has warranted development of a framework to efficiently represent data driven models in algebraic modeling languages. In this presentation, we introduce the Optimization and Machine Learning Toolkit (OMLT) which integrates trained neural networks and gradient boosted trees in Pyomo. OMLT uses ONNX interoperability features to support machine learning models from packages such as Keras, PyTorch, Tensorflow, and Scikit-Learn. As a demonstration, we include two IDAES examples - a neural network surrogate of an auto-thermal reformer and a machine learning application to flexibility analysis.

SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525

Acknowledging OMLT contributions from Jordan Jalving.

3 Optimal Design of Integrated Energy Systems Using First-principle and Machine Learning Models

Jaffer Ghouse[1], Jordan Jalving[2], Bernard Knueven[3], Xian Gao[4], Xinhe Chen[4], Damian Agi[4], Nicole Cortes[4], John Siirola[5], David Miller[1], Alexander Dowling[4], [1]National Energy Technology Laboratory, Pittsburgh, PA, [2]KPMG, Albuquerque, NM, [3]National Renewable Energy Laboratory, Golden, CO, [4]University of Notre Dame, Notre Dame, IN, [5]Sandia National Laboratories, Albuquerque, NM, Contact: jaffer.ghouse@netl.doe.gov

Integrated energy systems (IES) produce electricity, store thermal/electrical energy, and/or produce hydrogen/chemicals that allows for greater flexibility when operating in a grid with increased variable renewable energy penetration. The optimal design and operation of an IES needs to incorporate the interaction with the bulk power market. This study will present novel, multi-scale computational approaches to co-optimize the design and operation of an IES while capturing the bulk power market as machine learning surrogates and the candidate energy system as physics-based models. The data for generating the market surrogates consists of 64,000 simulations obtained by varying generator characteristics that are the decision variables in the optimization problem. The results show that the proposed approach outperforms the conventional price-taker assumption.

4 Improved Characterization of Membrane Transport Properties Through Data Analytics

Xinhong Liu[1], Jonathan Ouimet[1], Laurianne Lair[1], William Phillip[1], Alexander Dowling[2], [1]University of Notre Dame, Notre Dame, IN, [2]University of Notre Dame, Notre Dame, IN, Contact: xliu27@nd.edu

We recently proposed the Diafiltration Apparatus for high-Throughput Analysis (DATA), which enables a 10-times reduction in the time necessary to characterize membrane transport properties. In this talk, we apply Fisher information matrix (FIM) analysis and model-based design of experiments (MBDoE) techniques to further improve DATA. We show that modeling the start-up process leverages additional data to elucidate the underlying physics, improve the parameter precision, and bring insights to design a time-varying applied pressure in DATA. A time correction for permeate product collected is also introduced to improve the model predictions. Moreover, our framework, which integrates data analytics and instrumentation design can be applied to investigate concentration-dependent membrane performance to further accelerate the development of materials.

Frontiers in Online Resource Allocation

General Session

Session Chair

Rajan Udwani, UC Berkeley, Berkeley, CA

1 Single-leg Revenue Management with Advice

Santiago Balseiro[1], Christian Kroer[1], Rachitesh Kumar[2], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY

Single-leg revenue management is a foundational problem of revenue management that has been particularly impactful in the airline and hotel industry: Given n units of a resource and a stream of sequentially-arriving customers segmented by fares, what is the optimal online policy for allocating the resource. Previous work focused on designing algorithms when forecasts are available, which are not robust to inaccuracies in the forecast, or online algorithms with worst-case performance guarantees, which can be too conservative. In this work, we look at the single-leg revenue management problem through the lens of the algorithms-with-advice framework, which attempts to incorporate predictions into online algorithms in a manner that optimally trades off consistency (performance when advice is accurate) and competitiveness (performance when advice is inaccurate).

2 A New Class of Revenue Management Problems with Overbooking and No-shows: Shoring up Trust Between Shippers and Carriers in Maritime Container Shipping

Jacob Feldman[1], Panos Kouvelis[2], Yunzhe Qiu[3], [1]Olin Business School, Saint Louis, MO, [2]Washington University in St. Louis, Clayton, MO, [3]Washington University in St. Louis, St. Louis, MO

In this work, we propose and study a deposit-based booking system that draws inspiration from current practices that have been shown to be successful in mitigating no-show behavior and overbooking in the container shipping industry. Our main algorithmic finding is the development of a simple and easy to implement booking policy, which we show to be 1/4th-competitive against a clairvoyant benchmark that knows the full sequence of deposits.

3 Online Algorithms for Matching Platforms with Multi-channel Traffic

Vahideh Manshadi, Yale University, New Haven, CT

Two-sided platforms rely on their recommendation algorithms to help visitors successfully find a match. However, on platforms such as VolunteerMatch -- which has facilitated millions of connections between volunteers and nonprofits -- a sizable fraction of website traffic arrives directly via an external link, thus bypassing the platform's recommendation algorithm. We study how such platforms should account for this *external traffic* in the design of their recommendation algorithms. We model the platform's problem as a special case of online matching, and we propose a new algorithm (Adaptive Capacity) which accounts for matches differently based on whether or not they originate from external traffic. We establish theoretical guarantees on the performance of our algorithm, and we demonstrate its strong performance in a case study motivated by VolunteerMatch data.

4 Online Bin Packing with Known T

Shang Liu, Xiaocheng Li, Imperial College Business School, London, United Kingdom. Contact: s.liu21@imperial.ac.uk

In this paper, we revisit the online bin packing problem under a setting where the total number of items T is known in advance (also known as *closed*). We study both the stochastic model and the random permutation model. We develop and analyze an adaptive algorithm that solves an offline bin packing problem at geometric time intervals as guidance. Under both models, we show that the algorithm achieves $C\sqrt{T}$ regret, where C is a universal constant (≤13). We develop a new approach to analyzing the packing dynamic using exchangeable random variables. The approach is used to analyze both the algorithm performance and the benchmarks related to the bin packing problem. Our analysis provides an alternative treatment and tightens the analysis of the asymptotic benchmark of the stochastic bin packing problem.

Online Advertising & Revenue Management

General Session

Session Chair

John G. Turner, University of California - Irvine, Irvine, CA

1 Serving Online Ads with Reach and Frequency Requirements on a Moving Time Window

John G. Turner[1], Ali Hojjat[2], [1]University of California - Irvine, Irvine, CA, [2]University of Michigan - Ann Arbor, Ann Arbor, MI, Contact: john.turner@uci.edu

We propose and study a new form of online advertising contract in which ad exposures are counted over a moving time window (e.g., a 24-hour time interval) that shifts forward as the time passes. We model a user's ad exposure as a birth-and-death Markov process. Then we derive a closed-form ad serving policy that can achieve a desired frequency distribution for an online ad campaign and characterize the necessary and sufficient conditions for such a policy to exist.

2 Strawberry or Vanilla This Week? How to Optimize Tailored Assortments for Variety-Seeking/Avoiding Consumers

Dorothee Honhon[1], ismail KIRCI[2], Sumit Kunnumkal[3], Sridhar Seshadri[4], [1]University of Texas at Dallas, Richardson, TX, [2]UIUC, champaign, IL, [3]ISB, India, India; [4]University of Illinois, Champaign, IL, Contact: kirci.ismail@gmail.com

We consider the problem of a retail personalizing an assortment to a consumer who is variety-seeking or variety-avoiding, that is, less or more likely to buy the same product as in the previous period. We characterize the structure of the optimal assortment in single- and multi-period settings.

3 Dynamic Two-part Pricing and Bidding for Display Ad Campaigns on Advertising Exchanges

Naren Agrawal[1], Sami Najafi-Asadolahi[2], Stephen A. Smith[3], [1]Santa Clara University, Santa Clara, CA, [2]Santa Clara University, Morgan Hill, CA, [3]Santa Clara University, Saratoga, CA, Contact: snajafi@scu.edu

We consider an ad agency that manages multiple ad campaigns by bidding for campaigns targeted viewers on an ad exchange and charging campaigns based on a two-part pricing scheme: a part that is charged upfront (upfront fee) and a part that is charged each time a viewer is shown an ad (the CPM price). The agency faces a delay cost for each undelivered impression per unit time as well as a terminal penalty proportional to the number of undelivered impressions. We formulate the problem as a Markov Decision Process and determine the optimal dynamic bidding policy to serve campaigns as well as the optimal dynamic policies for the upfront fee and the CPM price (given the remaining periods and the remaining number of impressions that are waiting to be delivered to campaigns). We show the counterintuitive result that the upfront fees can increase as the time approaches the terminal period.

Monday, 8AM–9:15AM

Data-Driven Retail Operations

General Session

Session Chair

Chloe Kim Glaeser, University of North Carolina at Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

1 Inferring Customers' Consideration Sets from Heat-map Data

Zahra Ziaei[1], Adam J. Mersereau[1], Seyedmorteza Emadi[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, Contact: zahra_ziaei@kenan-flagler.unc.edu

In this research, we study the application of heatmap data from a brick-and-mortar store for improving the modeling and prediction of customer purchase behavior. We demonstrate how heatmap data, along with aggregate sales data, can be used to infer customer consideration sets, while estimating the effects of covariates influencing consideration of a product or/and utility of a product.

2 Omnichannel Fulfillment in Grocery Retail

Chloe Kim Glaeser[1], Ken Moon[2], Xuanming Su[2], [1]University of North Carolina at Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [2]University of Pennsylvania, Philadelphia, PA, Contact: chloe_glaeser@kenan-flagler.unc.edu

We partner with an online grocery retailer to answer the practice-based question of the optimal mix of delivery zones and fulfillment options using data-driven analytics. We investigate how consumers respond to the locally tailored fulfillment options made available to them by the online grocer. We employ a geographical regression discontinuity design to find the causal effect of delivery introduction. Based on this empirical evidence, we build and estimate a structural model and perform a counter-factual analysis to estimate the revenue increase from additionally offering delivery. We examine how the retailer can leverage data to customize locally available fulfillment options while scaling operations.

3 Store Closures and Online Shopping: Evidence from a Natural Experiment

Ragip Gurlek[1], Diwas S. Kc[1], Paolo Letizia[2], [1]Emory University, Atlanta, GA, [2]University of Tennessee, Knoxville, TN, Contact: rgurlek@emory.edu

We examine the impact of retail store closures on omnichannel sales and consumer shopping behavior. We utilize the business closure shocks caused by COVID-19 pandemic to empirically identify omnichannel effects of retail store closures. Using data from a fashion retailer on store closures due to COVID-19 shocks, we find that when a store is closed, the volume of online orders originating from its location increases by 29%. Furthermore, even after store reopening, store locations with temporary closures continue to generate greater online sales proportional to the duration of the closure. For instance, a 30-day temporary closure leads to 49% increase in the post-closure online sales right after the reopening and 37% increase 60 days after the reopening. Omnichannel total sales (offline + online), on the other hand, decrease by 5.5% if the retailer closes 10% of the stores.

4 Inventory Record Inaccuracy Explains Price Rigidity in Perishable Groceries

Ioannis Stamatopoulos[1], Robert E. Sanders[2], Naveed Chehrazi[3], [1]The University of Texas at Austin, McCombs School of Business, Austin, TX, [2]UC, San Diego, Beverly Hills, CA, [3]Olin Business School, St. Louis, MO

Grocery retailers cannot engage in inventory-based pricing without physically auditing their shelves, because their inventory records are inaccurate and incomplete. We argue that this informational friction, known in the literature as inventory record inaccuracy (IRI), is much more powerful than physical menu costs in explaining price rigidity in perishable groceries.

Machine Learning for Discrete Optimization

General Session

Session Chair

Mikhail Bragin, University of California, Riverside, CA

Session Chair

Bing Yan, Rochester Institute of Technology, Rochester, NY

1 An Optimization Method-assisted Ensemble Deep Reinforcement Learning Algorithm to Solve Unit Commitment Problems

Jingtao Qin, Yuanqi Gao, Mikhail Bragin, Nanpeng Yu, University of California-Riverside, Riverside, CA, Contact: jqin020@ucr.edu

Unit commitment (UC) is a fundamental problem in the day-ahead electricity market. It is critical to solve the UC problems in a computationally efficient manner. Recent advances in artificial intelligence have demonstrated the capability of reinforcement learning to solve UC problems. Unfortunately, the existing research on solving UC problems with RL suffers from the curse of dimensionality when the size of UC problems grows. To address these issues, we propose an optimization method-assisted ensemble deep reinforcement learning algorithm, where UC problems are formulated as a Markov Decision Process (MDP) and solved by multi-step deep Q-learning in an ensemble framework. The proposed algorithm establishes a candidate action set by solving tailored optimization problems to ensure a relatively high performance and the satisfaction of operational constraints.

2 An Innovative Formulation Tightening Approach for Job-shop Scheduling

Bing Yan, Rochester Institute of Technology

Job shops are an important production environment for low-volume high-variety manufacturing. Its scheduling has been formulated as a Mixed-Integer Linear Programming (MILP) to take advantage of popular MILP methods. With a large number of parts, MILP methods may experience difficulties. To address this, a critical but overlooked issue is formulation tightening, i.e., if constraints can be transformed to delineate the convex hull, then a solution can be obtained by linear programming methods. In this talk, an innovative and systematic approach is presented to tighten formulations of individual parts by innovatively linking integer and binary variables with potential machine learning-based parameterization. Results show significant benefits in solution quality and computational efficiency. The approach also applies to other MILP problems with similar features.

3 Learning for Power Systems Optimization with MIPLearn and UnitCommitment.jl

Alinson Xavier, Argonne National Laboratory, Argonne, IL

With the increased adoption of renewables and other modern grid elements, the computational performance of existing tools for power systems optimization has become a critical bottleneck. The computational challenge often comes from having to solve a large number of closely-related problems to optimality. In this talk, we first introduce MIPLearn, an open-source general-purpose framework that accelerates, under this scenario, the performance of conventional MIP solvers using machine learning. We then illustrate its usage with UnitCommitment.jl, an open-source Julia/JuMP library of state-of-the-art unit commitment solution methods and formulations.

4 Synergistic Integration of Machine Learning and Mathematical Optimization for Unit Commitment

Jianghua Wu[1], Peter B. Luh[1], Yonghong Chen[2], Bing Yan[3], Mikhail Bragin[4], [1]University of Connecticut, Storrs, CT, [2]Midcontinent ISO, Carmel, IN, [3]Rochester Institute of Technology, Rochester, NY, [4]University of California, Riverside, Riverside, CA

Unit Commitment (UC) is important for power system operations. With increasing challenges, e.g., growing intermittent renewables and intra-hour net load variability, traditional mathematical optimization could be time-consuming. Machine learning (ML) is a promising alternative. However, directly learning good solutions is difficult in view of the combinatorial nature of UC. In this work, we synergistically integrate ML within our recent decomposition and coordination method of Surrogate Lagrangian Relaxation to learn “good enough” subproblem solutions of deterministic UC. Compared to the original UC, a subproblem is much easier to learn. Nevertheless, predicting good-enough subproblem solutions is still challenging because of the “jumps” of binary decisions and many types of constraints. To overcome these issues, subproblem dimensionality is reduced via aggregating multipliers. Multiplier distributions are novelly specified based on “jumps” for effective learning. Loss functions are innovatively designed to improve prediction qualities. Ordinal Optimization and branch-and-cut are used as a backup for unfamiliar cases. Furthermore, online self-learning is seamlessly integrated with offline learning to exploit solutions from daily operations. Results on the IEEE118-bus system and the Polish 2383-bus system demonstrate that continual learning keeps on improving the subproblem-solving process with near-optimality of the overall solutions maintained. Our method opens a new direction to solving complicated UC.

New Approximations to Hard Discrete Optimization Problems

General Session

Session Chair

Jean Pauphilet, London Business School, London, United Kingdom.

1 Approximation and Hardness for Submodular Linear Ordering Problems

Majid Farhadi[1], Swati Gupta[2], Shengding Sun[3], Prasad Tetali[4], Michael Wigal[3], [1]Georgia Tech, Georgia, GA, [2]Georgia Tech, Atlanta, GA, [3]Georgia Tech, Georgia, GA, [4]Carnegie Mellon University, Pittsburgh, PA, Contact: wigal@gatech.edu

The minimum linear ordering problem (MLOP) asks to minimize an aggregated cost of a given set function f with respect to an ordering of the base set. Various special cases have been previously studied, for example, the minimum linear arrangement problem, when f is the cut function of a graph. In this talk, we will show how both graphic matroid MLOP (when f is the rank function of a graphic matroid) and minimum latency vertex cover (MLVC) are NP-hard. With techniques from scheduling theory, we will also give a randomized 4/3 approximation algorithm for the MLVC problem. Previously, Iwata, Tetali, and Tripathi gave 2 - 1/(1 + |E|) approximation for monotone submodular MLOP. Using the theory of principal partitions, we give a refinement to this bound, which as a corollary leads to a 2 - (1 + f(E))/(1 + |E|) approximation algorithm for graphic matroid MLOP. We will end with open questions.

2 Sparse PCa with Multiple Components

Ryan Cory-Wright[1,2], Jean Pauphilet[3], [1]IBM Research, Cambridge, MA, [2]Imperial College Business School, London, United Kingdom; [3]London Business School, London, United Kingdom.

Sparse PCA is a cardinal technique for obtaining combinations of features that explain the variance in high-dimensional datasets in an interpretable manner. Most works either analyze the single principal component case, assume that all PCs share the same support or are fully disjoint, which allows the orthogonality constraint to be omitted and simplifies the problem dramatically. By reformulating sparse PCA as a sparsity and rank constrained optimization problem, we design exact, approximate, and feasible methods and second-order cone and semidefinite relaxations that collectively obtain bound gaps on the order of 5% for real-world datasets with 100s or 1000s of features, and demonstrate that considering the orthogonality and sparsity constraints simultaneously can lead to improvements in the Area Under the ROC curve of 14%-20% compared to deflation methods.

3 A Level-set Approach for Solving Nonlinear Discrete Optimization Problems

Ryan Killea[1], Andrew C. Trapp[2], [1]Worcester Polytechnic Institute, Worcester, MA, [2]Worcester Polytechnic Institute, Worcester, MA, Contact: rbkillea@wpi.edu

There are many discrete optimization problems that must be regularly solved, some of which involve unknown resource vectors. We propose a novel method to solve nonlinear discrete optimization problems parameterized over right-hand side vectors within a bounded region. Our approach is based upon constructing level-sets of the value function. We employ a tree-based data structure that supports efficient queries and, upon completion, the ability to rapidly reason over the region of interest. Our approach leverages problem structure and combines bounding with incremental solution construction to avoid excess computation arising from repeated solves. We test the scalability of our algorithm using a set of computational experiments, obtaining promising performance.

4 Warm-Starting Benders Decomposition with Inner and Outer Approximation

Arnaud Robin[1], Alexandre Jacquillat[2], Jean Pauphilet[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT Sloan School of Management, Cambridge, MA, [3]London Business School, London, United Kingdom. Contact: arobin@mit.edu

Many companies need to routinely solve large-scale two-stage stochastic optimization problems (e.g., inventory allocation, facility location, traffic management). However, decomposition methods like Benders' decomposition (BD) are notoriously slow in high dimension. In a data-driven setting, we accelerate the convergence of BD via a two-step procedure. First, we use historical instances to generate multiple valid cuts. Second, we apply an optimization-based cut-selection algorithm to select a small subset of these cuts to use as an efficient warm start. We demonstrate the computational benefits on capacitated facility location instances and report an overall 10-40% reduction in computational time.

Topics in Social Media Analytics

General Session

Session Chair

Theodore T. Allen, Ohio State University, Columbus, OH

1 Interpretable AI Modeling of the Probabilities New Cyber Vulnerabilities Have Exploits

Tu Feng[1], Enhao Liu[2], Theodore Allen[3], John McCarty[3], [12]University of Maryland, Hanover, MD, [3]Ohio State University, Columbus, OH

Cyber vulnerabilities within recent time windows with exploits are critical intelligence for all types of organizations. We review methods for scraping and feature generation involving Twitter and open-source databases. We also describe the tradeoffs for exploit prediction associated with interpretability.

2 A Decision-Tree Framework for Automatic Classification of Tweets

Evelyn Arrey[1], Enhao Liu[2], Theodore Allen[1], [1]Ohio State University, Columbus, OH, [2]University of Maryland, Hanover, MD

Classifying social media posts continues to have many applications. Yet, doing classification in an interpretable way can help all stakeholders participate in the relevant processes including diagnosing the sources of model errors. We propose a framework for feature engineering and classification and use language identification as an example.

3 New Methods for Deep Learning Hyperparameter Tuning Applied to Misinformation Classification

Mehdi Mashayekhi[1], Maha Yazbeck[2], Theodore Allen[2], [1]Columbus, OH, [2]Ohio State University, Columbus, OH

We consider 12 standard datasets and one additional dataset relating to the BERT reddit COVID misinformation. We show how our proposed extension of the R-BEESE simulation optimization leads to improved model accuracy compared with four alternatives. The insights about COVID misinformation are reviewed.

4 A Framework for Modeling the Effects of Strategic Information Sharing on Sentiments and Misinformation on Social Media

Theodore T. Allen[1], Richie Vanderburgh[1], Antor Rashid[2], [1]Ohio State University, Columbus, OH, [2]FactSpread, Columbus, OH

We are all concerned about the spread of misinformation and political polarization. One important option to consider is the deployment of transparently and well-sourced factual information to reduce the effects of misinformation and depolarize discourse. This presentation proposes the steps needed to develop an optimized system for low-cost information interventions on social media with measurable benefits.

Empirical Service Operations

General Session

Session Chair

Mohamad Soltani, University of Alberta, Edmonton, AB, Canada.

Session Chair

Hessam Bavafa, Wisconsin School of Business, Madison, WI

1 How Schedule Flexibility Affects Job Applications

Maria R. Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL

Struggling to attract talent, companies are scrambling to offer schedule flexibility. Analyzing data from a major job-search platform, we investigate how offering or requiring worktime flexibility affects worker attraction.

2 Racial and Gender Biases in Customer Satisfaction Surveys: Evidence from The Restaurant Industry

Masoud Kamalahmadi[1], Qiuping Yu[2], Yong-Pin Zhou[3], [1]University of Miami, Miami, FL, [2]Scheller College of Business, Georgia Tech, Atlanta, GA, [3]University of Washington, Seattle, Seattle, WA

We explore whether customers exhibit any racial or gender biases when evaluating workers' performance in a racially diverse and *female-dominated occupation*. Specifically, we analyzed over 260,000 customer satisfaction surveys and 1.5 million transactions at a U.S. national casual dining restaurant chain. We found that customers were biased against female servers despite female being the majority. This contradicts the *taste-based* and *statistical discrimination* theories in the economic literature which predict biases against men in female-dominated industry. Our further analysis showed that biases against female workers could be explained by *status-based gender biases*. We also found customer biases against racial minority servers, which were driven by *statistical discrimination* rather than *taste-based or status-based discriminations*.

3 Impact of Physicians' Workstyles on EHR Workload

Umit Celik[1], Sandeep Rath[2], Bradley R. Staats[3], Saravanan Kesavan[4], [1]UNC Kenan Flagler Business School, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]UNC Chapel Hill, Guangzhou, China. Contact: Umit_Celik@kenan-flagler.unc.edu

Physicians spend a significant amount of time on Electronic Health Records (EHR). Time spent on EHR affects physician burnout, operational productivity, the degree of quality of care, and the workload of physicians. We obtain data on EHR usage by 74 primary care physicians under a large health care system. With this data, we show that in addition to clinical complexity, physician work style impacts the amount of time the physicians spend on EHR. We used instrumental variables, probit, and OLS estimation approaches in our empirical analyses. We find that performing EHR work before an appointment is efficient for the total EHR workload. Moreover, performing EHR work after the appointment is efficient, and helps to decrease the end-of-day EHR workload. In the light of these results, we recommend that an EHR break during the day helps physicians perform more efficient EHR work.

Blockchain in Finance and Insurance

General Session

Session Chair

Andreea Minca, Cornell University, Ithaca, NY

Session Chair

Hamed Amini, Georgia State University, Atlanta

1 Cryptocurrency Venues: Segmentation, Fees, and Tax Policies

Kerry Back[1], Oğuzhan Çelebi[2], Ali Kakhbod[1], Max Reppen[3], [1]Jesse H. Jones School of Business, Houston, TX, [2]MIT, Cambridge, MA, [3]Questrom School of Business, Boston, MA

We study interactions between cryptocurrency trading venues, traders, and taxation in which the venues differ in technology. This market is distinguished from markets like equities because each venue clears trades separately from one another. We show that trading fees rise when the venues are technologically differentiated. Improvements in the lower tech venue is associated with greater trading volumes, whereas improvements in the higher tech venue has an ambiguous impact. When the two venues have similar technologies, differentiation has a positive effect on trading volumes. Our welfare analysis suggests that in equilibrium, the tax rate to optimize tax revenue depends only on trader preferences, and it is thus independent of the venue properties and competition. With other government welfare weights, the aggregate welfare can have a maximum for nontrivial tax rates

2 Decentralized Payment Clearing Using Blockchain

Hamed Amini[1], Maxim Bichuch[2], Zachary Feinstein[3], [1]Georgia State University, Atlanta, [2]Johns Hopkins University, Baltimore, MD, [3]Stevens Institute of Technology, Hoboken, NJ

In this talk, we construct a decentralized clearing mechanism which endogenously and automatically provides a claims resolution procedure through blockchain. In so doing, we provide an algorithm which constructs the blockchain so as to guarantee the payments can be verified and the miners earn a fee. We, additionally, consider the special case in which the blocks have unbounded capacity to provide a simple equilibrium clearing condition for the terminal net worths. Finally, we consider the optimal bidding strategies for each firm in the network so that all firms are utility maximizers with respect to their terminal wealths. The implications of these strategies, and more broadly blockchain, on systemic risk are considered.

3 Blockchain Adoption and Optimal Reinsurance Design

Hamed Amini[1], Romain Deguest[2], Andreea Minca[3], Engin Iyidogan[4], [1]Georgia State University, Atlanta, GA, [2]IESEG School of Management, Paris la Defense, France; [3]Cornell University, Ithaca, NY, [4]SKEMA Business School, Paris, France. Contact: r.deguest@ieseg.fr

We study blockchain adoption in a reinsurance market. Unlike standard operational costs related to claim processing that scale linearly with claim volume, blockchain operating costs per firm are independent of claim volume and decrease with the adoption rate since verification and storage costs are distributed among the adopters. In a consortium of insurance firms, we quantify how the equilibrium adoption decisions depend on the reinsurance contract characteristics, the risk aversions of insurance companies, the distributions of their potential losses and the blockchain cost structure. When a reinsurance firm acts as a central planner in the blockchain consortium, the optimal adoption rate from planner's viewpoint is higher than the Nash equilibria adoption rate. We observe that this gap widens when the blockchain cost becomes more sensitive to the adoption level.

Monday, 8AM–9:15AM

Statistical Inference on Hidden Structures and Beyond

General Session

Session Chair

Dana Yang, 1</sup

1 Kernel Feature Selection: Automatic Sparsity without l_1 Regularization

Feng Ruan[1], Michael Jordan[2], Keli Liu[3], [1]Northwestern, Evanston, IL, [2]University of California, Berkeley, Berkeley, CA, [3]Stanford University, Stanford, CA, Contact: fengruan@berkeley.edu

Kernel feature selection is an important tool in nonparametric statistics. In this talk, I am going to describe a surprising property about the (non-convex) kernel feature selection objective: all stationary points of the objective are automatically sparse in finite samples without use of known regularization techniques, e.g., l_1 penalization and early stopping.

2 Optimality of Approximate Message Passing

Alex Wein[1], Andrea Montanari[2], [1]UC Davis, Davis, CA, [2]Stanford, Stanford, CA

The approximate message passing (AMP) framework has been widely successful at producing algorithms with provable guarantees for a variety of high-dimensional statistical inference tasks. In some settings, AMP is conjectured to be optimal in the sense that no computationally efficient estimator can achieve a better mean squared error (MSE) than AMP. In a simple "signal plus noise" model (spiked Wigner), we prove a variant of this conjecture by showing that AMP has the best possible MSE within the class of so-called "low-degree polynomial algorithms." This result is sharper than existing low-degree lower bounds, matching AMP's exact asymptotic MSE (given by the replica symmetric formula). The proof sheds some light on what makes AMP optimal for some problems but not others.

3 Random Graph Matching in Geometric Models

Haoyu Wang[1], Yihong Wu[1], Jiaming Xu[2], Israel Yolou[1], [1]Yale University, New Haven, CT, [2]Duke University, Durham, NC, Contact: haoyu.wang@yale.edu

We study the problem of matching two graphs with edge weights correlated through latent geometries. Given a random permutation π and n iid pairs of correlated d-dimensional Gaussian vectors $\{X_{\pi(i)},Y_i\}$ with noise parameter □, the edge weights are given by $A_{ij}=\langle X_i,X_j\rangle$ and $B_{ij}=\langle Y_i,Y_j\rangle$. The goal is to recover the hidden vertex correspondence π based on the observation of A and B. We focus on the low-dimensional regime of d=o(log n) wherein the underlying geometry is most evident. We derive an approximate MLE, which provably achieves, with high probability, perfect recovery of π when □=$o(n^{-2/d})$ and almost perfect recovery when □=$o(n^{-1/d})$. Furthermore, these conditions are information-theoretically optimal even when the latent coordinates are observed, complementing the recent results of Kuniskty-Niles Weed in geometric models of the planted bipartite matching problem.

4 Tensor-on-tensor Regression: Riemannian Optimization, Over-parameterization, Computational Barriers, and Their Interplay

Yuetian Luo, University of Wisconsin-Madison

We propose the Riemannian gradient descent and the Riemannian Gauss-Newton methods to solve tensor-on-tensor regression without prior knowledge of the intrinsic rank and cope with the challenge of unknown rank by studying rank over-parameterization. We show RGD and RGN converge linearly and quadratically to a statistical optimal estimator in both rank correctly/over-specified settings. Our theory reveals Riemannian optimization adapts to rank over-parameterization. Our results improve upon the existing results of over-parameterized matrix trace regression. We also give the first evidence for the computational barrier in scalar-on-tensor regression under the low-degree polynomials framework and reveal a blessing of computational barriers phenomenon in the over-parameterized tensor-on-tensor regression when the tensor order is at least three.

Emerging Topics in Supply Chain Risk Management

General Session

Session Chair

Piyal Sarkar, Ryerson University, Canada, Toronto, Canada.

1 Risks in Global Supply Chain Management

Amulya Gurtu, Cofrin School of Business, University of Wisconsin-Green Bay, Green Bay, WI, Contact: gurtua@uwgb.edu

Globalization increased the complexities and risks in supply chain management (SCM). Global supply chains heavily rely on efficiencies across the systems. Digitization improves SCM performance, but it makes SCM vulnerable. COVID-19 and the Russia-Ukraine conflict have presented many new dimensions of risks in SCM. The cost of managing these risks affects financial performance. Building resilience and reducing risks in SCM provides competitive advantages. The sources of risks are evolving. The risk assessment and mitigation strategies need to be expanded to include new risks because the influence and impact of modern risks in SCM are potentially catastrophic. There is a need to explore supply chain risks in the contemporary context.

2 Design of Weather Rebate Sharing Contract

Piyal Sarkar[1], Mohamed Wahab Mohamed Ismail[2], Liping Fang[2], [1]Ryerson University, Canada, Toronto, ON, Canada; [2]Ryerson University, Toronto, ON, Canada. Contact: piyal.sarkar@ryerson.ca

To address weather risk in supply chains, we propose a class of contract that performs better than a traditional revenue sharing contract. Contract parameters are designed to consider the risk aversion attitude of supply chain members. Conditional Value at Risk (CVaR) is used as the risk measure. The new class of contract combines a Cooling Degree Days (CDD)-based rebate structure with financial risk hedging. This class of contract can be utilized for administering supply chains of weather-sensitive products.

3 DISRUPTION MITIGATIOn and PRICING FLEXIBILITY

Florian Lucker[1], Oben Ceryan[2], [1]Bayes Business School, City University of London, London, United Kingdom; [2]City, University of London, London, United Kingdom.

We study a firm that is exposed to random supply chain disruptions. We focus on the optimal use of pricing to mitigate disruptions, i.e. the option to increase prices during the disruption to better match available supply with demand (referred to as pricing option). We find that the pricing option often complements other operational mitigation strategies such as holding additional inventory or reserving capacity that can be used during the disruption. In other words, when a firm has the pricing option, it may be incentivized to hold larger quantities of inventory and reserve capacity.

Behavioral Supply Chain Management

General Session

Session Chair

Andrew M. Davis, Cornell University

1 Presenter

Anna Devlin[1], Jatinder N. J. Gupta[2], [1]Drexel University, Philadelphia, PA, [2]University of Alabama Huntsville, Huntsville, AL

Many landlords opt to hire property management (PM) firms to manage their properties, creating a principal-agent scenario. These relationships are governed by contracts with rent-based fees such as a payment to the PM firm for filling vacancies or extending leases. These fees incentivize appropriate short term behavior from the PM firm, but can be in direct conflict with a landlord's long term profits. This research studies an analytical model to investigate how contract terms should be set to incentivize effort from PM firms and maximize a landlord's long-term profits. Taking into account vacancy rates and effort finding high-quality renters, we examine long-term profits for landlords and PM firms under a contract with fees that increase as renters stay longer. Implications on rent increases due to landlord cost savings and landlord/PM relationships are also discussed.

2 Full Quantity or Full Credit? Choosing The Right Buyback Policy for a Boundedly-Rational Retailer

Yinghao Zhang[1], Peiwen Yu[2], Tianjun Feng[3], [1]University of Cincinnati, Cincinnati, OH, [2]Chongqing University, Chongqing, China; [3]Fudan University, Shanghai, China. Contact: zhang5y7@ucmail.uc.edu

We compare two forms of buyback policies - a traditional full-quantity partial-credit (FQ) buyback contract and an alternative full-credit partial-quantity (FC) contract. Through lab experiments, we find that retailer's orders are influenced by behavioral tendencies such as loss aversion, prospective accounting, and inventory error. Taking into account the retailer's behavioral biases, a supply firm should adopt the FC contract when the wholesale price is endogenously set and when the production cost is high. On the other hand, when the wholesale price is exogeneous or when the production cost is low, the supplier should adopt the FQ policy.

3 Sourcing Under Supplier-induced Risks: A Behavioral Investigation

Junhao Vincent Yu[1], Karen L. Donohue[2], Karthik V. Natarajan[2], [1]NC State University, Raleigh, NC, [2]University of Minnesota, Minneapolis, MN, Contact: jyu37@ncsu.edu

Various types of supplier-induced risks occur in supply chains. In this study, we compare risks that disrupt product supply and that influence consumer demand. We combine modeling and experimental methods to investigate buyers' sourcing behaviors and associated profit implications when facing suppliers with different types and levels of risks.

1 How to Sell Your Crypto Art? Evidence from Non-fungible Token Art Drops

Yuan (Lucy) Zhang[1], Kenny Cheng[1], Liangfei Qiu[2], [1]University of Florida, Gainesville, FL, [2]University of Florida Warrington College of Business Administration, Gainesville, FL

Crypto art is an early use case for NFT because of the ability of blockchain technology to assure the unique signature and ownership of the artwork. While artists see opportunities in the fast-growing NFT collectible market, little is known about the NFT release and sales strategies. In this study, we use one of the earliest NFT art collection datasets to empirically investigate the effect of NFT drop mechanisms and promotional strategies on the price of NFT arts. As one of the first empirical studies investigating NFT drop mechanisms and NFT characteristics' influence on NFT value, we provide meaningful investment insights on crypto art and stimulate further research on NFT releasing and trading in different contexts.

2 Informational Efficiency of Cryptocurrency Markets

Mariia Petryk, 1</sup

Our study investigates price discovery in the cryptocurrency markets by analyzing the evolution and determinants of their (in)efficiency. First, we compare the informational efficiency of cryptocurrencies to regulated stocks using time series estimates of variance ratios. We find that stocks are more efficient than cryptocurrencies. We also find that "mildly regulated" cryptocurrencies are more efficient than unregulated ones. Our results point to the role of regulation on price efficiency. We further investigate the factors that contribute to cryptocurrency market (in)efficiency, including social media activity and type of technology. Our findings will be interesting for policymakers and cryptocurrency trading platforms to design policies that control investment risks.

1 Anchoring Search: An Investigation of The Role of Abstraction and Traversal in Creative Problem Solving

Shi-Ying Lim[1], Tian Chan[2], [1]National University of

Singapore, Singapore, Singapore; [2]Emory University, Atlanta, GA, Contact: sylim@nus.edu.sg
Conceptualizing creative problem-solving as a search process that may involve individuals navigating between a problem space and a solution space, we theorize on the dual roles of abstraction (which expands the search area) and traversal (in terms of the total number of ideation steps and the jumps between the problem to solution-space) affect problem-solving. Using a data set of users' creative modification of IKEA products, we document evidence that creative problem-solving involving 1. changes in the levels of abstraction (concrete vs. abstract), 2. increased number of ideation steps, and 3. reduced number of traversals between the problem and the solution spaces, can lead to more successful problem-solving.

2 Product Development in Crowdfunding: Theoretical and Empirical Analysis

Sidika Tunc Candogan[1], Philipp Benjamin Cornelius[2], Bilal Gokpinar[3], Ersin Korpeoglu[1], Christopher S. Tang[4], [1]University College London, London, United Kingdom; [2]Rotterdam School of Management, Rotterdam, Netherlands; [3]UCL School of Management, London, United Kingdom; [4]University of California-Los Angeles, Los Angeles, CA, Contact: sidika.tunc.16@ucl.ac.uk
We analyze an entrepreneur's product development and improvement decisions in crowdfunding. We show that both the chances of campaign success and the likelihood of product improvement first increase but then decrease with the product's level of enhancement. We also characterize the initial enhancement level that maximizes the entrepreneur's profit.

3 CDC Announcements and User Participation

Lijia Ma[1], Xue Tan[2], Yingfei Wang[1], Yong Tan[1], [1]University of Washington, Seattle, WA, [2]Indiana University, Bloomington, IN, Contact: lijiam@uw.edu
In the COVID-19 pandemic, the overabundance of information makes it hard to find trustworthy sources and reliable guidance. An important role of the CDC is to promote healthy and safe behaviors, communities, and the environment. Its social media channel also allows conversations (in the comment section) for people to exchange information and possibly refine their beliefs. Our study seeks to analyze the relationship between the official announcement (e.g. CDC)and the discussion it sparks. To be more specific, we would like to answer the two research questions: How does the content CDC posts affect the conversation? How does the influence vary with the political orientation of readers? To answer these questions, we collect data from both the CDC and the state-level health departments on a social media platform. Our results provide managerial implications for policymakers.

4 Automation, Productivity, and It Workforce: The Case of ContainerTechnology

Yutong Liu[1], Wei Chen[2], Muhammad Taqi Raza[1], [1]The University of Arizona, Tucson, AZ, [2]The University of Arizona, Tucson, AZ, Contact: yutong@email.arizona.edu
This study investigates the impact of adopting container technology in organizations as process automation in software development. We separate container-adopted and non-container-adopted organizations to assess how the organizational productivity and IT workforce change after adopting container technology. Our findings suggest that the adoption of container technology positively affects both productivity and the size of the IT workforce. In addition, we find that the pre-adoption size of the organization attenuates the effect of container adoption, while the complexity of the development environment amplifies it. The implication is that the encapsulation of application dependencies in containers automates the creation of software development environments and furthers a cross-machine consistency for better collaboration.

Siyuan Liu, Penn State University

1 A Tale of Two Tasks: The Imperative of Goal Adjustment in Fairness-aware Machine Learning

Heng Xu[1], Nan Zhang[2], [1]American University, Washington, DC, [2]University of Florida, Gainesville, FL
Numerous efforts in machine learning (ML) have been devoted to develop what are now known as fairness-aware ML algorithms. Most existing such algorithms were designed as drop-in replacements for ranking or selection tasks in practice. This paper demonstrates that a seemingly minor adjustment on this problem definition, specifically a modification of the weights assigned to false positives and false negatives, can help address some longstanding obstacles facing fairness-aware ML, such as

the intrinsic conflict between different fairness definitions. Our results suggest that assigning ML with a carefully designed optimization goal, rather than as a straightforward replacement of existing ranking/selection tasks, can enable fairness-aware ML to reach a considerably better tradeoff between predictive accuracy and fairness in practice.

2 A Point Process Based Graphical Attribution Model

Jun Tao[1], Qian Chen[2], Lingzhou Xue[1], Jim Snyder[3], Amirhossein Meisami[3], [1]Pennsylvania State University, State College, PA, [2]Pennsylvania State University, State College, PA, [3]Adobe Inc., San Francisco, CA

Marketers employ various online advertising channels to reach customers, and they are particularly interested in the attribution problem -- measuring the degree to which each channel contributes to the conversion. To tackle this problem, this study develops a novel graph-based attribution modeling approach in the multi-channel setting. The proposed model utilizes customer-level path-to-purchase data to learn the conversion effects of different types of touch points, accounting for the full relational structure among touches. Based on the learned graph, we further proposes graphical attribution methods that assign more accurate conversion credits to each touch point and the corresponding channel. Our model results shed lights on resource allocation across channels and effective marketing.

3 CFPrice: Robust Pricing of Airline Ancillaries Under Distribution Shift Using Causal Information

Abhinav Garg[1], Sriram Somanchi[2], Lavanya Marla[3], [1]University of Illinois, Urbana Champaign, IL, [2]University of Notre Dame, Notre Dame, IN, [3]U of Illinois at Urbana-Champaign, Urbana, IL, Contact: garg19@illinois.edu

Many machine learning algorithms rely on the assumption that the test data are drawn from the same distribution as the training data to guarantee performance. COVID-19 has significantly affected the travel demand and purchase of ancillaries. We present a causal forest-based method for building robust pricing models under distribution shift using causal information. Extensive experiments on real-world airline customer data show that our proposed method can significantly improve the model performance and stability of prediction under distribution shift through simulations in an offline setting.

1 Clinical Supply Chain Waste Reduction Using AI/ML

Ankush Chandna, ZS Associates, Princeton, NJ, Contact: ankush.chandna@zs.com

Clinical Supplies, especially comparators and co-medications, represent a significant portion of the total cost of clinical trials. Across our industry, average waste is estimated at 55% of total production volume. The use of AI/ML techniques for clinical demand forecasting and supply planning, for both new and ongoing studies, presents an opportunity to reduce wastage and realize significant savings

2 What is the Length of Medication Therapy? a Special Class of Duration Models for Claims Data

Ka Lok Lee, Srihari Jaganathan, UCB Pharma, Atlanta, GA

Claims database is rich source for life science academics and practitioners to track and study patients' behavior longitudinally. An important and frequently studied metric is the length of medication therapy. A frequently seen phenomenon from the data is a sizeable drop-off that happens within the first month after initial fill. Various reasons can cause this phenomenon, and is quite unique for medication duration data. We show that standard models are ill-equipped to deal with the drop-off. In this work, the authors propose a special class of probability models that can specifically handle the initial drop and model the data accurately. We adopt the idea from a zero-inflated count model and apply it here. We illustrate the impressive performance with a numerical example and discuss further applications.

Creating Environments to Foster Diversity

Contributed Session

Session Chair

zeynep Yavic, The Ohio State University, Columbus, OH

1 **Championing of Digital Payments Platforms by Subsistence Entrepreneurs in Developing Country, Expanding Technology Adoption Models**

Alka Agarwal[1], Ashish K. Jha[2], Jyoti Jagasia[3], [1]S.P. Jain Institute of Management and Research, Mumbai, India; [2]Trinity Business School, Trinity College Dublin, University of Dublin, Dublin, Ireland; [3]S.P. Jain Institute of Management and Research, Mumbai, India. Contact: fpm18.alka@spjimr.org

We study how Digital payments platforms adoption was accelerated in the pandemic for subsistence entrepreneurs who suffer double jeopardy of resource scarcity and institutional voids hindering their technology adoption. We study this hitherto uncharted area in IS research using constructivist grounded theory. From 20 interviews we highlight a process that entails adoption and persistent use and also a new construct of championing.

2 **Into a Vicious Cycle: A Negative Spillover Effect of An Entrepreneurial Failure on An Assessment of Minority Entrepreneurs' Managerial Competence**

Seonghoon Kim[1], Matthew Potoski[1], Jessica Santana[2], [1]University of California, Santa Barbara, Santa Barbara, CA, [2]University of California, Santa Barbara, Santa Barbara, CA, Contact: seonghoon_kim@bren.ucsb.edu

In this research, we argue that when people see a business failure of a certain female or minority entrepreneur, they negatively assess managerial competence of all other female or racial-minority entrepreneurs of the same field. At the core of our argument is the role of group stereotypes. In the entrepreneurial domain, a stereotype has existed about female vs. male (or Black vs. white) entrepreneurs, such that people assess those underrepresented entrepreneurs as less competent than their counterparts. Under this circumstance, a female or racial-minority entrepreneur's business failure can trigger and reinforce people's already-negative stereotype, leading to more negative evaluations of all other female or minority entrepreneurs' managerial competence. In this paper, we derive relevant hypotheses and test them through an experimental vignette study approach.

3 **Regulations for Substitutable Medical Treatments**

Fan Zhou[1], Shima Nassiri[2], Ravi Anupindi[1], [1]University of Michigan, Ann Arbor, MI, [2]Amazon, San Bruno, CA, Contact: fanzhou@umich.edu

It is common practice for healthcare providers to offer several treatment choices to patients and make recommendations based on patients' characteristics. In this study, we consider the stent, a medical device used in percutaneous coronary intervention (PCI). There are two kinds of stents available in the market, and the high-price option shows higher quality only for high-risk patients. Without regulations, profit-maximizing providers can misuse these devices and limit patients' access to care by setting high prices. We are interested in regulation policies that help avoid such adverse effects.

4 **Pushing up Against The Glass Ceiling: Evaluation Apprehension, Gender, Creativity and Information Sharing**

zeynep yavic, The Ohio State University, columbus, OH, Contact: yavic.1@osu.edu

We outline an experiment to investigate the effect of expected evaluation on employees' creativity and information sharing patterns. We additionally examine the effect of gender on evaluation apprehension, as the psychological discomfort of evaluation has been theorized as a reason for gender discrimination in promotion policies. Subjects wrote short proposals and chose whether to submit their proposal for evaluation. We induced three organizational conditions: base, risk and competition. We predict that female subjects will try harder and write more creative proposals when subjected to evaluation apprehension, but will be less likely to share their proposals under expected evaluation than men. After carefully controlling for skill, we find support for the moderating role of gender and organizational conditions on evaluation apprehension effect.

1 **Analyzing Team Success in The NBa with Data Envelopment Analysis**

David W. Jacobson, Matthew Warner, Metropolitan State University, Saint Paul, MN, Contact: david.jacobson@metrostate.edu

Data Envelopment Analysis (DEA) is applied to analyze team success in the National Basketball Association (NBA). A two input and one output model is developed. The inputs considered are adjusted team offensive efficiency (points per 100 possessions) and adjusted team defensive efficiency (points allowed per 100 possessions). The output is regular season wins. The analysis looks at the efficiency scores for all 30 teams and compares the scores for the 16 playoff teams with the teams not making the playoffs.

2 Dynamic Scheduling of E-tournaments

Celso C. Ribeiro[1], Zhilong Dong[2], Yujie Ma[3], Ailec Zamora[1], Fengmin Xu[2], Kui Jing[2], [1]Universidade Federal Fluminense, Rio de Janeiro, Brazil; [2]Xi'an Jiaotong University, Xi'an, China; [3]Fudan University, Shanghai, China. Contact: celso.ribeiro@gmail.com

The Asian Olympic Council announced that electronic sports will be one of the 37 sports at the 2022 Asian Games. Optimization methods have been scarcely applied to e-sports scheduling: most of the viewership follow the games online and pay for viewing each game, teams do not move from one facility to another to play their games, and the number of teams may be very large. We propose a dynamic integer programming approach for scheduling e-tournaments, based on a modification of the Swiss system. The schedule of each round considers the rankings of the teams at the end of the previous round. The goal consists in maximizing the attractiveness to the viewership of the games played in each round. Repetitions of the same game should be avoided. The order of the games in each round enforces a fairness criterion. The approach was validated using data from tournaments of Arena of Valor and Dota 2.

3 The Multi-League Sports Scheduling Problem

Dries Goossens[1], Morteza Davari[2], Miao Li[1], [1]Ghent University, Gent, Belgium; [2]SKEMA Business School, Lille, France. Contact: dries.goossens@ugent.be

We introduce a general multi-league sports scheduling problem where timetables for multiple leagues must be determined simultaneously, a practical and challenging problem in amateur and youth sports. We consider round robin leagues with different numbers of teams. As the number of simultaneous home games that clubs can organize for their teams is limited by their venue capacity, the objective is to minimize capacity violations. Along with a MIP model which is formulated to optimize the starting round of each league as well as to settle when teams have their home games, we develop various methods to construct an initial solution, and a heuristic with several local search and perturbation components to improve on this. Extensive computational experiments reveal that our heuristic can efficiently provide high-quality solutions for artificial and realistic instances.

4 Instance Space Analysis. The Traveling Tournament Problem Explained

David Van Bulck[1], Fan Yang[2], Dries Goossens[1], [1]Ghent University, Gent, Belgium; [2]Shanghai Normal University: Shanghai, CN, Shanghai, China.

The traveling tournament problem (TTP) is to generate a sports timetable which minimizes the overall distance traveled by all teams. Since its introduction in 2003, dozens of algorithms have been proposed in the literature, of which the performance is typically compared on a set of well-known benchmark instances. Although these problem instances have undoubtedly revolutionized the field of sports timetabling, the diversity of these instances is rather limited. This talk proposes a new set of more diverse problem instances, explains what properties make that an instance is hard to solve, and explains which approach from the literature typically works well for what type of problem instances.

1 Bayesian Optimization with RKHS Kernels for Set-valued Input Functions

Poompol Buathong[1], David Ginsbourger[2], Tipaluck Krityakierne[3], [1]Cornell University, Ithaca, NY, [2]University of Bern, Bern, Switzerland; [3]Mahidol University, Bangkok, Thailand. Contact: pb482@cornell.edu

In this talk, we present a Bayesian optimization framework for expensive black-box set-valued input functions. The algorithm implements a Gaussian process surrogate model with a newly introduced class of set kernels using RKHS embeddings and the expected improvement criterion. Optimization capabilities of the proposed framework are numerically demonstrated on several synthetic datasets and two real-world applications, namely monitoring well selection in hydrogeology and material design in mechanical engineering. Performances compared to a previously studied class of set kernels are also discussed.

2 Real-time Digital Twin-based Optimization with Predictive Simulation Learning

Travis Goodwin[1], Jie Xu[1], Nurcin Celik[2], Chun-Hung Chen[1], [1]George Mason University, Fairfax, VA, [2]University of Miami, Coral Gables, FL, Contact: jxu13@gmu.edu

Digital twinning presents an exciting opportunity enabling real-time control of cyber-physical systems (CPS) with data-driven simulation, while facing prohibitive computational burdens. We introduce Sequential Allocation using Machine-learning Predictions as Light-weight Estimates (SAMPLE) to address this computational challenge by leveraging machine learning models trained off-line in a predictive simulation learning setting. SAMPLE integrates machine learning predictions with real-time simulation data to improve computational efficiency. Numerical results show the viability of SAMPLE to select in real-time optimal CPS control decisions.

3 Nested Heteroscedastic Gaussian Process for Simulation Metamodeling

Jin Zhao, Xi Chen, Virginia Tech, Blacksburg, VA, Contact: zjin20@vt.edu

In this work, we propose nested heteroscedastic Gaussian process (NHGP) modeling for the mean response surface prediction and inference based on large-scale heteroscedastic data sets. Consisting of sub-heteroscedastic GP models, NHGP has similar theoretical properties as standard heteroscedastic GP models but enjoys much lower computational complexity. Numerical evaluations are performed to demonstrate the performance of NHGP in comparison with competing methods.

4 A Discovery on Process Improvement Opportunities on a Covid Pcr Test Laboratory

Felipe Haro, Noorjax Consulting, Tallinn, Estonia.

PCR testing has become a mainstream activity since the COVID-19 pandemic. For this reason, laboratories need to improve throughput and speed, while maintaining an adequate service level. On this presentation we are not looking on how to improve the processes, but instead, we will look on the roadmap that lead to several discoveries on what really happens in these labs, how intelligent attempts to improve the processes lead to unexpected results, how process data information can be misinterpreted resulting in misleading turn around times, and the psychology of the laboratory scientists with respect to the intelligent rules that should govern the priority of samples processing.

5 Fixed Budget Ranking and Selection with Streaming Input Data

Yuhao Wang, Enlu Zhou, Georgia Institute of Technology, Atlanta, GA, Contact: yuhaowang@gatech.edu

We consider a fixed budget ranking and selection problem with input uncertainty, where unknown input distributions can be estimated using input data arriving in batches of varying sizes over time. Each time a batch arrives, the input distribution is updated and additional simulations are run with a given simulation budget. Within each time stage, we apply the large deviations theory to formulate an optimal budget allocation problem. We derive the optimality condition and design a dynamic optimal budget allocation procedure under streaming input data. We prove the consistency and asymptotic optimality of the procedure and numerically show its high efficiency.

6 Empowering Object Detection Models in Dynamic Environments with Novel Data Sampling and Augmentation Techniques

Mohammad Noroozi, Ankit Shah, University of South Florida, Tampa, FL

Object detection is focused on identifying pre-defined object classes and their precise locations. However, these AI-based models perform poorly in dynamic environments with unbounded sets of objects. Unlike human perception that can recognize new types of objects, which are previously unseen, based on numerous experiences, the AI models need to be trained effectively to identify new classes of objects. In this talk, we will present novel data sampling and data augmentation techniques to counter this shortcoming by synthesizing new images from historical data and demonstrate the effectiveness of our approach on a real-world data set using the YOLO family of deep learning models.

7 A Proactive Approach for Operational Decision Support in Primary Care

Yuan Zhou[1], Amith Viswanatha[1], Ammar Abdul Motaleb[1], Prabin Lamichhane[1], Kay-Yut Chen[1], Richard Young[2], Ayse Gurses[3], Yan Xiao[1], [1]The University of Texas at Arlington, Arlington, TX, [2]John Peter Smith Family Medicine Residency Program, Fort Worth, TX, [3]Johns Hopkins University, Baltimore, MD, Contact: yuan.zhou@uta.edu

Due to the large complexities in the primary care delivery system, one major challenge presented in its operations management is to make effective decisions proactively. In this research, we developed an integrated approach that combined predictive analytics, simulation modeling, and decision analytics to enable proactive decision-making in primary care settings. A case study was conducted in a local family medicine clinic to demonstrate the use of the proposed approach in managing patient no-shows. Three double-booking policies were developed and evaluated in terms of their impacts on the clinic productivity and efficiency, as well as the trade-offs between these two performances.

8 Automatic Differentiation for Gradient Estimators in Simulation

Matthew T. Ford[1], David J. Eckman[2], Shane Henderson[3], [1]Cornell University, Ithaca, NY, [2]Texas A&M University, College Station, TX, [3]Cornell University, Ithaca, NY, Contact: mtf62@cornell.edu

Automatic differentiation (AD) can provide infinitesimal perturbation analysis (IPA) derivative estimates directly from simulation code. These gradient estimators are simple to obtain analytically, at least in principle, but may be tedious to derive and implement in code. AD software tools aim to ease this workload by requiring little more than writing the simulation code. We review considerations when choosing an AD tool for simulation, demonstrate how to apply some specific AD tools to simulation, and provide insightful experiments highlighting the effects of different choices to be made when applying AD in simulation.

9 Rapid Machine Learning Using Simulation Technology

Thomas Brady[1], Edward J. Yellig[2], [1]Purdue University Northwest, Westville, IN, [2]Intel Corporation, Chandler, AZ, Contact: tbradyjr@pnw.edu

The marrying of computer simulation technology and machine learning algorithms can significantly shorten the *time* for Machine Learning to function. Simulation models generate large amounts of 'system data' in condensed time periods for Machine Learning algorithms to process, enabling knowledge extraction and generation to be completed efficiently. This presentation discusses an approach to architecture and knowledge representation of the combined technologies.

1 Conditional Uniformity and Hawkes Processes

Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

The distribution of a Hawkes process's cluster size is classically known through a connection to branching processes, but this is irrespective of time. Insight into the chronology of the cluster has been much more elusive. Here, we employ a novel adaptation of the random time change theorem to establish an analog of the conditional uniformity property enjoyed by Poisson processes, yielding a parking-function-based decomposition that is valuable both methodologically and practically.

2 Online Capacity Scaling Augmented with Untrusted Machine Learning Predictions

Daan Rutten, Debankur Mukherjee, Georgia Institute of Technology, Atlanta, GA

In this paper, we analyze a continuous-time model for capacity scaling that generalizes much of the earlier related approaches. We propose a novel low-complexity algorithm, called the Adaptive Balanced Capacity Scaling (ABCS) algorithm, that has access to black-box ML predictions. Although ABCS is completely oblivious to the accuracy of these predictions, its performance depends on the error of the predictions. In particular, we prove that ABCS is (1 + epsilon)-competitive if the predictions are accurate, and yet, it has a uniformly bounded competitive ratio even if the predictions are completely inaccurate. Finally, we investigate the performance of this algorithm on a real-world dataset and carry out extensive numerical experiments, which positively support the theoretical results.

3 Convex Fairness Measures: Theory and Optimization

Man Yiu Tsang, Karmel S. Shehadeh, Lehigh University, Bethlehem, PA

We propose a new parameterized class of fairness measures, convex fairness measures, suitable for optimization contexts. This class includes our new proposed order-based fairness measure and several popular measures. We provide theoretical analyses and derive a dual representation of these measures. Importantly, this dual representation renders a unified mathematical expression and a geometric characterization for convex fairness measures through their dual sets. Moreover, we propose a generic framework for optimization problems with a convex fairness measure objective, including reformulations and solution methods. Finally, we provide a stability analysis on the choice of convex fairness measures in the objective of optimization models.

Modeling Advanced Air Mobility

General Session

Session Chair

Bo Zou, University of Illinois, Chicago, IL

1 Automated Pre-departure Flight Planning for High-density Advanced Air Mobility

Yu Zhang, University of South Florida, Tampa, FL, Contact: yuzhang@usf.edu

Advanced air mobility (AAM) is envisioned to move to highly automated and high-density operations in low altitude urban airspace in the future. Third-party service providers are anticipated to provide traffic management for hundreds of thousands of flights. This AAM research at USF attempts to provide pre-departure flight plans for medium to high-density AAM operations that can be employed by service providers. Besides developing mixed-integer programming models and efficient solution algorithms to obtain the conflict-free 4D trajectories at flight planning stage, experiments are performed to investigate the sensitivity of operating cost to three key cost parameters (electricity price, crew hourly rate, and maintenance hourly rate).

2 Presenter

Hsun Chao, Seejay Patel, Daniel DeLaurentis, Purdue University, West Lafayette, IN, Contact: chaoh@purdue.edu

The Federal Aviation Administration reported that the number of registered commercial drones is more than 300 thousand in 2022. Since the autonomous last-mile delivery is one of the popular drone applications, how delivery companies use drones is crucial to assess if the current airspace infrastructure can support the drone operations. This research assumes a drone can only leave from delivery centers and deliver one package. Then, the drone-van routing problem can identify the preferred delivery option for each census tract in the study region. Even though the estimated drone operation cost is lower than the van operation cost, the approach estimated more than 600 daily drone flights in the Chicago metropolitan area for only delivering 0.6% of the total package demand. The low payload capacity of drones seems to be the bottleneck in preventing pervasive drone usage.

3 Urban Air Taxi Fleet Operation Problem with Demand Consolidation

Haleh Sadat Ale Ahmad, Hani S. Mahmassani, Northwestern University, Evanston, IL

To address *Urban Air Taxi (UAT)* fleet operation problem, a concept of operations, including air pooling and short repositioning elimination, is proposed. Subsequently, a dynamic solution framework is developed, where a static and deterministic problem, modeled as a *Capacitated Location-Allocation-Routing Problem with Time Windows and Short Repositioning Elimination (CLARPTW-SRE)*, is solved at each decision epoch on a rolling horizon basis. The corresponding MIP could be solved quickly using commercial software for narrow time windows, enabling its real-time application. Consequently, the impacts of various exogenous and design parameters on demand consolidation are examined using comprehensive sensitivity analyses in a synthetic network. Furthermore, the framework is applied to the Chicago network using Chicago *Transportation Network Providers'* demand.

4 Data-driven Approach for Comprehensive Airspace Assessment of Small Unmanned Aircraft System Operations in Urban Environments

Soohwan Oh[1], Yoonjin Yoon[2], [1]Korean Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of; [2]Korean Advanced Institute of Science and Technology (KAIST), Daejon, Korea, Republic of. Contact: suhwan@kaist.ac.kr

This study proposes a data-driven framework for comprehensive airspace assessment of small unmanned aircraft system operations in urban environments. We first define and estimate population risk of UAS operations, considering spatiotemporal variations of population movement. We then define and estimate airspace accessibility of UAS operations, considering the complexity of building distributions. Based on population risk and airspace accessibility, we perform a comprehensive airspace assessment for small unmanned aircraft system operations. Using our approach, we reflect the impact of the urban environment, including buildings and people, on the operable airspace, and we can identify areas with operable airspace even in urban areas with many buildings and people.

Flight Delays in Airline Networks

General Session

Session Chair

Vishwakant Malladi, Indian School of Business, Mohali, Punjab, India.

1 It's Not Simply Luck: The Impact of Network Strategy, Schedule Padding, and Operational Improvements on Domestic On-Time Performance in the US Airline Industry

Milind Sohoni[1], Chandrasekhar Manchiraju[2], Vinayak Deshpande[3], [1]Lubbock, [2]University of Texas - Dallas, Dallas, TX, [3]UNC Kenan-Flagler, Chapel Hill, NC

Airlines showcasetheir on-time performance (OTP), a globally accepted operational performancemetric, to demonstrate punctuality and service reliability and attract airtravelers. Airlines can adopt passive strategies, such as "schedulepadding", and active strategies, such as making "operationalchanges/improvements", to improve their OTP. We develop a framework inthis paper to study the impact of these active and passive actions on the OTPof airlines. Additionally, we study the effect of these strategies on OTPrankings, routinely used to compare airlines. We demonstrate through ouranalysis that operational improvements have the highest association with boththe change in OTP and OTP rankings of airlines, followed by schedule padding;the impact of network changes on OTP and OTP rankings is the lowest.

2 Resilient Airline Scheduling to Minimize Delay Risks

Deniz Simsek[1], M. Selim Akturk[2], [1]Northwestern University, Evanston, IL, [2]Bilkent University, Ankara, Turkey. Contact: deniz.simsek@kellogg.northwestern.edu

We show that by allowing a small deviation from the minimum cost schedule at the schedule generation phase, the potential recovery costs in the future can be reduced significantly due to the trade-off between the total operational costs and the deviation of the aircraft path variabilities. We aim to create resilient schedules, which could recover from the disruptions with a smaller number of flight cancellations. In order to incorporate the variability into our formulation as a surrogate measure to the resilience, we propose a data-driven methodology to estimate departure and arrival delay probabilities of flights and turnaround times of the aircraft. We formulate the problem as a bi-criteria nonlinear mixed-integer mathematical model with chance constraints, and utilize second order cone programming. This study is partially supported by TUBITAK Grant 2219.

3 Analysis of Centralized and Distributed Air Traffic Management

Rex K. Kincaid, William & Mary, Williamsburg, VA, Contact: rrkinc@wm.edu

To fully understand the key differences between centralized and distributed control of air traffic, the control problem is modeled abstractly, as an optimization problem, without the use of heuristics. By using this approach, specific conflict detection and resolution algorithms are not needed. Results indicate the strengths and weaknesses of each concept as a whole rather than an individual algorithm

4 A Statistical Analysis of Airline On-time Performance Data Using Benford'S Law

Shikhar P. Acharya[1], Biniv Maskay[2], [1]University of North Texas at Dallas, Dallas, TX, [2]Loras College, Dubuque, IA

Airline on-time data are reported to Bureau of Transportation Statistics (BTS) by air carriers that have at least 0.5 percent of total domestic scheduled-service passenger revenues. Since these data are *reported* rather than automatically collected by BTS, it may be subjected to human errors. We apply Benford's law to assess the reliability of departure delays reported by Delta Airlines and American Airlines departing from their major hubs for the years 2017-2021. The analysis shows that departure delay reported between 10 to 99 minutes does not conform to Benford's law. There seems to be rounding errors when the reported time delays are multiples of 10.

5 Data-driven Modeling of Delay Propagation in Air Transportation Networks

Vishwakant Malladi[1], Milind Sohoni[2], [1]Indian School of Business, Mohali, Punjab, India; [2]Indian School of Business, Hyderabad, India.

The propagation of delays in modern air transportation networks has significant financial implications. Modeling the propagation of delays in a stochastic environment is difficult due to the complexity of schedules, the size of the network, and the inter-temporal nature of dependencies. To model delay propagation in such networks we propose a framework called time-lagged subordinated Markov chains. The advantage of ou rproposed framework is that it is parsimonious and easy to simulate. We develop techniques to calibrate our framework, and estimate the lag and the intensity of delay propagation across the network. Using our model, we estimate the total impact of propagation on delay times, the contribution of each airport in the airline's network to delays, and identify the edges in the network with the highest impact on delay

1 Feature Extraction of Echocardiograms Using Neural Network Image Segmentation

Gabriel Cacao, Dongping Du, Texas Tech University, Lubbock, TX

Echocardiograms contains many diagnostically useful features which have not been used in clinical decision-making. This study develops a Deep Learning model trained end-to-end on echocardiograms to predict segmentation for all structures of the heart, which facilitates rapid quantitative and qualitative analysis of the videos. A CNN associated with an unsupervised methodology is used to segment the structures of the heart, to reduce noise and ensure accuracy in edge detection. The network is built to work with multiple frames in the three-dimensional (3D) ultrasound. The unsupervised approach will enable automatic extraction of features from the segmented images without manual interventions.

2 Biologically Informed Machine Learning to Quantify Regional Heterogeneity of Tumor Recurrence in Glioblastoma

Hairong Wang[1], Michael Argenziano[2], Hyunsoo Yoon[3], Leland S. Hu[4], Andrea Hawkins-Daarud[4], Jack Grinband[2], Peter Canoll[2], Kristin Swanson[4], Jing Li[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]Columbia University, New York, NY, [3]Yonsei University, Seoul, Korea, Republic of; [4]Mayo Clinic, Phoenix, AZ, Contact: hairongwhr@gatech.com

Glioblastoma is the most common primary malignant brain tumor. Glioma heterogeneity has become increasingly appreciated with the advent of single cell transcriptomic analyses. We designed a non-invasive deep learning (DL) algorithm that leveraged unlabeled samples and biological domain knowledge from neuropathologists to augment the capability of data-driven DL training to predict three tissue-specific gene modules associated with cell proliferation, neuronal signaling, and cytokine/immune response using magnetic resonance imaging. Our model, composed of Uncertainty Transfer Network and Knowledge-Regularized Adversarial Autoencoder, substantially mitigates the biopsy sample shortage in training a robust model. Our study provides insights into data augmentation and model design, and has the potential to be applied to other biomedical applications.

3 An Unsupervised Ensemble Learning Approach to Fusing Multisource Prediction Scores

Shiva Afshar[1], Ying Lin[1], Shizhong Han[2], Yinghan Chen[3], [1]University of Houston, Houston, TX, [2]Johns Hopkins School of Medicine, Baltimore, MD, [3]University of Nevada, Reno, NV

Combining the predictors obtained from distributed data sources or machine learning algorithms is promising to achieve enhanced and robust performance in lots of classification problems. Ensemble learning is commonly used for combining predictors. However, it usually requires a large set of labeled data to estimate the accuracy of each predictor. Estimating the accuracy of each predictor without labeled data is still a challenging problem. This study developed a spectral-based unsupervised ensemble learning model to combine various correlated prediction scores and applied the proposed method to integrate the multisource disease-gene association scores for risk gene discovery.

4 DeepMiceTL: A Deep Transfer Learning Based Prediction of Mice Cardiac Arrhythmias Using Early Electrocardiograms

Ying Liao[1], Yisha Xiang[2], [1]Texas Tech University, LUBBOCK, TX, [2]Texas Tech University, Lubbock, TX

Genetic defects are among common causes of cardiac arrhythmias. Early detection of patients with such genetic defects prior to severe cardiac events is a healthcare imperative. However, developing effective and inexpensive screening tools for early identification of these patients is challenging because it is difficult to test the efficacy of any such tools on humans. Due to a high genetic homology, we use mouse models to develop a method to predict genetic abnormality associated arrhythmias. We hypothesize that mice with genetic defects present subtle abnormalities in their early ECGs before severe arrhythmias occur and that these subtle patterns can be detected by deep learning methods. To address the issue of data scarcity, we propose a deep transfer learning (TL) model, DeepMiceTL, which leverages knowledge from human ECGs to predict cardiac arrhythmias in mice .

Deep Learning Methods in Energy Systems Research

General Session

Session Chair

Jie Han, University of Texas, Arlington, TX

Session Chair

Shouyi Wang, University of Texas at Arlington, Arlington, TX

1 Electricity Price Forecasting with Transformer

Jie Han, Rhitu Thapa, Sanyogita Piya, University of Texas at Arlington, Arlington, TX, Contact: jie.han@mavs.uta.edu

Electricity price forecasting is increasingly critical for participants to make competitive bids in deregulated markets due to the higher uncertainty brought by escalated percentage of electricity generated by renewable energies. we developed a transformer based electricity price forecasting model for Texas electricity company, ERCOT. Extreme spikes, as high as 9000 dollars per MWh, were considered and coped with classification techniques. Besides, our model can be used for different horizons, whether intraday or day-ahead, of electricity forecasting. By comparing with different state-of-the-art models, our model shows better performances in different forecasting scenarios.

2 Visual Interpretation of Convolutional Neural Networks for Tree-risk Prediction and Conflict Detection

Nasko Apostolov[1], Ryan Suttle[2], Sanjay Arwade[1], Brian Kane[3], Jimi Oke[1], [1]University of Massachusetts Amherst, Amherst, MA, [2]HortScience | Bartlett Consulting, Berkeley, CA, [3]University of Massachusetts Amherst, Amherst, MA, Contact: aapostolov@umass.edu

Power outages are often caused by tree-powerline conflicts. Pruning efforts increase clearing costs and impact tree health, leaving communities susceptible to hazardous conditions. Automated approaches for risk assessment are thus a cost-effective solution for mitigation. First, we train a convolutional neural network (CNN) to predict high-risk tree-powerline conflicts using expert-labeled images. Second, we train another CNN to identify conflict regions within the labeled images. Integrating the conflict identifier with the conflict risk predictor, we develop the Visual Interpretability Score (VIS) metric, which quantifies the extent of a CNN's attention on the areas of interest in an image for enhanced model selection. This novel method thus promotes sustainable resilience via interpretable artificial intelligence.

3 A Deep Learning-based Battery Sizing Optimization Tool for Hybridizing Generation Plants

Yingqian Lin[1], Binghui Li[2], Thomas Mosier[1], [1]Idaho National Laboratory, Idaho Falls, ID, [2]Idaho National Laboratory, Idaho Falls, ID, Contact: yingqian.lin@inl.gov

Hybrid generation and energy storage systems offer the ability to increase flexibility of the combined asset. Yet, existing tools to optimize energy storage sizing are either too rudimentary or too complex to implement. This work presents a novel deep learning-based battery sizing optimization tool that is designed to help generation asset owners easily assess preliminary sizing considerations for potential battery investments to hybridize their generation facility. The tool uses deep learning to predict revenue and battery degradation over a broad search space of potential battery sizes, estimates capital and operating costs, and computes financial performance of each potential battery system investment, recommending a system with maximum financial performance. The tool is tested and validated for hydropower generation.

4 Econometric Modeling of Intraday Electricity Market Price with Inadequate Historical Data

Saeed Mohammadi, Mohammad Reza Hesamzadeh, KTH Royal Institute of Technology, Stockholm, Sweden. Contact: saeedmoh@kth.se

The intraday (ID) electricity markets have received an increasing attention in the recent EU electricity market discussions. This is partly due to the growing uncertainty in the underlying power system. The ID market is an adjustment platform which provides the liquidity to deal with such trading risks. To have the most favorable trade, market participants need a proper model for ID market price to optimally adjust their positions by trading in ID market. Inadequate historical data for ID market makes it further challenging to model. This research proposes econometric models, i.e. long short-term memory, deep convolutional generative adversarial networks, and No-U-Turn sampler algorithms, to model the ID hourly prices. Our proposed econometric models show a promising performance in the Nordic ID database.

5 A Neural Network Approach to High-dimensional Optimal Switching Problems with Jumps in Energy Markets

April Nellis[1], Erhan Bayraktar[2], Asaf Cohen[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: nellisa@umich.edu

We consider optimal switching problems represented by a coupled system of forward-backward stochastic differential equations, in which finite-variational jumps in the forward process drive jumps in a backward process representing the value function of a switching problem. We develop a backward-in-time machine learning algorithm that uses a sequence of neural networks and the dynamic programming principle to solve for optimal switching strategies, where the neural networks accurately learn the added jump components. We then apply this algorithm to a variety of problems arising from energy production and scheduling problems, ranging in dimension from two to ten. Our results show that the algorithm performs with accuracy and the computation time grown linearly with dimension, demonstrating the value of the algorithm for solving high-dimensional problems.

1 Overparametrized Multi-layer Neural Networks: Uniform Concentration of Neural Tangent Kernel and Convergence of Stochastic Gradient Descent

Jiaming Xu[1], Hanjing Zhu[2], [1]Duke University, Durham, NC, [2]Fuqua School of Business, Duke University, Durham, NC, Contact: hz176@duke.edu

There has been a recent surge of interest in understanding the convergence of gradient descent (GD) and stochastic gradient descent (SGD) in overparametrized neural networks. Most previous works assume that the training data is provided a priori in a batch, while less attention has been paid to the important setting where the training data arrives in a stream. In this paper, we show the neural tangent kernel (NTK) function of every hidden layer converges uniformly to some deterministic kernel function. This significantly improves over existing results which only prove pointwise concentration of the NTK function of the last hidden layer. Furthermore, we apply the uniform concentration result to the streaming data setup and show that with overparametrization and random initialization, the prediction error of multi-layer neural networks under SGD converges in expectation.

2 Deep Learning Based Sleep Detection Model

Jaynish Vaghela, Dell Inc., Austin, TX

Driving while drowsy is a serious problem in the United States. A report from the NHTSA estimates that drowsy driving leads to 100,000 reported crashes each year, 71,000 injuries & 800 fatalities, & a $12.5B cost. One solution is to identify & alert when a driver is falling asleep. In this work I propose two image-based frameworks for the detection & recognition of drowsiness based on a video feed of the driver's face. Both frameworks are broadly divided into two parts, namely, feature extraction followed by time series-based prediction. The two frameworks differ in the way

features are extracted & fed into an LSTM Network to make predictions. The model aims to monitor a driver's condition in real-time. From the video, an image-based noninvasive technique is used to detect the facial features of the driver with time & classify drowsiness & sound an alarm if drowsy.

3 Molecules Classification from Ultra-violet Spectra by Different Featurization Methods

Linh Ho Manh[1], Victoria C. P. Chen[2], Kevin Schug[1], Shouyi Wang[3], [1]University of Texas at Arlington, Aarlington, TX, [2]The University of Texas at Arlington, Arlington, TX, [3]University of Texas at Arlington, Arlington, TX, Contact: linh.homanh@mavs.uta.edu

Machine Learning has been applied to several domains in material science and chemistry, to predict molecular properties such as partition coefficient (logP), and rate of absorption, Vacuum ultraviolet spectroscopy (VUV), similar to mass spectra, is an interesting chemical property and provides quantitative information, especially for fuels. In addition, evidence also suggests that machine learning models require sufficient and organized data. In this research, 122 molecules of four different types: monoaromatic, diaromatic, alkene, and diene are studied. The truth labels of datasets are retrieved by clustering the corresponding VUV spectra in four different clusters. Another interesting aspect of this research is the characterization of molecules from structural information to the graph representation of molecules.

1 Predicting Flight Error for Pilot Training Using Explainable Multimodal Physiological Signals

Gregory Barry, Air Force Institute of Technology

Throughout the USAF's pilot training, student pilots are evaluated at the end of a mission and given a grade from their instructor. The delay in starting and finishing pilot training is a continual crux the USAF has attempted to fix, while working to better train each and every pilot. We hypothesize that recorded multimodal physiological data from training flights can have key features extracted, which then enable proper prediction of cumulative flight error. Such predictions can expedite grading, and allow the proper personalization of training curriculums to minimize training duration while maximizing effectiveness of training missions experienced. Extracting explainable features will allow precise selection of key physiological sensors to begin integrating within every pilot training mission.

2 Federated Generalized Scalar-on-Tensor Regression

Elif Konyar, Mostafa Reisi Gahrooei, University of Florida, Gainesville, FL, Contact: elif.konyar@ufl.edu

Increase in the need to generate, store, and analyze data at the edge of networks, and the rise of concerns about data privacy have led to federated learning frameworks. These frameworks allow local clients to learn local models and collaborate with other clients in developing a global model while handling communication and storage limitations, and data privacy issues. Moreover, complex systems are generating high dimensional data for which tensor regression approaches provide accurate results by capturing complex correlation structures of data. In this paper, we propose federated scalar-on-tensor regression model where local tensor regression models are learned at the edge, and their parameters are shared with and updated by a global client. This new approach is promising in many areas such as agriculture and healthcare where data is high dimensional and localized.

3 AVATAR: Adversarial Self-supervised Domain Adaptation Network for Target Domain

Jun Kataoka[1], Hyunsoo Yoon[2], [1]Binghamton University, Binghamton, NY, [2]Yonsei University, Seoul, Korea, Republic of. Contact: jkataok1@binghamton.edu

We propose an unsupervised domain adaption (UDA) method to predict unlabeled data on the target domain, given labeled data from the source domain. Mainstream UDA models aim to learn domain-invariant features from the two domains. However, such methods risk misclassifying the target domain when domain discrepancy is large. To tackle this problem, we propose Adversarial self-superVised domain Adaptation network for TArget domain (AVATAR) algorithm, which outperforms state-of-the-art UDA models by reducing the domain discrepancy while enhancing the discrimination using a domain adversarial learning, a discriminative deep clustering, and a confidence-based pseudo-labeling strategy. Our proposed model outperforms the state-of-the-art methods in two UDA benchmarks.

1 Ultra-high Dimensional Quantile Regression for Longitudinal Data: An Application to Blood Pressure Analysis

Tianhai Zu[1], Heng Lian[2], Brittany Green[3], Yan Yu[4], [1]University of Cincinnati, Cincinnati, OH, [2]City University of Hong Kong, Hong Kong, China; [3]University of Louisville, Louisville, KY, [4]University of Cincinnati, Cincinnati, OH, Contact: zuti@mail.uc.edu

Despite advances in research, identifying important genotype risk factors for high blood pressure remains challenging. Traditional genome-wide association studies (GWAS) focus on one SNP at a time. We aim to select over half a million SNPs and phenotype variables via simultaneous modeling and variable selection, focusing on the blood pressure levels at high quantiles. We develop and apply a novel penalized quantile generalized estimating equations approach to tackle this high dimensional, longitudinal, quantile problem with time-varying covariates. Importantly, we identify interesting new SNPs and some plausible pathways for high blood pressure. Besides, blood pressure levels are likely heterogeneous, where the risk factors identified differ among quantiles. We provide an efficient computational algorithm and establish challenging theoretical properties.

2 Feature Selection for Brain Imaging Predictors of Potential Super-ager and Cognitive Decline Trajectories - a Uk Biobank Classification Study

Parvin Mohammadiarvejeh, Guiping Hu, Auriel A. Willette, Iowa State University, Ames, IA, Contact: pmohamm@iastate.edu

Aging is characterized by cognitive decline in cognitive processes. Adults, aged 80 years or older, are "Super-Agers" that exhibit cognitive performance like younger adults. Due to the unknown association between the anatomical and neuropathological structure of the brain in mid-life with improvement or decline in executive function, we aim to use machine learning techniques to select the most relevant structural magnetic resonance imaging (sMRI) features to classify the observations into the Positive-Ager or Cognitive Decline groups.

a Predictive Framework for Otolaryngology Outpatient's Endoscope Need Analysis

David Lanier, Wayne State University

The ENT clinic at a medium-sized health career facility in the Midwest serving the veteran population recently transitioned reprocessing of scopes from a high-level disinfectant method to a safer process performed by the sterile processing department (SPD). The demand for scopes for future patient visits is not clearly known but may be understood based on patient, provider, and other visit-related factors. These factors are available to the clinic before the visit and using binary classification, may be used to help inform SPD of ENT scope needs earlier out. Using several classification packages available in Python, we were able to define a model to determine clinic day scope needs with high accuracy.

1 Feature-Level Geometric Accuracy Prediction for Additive Production

Yuhang Yang, Davis McGregor, Sameh Tawfick, William King, Chenhui Shao, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: chshao@illinois.edu

This talk will present a new hybrid hierarchical modeling (HHM) approach to characterize the feature-level geometric accuracy of parts produced across multiple identical additive manufacturing (AM) machines. HHM organizes part measurement data into a hierarchy that represents data from individual parts, the positions of parts within the builds, and the machines that produced those parts. Part geometric variability is decomposed into a large-scale part-to-part trend and a small-scale feature-level variability. The effectiveness of the HHM method is demonstrated using experimental data collected from 70 hexagonal lattice parts over seven builds produced by three identical AM machines.

2 A Bayesian Neural Network-based Cox Model for Time-to-event Analysis

Ye Kwon Huh[1], Minhee Kim[1], Kaibo Liu[2], [1]University of Wisconsin-Madison, Madison, WI, [2]UW-Madison, Madison, WI, Contact: yhuh8@wisc.edu

We present a new framework for analyzing time-to-event data by extending the Cox proportional hazards model with Bayesian Neural Networks. Existing deep learning-based survival models only offer point estimates of the time-to-event, which can be insufficient to fully capture the stochastic nature of degradation processes. In contrast, our proposed model provides accurate interval estimates of the time-to-event and quantifies the uncertainty of the predictions. Furthermore, the proposed method can support both time-independent and time-dependent covariates. Numerical studies on both simulation data and real-life degradation datasets demonstrate the effectiveness of our model compared to established survival analysis models.

3 Enhancing Reduced-order Finite Element Analysis with Statistical Learning and Its Application to Additive Manufacturing

Xinchao Liu, Xiao Liu, University of Arkansas, Fayetteville, AR, Contact: xl037@uark.edu

The development of reduced-order Finite Element Analysis (FEA) is an active research field, which aims to relieve the computational burden in numerically solving various complex engineering problems. We use statistical learning to enhance the reduced-order FEA and provide two solutions. The first solution is to treat the FEA as a black box. We propose a DMD-VARX model to make probabilistic predictions for future time steps. The second solution is to intrusively build a physical Ordinary Differential Equation (ODE) based reduced-order model with parametric local POD bases. We predict local POD bases using regression trees on Grassmann Manifold. Both solutions are illustrated by the heat transfer numerical example of Electron Beam Melting (EBM) additive manufacturing and the results are compared with the full-order FEA.

4 Predictive Machine Learning for Prescriptive Applications: A Coupled Training-validating Approach

Ebrahim Mortaz[1], Alexander Vinel[2], [1]Pace University, New York, NY, [2]Auburn University, Auburn, AL

We propose a new method for training predictive machine learning models for prescriptive applications. Coupled validation approach is based on tweaking the validation step in the standard training-validating-testing scheme, specifically considering the prescription loss as the objective for hyper-parameter calibration. It allows for intelligent introduction of bias in the prediction stage to improve decision making at the prescriptive stage, and is generally applicable to most machine learning methods, including recently proposed hybrid prediction-stochastic-optimization techniques, and can be easily implemented without model-specific mathematical modeling. Several experiments with synthetic and real data demonstrate promising results in reducing the prescription costs in both deterministic and stochastic models.

Explainable AI in Practice: Challenges and Methodologies

General Session

Session Chair

Swarup Chandra, HPE, San Jose, CA

1 Explainable AI The Last Mile

Venkatesh Ravichandran, Amazon, Sunnyvale, CA

Explainable AI in practice is a challenging art. Deep learning techniques have helped in development of powerful pattern recognition software that maps sequences to other sequences or a set of observed features to a classification decision. Given the luxury of vast amounts of data and computing resources, it’s easier to make a prediction but harder to explain it. This reduces overall trust in prediction, yielding a solution that is not adopted in practice. In this talk, we explore popular techniques that has helped explainability in the areas of computer vision and natural language processing. Explainability leads to trust which in turn helps users to adopt AI solutions. It's the last mile, that helps deliver the value AI promises at scale.

2 **Robust Vulnerability Detection Systems Using Explainable AI Methods**
Mahmoud Zamani[1], Kevin Hamlen[2], Latifur Khan[3], [1]UTDallas, Richardson, TX, [2]The University of Texas at Dallas, RIchardson, TX, [3]The University of Texas at Dallas, Richardson, TX, Contact: mxz173130@utdallas.edu
Software vulnerability is one of the main reasons why programs are prone to attacks. These attacks can often have irrecoverable consequences such as leaked information and compromised systems. Explainable AI techniques are one way to identify the features that make a program vulnerable with learning default rules directly from data or using statistical methods. This allows one to claim a program as vulnerable if they share the same set of features and scores. In this work, we plan on testing different state-of-the-art Explainable AI techniques to determine which features make a program the most vulnerable and generate description about those vulnerabilities for the end users to take action against.

3 **On AI Visualization**
Ran Jin[1], Parshin Shojaee[2], Xiaoyu Chen[3], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Blackburg, VA, [3]University of Louisville, Louisville, KY, Contact: jran5@vt.edu

1 **The Digital-enabled Sharing Economy: The Role of Matching Technology**
HUIYI LITAN, Institute of Economics, School of Social Sciences, Tsinghua University, Beijing, China. Contact: lthy19@mails.tsinghua.edu.cn
Much of the success in the sharing economy surrounds digital platforms and large-scale matching technologies. We construct game-theoretic models to examine the impacts of B2C and C2C sharing and analyze how technology provides benefits to various parties. In the B2C sharing, platform profit has an inverse U-shape relationship with its technology level. Notably, platform-optimal technology is less than social-optimal technology. The improvement of technology benefits high-preference consumers more. Our findings have practical implications for sharing business operations and the governments. In the C2C sharing, the improvement of technology brings more sharing consumers. However, the platform faces the dilemma of consumer quantity and profit margin. Our finding explains the phenomenon that C2C platforms like Uber have been bleeding money.

2 **Strategic Approaches in Enhancing The Crowdsourcing Platforms' Performance**
Sina Zare, Loyola Marymount University, Los Angeles, CA
There are many strategic factors contributing to the performance of different crowdsourcing platforms. Investigating such factors may help the platforms' designers, managers, and players maximize mutual outcomes.

3 **Can Crowd-funding Inhibit the Initiators' Overconfidence Under the Background of Digital Economy?**
Wei Wang[1], Ying Li[2], [12]Huaqiao University, Quanzhou City, China.
Short-sighted behavior resulting from overconfidence is a topic of key concerns in academia and management practice. Based on behavioral finance, we investigated the relationship between initiators' confidence and crowd-funding fundraising outcomes by text mining, taking into account the realities of China's digital economy. The results show that overconfidence is common among crowd-funding projects initiators. Moreover, digital economy can effectively inhibit the degree of overconfidence of crowd-funding initiators. The path analysis shows that digital economy is increasing the rationality of crowd-funding projects implementation by reducing the degree of information asymmetry. In addition, digital economy clearly boosts the success rate of crowd-funding.

1 Will Negative Emotions in Reviews Always Moderate The Impact of Tailored Managerial Responses on Customer Satisfaction?

Yimei Zhou[1], Hewei Yang[1], Yifan Yu[2], Jinghua Huang[3], [1]Tsinghua University, Beijing, China; [2]University of Washington, Seattle, WA, [3]Tsinghua University, Beijing, China. Contact: zhouym.18@sem.tsinghua.edu.cn

Many firms are struggling with how to respond to online reviews, especially negative reviews. However, there is limited work on managerial response (MR) considering the differences among the various negative emotions. Utilizing a dataset from a restaurant review platform, this study aims to investigate whether the impact of tailored MR on customer satisfaction is moderated by four basic negative emotions (anger, disgust, anxiety, and sadness), and how the moderating effects of these negative emotions are influenced by psychological distance. We found that the positive moderating effect of different negative emotions varies and the negative moderating effect of psychological distance varies.

2 Towards Venture Capital Investment Strategy: A Reinforcement Learning Perspective

Howard Zhong, ESCP Business School, Paris, France.

Venture capital investments play an essential role in the growth and evolution of early-stage startups. However, only a significant small portion of VC-backed startups can successfully exit. In this paper, we propose a novel reinforcement learning-based model to facilitate venture capitalists' decision-making. Our multi-agent RL model can dynamically choose the best candidates and optimize sequential investment decisions for a portfolio of startups. We conduct extensive experimental studies to demonstrate our method's superiority and present interesting managerial insights.

3 Detecting Intentions of Image Posts by Leveraging The Crowd Wisdom

Shuang Gao, Arizona State University, Tempe, AZ

Marketers nowadays can learn from UGC to better understand the consumer needs and improve service quality. In recent years, the trend of UGC has moved from text format to visual format. For visual analytics, most machine vision models are set up to recognize objects, but usually not able to understand the intentions of image posts. However, human readers can understand the intention and react with their likes and comments, which may contain their understanding. Therefore, we proposed to leverage the crowd wisdom from selected comments to help the machine in intention classification. Our work benefits brand management in social media.

4 Online Stock Portfolio Selection with Hints: An Empirical Study

Kevin Xiao[1], Cong Zhou[2], Jialiang Chen[2], Yu Xia[3], Zhengyuan Zhou[2], [12]Stern School of Business, New York University, NYC, NY, [3]New York University, NYC, NY

There are (at least) two common paradigms when it comes to portfolio selection: one is based on making accurate predictions about equity prices using sophisticated machine learning models, and the other is universal portfolio allocation that does not attempt to predict -- and hence does not make any statistical assumptions of --the movements of prices. We perform an empirical study to see whether algorithms that combine statistical predictions with the universal portfolio allocation algorithms would be able to retain the best of both worlds of robustness and high returns.

5 Algorithmic Bias and Corporate Responsibility: How Companies Hide Behind The False Veil of The Technological Imperative

Kirsten Martin, University of Notre Dame

In this presentation, I argue that claiming algorithms are neutral or that the design decisions of computer scientists are neutral obscures the morally important decisions of computer and data scientists. I argue specifically that judging AI on efficiency or accurate and pretending algorithms are inscrutable produces a veil of the technological imperative which shields corporations from being held accountable for the value-laden decisions made in the design, development and deployment of algorithms. While there is always more to be researched and understood, we know quite a lot about testing algorithms. I then outline how the development of algorithms should be critically examined to elucidate the value-laden biases encoded in design and development. The moral examination of AI pierces the (false) veil of the technological imperative.

6 Evidential Reasoning Rule for Bayes Inference with Big Data and Belief Rule Based System for Interpretable Machine Learning

Dong-Ling Xu, Jian-Bo Yang, Manchester University, Manchester, United Kingdom. Contact: l.xu@manchester.ac.uk

Bayes inference is a powerful tool for inference under uncertainty. However it needs perfect probability information which is achievable in small scale but not in big data. In this presentation, we present the evidential reasoning (ER) rule which extends Bayes rule in situations where there may be missing data and therefore unknown probability information, and when probability information may not be reliable. Using examples from fraud detection application, we demonstrate how Bayes inference can be conducted through the ER rule when there is missing and unreliable probability information. Based on the ER rule, a belief rule base (BRB) system technique for interpretable machine learning is also presented. Its learning capability, interpretability and potential applications in machine learning are illustrated by examples.

7 Flash Paper

Zhiwei Qin[1], Hongtu Zhu[2], Jieping Ye[3], [1]Lyft, San Francisco, CA, [2]UNC Chapel Hill, Chapel Hill, NC, [3]University of Michigan, Ann Arbor, MI

In this paper, we systemically review the literature on reinforcement learning approaches to decision optimization problems in a typical ridesharing system. Papers on the topics of rideshare matching, vehicle repositioning, ride-pooling, routing, and dynamic pricing are covered. We also introduce popular data sets and open simulation environments to facilitate further research and development. Subsequently, we discuss a number of challenges and opportunities for reinforcement learning research on this important domain.

8 Flash Paper

Honghao Wei, Ann Arbor, MI

Existing start-of-the-art approaches for solving repositioning in large-scale ride-hailing platforms are optimization based methods, which has high computational complexity and are restricted by the size of the vehicle network. Each time a new optimization problem needs to be solved when the traffic pattern varies, which bring more limitations when deploying to real-time system. We propose a neural-network based optimizer for solving particular forms optimization problems, including the ride-hailing problem, using insights from the Actor-Critic method in reinforcement learning. Our approach can be trained with different traffic patterns offline and output the near-optimal solution when implemented online without further training, which is more efficient and desirable. Numerical results verifies the robustness of our approach.

9 Flash Paper

Seoung Bum Kim, Korea University, Korea, Republic of.

Robust artificial intelligence (AI) is AI capable of maintaining good performance under various analytic constraints. I will be presenting the methods and applications of robust AI.

10 Projected Randomized Smoothing for Certified Adversarial Robustness

Samuel Pfrommer[1], Brendon Anderson[2], Somayeh Sojoudi[2], [1]University of California, Berkeley, Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA, Contact: sam.pfrommer@berkeley.edu
