A Practitioner's Guide to Digital Twin Development

Tutorial Session

Session Chair: Ebru Korular Bish, University of Alabama, Tuscaloosa, AL

1 A Practitioner's Guide to Digital Twin Development

Bahar Biller[1], Stephan Biller[2], Jinxin Yi[3], [1]SAS Institute, Carmel, IN, [2]Purdue University, West Lafayette, IN, [3]SAS Institute, Inc., Cary, NC

This tutorial describes industrial digital twin development including advanced analytics. Using factory and supply chain digital twins as example applications, we present two different digital twin frameworks that serve as a guide for practitioners interested in developing digital twin solutions. The resulting digital twins are expected to help understand what did happen, predict what may happen and prescribe actions to address future problems before they happen. We conclude with examples of digital twin use cases and challenges of their implementations.

1 AI-enabled Models to Assist and Optimize the Decision-making Process in the Kidney Transplantation Network

Cihan H. Dagli, University of Missouri-Rolla, Wildwood, MO, Contact: dagli@mst.edu

Discover the game-changing potential of AI-powered models in optimizing the decision-making process for deceased donor kidney transplantation. Unleash the power of advanced deep learning techniques to revolutionize patient care with streamlined processes. Experience the real-time identification of key features that can confidently leverage decision-making and significantly reduce the non-utilization of deceased donor kidneys. Join us in embracing the future of healthcare with AI-powered models.

Revenue Management, Online Platforms, and Perishability

Community Committee Choice Session

Session Chair: Nasser Barjesteh, Rotman School of Management, University of Toronto, Toronto, ON, Canada

Session Chair: Sajjad Najafi, HEC Paris, VERSAILLES, France

1 Optimizing Fees for Restaurants and Customers and Payments to Drivers by a Food Delivery Platform

Candace Arai Yano[1], Gabriel Deza[2], [1]University of California-Berkeley, Berkeley, CA, [2]Tel Aviv University, Tel Aviv, Israel. Contact: yano@ieor.berkeley.edu

Restaurant food delivery platforms need to decide service charges for customers and restaurants, and how much to pay drivers for delivery. A restaurant's willingness to participate on the platform depends on the platform's service charge. Increasing payments to drivers increases their supply and thereby reduces waiting times for customers whose demands are affected by the number and variety of participating restaurants, the platform's service charge, and waiting times. We take a step in analyzing these complicated multi-party interactions, focusing on the platform's problem of setting service charges for restaurants and customers as well as driver pay when restaurants and customers also seek to maximize their net utility, and the platform must compete for drivers.

2 A Data Marketplace with Privacy-Aware Sellers Under Endogenous Privacy Costs

Diptangshu Sen, Juba Ziani, Georgia Institute of Technology, Atlanta, GA

We study an online data ecosystem comprised of an online platform, users on the platform, and downstream learners. Learners buy data from the platform's users to perform a machine-learning task; users decide whether to join the platform by trading off their benefit from joining the platform and the privacy costs they incur from sharing their data. Our first contribution is to introduce a novel modeling element in that the privacy costs of the users are endogenous and depend on how much of their data is collected by the downstream learners. We then characterize the equilibria of the marketplace in terms of i) the platform's price for each data point, ii) the data collected by each buyer, and iii) the users' participation decisions.

3 Inventory Record Inaccuracy Explains Price Rigidity in Perishable Groceries

Naveed Chehrazi[1], Ioannis Stamatopoulos[2], Robert E. Sanders[3], [1]Olin Business School, SAINT LOUIS, MO, [2]The University of Texas at Austin, McCombs School of Business, Austin, TX, [3]UC, San Diego, Beverly Hills, CA, Contact: naveed.chehrazi@wustl.edu

Grocery retailers cannot engage in inventory-based pricing without physically auditing their shelves, because their inventory records are inaccurate and incomplete. We argue that this informational friction, known in the literature as inventory record inaccuracy (IRI), is much more powerful than physical menu costs in explaining price rigidity in perishable groceries.

Portfolio Optimization

Contributed Session

Session Chair: Ruijing Yang, Stevens Institute of Technology, Hoboken, NJ

1 Portfolio Diversification Based on Trading Strategies

WenYi Lee, Cheng-Wei Ke, National Taipei University of Business, Taipei City, Taiwan. Contact: wy.lee@ntub.edu.tw

Raising invested number is efficient in decreasing portfolio risk. Studies have considered a naive portfolio, which invests stocks equally, or Shannon and Yager's entropy to increase the investment number of portfolios. However, studies have underestimated the importance of featured stocks while constructing a portfolio with diversification. We should enforce profitable stocks instead of all the alternatives, even though increasing investment is crucial for lower portfolio risk. Thus, this study proposes a diversified portfolio based on mixing benchmark portfolio models and trading strategies, such as momentum and reversal. We apply a parametric policy to better mix the benchmark portfolio and trading strategies as a convex problem.

2 Performance of Active Portfolio Managers when the Benchmark is Not Observed

Luis Chavez-Bedoya, ESAN Graduate School of Business, Lima, Peru. Contact: lchavezbedoya@esan.edu.pe

In the framework of active portfolio management, we propose a methodology to evaluate the performance of active portfolio managers when the benchmark portfolio cannot be either observed or determined by the agent performing the analysis. The suggested methodology assesses performance with respect to a combination of funds that minimizes residual risk; and, it is well-suited for evaluating the performance of pension-fund managers in defined-contribution pension systems, especially those operating in Latin America. We also provide numerical results when our methodology is applied to appraise the historical performance of the pension fund administrators of the Peruvian Private Pension System.

3 Optimal Goal-Based Wealth and Retirement Management

Jeffrey Choy[1], Ben Wang[2], Abdullah AlShelahi[3], Romesh Saigal[1], [1]University of Michigan, Ann Arbor, MI, [2]Univerisity of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, Contact: jeffchoy@umich.edu

We examine an investor with multiple spending and retirement goals who must choose the optimal portfolio allocation, retirement account contribution, and consumption under taxes, stochastic income, and market-income correlation. We find the optimal portfolio and income allocation that maximize the investor's expected discounted lifetime utility as a function of his or her portfolio value, retirement account value, and income. Taking a martingale perspective of future investor utility, we find continuous-time solutions to this problem. We demonstrate the model's general applicability with a series of numerical experiments solving discrete-time problems for hypothetical investors. The model highlights how decision-making changes under a variety of investment conditions, including different income levels, goal priorities, and duration to retirement.

4 Optimal Portfolio Execution Strategies Under Chance Constraints on Capital Ratio Requirement

Ruijing Yang, Zachary Feinstein, Somayeh Moazeni, Stevens Institute of Technology, Hoboken, NJ, Contact: ryang13@stevens.edu

We investigate the optimal portfolio liquidation problem under capital adequacy requirements. In this setting, selling risky assets induces temporary and permanent price impacts which need to be considered. We formulate this problem with chance constraints for the regulatory requirements.

We present a conservative reformulation for the problem and establish sufficient conditions for its convexity. Our study shows that in general the optimal portfolio liquidation strategy under the capital ratio requirement constraints differs from the optimal strategy in the absence of the constraints.

Data-driven Bundling and Assortment Optimization

Community Committee Choice Session

Session Chair: Xiaobo Li, National University of Singapore, Singapore, Singapore

1 The Benefit Of Learning

Lan Wu[1], Changchun Liu[2], Chung Piaw Teo[3], Zhang Xun[4], [1]The National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapre, Singapore; [3]National University of Singapore Business School, Singapore, Singapore; [4]The National University of Singapore, Singapore, Singapore. Contact: lanwu@u.nus.edu

This paper addresses the evolving complexities in airline Revenue Management (RM), particularly in seat allocation given diverse ancillary services and fare types. Traditional Independent Demand Model (IDM) is seen as limited, suffering from customer ‘buy-down’ where higher paying customers opt for cheaper fare classes. We propose a mixed-fare customer demand model which combines IDM with the consideration of customer behavior based on product availability and prices. Our key contributions include the development of the Bayes Selector online learning algorithm for seat allocation, which offers a constant regret irrespective of time, and extensive performance testing using synthetic and real airline data. The algorithm’s applicability in various settings is also demonstrated.

2 Optimizing Size-Based Bundle Promotions

Ruijiu Mao[1], Xiaobo Li[2], Chung Piaw Teo[3], Shuai Jia[4], [1]University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]National University of Singapore Business School, Singapore, Singapore; [4]The Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: maoruijiu@u.nus.edu

Current size-based bundle promotions often overlook the diverse needs of customers and variations among products. Recognizing these limitations, we conducted a comprehensive exploration of size-based bundling promotions. We examined key elements such as determining promotion numbers, selecting product pools, setting bundle prices, and estimating customer utility for different products. We devised a discrete bilevel programming model and proposed an efficient MIP-based solution method. In addition, we delved deeply into the theoretical aspects of bundle pool selection. Our case study, based on data from a major Chinese e-tailing company, accurately predicted reservation prices and demonstrated a remarkable 41% increase in profits.

3 Assortment Optimization for General Multi-Item Choice Models

Wenhao Gu[1], Anton Braverman[2], Tarek Abdallah[3], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, [3]Northwestern University, Kellogg School of Management, Chicago, IL, Contact: wenhao.gu1@kellogg.northwestern.edu

Utility maximization choice models that capture customer behaviors in assortment optimization problems are generally hard to solve. While the single-choice setting is well studied, e.g., multinomial logit model, models where customers make multiple decisions have received less attention. We consider a multiple-choice utility maximization model with general utility distributions and study optimal assortment policies through an asymptotic lens.

Assortment Optimization: Theory and Applications

Community Committee Choice Session

Session Chair: Omar El Housni, Cornell Tech, New York, NY

1 Placement of Substitutable Goods for a General Choice Model

Omar El Housni[1], Rajan Udwani[2], [1]Cornell Tech, New York, NY, [2]UC Berkeley, Berkeley, CA

Given a universe of substitutable goods and a set of display locations (for example, in a physical store), we consider the problem of picking an assortment of goods and placing at most one good at each location. A customer visiting the store looks at a subset of locations and picks at most one of the goods from the visited locations according to a choice model. We consider a very general setting of the problem and give an efficient algorithm for approximating revenue optimal product placement.

2 Maximum Load Assortment Optimization

Omar El Housni[1], Marouane Ibn Brahim[1], Danny Segev[2], [1]Cornell Tech, New York, NY, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: mi262@cornell.edu

Motivated by applications in e-commerce and scheduling, we introduce and study the Maximum Load Assortment Optimization problem. We are given a universe of items and a set of users. Each user makes their choice among the offered items according to a multinomial logit model. We define the load of an item by the total number of users who select it. Our goal is to offer an assortment that maximizes the expected maximum load across all items. We study the static and the dynamic version of this problem. For the static version, we develop a polynomial-time approximation scheme (PTAS). Additionally, we prove that a weight-ordered policy yields a 1/2-approximation for the static problem. Furthermore, we establish that this same static policy gives 1/4-approximation of the dynamic problem. Finally, we design an adaptive policy that gives a (1-ε)-approximation in quasi-polynomial time.

3 Display Optimization Under the Multinomial Logit Choice Model: Balancing Revenue and Customer Satisfaction

Puping Jiang[1], Jacob Feldman[2], [1]Shanghai Jiao Tong University, Antai College of Economics and Management, Shanghai, China; [2]Olin Business School, Saint Louis, MO, Contact: jiang.p@wustl.edu

In this paper, we consider an assortment optimization problem in which a platform must choose pairwise disjoint sets of assortments to offer across a series of T stages. The goal is to choose the sequential displays of product offerings to maximize expected revenue. Additionally, we impose stage-specific constraints that ensure that as each customer progresses farther and farther through the T stages, there is a minimum level of "desirability" met by the collections of displayed products. We show that our assortment problem of interest is strongly NP-Hard. Our main algorithmic result consists of a polynomial-time approximation scheme (PTAS). We also provide an additional approximation scheme, which, under mild assumptions, can handle a cardinality constraint that enforces that an exact number of new products are introduced at each stage.

4 Revenue Management with Flexible Products

Wenchang Zhu, Huseyin Topaloglu, Cornell Tech, New York, NY, Contact: wz368@cornell.edu

We provide an approximation algorithm for network revenue management problems with flexible products. Flexible products allow delaying the assignment decision of which resources to use to serve each request, but also make it difficult to track the inventory state when designing algorithms. Our algorithm uses value function approximations constructed by solving an integer program with linear objective to reshuffle inventories at each time period. We show that if each route uses at most L resources, then the total expected revenue obtained by our approximate policy is at least 1/(1+L) of the optimal total expected revenue. Our computational experiments demonstrate that our policy performs quite well and flexible products do increase the total expected revenue by delaying the assignment decisions to the end of the time horizon.

APS Special Session: Algorithms with Predictions

Award Session

Session Chair: Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

Session Chair: Christina Lee Yu, Cornell University, Ithaca, NY

1 Algorithms with Predictions

Michael Mitzenmacher, Harvard University

We survey the recent introduction of and advances in algorithms that use predictions applied to the input, such as from machine learning, to circumvent worst-case analysis. We aim for algorithms that have near optimal performance when these predictions are good, but still maintain provable bounds (such as for worst-case performance) even when the predictions have large errors. We look at several examples showing how predictions can be used effectively while still allowing for theoretical guarantees, covering our own work in scheduling and Bloom filter data structures, as well as several other recent results. Bio: Michael Mitzenmacher is a Professor of Computer Science in the School of Engineering and Applied Sciences at Harvard University. Michael has authored or co-authored over 250 conference and journal publications on a variety of topics, including algorithms for the Internet, efficient hash-based data structures, erasure and error-correcting codes, power laws, and compression. He is an ACM and IEEE Fellow. He has co-authored a widely used textbook on randomized algorithms and probabilistic techniques in computer science published by Cambridge University Press.

Experimental Design and A/B Tests in Marketplaces

Community Committee Choice Session

Session Chair: Zeyu Zheng, University of California, Berkeley, Berkeley, CA

Session Chair: Nian Si, University of Chicago Booth School of Business

1 Design of Panel Experiments with Spatial and Temporal Interference

Tu Ni[1], Iavor Bojinov[2], Jinglong Zhao[3], [1]NUS, Singapore, Singapore; [2]Harvard Business School, Somerville, MA, [3]Boston University, Boston, MA, Contact: nitu@u.nus.edu

One of the main practical challenges companies face when running experiments over a panel is interference. Existing literature has identified aggregating units into clusters as the gold standard to handle interference, yet the degree of aggregation remains an open question. In this work, we present a new randomized design of panel experiments and answer this question when all experimental units are modeled as vertices on a two-dimensional grid. Our proposed design has two features: the first feature is a notion of randomized spatial clustering that randomly partitions units into equal-size clusters; the second is a notion of balanced temporal randomization that extends the classical completely randomized designs to the temporal interference setting.

2 Measuring the Value of Boosting Algorithms in Online Advertising: A Two-Sided Randomized Ghost Ad Experiment

Zhihua Zhu[1], Zheng Cai[1], Chenglong Li[1], Yufei Shen[2], [1]Tencent, Shenzhen, China; [2]Nova School of Business and Economics, Lisbon, Portugal. Contact: yufei.shen@novasbe.pt

We propose a novel two-sided randomized ghost ad (TSR-GA) experimental design to reduce the bias and variance of the estimated effects of algorithmic intervention in online advertising. Our method is compatible with the TSR design that prevents various sources of interference, reducing the bias of estimates. It also incorporates the ghost ad design that allows us to identify and keep a very small fraction of observations relevant to statistical inferences, improving the precision of estimates. To validate the method, we conducted large-scale experiments on Tencent's ad platform. We show that the estimated effect of the algorithmic intervention would be insignificant if using TSR alone without ghost ads. By contrast, using our TSR-GA approach, we report a significant effect and the standard error of estimates decreased by 78%.

3 Switchback Experiments Under Geometric Mixing

Yuchen Hu[1], Stefan Wager[2], [1]Stanford University, Stanford, CA, [2]Stanford GSB, Stanford, CA, Contact: yuchenhu@stanford.edu

The switchback is an experimental design that measures treatment effects by repeatedly turning an intervention on and off for a whole system. Switchback experiments are a robust way to overcome cross-unit spillover effects; however, they are vulnerable to bias from temporal carryovers. In this paper, we consider properties of switchback experiments in Markovian systems that mix at a geometric rate. We find that, in this setting, standard switchback designs suffer considerably from carryover bias: Their estimation error decays as T^{-1/3} in terms of the horizon T, whereas in the absence of carryovers a faster rate of T^{-1/2} would have been possible. We also show, however, that judicious use of burn-in periods can considerably improve the situation, and enables errors that decay almost as fast as T^{-1/2}. Our formal results are mirrored in an empirical evaluation.

4 Machine Learning Assisted Experimental Design And Causal Effect Estimation

Yuhang Wu[1], Jinghai He[2], Zeyu Zheng[2], [1]University of California, Berkeley, Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA, Contact: zyzheng@berkeley.edu

Utilizing covariate information has been a powerful approach to improve the efficiency and accuracy for experiment design and causal effects. However, state-of-art approaches can become practically challenging when the dimension of covariate is high. We propose a covariate representation learning approach that can effectively make use of historical experiment or observational data in similar scenarios to understand which lower dimensions can effectively represent the higher-dimensional covariate. We then propose design and estimation methods with the covariate representation. We prove statistically reliability and performance guarantees for the proposed methods.

Healthcare Applications of Probability Theory

Community Committee Choice Session

Session Chair: Arielle Elissa Anderer, The Wharton School, University of Pennsylvania, Philadelphia, PA

1 Personalized Breast Cancer Screening

Yu Ma, MIT, Cambridge, MA

Current national cancer screening guidelines heavily rely on age in cancer screening decisions, neglecting other important medical characteristics. This approach either delays screening or prescribes excessive screenings. The current approach is also unable to combine information across hospital systems due to the lack of a coherent records system. We propose to use claims data to develop a clinical support tool to supply supplemental insights and precautions for physicians to make more informed decisions. Furthermore, we propose a novel machine-learning framework to recommend personalized, data-driven, and dynamic screening decisions. We apply this new method to the study of breast cancer mammograms from 378,840 patients to demonstrate that across different risk populations, personalized screening reduces the average delay in a cancer diagnosis by 2-3 months.

2 The Impact of Hospital-Physician Integration on Hospital Volume Competition

Jong Myeong Lim, University of Miami Herbert Business School, Coral Gables, FL, Contact: jonglim@mbs.miami.edu

We model the impact of physician-hospital integration on hospital competition for volume. We find that preferential admission policies for integrated physicians can lead to suboptimal patient-hospital matches. We explore information disclosure and payment policy reforms as potential solutions.

3 Optimizing Sampling Plans for Detecting Dangerous Medical Products in a Supply Chain

Eugene Wickett, Northwestern University, Evanston, IL, Contact: eugenewickett2022@u.northwestern.edu

Substandard and falsified products are an urgent global issue, causing millions of cases of excess morbidity and mortality. Low and middle income countries face a disproportionate burden of these products. Regulators in these countries conduct post-market surveillance at consumer-facing supply chain locations to assess the prevalence of substandard and falsified products as well as infer sources of these products throughout the supply chain. This work discusses the development of sampling plans for surveillance that allocate tests to consumer-facing locations. These plans must account for supply-chain connections and provide high utility for regulatory objectives. Fast Bayesian approaches for calculating plan utility have been developed; here, we discuss how simulation optimization approaches can leverage fast utility calculation in regulatory contexts.

4 Estimating Treatment Effects from Observational Data Using a Hidden Markov Model

Tongqing Chen, John R. Birge, University of Chicago, Chicago, IL

Treatment effect plays an essential role in the medical decision-making process and is a critical criterion for drug testing and development. However, with unobservable confounders, the treatment effect estimation can be invalid. In this work, we develop a model using observational data in which the confounder is partially observable to estimate the treatment effect. Moreover, we assume that observability can be correlated with the treatment and confounder which relax the assumptions posted by the existing works. Using maximum likelihood estimators and a hidden Markov Chain structure, the model is proved to be identifiable under some general conditions.

Behavioral Aspects of Donations

Community Committee Choice Session

Session Chair: Gloria Urrea, University of Colorado, Boulder, CO

1 Improving the Quality of In-Kind Donations: A Field Experiment

Sindy D. L. T. Pacheco[1], Mahyar Eftekhar[2], Chao Wu[2], [1]The Society of Saint Vincent de Paul, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: chaowu3@asu.edu

While in-kind donations contribute to charity's triple bottom line (i.e., generatingadditional revenue for the charity, contributing to social welfare, and reducing environmental waste through rechanneling used items), inappropriate material donations impose additional costs to sort, process, or discard them. Minimizing the amount of undesired in-kind donations, however, is a challenge given charities' sensitive relationship with their donors. This paper examines the effectiveness of behavioral interventions in improving the quality of in-kind donations gifted by individuals.

2 The Influence of Market Uncertainty on Donation Decisions

Gloria Urrea[1], Sebastian Villa[2], Eunae Yoo[3], Gordon Burtch[4], [1]University of Colorado Boulder, Superior, CO, [2]University of New Mexico, Albuquerque, NM, [3]Indiana University, Bloomington, IN, [4]Boston University, Boston, MA, Contact: yooeun@iu.edu

Cryptocurrency donations comprise an increasing proportion of charitable donations globally. Compared to cash donations, donors and charities find cryptocurrency appealing because it offers additional benefits, such as increased traceability, cost efficiency, and fast delivery. However, cryptocurrencies are more unpredictable and riskier assets than stocks and cash. While prior research has examined the impact of market changes for more stable assets (e.g., cash) on donors' behavior, it has not considered the context of a more unstable asset like cryptocurrency. Therefore, our research aims to shed light on how changes in the market value of cryptocurrency affect donor decision-making. We address this empirically by leveraging a combination of archival data from a platform for charitable cryptocurrency fundraising and a controlled online experiment.

3 Improving Volunteer Retention: Spillover Effect Of Recurring Volunteers

Vinit S. Tipnis[1], Christopher J. Chen[2], Fei Gao[3], [1]Kelley School of Business, Indiana University Bloomington, Bloomington, IN, [2]Indiana University Kelley School of Business, Bloomington, IN, [3]Indiana University Bloomington, Bloomington, IN, Contact: vtipnis@iu.edu

Nonprofit organizations rely on volunteers to alleviate some of the financial constraints around employing a large paid workforce. Low volunteer retention is costly and disruptive to operations. Using data from a food bank, we study how recurring volunteers improve the volunteering experience and increase the retention rate of new volunteers.

4 Behavioral Responses to Nonprofit Performance Metrics

Hasti Rahemi[1], Gloria Urrea[2], Leon Valdes[3], [1]University of Colorado Boulder, Boulder, CO, [2]University of Colorado Boulder, Superior, CO, [3]University of Pittsburgh, Pittsburgh, PA, Contact: hasti.rahemi@colorado.edu

Donors often want to evaluate the performance of nonprofit organizations (NPOs) before making their donation decisions. Among NPOs' performance metrics, the program spending ratio (PSR) - the percentage of an NPO's expenditures that goes to its programs - is highly pervasive. Heavily relying on PSR, though, can negatively impact operations, so NPOs are increasingly trying to provide additional metrics. In this study, we explore two *operational* metrics, namely outputs (the level of services provided by an NPO) and monetary value information (the value of these services). Using experiments, we shed light on how and why these metrics influence donors' willingness to donate to an NPO. We explore these questions under different levels of PSR.

Decision Analysis for Public Policy

Community Committee Choice Session

Session Chair: Katharina Ley Best, The RAND Corporation, Pittsburgh, PA

1 A Real Options Methodology for R & D Portfolio Selection and Management

Jeremy Eckhause, RAND Corporation, Arlington, VA

An important class of portfolio management problems in public contexts is one in which investments are staggered in multiple stages and the projects' potential monetary value is not a first-order consideration. We present a robust real options approach to select a portfolio of proposals in each stage, applied to historic data from the NASA's Small Business Innovation Research (SBIR) portfolio using the aerospace standard Technology Readiness Level (TRL) to estimate the factors of interest. We demonstrate the flexibility of our approach by proposing different specifications and tradeoffs.

2 Deep Reinforcement Learning for Assessing the Cost-Effectiveness of Epidemic Response

Giovanni S. P. Malloy, RAND Corporation, Santa Monica, CA, Contact: gmalloy@rand.org

During an infectious disease outbreak, it can be difficult for policymakers to determine which intervention(s) will be cost-effective due to changing disease dynamics and human behavior. Commonly, interventions of interest include prevention (such as vaccines or prophylaxis) and treatment, but efficacy and cost can vary by disease and geography. Deep reinforcement learning can help identify the cost-effective intervention for a disease over a given parameter space and simulated outbreak. Using a custom SIR reinforcement learning environment, monetary benefit as reward, and a trained deep learning model based on the A2C algorithm, I developed a novel method to assess the cost-effectiveness of interventions at different coverages and timing.

3 Depot Engine Planning and Allocation Readiness Tool (Depart)

Frank Wallace, Center for Naval Analysis

Depot Engine Planning and Allocation Readiness Tool (DEPART). CNA produced the Depot Engine Planning & Allocation Readiness Tool (DEPART), an interactive Program Objective Memorandum (POM) planning tool, to support the 1A5A Engine Maintenance account, Aviation Depot Maintenance. DEPART combines depot engine requirements generation, maintenance pricing, and resource allocation decisions into a unified framework. The tool processes data inputs within each component, calculates the desired component output, and passes that output to the next stage to ultimately arrive at a preliminary resourcing decision. The tool makes resourcing allocation choices using predicted requirement and pricing decisions that balances funding with readiness. DEPART is built in R and Shiny and is hosted in the Navy's Jupiter enclave of the DOD's Advana cloud environment.

4 Optimizing Portfolio Level Modernization Investments

Katharina Ley Best[1], Jeremy Eckhause[2], [1]The RAND Corporation, Pittsburgh, PA, [2]RAND Corporation, Arlington, VA, Contact: kbest@rand.org

We introduce the Aim Point Investment Model, an optimization model for portfolio-level resource allocation across U.S. Army programs and time. The model is the result of a study that was looking to develop a method and tool to support quick-turn exploration of modernization investment portfolios in light of changing budget constraints and operational priorities. The study explored alternative approaches to extracting the information needed about programs' relative utility and any constraints on the Army's ability to procure the capability from existing Army data sources. We describe one of these approaches, which uses Army prioritization guidance combined with plausible constraints to produce resource allocation solutions that are consistent with the Army's stated modernization strategy.

Judgmental Forecasting

Community Committee Choice Session

Session Chair: Jens Witkowski, Frankfurt School, Frankfurt, Germany

1 An Equivalence Between Fair Division and Wagering Mechanisms

Rupert Freeman[1], Jens Witkowski[2], Jennifer Wortman Vaughan[3], David M. Pennock[4], [1]University of Virginia, Charlottesville, VA, [2]Frankfurt School, Frankfurt, Germany; [3]Microsoft Research New York City, New York, NY, [4]Rutgers University, Plainsboro, NJ, Contact: freemanr@darden.virginia.edu

We draw a surprising and direct mathematical equivalence between the class of fair division mechanisms, designed to allocate divisible goods without money, and the class of weakly budget-balanced wagering mechanisms, designed to elicit probabilities. While this correspondence has applications in both settings, we focus on its implications for the design of incentive-compatible fair division mechanisms. In particular, we show that applying the correspondence to Competitive Scoring Rules, a class of wagering mechanisms based on proper scoring rules, yields the first non-trivial incentive-compatible fair division mechanism that is proportional and envy-free. Moreover, for two agents, we show that Competitive Scoring Rules characterize the whole class of non-wasteful and incentive-compatible fair division mechanisms, subject to mild technical conditions.

2 A Heterogeneous Bias-Information-Noise Model of Forecasting Skill and Event Predictability

Ville Satopaa[1], Marat Salikhov[2], [1]INSEAD, Paris, France; [2]New Economic School, Moscow, CT, Russian Federation. Contact: ville.satopaa@insead.edu

The BIN (Bias-Information-Noise) model decomposes differences in predictive performance between two groups of forecasters in terms of bias (systematic deviations from the base rate), information (use of relevant cues), and noise (use of irrelevant cues). In this work, we propose a new model that generalizes the insights of the BIN model by allowing bias, information, and noise to depend on the characteristics of the target event (e.g., the topic, geographical region, etc.) and the forecaster (e.g., intelligence test scores, open-mindedness, gender, etc.). This allows us to understand what kind of forecasters' predictions tend to have low noise, low bias, or high information, and whether certain types of events can exacerbate the negative effects of bias, (lack of) information, or noise.

3 Full Accuracy Scoring Accelerates the Discovery of Skilled Forecasters

Pavel Atanasov[1], Ezra Karger[2], Philip Tetlock[3], [1]IE University, Madrid, Spain; [2]Federal Reserve Bank of Chicago, Chicago, IL, [3]University of Pennsylvania, Philadelphia, PA

Reliable identification of skilled forecasters is time-consuming—learning which forecasters are consistently accurate, rather than lucky—may take months or years. To accelerate skill-spotting, we propose the Full Accuracy Score (FAS). It combines classic Brier scores on resolved questions with proper proxy scores on unresolved ones. The latter involve comparing individual with consensus estimates. Using data from two forecasting tournaments (ACE & HFC), we show that FAS outperforms classic Brier scores in predicting final performance scores from early data. FAS is also more effective at early spotting of top forecasters. Using elite crowds and advanced algorithms for deriving consensus estimates further improves FAS performance.

4 Willingness to use Ai and Algorithmic Dss in Judgment and Reasoning

Johannes Müller-Trede[1], Gwendolin Sajons[2], Elena Shvartsman[3], [1]IESE Business School, Barcelona, Spain; [2]ESCP Business School, Berline, Germany; [3]WHU Business School, Vallendar, Germany. Contact: jmuller@iese.edu

We report a series of experiments that assess people's reliance on AI and other algorithmic decision support systems in a judgment and a reasoning task. Our results suggest that people willingly rely on AI/DSS when they expect that doing so should improve their performance on the task. In contrast with prior findings, we do not find evidence for a generalized aversion to using AI/DSS or evidence for people avoiding AI/DSS (more so than decision support coming from another person) after observing the AI/DSS make mistakes. Our findings indicate that people's reliance on AI and other algorithmic decision support systems may be both simpler in theory and more diverse in practice than suggested by previous research.

5 Necessary and Sufficient Winners of Forecasting Competitions

Gerdus Benade[1], Jens Witkowski[2], [1]Boston University, Brookline, MA, [2]Frankfurt School, Frankfurt, Germany. Contact: j.witkowski@fs.de

Forecasting competitions rank forecasters by the accuracy of their probabilistic judgments. Accuracy is typically measured by a proper scoring rule. It is known that different proper scoring rules lead to different rankings. But how much wiggle room is there? Will the same forecaster typically win no matter the choice of proper scoring rule or can practically every forecaster be made the winner for the right choice of proper rule? I report on work in progress addressing this question both theoretically and empirically, devising an algorithm to evaluate it on real-world data.

Renewable Power, Energy Innovation, and Storage

Community Committee Choice Session

Session Chair: Christian Kaps, Harvard Business School, Boston, MA

1 Low Battery: Exploring Paths Toward a Renewable Electric Grid

Thomas Palley[1], Asa Palley[2], Oguz Cetin[3], R. Andrew Butters[4], Jackson Dorsey[5], [1]Indiana University, Bloomington, IN, [2]Indiana University, Bloomington, IN, [3]Kelley School of Business, Bloomington, IN, [4]Indiana University, Bloomington, IN, [5]University of Texas at Austin, Austin, TX, Contact: tpalley@iu.edu

Policymakers and utilities have set near-zero carbon targets over the next few decades for electricity generation, indicating substantial investments in renewables and utility-scale storage. We evaluate the cost side of decarbonization transition paths, constructing a model of both short-term operational decisions and long-term capacity investment. Using detailed data from the Texas Interconnection, we model optimal operational and investment decisions for a range of carbon taxes. Our results suggest that the costs associated with moderate to high targets of 70-80% reduction in carbon emissions are low and consistent with recent estimates of the social cost of carbon. However, costs rise exponentially for higher targets. Surprisingly, battery storage remains too expensive to justify investment for any emissions reduction target below 90% over the next 20 years.

2 Quality Adjusted Power Value: A New Way To Locate Renewable Energy Generation

Vishrut Rana[1], Christian Kaps[2], Serguei Netessine[1], [1]The Wharton School, Philadelphia, PA, [2]Harvard Business School, Cambridge, MA, Contact: vishrut@wharton.upenn.edu

Global investments in renewable energy generation are expected to rise due to growing policy support, energy security concerns, and cost competitiveness. In this scenario, selecting renewable generation plant locations using existing ad-hoc approaches poses challenges arising from the failure to capture impacts of time and location of electricity generation. As a remedy, we propose a new site selection metric - Quality Adjusted Power Value - which accounts for time and location of generation and measures impacts on electricity market clearing prices. We validate this

methodology to locate wind turbines in Texas under different development goals using high-granularity wind-speed and transmission infrastructure data.

3 Electricity Pricing Rules for Residential Solar Plus Storage: Economic and Environmental Impacts

Sinan Yorukoglu[1], Nur Sunar[1], Jayashankar M. Swaminathan[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina Chapel Hill, Chapel Hill, NC

We analyze the impacts of common pricing rules for residential solar plus storage customers on environment, utility profit and customer benefit. Using a large-scale dataset from California, we quantify these impacts. Our paper shows that prominent practical insights may fail depending on the adoption level of residential solar-plus-storage technology.

4 Distributed Energy Orchestration: Models And Empirics

Margaret Redfield, Omer Karaduman, Xu Kuang, Stanford Graduate School of Business, Stanford, CA, Contact: margred@stanford.edu

The alignment of energy demand and supply is expected to be increasingly challenging in the presence of intermittent renewable generation. Distributed energy orchestration (DEO), the management of demand-colocated generation and storage, presents a promising solution. We build a model to study the best practices when deploying and operating these systems. Using a highly granular household-level dataset from Australia, we quantify the value of DEO under different policy and operating scenarios. Our main results highlight the value of real-time price exposure and show that the value of coordination among storage units heavily depends on price signal precision.

Cybersecurity Analytics

Community Committee Choice Session

Session Chair: Ankit Shah, 1</sup

Session Chair: Soumyadeep Hore, USF IMSE, Tampa, FL

1 A Deep Reinforcement Learning Framework for Adversarial Example Generation to Deceive Network Intrusion Detection Systems

Soumyadeep Hore[1], Jalal Ghadermazi[1], Diwas Paudel[1], Ankit Shah[1], Tapas K. Das[1], Nathaniel D. Bastian[2], [1]University of South Florida, Tampa, FL, [2]United States Military Academy, West Point, NY, Contact: soumyadeep@usf.edu

Advancements in AI/ML algorithms have enhanced the security posture of cybersecurity operations centers (CSOCs). Concurrently, adversaries' abilities to evade security have also increased with the support of AI/ML models. Therefore, CSOCs must proactively prepare for evasion attacks exploiting ML-based network intrusion detection systems (NIDS). In this talk, we present an AI framework powered by deep reinforcement learning to generate adversarial examples that can deceive ML-based NIDS while maintaining functionality. Insights from our study on the AI-enabled adversary's ability to make specific evasive perturbations can help CSOCs enhance the robustness of their NIDS against evolving adversarial attacks.

2 Towards Real-Time Network Intrusion Detection with Image-Based Sequential Packets Representation

Jalal Ghadermazi[1], Ankit Shah[1], Nathaniel D. Bastian[2], [1]University of South Florida, Tampa, FL, [2]United States Military Academy, West Point, NY

In this talk, we propose a novel AI-enabled framework for a packet-based network intrusion detection system that effectively analyzes packet data while considering temporal connections among packets. Our framework transforms packets into images and passes them through a network intrusion detector model. Experiments using publicly available data sets indicate that our approach detects various network attacks earlier than flow-based approaches, with a detection rate of 97.7% to 99%.

3 A Novel Team Formation Framework Based on Performance in a Cybersecurity Operations Center

Ankit Shah[1], Rajesh Ganesan[2], [1]University of South Florida, Tampa, FL, [2]George Mason University, Fairfax, VA

A cybersecurity operations center defends an organization from cyber threats through collaborative efforts of different personnel. Ad hoc team formation leads to imbalance and increased risk. We present a framework integrating optimization, simulation, and scoring methods that forms effective and balanced teams with a new collaborative score metric. Our approach selects individuals to form effective teams that meet requirements for each shift. Results from simulated experiments show the formation of effective teams whose collaborative scores are maximized and balanced. Our approach is also able to identify high and low performers within the first few months of implementing the framework.

MSOM Data-Driven Research Challenge

Panel Session

Session Chair: Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

Session Chair: Marc Baaijens, Merck Animal Health, Boxmeer, Netherlands

1 Merck: Biomanufacturing Data for the MSOM Data Driven Research Challenge

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

To support the MSOM Data Driven Research Challenge, Merck is providing biopharmaceutical manufacturing data to the MSOM community and hosting a research competition. This session will be an interactive session organized by Merck and the MSOM Society. We will begin with a brief introduction to biomanufacturing and discuss current industry needs and challenges. We will then provide an overview of the production data to be shared with the MSOM community, and suggest future research directions at the intersection of operations management and biomanufacturing.

2 Panelist

Coen Dirckx, Merck Animal Health, Boxmeer, Netherlands

3 Panelist

Bram van Ravenstein, Merck Animal Health, Boxmeer, Netherlands

Human-Algorithm Interaction in OM

Community Committee Choice Session

Session Chair: Eirini Spiliotopoulou, Tilburg University, GH Amsterdam, Netherlands

1 Human Planners with AI Recommendations

Lijia Tan[1], Eirini Spiliotopoulou[2], Willem van Jaarsveld[1], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Tilburg University, Tilburg, Netherlands. Contact: l.tan1@tue.nl

How does an algorithm help human planners' decisions in supply chains? This study focuses on the interaction between human planners and an AI algorithm. We use a laboratory experiment to investigate the effect of the AI algorithm on planners' decisions in a complex decision environment. Our behavioral evidence contributes to the understanding of in which condition the AI would be effective in improving the performance of the human planners.

2 An Empirical Analysis of the Interaction Between Managers and Algorithms

Han Oh[1], Rogelio Oliva[2], [1]Tilburg University, Tilburg, Netherlands; [2]Texas A&M University, College Station, TX

Our research explores the interaction of retail managers and algorithms in a complex, dynamic decision-making environment involving inventory restocking decisions. Using data from a retailer that allows managers to manage and modify the automated stock ordering system, we investigate whether and how store managers influence store performance by interacting with the retailer's information system.

3 GPT and CLT: The Impact of ChatGPT's Abstraction Bias on Consumer Recommendations

Sam Kirshner, UNSW Business School, Sydney, Australia. Contact: s.kirshner@unsw.edu.au

I explore how ChatGPT interprets information through the lens of Construal Level Theory (CLT). My findings show that ChatGPT exhibits an abstraction bias, generating responses consistent with a high-level construal. This abstraction bias results in ChatGPT prioritising high-level construal features (e.g., desirability) over low-level construal features (e.g., feasibility) in consumer evaluation scenarios. Thus, ChatGPT recommendations differ significantly from traditional results based on human decision-making. Applying CLT concepts to large language models provides essential insights into how markets and consumer behaviour may evolve with the increasing prevalence and capability of AI.

4 The Impact of the Fear of Being Replaced by AI on AI-Augmented Decision-Making

SEYYED IMAN MOOSAVI[1], Jan C. Fransoo[2], Prisca Brosi[3], [1]Tilburg University, Tilburg, Netherlands; [2]Tilburg University, Tilburg, Netherlands; [3]Kühne Logistics University, Hamburg, Germany. Contact: s.i.moosavi@tilburguniversity.edu

In addition to various behavioral biases and contextual factors affecting AI-augmented decision-making, emotions play an important role. Across different emotions, the fear of being replaced by an AI system is one of the most reported ones among those who are working with it. Our study draws on psychological literature to explore how the fear of being replaced by an AI system for operations decision-making affects reliance on AI recommendations and decision-making performance. Using an online experiment, we manipulate this emotion by varying the likelihood of the AI system to replace participants in a demand-forecasting task. Participants are informed that they may lose their job and the opportunity for additional bonuses if they fail to improve on the algorithm's suggestion. Our results suggest a significant effect of fear on the AI-augmented decision making process.

5 The Return of "Optimal" Algorithms and Managerial Insight

Blair Flicker, University of South Carolina, Columbia, SC

Human newsvendors have been shown to place suboptimal orders due to several biases (e.g., pull-to-center and overconfidence). But human managers may also be able to *improve* inventory decision making by incorporating insights about the world that are missed by algorithms. I introduce this feature into the newsvendor setting by modeling managerial insight as private demand information accessible to humans but not algorithms. I then develop a method called FIND that consistently mitigates biases and earns more profit than (1) an automated store ordering system (ASOS) that cannot access managerial insight, (2) participants' direct orders, and (3) participants' adjustments to ASOS-generated orders.

OR Models in Healthcare Systems

Community Committee Choice Session

Session Chair: Ankit Bansal, State University of New York, Binghamton, Binghamton, NY

1 Effective Ways to Evaluate Sources of Infeasibility in Healthcare Scheduling Problems

Daiwen Zhang[1], Amy Cohn[2], [1]University of Michigan, Ann Arbor, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: dwzhang@umich.edu

Healthcare scheduling problems often have true "hard constraints" (e.g. laws-of-physics like a provider cannot be in two places at one time, regulatory policies governing rest, etc.). In addition, there may be additional constraints that are "required...unless you can't satisfy them." That is, the clinical setting strongly desires certain restrictions, but in rare cases these cannot be achieved. In such cases, "hard constraints" must be violated (with the clinical manager adjusting accordingly, e.g. by hiring moonlighters). Often, there are may different ways to achieve feasibility, i.e. many different subset of feasible constraints that could be honored. We present an integer programming-based algorithm to identify and assist the decision maker in evaluating these sets.

2 Incentives in Outcome-Based Regulation for Lung Transplantation

David Mildebrath[1], Saumya Sinha[2], Taewoo Lee[3], Andrew J. Schaefer[4], Howard J. Huang[5], Ahmed O. Gaber[5], [1]Amazon, Seattle, WA, [2]University of Minnesota, Minneapolis, MN, [3]University of Pittsburgh, Pittsburgh, PA, [4]Rice University, Houston, TX, [5]Houston Methodist Hospital, Houston, TX, Contact: saumya@umn.edu

Transplant programs in the US are subject to outcome-based regulations, whereby federal agencies evaluate them based on their patients' post-transplant survival. Clinical evidence indicates that such regulations induce programs to reject high-risk transplant candidates to avoid penalization. We present a game-theoretic model to study the incentives created by these outcome-based regulations. We show that harsh penalization, more than other factors, incentivizes programs to engage in adverse patient selection. We then propose a pay-for-performance reimbursement scheme that not only penalizes programs with below-average outcomes, but also pays a bonus to those with above-average outcomes. We demonstrate that our proposed scheme can incentivize programs to improve post-transplant outcomes, without inducing adverse patient selection.

3 Minimizing Nurse Anesthetist Intraoperative Handovers

Abhishrut Sinha[1], Ankit Bansal[2], Osman Ozaltin[3], Michael Russell[4], [1]State University of New York, Binghamton, Binghamton, NY, [2]State University of New York, Binghamton, Binghamton, NY, [3]North Carolina State University, Raleigh, NC, [4]West Virginia University School of Medicine, Morgantown, WV

Intraoperative handovers among Certified Registered Nurse Anesthetists (CRNAs) are susceptible to medical errors that can result in adverse health outcomes. We present a two-stage stochastic optimization model for assigning CRNAs to Operating Rooms. The model aims to minimize the number of intraoperative handovers by considering the operational constraints of the system and uncertainty in surgery times. Computational results using real data from a hospital system are presented to demonstrate the effectiveness of the proposed approach.

4 Optimizing Health and Social Care for Individuals in Complex Care Programs

Sindhoora Prakash, Hari Balasubramanian, University of Massachusetts, Amherst, MA

Patients with multiple chronic conditions, as well as unmet social needs, have significantly higher healthcare costs and utilization. Holistic, person-centered care interventions, often led by a multidisciplinary team consisting of nurses, community health workers, and social workers, have emerged as a strategy to engage with and help improve the health and well-being of such patients. The objective of these interventions is to reduce the occurrence of unnecessary hospitalizations and overall healthcare costs. In this talk, we highlight the potential benefits of using simulation, patient similarity, and mixed integer linear programming to estimate and optimize the allocation of health and social care services to patients, while minimizing their waiting times and the week-to-week (or day-to-day) variation in staff hours required.

Clinical Decision Making for Chronic Disease

Community Committee Choice Session

Session Chair: Jennifer Mason Lobo, University of Virginia, Charlottesville, VA

Session Chair: Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL

1 Optimize the Utilization of Peer Recovery Support Services with Limited Capacity: Take a New Patient or Follow up Existing Patients?

Qiushi Chen, Siyi Huang, Paul Griffin, The Pennsylvania State University, University Park, PA, Contact: q.chen@psu.edu

Over 100,000 Americans are dying from drug overdoses in one year. Although there are evidence-based treatments for substance use disorders, treatment initiation and retention remain low. Certified peer recovery support specialists are underutilized resources for improving the quality of substance use services in the hospital setting. In this study, we study a capacity management problem in peer recovery support services. We develop a Markov decision process model to optimize the early discharge decisions, aiming to efficiently utilize the limited capacity of peer recovery specialists to maximize the total treatment outcomes for patients with substance use disorders who had a hospital encounter. We analyze the optimal structure of discharge policy and evaluate multiple policies via a detailed simulation model in the computational study.

2 Estimating Chronic Kidney Disease Stages For Patients With Small Renal Masses And Influential Factors Using The Expectation-Maximization Algorithm

Wendy Qi[1], Jennifer Mason Lobo[2], Noah S. Schenkman[3], [1]University of Virginia, Charlottesville, VA, [2]University of Virginia, Charlottesville, VA, [3]University of Virginia, Charlottesville, VA, Contact: wq3vn@virginia.edu

Management of small renal masses involves cancer control and preservation of renal function. Estimation of future renal function values is challenging given that measurements are taken at uneven intervals. We employ the Expectation-Maximization algorithm to estimate the renal function transition probabilities, and extend our study to analyze how age, gender, Charlson Comorbidity Index, obesity, diabetes, and cardiovascular disease affect transition rates. Results illuminate the dynamic interplay between these factors and renal function transitions. Our findings improve understanding and interpretation of renal function transitions for patients and clinicians, enhancing clinical decision-making and informing treatment planning.

3 Prediction of Anti-Diabetic Medication Adherence Using Temporal Machine Learning Models

Peng Zhang[1], Hyojung Kang[2], Min-Woong Sohn[3], Jennifer Mason Lobo[4], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Champaign, IL, [3]University of Kentucky, Lexington, KY, [4]University of Virginia, Charlottesville, VA, Contact: pengz3@illinois.edu

Medication adherence rates are suboptimal among individuals with diabetes. Using Medicare data for patients with diabetes, this study aims to develop temporal machine learning models to predict anti-diabetic medication non-adherence and identify related risk factors. Study findings will help identify high-risk patients for medication non-adherence and inform targeted patient management strategies.

4 Analytical Modeling In The Emergency Department When The Class Of Interest Is Dynamic

M Gabriela Sava[1], Jerrold H. May[2], Ronald G. Pirrallo[3], [1]Clemson University, Clemson, SC, [2]University of Pittsburgh, Skokie, IL, [3]Prisma Health System / University of South Carolina School of Medicine Greenville, Greenville, SC, Contact: msava@clemson.edu

Diabetic screening of Emergency Department (ED)/Urgent Care (UC) patients can proactively improve health outcomes, but it is uneconomic to screen all such patients. We present a data-driven analytical approach, using near-time EHR data and clinical predictors recommended by the ADA, that could assist physicians with the yes/no diabetes screening decision. The approach is capable of dynamically switching among the appropriate statistical models as resource availability and patient frequency utilization change over time.

Emerging Topics in Empirical Healthcare

Community Committee Choice Session

Session Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

Session Chair: Shuai Hao, University of Illinois Urbana-Champaign, Champaign, IL

1 Matching Patients with Surgeons: Heterogeneous Effects of Surgical Volume on Surgery Duration

Behrooz Pourghannad[1], Guihua Wang[2], [1]Lundquist College of Business, University of Oregon, Eugene, OR, [2]The University of Texas at Dallas, RICHARDSON, TX, Contact: behroozp@uoregon.edu

This paper explores the potential of utilizing patient-specific information to enhance a hospital's operational efficiency, focusing on abdominal surgery as the clinical setting. We use the causal forest approach to obtain patient-specific volume effects, which are then used in an optimization model to evaluate the potential value of patient-specific information in improving a hospital's operational efficiency. We show that considering patient-specific volume effects in matching patients with surgeons could reduce surgery duration by 3% to 18%.

2 The Impact of Online Self-Scheduling on Patient Access to Hospital Services

Lesley Meng[1], Hummy Song[2], Christian Terwiesch[3], [1]Yale School of Management, Yale University, New Haven, CT, [2]The Wharton School, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, Contact: lesley.meng@yale.edu

Recent innovation in healthcare access has led to the launch of online patient platforms where patients are now able to digitally schedule and manage their own medical appointments within a health system. In many large academic medical centers, digital scheduling has become the default method for patients to request and schedule appointments, and many medical appointments are now made this way. In this study, we examine the impact of online self-scheduling access on patient scheduling and visit behavior at a large academic medical center.

3 What Drives Algorithm Use? An Empirical Analysis of Algorithm use in Type 1 Diabetes Self-Management

Wilson Lin[1], Song-Hee Kim[2], Jordan D. Tong[3], [1]Santa Clara University, Santa Clara, CA, [2]Seoul National University, Gwanak-gu, Korea, Republic of; [3]University of Wisconsin Madison, Madison, WI

Advancements in algorithms hold promise to better operations by improving users' decision-making. However, people sometimes fail to use algorithms, which could be a barrier from achieving such improvements. Using the bolus calculator (algorithm) use behavior from a field experiment on type 1 diabetes self-management, we show that 1) previous algorithm use increases future algorithm use, 2) being out of target with self-driven decisions increases subsequent algorithm use, while being out of target with algorithm-driven decisions does not impact algorithm use, 3) increasing the number of measurements provided to the user for a single algorithm input decreases algorithm use, 4) increasing one's need for precision increases algorithm use and 5) previous deviations from algorithm recommendations decrease future algorithm use.

4 Acquisition Of AI And Analytics Capabilities: Shareholder Value For Biopharmaceutical Firms

Jiatao Ding[1], Michael Freeman[1], Niyazi Taneri[2], [1]INSEAD, Singapore, Singapore; [2]Cambridge Judge Business School, Cambridge, United Kingdom

Biopharmaceutical companies are increasingly venturing into collaborations involving AI and analytics. These strategic alliances, aimed at improving drug candidate selection, speeding up development, and augmenting sales, are especially crucial in an industry challenged by low success rates and the patent cliff. Our in-depth analysis reveals that such AI-analytics partnerships not only bolster shareholder value on average but show particularly strong returns when centered on prelaunch R&D or targeting multiple indications. Furthermore, firm-specific traits, like R&D intensity and asset turnover, significantly moderate these outcomes. Our findings provide guidance to biopharmaceuticals seeking to optimize operations through AI and analytics.

Empirical Healthcare

Community Committee Choice Session

Session Chair: Christopher J. Chen, Indiana University Kelley School of Business, Bloomington, IN

Session Chair: Kraig Delana, University of Oregon, Eugene, OR

1 Can Employees' Past Helping Behavior be Used to Improve Shift Scheduling? Evidence from ICU Nurses

Zhaohui Jiang[1], John M. Silberholz[2], Yixin Iris Wang[3], Deena Costa[4], Michael Sjoding[5], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Michigan Ross School of Business, Ann Arbor, MI, [3]University of Illinois at Urbana-Champaign, Champaign, IL, [4]Yale School of Nursing, New Haven, CT, [5]Michigan Medicine, Ann Arbor, MI

Employees routinely make valuable contributions at work that are not part of their formal job description, such as helping a struggling coworker. However, the degree to which the past helping behavior of employees scheduled to a shift impacts that shift's operational outcomes remains an under-explored question. Our empirical results indicate that shift-level past helping measures are predictive of patient length of stay (LOS), more so than the broadly studied notion of team familiarity. Counterfactual analysis shows that relatively small changes in shift composition can yield a significant reduction in total LOS. Overall, our study suggests the potential value of shift scheduling using data on past helping behaviors, which may have promise far beyond the selected application to ICU nursing.

2 The Role of Physician Integration in Alternative Payment Models: The Case of the Comprehensive Joint Replacement Program

Christopher J. Chen[1], Kraig Delana[2], [1]Indiana University Kelley School of Business, Bloomington, IN, [2]University of Oregon, Eugene, OR

U.S. physicians are increasingly unifying (both horizontally and vertically) while transitioning from fee-for-service to alternative payment models (APM). We empirically examine the role of both horizontal and vertical integration of orthopaedic surgeons in driving heterogeneity in the impact of the Comprehensive Joint Replacement (CJR) alternative payment program. We find CJR hospitals with high horizontal and vertical integration see an increase in both hospital costs and risk-adjusted complication rates of 3.17% & 1.18, respectively. Moreover, we present evidence showing integration affects physician care decisions regarding length-of-stay and discharge disposition. Our findings provide novel insights into provider integration and clinical decisions that are relevant for policymakers, payors, and healthcare providers.

3 Community/Committee'S Choice Submission

Lina Song, University College London School of Management, London, United Kingdom

4 Improving Family Authorizations for Organ Donation via Budget-Neutral Contracts

Paola Martin[1], Diwakar Gupta[2], [1]Indiana University, Bloomington, IN, [2]University of Texas, Austin, TX, Contact: martipa@iu.edu

The successful recovery of deceased-donor organs depends on whether the donor hospital (DH) referred on time. Whereas Organ Procurement Organizations (OPOs) receive a standard fee for each transplanted organ, DHs do not receive compensation for referring in a timely manner.

We analyze a budget-neutral incentive scheme that could increase the proportion of timely referrals. A calibrated numerical study shows that, depending on the DH's cost of effort required to increase the proportion of timely referrals, the proposed contract could lead to 1.3% more viable donors annually. Extending the same approach to all referrals received by the OPO could increase the number of viable donors by 9% annually.

OM-Marketing Interface

Community Committee Choice Session

Session Chair: Michael Galbreth, University of Tennessee, Knoxville, TN

Session Chair: Bikram Ghosh, 1</sup

1 Social Product Feedback and Consumer Returns

Michael Galbreth[1], Bikram Ghosh[2], [1]University of Tennessee, Knoxville, TN, [2]University of Arizona, Tucson, AZ

We present insights from an analytical model of consumer returns that explicitly considers the impact of social product feedback (e.g. online user reviews) on consumer purchase and return decisions. Our results provide guidance regarding how the social feedback posted, and the manner in which consumers process that feedback, should impact optimal retailer strategies.

2 Product Return Policies: The Impacts of Vertical Bargaining and Contracting with Retail Competition

Chengzhang Li[1], Yufei Huang[2], Tingliang Huang[3], [1]Shanghai Jiao Tong University, Shanghai, China; [2]Trinity Business School, Trinity College Dublin, Dublin, Ireland; [3]The University of Tennessee-Knoxville, Knoxville, TN, Contact: cz.li@sjtu.edu.cn

We study the money-back guarantee (MBG) policies in distribution channels consisting of a manufacturer and two competing retailers. We adopt a multi-unit bilateral bargaining framework to flexibly capture the unbalanced power distributions among firms. We find that both bargaining power and contract forms are the key determinants of MBG policies. In symmetric distribution channels, i.e., both retailers possess the same bargaining power, while both retailers offer MBGs under the wholesale-price contract, the asymmetric MBG decisions arise when retailers are relatively powerful under the two-part tariff contract. When the retailers possess different bargaining powers, the retailer is less powerful in negotiation with the manufacturer than the other provides an MBG while the other may not.

3 A Field Experiment on AI-Assisted Physicians

Ting Hou[1], Meng Li[2], Yinliang Tan[2], Huazhong Zhao[3], [1]University of Science and Technology of China, Pearland, TX, [2]University of Houston, Houston, TX, [3]City University of Hong Kong, Kowloon, NY, Hong Kong

We collaborate with a leading healthcare platform to run a field experiment in which we compare physicians' adoption behavior, i.e., adoption rate and adoption timing, of smart and automated AI assistants under transparent and non-transparent conditions.

1 Should We All Work in Sprints? How Agile Project Management Improves Performance

Tobias Lieberum, Technical University of Munich, München, Germany

2 Sooner or Later? Promising Delivery Speed in Online Retail

Zhikun Lu, Emory University, Decatur, GA

Problem definition: Online retailers have to provide customers with an estimate of how fast an order can be delivered before they decide to make the purchase. Retailers can strategically adjust this delivery speed promise online without changing offline infrastructure, and doing so may fundamentally impact business outcomes. It can influence consumers' purchasing decisions and postpurchase experiences, often in the opposite direction. On one hand, an aggressive (i.e., faster) delivery estimate could ensure that more customers meet their deadlines and thus, may increase their purchases ex ante. On the other hand, an aggressive estimate tends to overpromise, potentially leading to a longer than expected wait time, which can lower customer satisfaction and increase product returns ex post. In this research, we estimate the causal effect of retailers' delivery speed promise on customer behaviors and business performance. Methodology/results: Collaborating with Collage.com, an online retailer that sells customized photo products across the United States, we exogenously varied the disclosed delivery speed estimates online while keeping the physical delivery speed unchanged. Using the difference-in-differences identification strategy, we find that a faster promise increases sales and profits, but it also increases product returns and reduces customer retention. In addition, we propose a data-driven model that uses the estimated parameters to optimize delivery promises to maximize customer lifetime value. Managerial implications: Our findings provide managerial insights and a data-driven policy that retailers can leverage to optimize and customize their delivery promises.

3 Food Subsidies at the Base-of-the-Pyramid: Take-up, Substitution Effects and Nutrition

Issues in Retail Operations Management

Community Committee Choice Session

Session Chair: Eda Kemahlioglu Ziya, NC State University, Raleigh, NC

Session Chair: Mert Çetin, IESE Business School, Barcelona, Spain

1 Store-Specific Assortments in the Presence of Product Constraints

Mert Cetin, Victor Martinez de Albeniz, IESE Business School, Barcelona, Spain. Contact: MCetin@iese.edu

When allocating products to brick-and-mortar stores, retailers face product availability constraints which force them to balance product offerings across stores. We model this problem and show that the product-store assignment problem is NP-complete under a multinomial logit (MNL) type demand. We develop a tractable continuous relaxation of the problem which has a unique local maximum and allows us to build near-optimal solution algorithms. We then apply our algorithms to mixed-MNL and nested-MNL type demand structures, and conduct extensive numerical analyses on their performances. We further offer an application using real data from a large multinational apparel retailer where we estimate model parameters and run the approximation algorithms. We identify a significant revenue increase potential by matching the right products with the right stores.

2 Online Product Display Optimization

Alara Tasçioglu, Gürhan Kok, Selcuk Karabati, Koc University, Istanbul, Turkey

We consider an online retailer with a diversified product portfolio serving multiple customer segments. Our goal is to determine optimal product rank, location and page layout in the first page of an online store to maximize expected profit margin per consumer. We allow product locations to be of different sizes and shapes within the first page of the online store by "combining" the smallest sized locations into "combined locations".We model the revenue impact of product rank, location and page layout with an extended Multinomial Logit Model. Our model's parameters include a location weight and a space elasticity weight that helps us determine larger positions' weights. We then approximate our model with a simpler profit margin-based search heuristic. Our numerical study shows a 34.7% increase in expected profit margin per customer by introducing "combined locations".

3 Inventory Reservation and Allocation for Multi-Item Orders with Uncertain Supply Lead Times and Demand Patterns

Aaron Huang Jinjia[1], Stanley Lim[2], Chung Piaw Teo[3], [1]Institute of Operations Research and Analytics, Singapore, Singapore; [2]Michigan State University, East Lansing, MI, [3]National University of Singapore Business School, Singapore, Singapore. Contact: oraahj@nus.edu.sg

We develop an efficient inventory reservation and allocation policy to fulfill multi-item orders in a warehouse. We account for correlated demand patterns and forecast order-level supply lead times by using machine learning techniques. We demonstrate the efficacy of the proposed approach using transaction and supply data from a furniture retailer.

Risk Management in Production and Agriculture Supply Chains

Community Committee Choice Session

Session Chair: Mert Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY

1 Cascading Effects of Climate Change in Production Networks: Evidence from Extreme Weather Events

Sai Palepu[1], Brian Clark[2], Bill Francis[1], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Lally School of Management, RPI, Troy, NY, Contact: paleps@rpi.edu

We investigate climate change-induced economic spillovers in the production networks. We exploit the billion-dollar hurricanes as natural exogenous shocks to these networks. We demonstrate the role of supply-chain linkages in the propagation of climate change-induced economic spillovers and highlight the role of network centrality in moderating these negative effects in production networks. Our event studies during hurricanes show that customers who have suppliers in the disaster-affected zone experience a 15% decline in average cumulative abnormal returns compared to customers who do not have suppliers in the same zone. However, the centrality of the firms in the networks moderates this relative decline by approximately 3.5%. Further, we find that climate risk spillovers are unidirectional and propagate from suppliers to customers and not vice-versa.

2 VinTech: Robo-Advising Using Wine Analytics

Mert Hakan Hekimoglu[1], Burak Kazaz[2], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Syracuse University, Syracuse, NY, Contact: hekimm@rpi.edu

This paper examines a comprehensive path regarding how analytics can be employed for automated trading of wine. We coin this as VinTech. The paper highlights the essential components of data analytics necessary for robo-advising. We first develop a pricing algorithm to represent the realistic value of a wine. Using this algorithm, we then compare the price evolution of underpriced wines to overpriced wines. Last, our robo-advising algorithm constructs wine portfolios for different investment goals and risk preferences. We demonstrate the performance of our algorithm using out-of-sample testing. This paper aims to convert an opaque market into a transparent and efficient investment market.

3 Developing Smart Supply Chain Contracts Using Data Analytics and Block Chain Models

Sevilay Onal[1], Sanchoy Das[2], Chandra Adhikari[1], Tripathi Shashank[1], [1]University of Illinois Springfield, Springfield, IL, [2]New Jersey Institute of Technology, Newark, NJ, Contact: sevilayonal@gmail.com

The three main elements of a supply chain contract are price, quantity, and supply lead time. Supply chain risk is a function of these three elements and managers are constantly monitoring this to minimize supply risks. A smart supply chain contract is designed to monitor several data parameters across the supply chain, and then use intelligent decision models to trigger actions before the perceived risk causes supply chain disruptions. This research will use a survey method to (i) Identify risk sensitive data parameters that can be tracked in real-time at one or more supply chain nodes (Examples: inventory levels, market price data), and (ii) Develop decision triggers models that relate the tracked data to risk quantification models. The trigger models are amenable to blockchain analysis, and the research will investigate how this approach will provide superior results.

4 Risk Sharing in a Two-Level Supply Chain with Variable Capacity and Random Yield

Xiao Xiao[1], Xiang Fang[2], [1]University of Wisconsin Milwaukee, Milwaukee, WI, [2]University of Colorado Denver, Denver, CO

The research on production uncertainty in the supply chain holds tremendous significance in the complex and interconnected business environment. Supply chains are affected by various uncertainties, including demand fluctuations and supply disruptions. Based on three centralized supply chains and three decentralized supply chains, this study examines two types of production uncertainty: Variable Capacity (VC) and Random Yield (RY), and the impact they have on supply capability, relationships among supply chain members, behavior, and performance. RY arises from imperfect processes and is predictable and measurable. In contrast, VC is caused by random factors like unforeseen interruptions and unplanned maintenance, making it uncontrollable. Our research findings indicate that VC and RY do not always affect production and ordering decisions in certain cases.

Managing Customer/Patient Experience in Service

Community Committee Choice Session

Session Chair: Nan Liu, Boston College, Chestnut Hill, MA

1 Under-Promising and Over-Delivering to Improve Patient Satisfaction at Emergency Departments

Sina Ansari[1], Laurens G. Debo[2], Maria R. Ibanez[3], Seyed Iravani[4], [1]Driehaus College of Business, DePaul University, Chicago, IL, [2]Dartmouth College, Hanover, NH, [3]Kellogg School of Management at Northwestern University, Evanston, IL, [4]Northwestern University, Evanston, IL,

Contact: sina.ansari@depaul.edu
The study explores how emergency departments (EDs) can improve patient satisfaction and financial performance by communicating wait times. By providing patients with personalized estimated wait times, the study finds that patients report 21% higher satisfaction. Overestimating wait times moderately (70th percentile) can further improve patient satisfaction and can be a cost-effective strategy for EDs. This approach can be especially useful in settings where queues are partially observable.

2 Queueing Causal Models for Comparative Analytics in Service Systems

Opher Baron[1], Dmitry Krass[2], Mark van der Laan[3], Arik Senderovich[1], Zhenghang Xu[1], [1]University of Toronto, Toronto, ON, Canada; [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada; [3]University of California, Berkeley, Berkeley, CA, Contact: zhenghang.xu@mail.utoronto.ca
Simulation is a powerful tool for comparative analysis of queueing models. With expert knowledge of underlying system structure, simulator can be constructed to predict intervention effects. However, such manual construction is time- and skill-demanding. It could also be subjective - if expert failed to note an important system feature (e.g. different customer types receiving different service priorities), the model will not be accurate. As an alternative, we propose a data-driven representation of system building blocks, justified by G-computation formula. We describe the queueing data generation process with structural equations and apply machine learning models to fit the equations. Through numerical experiments, we show that this approach can replace the explicit queueing dynamics and capture intervention effect in overtake-free queues.

3 The Role of Artificial Intelligence (AI) Technologies in Service Process Design

Chia-Chun Yang, Craig Froehle, University of Cincinnati, Cincinnati, OH, Contact: yangcc@mail.uc.edu
As organizations deploy AI-powered "chatbot" technologies in customer-facing service roles, we need to better understand how they affect customers' experiences. Historically, customers have tended to be wary of automated service technologies as they often perceive them to offer little value. Modern chatbots promise previously unrealized levels of personalization and responsiveness, which may convince customers they are reasonable substitutes for human reps in many cases. How will customers' expectations of, and experiences with, chatbots drive their satisfaction with the service experience? This research empirically investigates this behavioral operations issue using a mix of survey and experimental methodologies across multiple studies.

4 Design of Patient Visit Itineraries in Tandem Systems

Nan Liu[1], Guohua Wan[2], Shan Wang[3], [1]Boston College, Chestnut Hill, MA, [2]Shanghai Jiao Tong University, Shanghai, China; [3]Sun Yat-sen University, Guangzhou, China. Contact: nan.liu@bc.edu
Multi-stage service is common in healthcare. One widely adopted approach to manage patient visits in multi-stage service is to provide patients with visit itineraries, which specify individualized appointment time for each patient at each service stage. We develop the first optimization modeling framework to design such visit itineraries. We show that a well-designed patient visit itinerary, which carefully addresses the interdependence among stages, can significantly improve patient experience and provider utilization. A case study populated by data from a large cancer institute shows that our approach makes a remarkable 27% cost reduction over practice on average.

CC-North 132A

Incentives, Contracts, and Mechanisms for Service Operations

Community Committee Choice Session

Session Chair: Xiaohan Zhu, University of Florida, Gainesville, FL

1 Creating an Incentive Compensation Plan for a Project

Xiaohan Zhu, University of Florida, Gainesville, FL, Contact: zhuxiaohan@ufl.edu
This presentation investigates a principal-agent problem that arises in a collaborative project between a principal and an agent. The project is sponsored by the principal, who hires an agent to dedicate effort towards managing the project. The project does not have a fixed deadline but rather a predetermined target. Once the project reaches the target, it is considered complete. The principal's revenue is generated upon the completion of the project, while the agent is entitled to a lump-sum payment upon its completion as well. The agent's effort can be categorized into two types: base and additional effort. The base effort represents the minimum effort required by the principal, whereas the agent

has the freedom to determine the level of additional effort he chooses to contribute. The more additional effort the agent puts in, the faster the project is expected to be completed.

2 Customer Scheduling in Large Service Systems Under Model Uncertainty

SHIWEI Chai, GAINESVILLE, FL

Current studies on scheduling in the context of many-server queues typically rely on simplified assumptions such as exponential and class-independent service time, which is usually inconsistent with real-world data. While relaxing these assumptions can result in a high-fidelity model, it can be complex and difficult to solve. In this paper, we present a new approach for decision makers to generate high-quality scheduling policies through a robust formulation. We demonstrate through a numerical study based on a US call center dataset that our approach can achieve cost savings of 10% to 20% compared to an established benchmark in the literature.

3 Optimal Contract Design with Two-Layer Signals

Qingye Wu, Xiaoshuai Fan, Southern University of Science and Technology, Shenzhen, China

Live commerce contract emerge on platforms like Taobao.com. An implication of such contract is retailers grant hosts authority to send product signal to consumers by paying commission costs. We build a game-theoretical model to explore when and why a retailer contracts with a host. Without the contract, the retailer personally conveys product signal at no extra cost. Signal affects senders' reputation, defined as consumers' perception of signal accuracy. Our findings indicate that when the retailer possesses a low initial reputation, a high-quality retailer can effectively differentiate his type himself. Moreover, when retailer's reputation is moderate, a high-quality retailer can prevent imitation through contract adoption while a low-quality retailer chooses not to contract to mitigate reputation loss especially when consumers lack confidence in high quality.

4 Partial Information Sharing In Competitive Markets

Xiao Wei, Tsinghua University, Beijing, China

This paper studies a Cournot competition problem with two firms, each of which can observe a private signal about the uncertain market demand and decide how to share this signal. We formulate a linear optimization problem to model incentive compatible information sharing mechanisms based on the framework of Bayesian games with communication. We propose a specific information sharing mechanism to provide guidance on firms' operations. To evaluate whether our proposal is close to optimal, we also construct an upper bound for the optimal result. We show that generally, it is nearly optimal for firms to share nothing. However, when the signal is accurate, the market uncertainty is high, and the prior belief of high demand is low, our mechanism provides firms an approach to implement partial information sharing that can outperform no sharing.

Supply Chain: Security/Sustainability Information/ Disclosure

Community Committee Choice Session

Session Chair: Hyoduk Shin, UC-San Diego, La Jolla, CA

1 How Do Producers Fare with Fair Trade?

Yen-Ting (Daniel) Lin[1], Adem Orsdemir[2], Ying Zhang[3], [1]University of San Diego, San Diego, CA, [2]University of California Riverside, Riverside, CA, [3]Clemson University, Clemson, SC, Contact: linyt@sandiego.edu

In this paper, we examine the impact of fair trade certificate on a fair trade retailer's decisions, profitability and participating producers' welfare. We also examine a retailer's choice between fair trade and direct trade, which is another common socially responsible sourcing strategy.

2 Understanding the Competitive Sales Impact of Automobile Features in New and Used-Car Markets

Hojun Choi[1], Ahmet Colak[2], Sina Golara[3], Achal Bassamboo[1], [1]Northwestern University (Kellogg), Evanston, IL, [2]Clemson University, Clemson, SC, [3]Kennesaw State University, Marietta, GA

The automotive industry is highly competitive, prompting manufacturers and dealerships to constantly make efforts to cater to consumer preferences and lifestyles through features. These features are optional and increase product attractiveness. However, the impact of these features on sales performance remains uncertain. This study examines the influence of car features on revenue rates and sales times for new and used-car segments, using Cars.com dataset. We propose an economic framework to quantify feature values and estimate their impact. Results indicate that features explain 70% price variations. New cars with lower feature values yield higher revenue rates, contrasting with used cars. Higher feature values reduce new-car sales times but increase used-car sales times. This study contributes to product variety and inventory management literature.

3 An Empirical Investigation of Investment Substitutability and Complementarity Between Flexible and Intermittent Electricity Generation

Ahmet Colak[1], Seyed Amin Seyed Haeri[2], Safak Yucel[3], [1]Clemson University, Pendleton, SC, [2]Clemson University, Clemson, SC, [3]Georgetown University, Washington

In this study we evaluate the role of the operational flexibility on capacity investment decisions made in electricity grids. We adopt an empirical approach and evaluate this role using a unique panel data set of United States electricity grid spanning across 2002-2019. We particularly evaluate how investment in a particular generation technology can influence future investments in other types of generation technologies. We essentially shed light on the evolving nature of the electricity generation portfolio from an operations management perspective while informing policy makers in designing more effective technology-specific policies that facilitate the transition toward renewable generation.

Agricultural and Environmental Operations

Community Committee Choice Session

Session Chair: Canberk Ucel, Bilkent University, Philadelphia, PA

1 Agricultural Index Insurance: An Optimization Approach

Jose Velarde Morales, Linwei Xin, University of Chicago, Chicago, IL, Contact: jvelarde@chicagobooth.edu

Index insurance is a popular way of providing agricultural insurance in low-income countries, and it is estimated that tens of millions of farmers worldwide are covered by index insurance programs. However, these programs are very costly and have to be heavily subsidized by governments in most cases. We develop an optimization-based approach to designing index insurance contracts that improves its cost effectiveness.

2 Health Coverage and Farmworker Productivity

Zachariah Rutledge[1], John Lowrey[2], Timothy Richards[3], [1]Michigan State University, East lansing, MI, [2]Northeastern University, Boston, MA, [3]Arizona State University, Mesa, AZ

Farmworkers are often subject to hazardous working conditions, experience a disparity in health insurance coverage and are vulnerable to chronic health conditions and injury. Many agricultural employers still do not offer coverage for their employees. We quantify the economic value of offering health coverage to farmworkers using a structural search, match, and bargaining model. We find that farmworkers with employer-provided health coverage are significantly more productive than those without and, on average, generate an additional $0.78 in economic surplus for each hour worked. Employers who offer health coverage retain an additional $0.60 of economic surplus for each hour of work performed by their employees due to a health productivity premium.

3 Predicting Demand for Wildfire Suppression Resources

Yasser Zeinali[1], Ilbin Lee[1], Mostafa Rezaei[2], [1]University of Alberta, Edmonton, AB, Canada; [2]ESCP Business School, Parisa, France. Contact: yzeinali@ualberta.ca

Between 2013 and 2022, an average of 61,410 wildfires occurred annually, burning an average of 7.2 million acres per year in the United States. As a result of the significant costs and damages incurred by these wildfires, there is immense pressure on wildfire management agencies to devise a more effective resource allocation strategy for fighting fires. However, a model predicting the demand of firefighting resources in the coming days has not been developed in literature. We propose a newsvendor formulation and quantile regression models to generate distributional forecasts for the demand. Our results indicate that the proposed models outperform baselines mimicking the strategy currently in use.

4 Profitable Nitrogen Loss Mitigation in the U.S. Midwest Through Farm Management, New Policies and "Lean" Technologies

Canberk Ucel[1,2], [1]Bilkent University, Ankara, Turkey; [2]INSEAD, Singapore, Singapore. Contact: canberk.ucel@bilkent.edu.tr

Use of "precision" farming practices have remained persistently low in the US Midwest, despite extant research demonstrating vast economic, environmental benefits, particularly associated with the prevention of N loss. While our analysis of crop yield and novel nutrient applications data from a large sample of fields corroborates previous findings that spatiotemporal variation in yields is strongly predicted by topography-weather interactions, we find that a significant portion of the variance in N loss is driven by disproportionately large losses on a few fields. We find the economic returns to proposed practices to be 90.5% of the net profits on average, but that these returns are only 6.9% of the operating profits, which may be prohibitive. Based on these findings, we propose technologies and policies to enable the profitable adoption of N loss mitigation measures.

Amazon Last Mile Resources Optimization

Community Committee Choice Session

Session Chair: Liron Yedidsion, Amazon, Redmond, WA

1 Muti-Stage Newsvendor Optimization for Capacity Planning

Gah-Yi Ban[1], Chinmoy Mohapatra[2], Liron Yedidsion[3], Abhilasha Katariya[4], [1]Imperial College Business School, London, United Kingdom; [2]Amazon, Bellevue, WA, [3]Amazon, Redmond, WA, [4]Amazon, Issaquah, WA, Contact: g.ban@imperial.ac.uk

Labor constitutes one of the most expensive resources within the supply chain, necessitating careful advanced planning. Adjusting labor capacity entails the processes of recruitment and training, which consume both time and resources. The demand for labor is subject to fluctuations, encompassing seasonal patterns and variations occurring throughout the week. Actual demand often manifests itself long after a plan has been formulated and committed to. Excessive planning leads to the payment for unnecessary routes, while insufficient planning results in higher delivery costs to uphold the commitment of timely customer deliveries. We approach this issue by modeling it as a multi-stage newsvendor optimization problem, with the aim of minimizing expected overage and underage costs, alongside labor change expenses.

2 Mobile Fueling at Amazon Last Mile

Anish Dhananjay Khare[1], Monchen Kao[1], Chinmoy Mohapatra[2], Lois Nersesian[1], Liron Yedidsion[3], [1]MIT, Cambridge, MA, [2]Amazon, Bellevue, WA, [3]Amazon, Redmond, WA, Contact: lirony@amazon.com

Refueling for internal combustion engines (ICE) vehicles and charging electric vehicles (EV)s are none value adding operation for last mile deliveries. Amazon decouples such operations and outsources them from the driver. Mobile refueling services, handled by external agents while vehicles are parked, are a newer approach. However, these contracts charge a fixed cost for each operation, regardless of tank level. Amazon aims to reduce unnecessary refueling while keeping the risk of on-road refueling low. We compare two refueling policies: cyclic refueling every fixed number of days and refueling on fixed days of the week. The former is more efficient, while the latter is more practical. We prove an approximation ratio of 1.76 for the day-of-week policy with respect to cyclic refueling and demonstrate a tight actual ratio of 1.065 through simulation.

3 Hierarchical Consensus Planning for Amzl Operations

Mahdieh Allahviranloo[1,2], Chinmoy Mohapatra[3], Rohit Malshe[4], [1]Amazon, New York, NY, [2]CUNY, New Yrok, NY, [3]Amazon, Bellevue, WA, [4]Amazon, Seatle, WA, Contact: allahvir@amazon.com

A hierarchical consensus planning framework is proposed to model the consensus process across Amazon delivery stations and third-party carriers. This framework is set to come up with planning targets for various components of the system while respecting the corresponding constraints of each agent within the delivery stations and between the delivery stations. We propose a bi-level consensus planning structure where the coordinator at the top-level coordinates the operation of stations. And, at the lower level, each station has its own consensus planning structure across its agents.

4 Last Mile Operations Planning Optimization at Amazon

Louis Faugère, Amazon, Seattle, WA

Efficient package delivery throughout the year requires the seamless coordination of last mile carriers with network topology and resource planning. This coordination is particularly important when continuously striving to meet increasing delivery capacity and speed requirements amidst seasonality and uncertainty. In this presentation, we will discuss challenges and provide practical insights regarding a range of activities aimed at guiding the allocation of delivery workloads and resources across last mile nodes through the lens of optimization.

Conic Optimization and Machine Learning

Community Committee Choice Session

Session Chair: Swati Padmanabhan, University of Washington, Seattle, Seattle, WA

1 Solving Tall Dense SDPs in the Current Matrix Multiplication Time

Shunhua Jiang, Columbia University, New York City, NY, Contact: sj3005@columbia.edu

In this talk I will introduce a new interior point method algorithm that solves semidefinite programming (SDP) with variable size n×n and m constraints in the (current) matrix multiplication time m^[illegible] when m=Ω(n^2). This suggests solving SDP is nearly as fast as solving the linear system with equal number of variables and constraints. This is the first result that tall dense SDP can be solved in the nearly-optimal running time, and it also improves the state-of-the-art SDP solver. Our algorithm maintains the inverse of a Kronecker product using lazy updates, and we design a general amortization scheme for positive semidefinite matrices. Based on joint work with Baihe Huang, Zhao Song, Runzhou Tao, and Ruizhe Zhang.

2 Optimization via Semidefinite Programming Hierarchies

Goutham Rajendran, Carnegie Mellon University, Pittsburgh, PA, Contact: gouthamr@cmu.edu

The Sum of Squares (SoS) hierarchy is a powerful optimization technique that harnesses the power of semidefinite programming (SDP) and has achieved tremendous success for various problems in combinatorial optimization, robust statistics and machine learning. In particular, SoS is a family of SDPs that can be applied to general polynomial optimization and it lets us smoothly trade off running time for approximation guarantees. In this talk, I will introduce SoS from an optimization viewpoint, present some highlights and breakthroughs of SoS, e.g. robust clustering, and finally discuss various threads of fascinating research it has led to, e.g. hypothesis testing with limited power.

3 Large-Scale Portfolio Optimization Using Graph Attention Networks

Kamesh Korangi[1], Christophe Mues[1], Cristian Bravo[2], [1]University of Southampton, Southampton, United Kingdom; [2]University of Western Ontario, London, ON, Canada. Contact: cbravoro@uwo.ca

In addition to assessing individual firm performance, investors in financial markets must also consider how their set of firms performs together as a portfolio. Portfolio optimisation is essential for mid-cap firms, which are riskier and more volatile than large-caps, while also being more numerous. We empirically test a novel method of deploying Graph Attention networks (GATs) that exploit high-dimensional network data to find intricate relationships between firms. Benchmarked against established models over a large-scale portfolio of over five thousand firms, the results show that the portfolio produced by the GAT-based model outperforms them significantly and provides stronger diversification, while being more robust.

Sunday, October 15, 8:00 AM - 9:15 AM

Large Scale Supply Chain Network Optimization

Community Committee Choice Session

Session Chair: Chun Ye, Amazon.com, Seattle, WA

1 Optimizing Large Scale Temporal Multi-Commodity Capacitated Flow Problem

Arash Haddadan[1], Cristiana L. Lara[2], Jochen Koenemann[3], [1]Modeling and Optimization, Amazon, Bellevue, WA, [2]Amazon, Bellevue, WA, [3]University of Waterloo, Waterloo, ON, Canada

We study the temporal fixed-charge multi-commodity flow problem. This problem arise when modeling large scale fulfillment networks where timing impacts both consumer experience as well as operations in the network. To this end, we wish to maximize the volume of the flow that arrive within the promised times while obeying capacity and cost constraints. Due to the sheer size of this problem, it cannot be solved directly even on moderate size transportation networks. In this work, we propose a light-weight combinatorial heuristic algorithm that can produce high-quality solutions for this problem while significantly reducing the computation time when compared to previous solution methods. The simplicity of the combinatorial algorithm allows straightforward interventions to ensure that solutions are aligned with operations expectations.

2 Designing Partially Timing-Aware Network Topologies

Daniel Ulch, Amazon, Bellevue, WA, Contact: danulch@amazon.com

Large scale service network design is a core problem faced by E-retailers and parcel express companies. Even the static version of the problem, where the geographic flow of goods is determined, is difficult to solve. In practice these companies require timed-solutions to determine linehaul schedules and resource requirements. This work focuses on bridging the gap between static and dynamic network design optimization models. We introduce time-window constraints into the static network design model to prevent timing-infeasible consolidations without using a time-expanded network. We then focus on solving the resulting problem efficiently.

3 A Solution Framework for a Multi-Period Uncapacitated Topology Optimization

Myunseok Cheon, Amazon, Bellevue, WA

In this talk, we discuss a multi-period uncapacitated facility location problem. The unique characteristic is that the model needs to consider the backlog level and its incurring cost. The multi-period aspect is to capture the backlog behavior over time and the uncapacitated perspective is to represent the fact that each facility can receive more units than its capacity by utilizing the backlog capability. This talk discusses two main technical topics. One is a surrogate model technique to transform the multi-period model into a single period topology optimization model. The other is a hierarchical large-neighborhood search approach to solve the resulting problems, which have over 3 to 5 million variables. We will discuss the efficacy of the proposed approach compared to a commercial solver and the accuracy of the surrogate modeling approach.

4 Launch Policies for a Multiperiod Capacitated Facility Location Problem Considering Demand Uncertainty

Francisco Trespalacios, Amazon, BELLEVUE, WA

Launch planning defines the evolution of network topology over a forward-looking planning horizon. Sophisticated methodologies have been proposed in the literature, most notably leveraging stochastic facility location models. However, many of these are not used in practice due to the difficulty for planners to comprehend and implement their solutions. In this work, we propose a launch policy approach to generate practical plans considering demand uncertainty. Our methodology is based on a capacitated facility location-allocation model and a three-staged solution approach using neighborhood search routines.

5 Decision Alignment Across Different Business Entities via a Large Scale Min-Cost Network Flow Model

Zihao Li[1], Rohit Injeti[2], Kamalesh Somani[1], [1]Amazon, Bellevue, WA, [2]Amazon, El Paso, TX

In this talk, we solve a business problem using a large-scale multi-period min-cost network flow problem with cross-period constraints, in which decisions are currently being made in a decentralized fashion by different business entities. Our work focus on aligning the decision-making processes of the different business entities and provide an optimal solution at the network level. We present various techniques to limit the solution space to better fit the business practice the model is trying to serve, and discuss the implication of the model results on business decisions.

Decentralized Learning and Optimization

Community Committee Choice Session

Session Chair: Ceyhun Eksin, Texas A&M University, College Station, TX

Session Chair: Sarper Aydin, Texas A&M University, College Station, TX

1 Policy Gradient Play over Time-Varying Networks in Markov Potential Games

Sarper Aydin, Ceyhun Eksin, Texas A&M University, College Station, TX

We design a multi-agent and networked policy gradient algorithm in Markov potential games. Each agent has its own rewards and utility as functions of joint actions and a shared state among agents. The state dynamics depend on the joint actions taken. Agents implement continuous parameterized policies defined over the state and other agents' parameters to maximize their utilities against each other. Agents share their parameters with neighbors over a time-varying network. Agents compute their stochastic gradients to update their parameters with respect to their local estimates of Q-functions and joint parameters. We prove the convergence of joint parameters to a first-order stationary point of the potential function in probability for any type of state and action spaces. Numerical results validate the convergence in the lake game.

2 Optimal Control of Spatially Exponential Decaying Linear Quadratic Regulator

Runyu Zhang[1], Weiyu Li[2], Na Li[3], [1]Harvard University, Cambridge, MA, [2]Harvard University, Allston, MA, [3]Harvard University, Cambridge, MA, Contact: runyuzhang@fas.harvard.edu

This talk focuses on network LQR problems with system matrices being spatially-exponential decaying (SED) between nodes in the network. The major topic is to study whether the optimal controller also enjoys a SED structure, which is an appealing property for ensuring the optimality of decentralized control over the network. We start with studying the open-loop asymptotically stable system and show that the optimal LQR state feedback gain is `quasi'-

SED in this setting. Then the result is further generalized to unstable systems under a stabilizability assumption. Further, the results are obtained by analyzing the structure of disturbance response control, thus as a side result, it also proves the `quasi'-SED property of the optimal disturbance response control.

3 Independent Natural Policy Gradient for Markov Potential Games with Provable Fast Convergence

Youbang Sun, Northeastern University, Boston, MA, Contact: sun.youb@northeastern.edu

Reinforcement Learning (RL) has shown remarkable success in solving complex tasks in the field of robotics, economic decision making, autonomous driving, etc. Typically, RL is considered to be single-agent, with the environments formulated as Markov Decision Processes (MDPs). However, many problems in practice can not be formulated as single-agent systems, these challenges have motivated recent studies for multi-agent reinforcement learning (MARL). However, due to the unique geometry of the problem and complex relationships between agents, the theoretical aspects of MARL are faced with many challenges, with most works showing slow convergence results for algorithms when compared to their single-agent versions. We study the NPG update in multi-agent systems and propose novel analysis in order to find a better convergence speed for the algorithm.

4 Fedbc: Calibrating Global and Local Models via Federated Learning Beyond Consensus

Amrit Singh Bedi[1], Chen Fan[2], Alec Koppel[3], Anit Kumar Sahu[4], Brian Sadler[5], Furong Huang[1], Dinesh Manocha[1], [1]university of maryland, College Park, MD, [2]UBC, Canada, VANCOUVER, BC, Canada; [3]JP Morgan Chase & Co., New York, NY, [4]Amazon, Seattle, WA, [5]US Army Research Lab, Adelphi, MD, Contact: amrit0714@gmail.com

We quantitatively calibrate the performance of global and local models in federated learning through a multi-criterion optimization-based framework, which we cast as a constrained program. The objective of a device is its local objective, which it seeks to minimize while satisfying nonlinear constraints that quantify the proximity between the local and the global model. We develop a novel primal-dual method called Federated Learning Beyond Consensus (FedBC). Theoretically, we establish that FedBC converges to a first-order stationary point at rates that matches state of the art, up to an additional error term that depends on a tolerance parameter introduced to scalarize the multi-criterion formulation. Finally, we demonstrate that FedBC balances the global and local model test accuracy metrics across a suite of datasets (Synthetic, MNIST, CIFAR-10, Shakespeare).

5 Learning Trust over Directed Graphs in Multiagent Systems

Orhan Eren Akgün, Harvard University, Cambridge, MA, Contact: erenakgun@g.harvard.edu

We address the problem of learning the legitimacy of other agents in a multiagent network when an unknown subset is comprised of malicious actors. We specifically derive results for the case of directed graphs and where stochastic side information, or observations of trust, is available. We refer to this as "learning trust" since agents must identify which neighbors in the network are reliable, and we derive a learning protocol to achieve this. We also provide analytical results showing that under this protocol i) agents can learn the legitimacy of all other agents almost surely, and ii) the opinions of the agents converge in mean to the true legitimacy of all other agents in the network. Lastly, we provide numerical studies showing that our convergence results hold for various network topologies and variations in the number of malicious agents.

Recent Advances in Large-scale Optimization

Community Committee Choice Session

Session Chair: Mateo Diaz, 1</sup

1 Any-Dimensional Convex Sets

Eitan Levin, Caltech, Pasadena, CA

Classical algorithms are defined on inputs of different sizes. In contrast, algorithms learned from data may only be defined on inputs of the same size as the data. What does it mean for an algorithm to be defined on infinitely-many input sizes? How do we describe such algorithms? We tackle these questions for convex optimization-based algorithms, whose description reduces to describing convex sets. We show that descriptions of convex sets defined in any dimension often arise from (a) group invariance and the recently-identified phenomenon of representation stability; (b) relations between different-sized problem instances. We combine these ingredients to parametrize families of any-dimensional convex sets.

2 Higher-Order Newton Methods

Amir Ali Ahmadi[1], Abraar Chaudhry[2], Jeff Zhang[3], [1]Princeton University, Princeton, NJ, [2]Princeton University, Princeton, NJ, [3]Carnegie Mellon University, Pittsburgh, PA, Contact: azc@princeton.edu

We present generalizations of Newton's method that incorporate derivatives of arbitrarily high order, but maintain a polynomial dependence on dimension in their cost per iteration. At each step, our algorithms use semidefinite programming to construct and minimize a convex approximation to the Taylor expansion of the function we wish to minimize. We analyze the convergence rates of our higher-order Newton methods and compare their basins of attraction around local minima to those of the classical Newton method.

3 Asynchronous Gradient Play in Zero-Sum Multi-Agent Games

Shicong Cen, Yuejie Chi, Carnegie Mellon University, Pittsburgh, PA, Contact: shicongc@andrew.cmu.edu

Finding equilibria via gradient play in competitive multi-agent games has been attracting a growing amount of attention, with emphasis on designing efficient strategies where the agents operate in a decentralized and symmetric manner with guaranteed convergence. Despite recent activities, the performance in zero-sum multi-agent games remains inadequately explored, especially in the presence of delayed feedbacks, leaving the scalability and resiliency of gradient play open to questions. In this paper, we make progress by studying asynchronous gradient plays in zero-sum polymatrix games under delayed feedbacks. To the best of our knowledge, this work is the first that aims to understand asynchronous gradient play in zero-sum polymatrix games under a wide range of delay assumptions, highlighting the role of learning rates separation.

4 Stochastic Approximation with Decision-Dependent Distributions: Asymptotic Normality and Optimality

Mateo Díaz, Johns Hopkins University, Baltimore, MD, Contact: mateodd@jhu.edu

We analyze a stochastic approximation algorithm for decision-dependent problems, wherein the data distribution used by the algorithm evolves along the iterate sequence. The primary examples of such problems appear in performative prediction and its multiplayer extensions. We show that under mild assumptions, the deviation between the average iterate of the algorithm and the solution is asymptotically normal, with a covariance that nicely decouples the effects of the gradient noise and the distributional shift. Moreover, building on the work of H\'ajek and Le Cam, we show that the asymptotic performance of the algorithm is locally minimax optimal.

Optimal Traffic Control Session

Community Committee Choice Session

Session Chair: Qichao Wang, National Renewable Energy Laboratory

1 The Green Light Sonata: Foundations for Musical Control of Traffic Signals

Montasir M. Abbas, Virginia Polytechnic Institute, Blacksburg, VA

The goal of this research is to improve signal operation and reduce delay through an innovative transdisciplinary integration of traffic signal control and music theories. The main hypothesis in this research is that "the underlying sense that musicians exhibit during improvisation can be utilized to better synchronize signal control with internal traffic rhythm." In this work, we developed and used a novel Signal Operation with Neuro-fuzzy Acoustic Tuning Application (SONATA) interface to control a simulated traffic signal. Three musicians utilized the SONATA framework to control their respective traffic signal using visual/auditory information and auditory only information to minimize queues. This presentation lays out the foundation for a new area of research and proves that harmonization of control and traffic with music-based control has merits.

2 Deep Learning Traffic State Estimation in a Connected Vehicle Traffic Control Systems

Larry Head[1], Debashis Das[2], [1]The University of Arizona, Tucson, AZ, [2]Argonne National Laboratory, Chicago, IL, Contact: klhead@arizona.edu

Connected vehicle technologies are idea for the design and development of adaptive traffic signal control systems. They provide the location, speed, heading, and other critical vehicle data that can be used to make traffic signal control decision. Unfortunately, the market penetration of connected vehicles is low and will likely remain low as the technology is introduced thought new vehicles design and sales. A few connected vehicles in the traffic stream can be used to estimate the location of non-connected vehicles. This paper presents a deep learning model that uses connected vehicle data to estimate the location of all vehicles in the traffic stream. This data is used by a dynamic programming based optimization algorithm to provide adaptive signal control, priority for special classes of connected vehicles, and traffic signal coordination.

3 Optimal Traffic Signal Control with VPL Model

Qichao Wang, National Renewable Energy Laboratory,

Golden, CO, Contact: Qichao.Wang@nrel.gov

The Virtual Phase-Link (VPL) model describes the dynamics of vehicle distributions across a road network which can be used to optimize the traffic intersections signal control. The states of the model are the number of vehicles in every VPLs at each time step. The control variables of the model are the active green times and the green splits. The optimal traffic signal control problem can be solved as a nonlinear programming problem with linear constraints and quadratic objective function. This presentation will present the mathematical formulation of the VPL model and the applications in simulations and real-world deployments.

4 Making Smart Traffic Signals Smarter, Safer and More Sustainable Through Real-Time Connectivity with Travelers

Stephen Smith, Carnegie Mellon University

This talk describes work aimed at utilizing traveler-to-infrastructure communication in three ways: (1) to improve the throughput of a real-time adaptive traffic signal control system, (2) to make its operation safer for vulnerable road users, and (3) to enable more sustainable models for urban infrastructure funding. We focus specifically on what might be possible in the near-term, when the number of connected travelers on the road can be expected to be relatively small. We present results obtained both in simulation studies and in field test experiments with connected autonomous vehicles and pedestrians with disabilities that demonstrate progress across each of the three objectives mentioned above.

Applications of Mathematical Models to Inform Decision Making in Healthcare

Community Committee Choice Session

Session Chair: Iakovos Toumazis, The University of Texas MD Anderson Cancer Center, Houston, TX

1 Assessing the Loss in Effectiveness and Efficiency of Lung Cancer Screening by Enforcing a Structure on the Screening Policy

M. Soheil Hemmati[1,2], Andrew J. Schaefer[2], Iakovos Toumazis[1], [1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX, Contact: soheil.hemmati@rice.edu

Current annual lung cancer screening recommendation by the US Preventive Services Task Force enjoys high degree of practicality, yet with no account for the optimality of the screening effectiveness. In contrast, the recently proposed ENGAGE framework, a partially observable Markov decision process model, derives optimal lung cancer screening schedules that achieve highest effectiveness level. In this study, we assessed the effectiveness and efficiency of alternative screening policies with fixed screening frequencies and compared their performance against the ENGAGE-derived optimal schedules. Through simulations, we found that the screenings with fixed, predetermined frequencies may achieve reasonable levels of either effectiveness or efficiency but not both and quantified how much benefit we sacrifice to achieve practicality.

2 Calibration of Histology-Specific Natural History Models for Ovarian Cancer Using Simulated Annealing

Sayaka Ishizawa[1], Jiangong Niu[1], Maddie Tumbarello[2], Mehdi Hemmati[2], Larissa A. Meyer[1], Iakovos Toumazis[1], [1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Rice University, Houston, TX, Contact: sishizawa@mdanderson.org

Ovarian cancer is the leading cause of death from gynecological cancers accounting for approximately 13,200 cancers in 2023. Well validated natural history models could provide insights on the natural disease progression. In this study, we develop natural history models for the seven most common histologies of ovarian cancer using Markov models that share the same overall structure. Each model consists of 13 health states and 39 transition probabilities. We calibrate 133 parameters total (ranging from 18-23 per model) using an adaptive simulated annealing algorithm such that the natural history models reproduce observed incidence and mortality rates from the Surveillance, Epidemiology, and End Results (SEER) registry.

3 Development of an Ovarian Cancer Risk Prediction Model

Seyyed Mostafa Mousavi Janbeh Sarayi[1], Jiangong Niu[1], Martin Tammemagi[2], Larissa Meyer[1], Iakovos Toumazis[1], [1]The University of Texas MD Anderson Cancer Center, Houston, TX, [2]Brock University, St. Catharines, ON, Canada

Ovarian cancer is the leading cause of death from gynecological cancers. Screening for ovarian cancer at the population was shown to be ineffective in reducing ovarian cancer mortality. Targeting screening on high-risk individuals has the potential to be more effective, but existing risk prediction models have modest predictive performance in selecting individuals for screening. We used data from the Prostate, Lung, Colorectal, and Ovarian (PLCO) randomized screening trial to develop a risk prediction model with sufficient predictive performance. Supervised machine learning methods were trained, and model's discrimination and calibration was evaluated. We present the model's performance on the training and the testing dataset and the methodology we used to develop the model.

Learning and Optimization Algorithms

Contributed Session

Session Chair: Dinesh Krishnamoorthy, Eindhoven University of Technology, Eindhoven, Netherlands

1 A Multi-Agent Reinforcement Learning-Based Branch-And-Price Algorithm for Resource Allocation with Trimming Allowance and Batching Requirements

Baiyang He, Ying Meng, Lixin Tang, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, China, Shenyang, China. Contact: hebaiyangneu@163.com

In this study, we address a resource allocation problem with trimming allowance and batching requirements. We formulate the problem as a set-covering model, and then develop a branch-and-price algorithm to obtain the optimal solutions. In the algorithm, a label-correcting method is designed to optimally solve pricing problems, whose efficiency is guaranteed by dominance rules. In addition, a hybrid-rules branching strategy is proposed to enhance branching efficiency. Finally, we propose an adaptive cutting plane procedure based on multi-agent reinforcement learning to find cutting planes that can tighten the model. The numerical experiments show that our algorithm outperforms the state-of-the-art branch-and-price algorithms, especially regarding the effectiveness of the adaptive cutting plane procedure.

2 Aggregate Then Predict and Optimize: Addressing Uncertainties in Multi-Item Spare Part Inventory Systems

Alireza Sheikh-Zadeh, Texas Tech University, Lubbock, TX

This research addresses this issue of the inconsistency between the criteria we train learning algorithms and decision-making by simultaneously capturing the objective costs of the prediction and prescription problem and utilizing aggregation and disaggregation approaches to ensure tractability. The solution approach is applied to a multi-item spare-part replenishment problem.

3 Optimizing Package Storage In Amazon Mechlite Delivery Stations

ROHIT MALSHE, Marc Anderson, Sourabh Puri, Dipal Gupta, Liron Yedidsion, Amazon.com, Kirkland, WA, Contact: malshe.rohit@gmail.com

AMZL's Mechlite delivery stations (DS) in various countries handle daily shipments of Non-Oversized (Non-OV) and Oversized (OV) packages. To improve space utilization and reduce labor costs, we present novel techniques for packaging and storing these items. Our 3D bin packing and set cover algorithms enable efficient Non-OV bin allocation and assignment, while our Dynamic Rack Optimization Program (DROP) algorithm optimizes the storage of OV packages by minimizing volume variation, spillover, picker search time, and maximizing aisle use. These approaches increase station capacity by up to 5%, decrease labor by 3.6%, and lower storage space requirements by up to 4%. To further enhance space utilization, our fungible racks also use a set of algorithms that can increase space usage efficiency by up to 25%, enabling sustainable operation for up to three additional years.

4 Leveraging Parametric Sensitivities to Accelerate Distributed Optimization Algorithms

Dinesh Krishnamoorthy, Eindhoven University of Technology, Eindhoven, Netherlands

Large-scale optimization problems, common in applications, such as optimal resource allocation and multi-agent networks, can be decomposed into several smaller subproblems that take coordinated actions. This work focuses on addressing the computational burden of repeatedly solving the subproblems arising in wide range of distributed optimization problems. Noting that in most decomposition strategies (both centralized/decentralized coordination), the subproblems solved between consecutive iterations differ only by a few variables, the key idea of this work is to exploit the parametric nature of the subproblems to reduce the computation time of the subproblems in each iteration. Convergence Guarantees for a class of ADMM problems will be presented, along with numerical examples including flow routing, resource allocation, and distributed learning problems.

Smart Urban Mobility and Logistics: Emerging Technologies and Innovative Solutions

Community Committee Choice Session

Session Chair: Meng Zhao, Dalian University of Technology, Dalian, China

2 PPP Contract Design for Smart Road Infrastructure

Zhuo Feng, Jinbo Song, Dalian University of Technology, Dalian, China. Contact: zhfeng@dlut.edu.cn

The aging road infrastructure is deterring the wide-scale deployment of autonomous vehicles (AVs). In this study, we focus on the provision of smart road infrastructure through public-private partnerships (PPPs). Considering congestion time reduced by AVs compared to human-driving vehicles (HVs) with the help of the smart road, we investigate the firm's decisions on (differentiated) toll prices and road capacity as well as the allocation of it between AVs and HVs. We also discuss the government's subsidy design to improve social welfare.

Delivery Systems Modeling with Emerging Vehicle Technologies

Community Committee Choice Session

Session Chair: Tom Shi, 1</sup
Session Chair: Zhiwei Chen, Drexel University, Philadelphia, PA
Session Chair: Qianwen Li, University of South Florida, Tampa
Session Chair: Xiaopeng Li, University of Wisconsin-Madison, WI

1 Integrated Truck and Drone Delivery Systems

Juan Zhang[1], James F. Campbell[2], Donald C. Sweeney II[3], [1]University of Wisconsin - Eau Claire, Eau Claire, WI, [2]University of Missouri - St. Louis, Saint Louis, MO, [3]University of Missouri - St. Louis, St. Louis, MO

Unlike most studies considering either truck-drone tandems or drone standalone delivery operations, our research provides a strategic analysis for the optimal design of an integrated drone delivery system in which customers in a service region can be served by a combination of truck-drone (TD) delivery, drone-only (DO) delivery, and truck-only (TO) delivery. We formulate and optimize continuous approximation models to identify the optimal delivery service combination that minimizes the total delivery costs including truck and drone operating and stop costs. We evaluate the impact of a wide range of operating characteristics and delivery environments on the optimal delivery system and the benefits of using drones. Our results suggest that an optimal delivery system design often uses a mix of DO and TD, but TD is the dominant delivery service in most scenarios.

2 Modular Autonomous Vehicle Operations for Airport Baggage Transportation

Xiaowei(Tom) Shi, University of Michigan, Ann Arbor, MI

Modular autonomous vehicles (MAV) are an emerging transportation technology that allows vehicles to adjust their capacity flexibly. This technology offers us a new perspective on solving baggage transport problems for airports. To investigate this possibility, this study proposes an operational design and a corresponding MAV scheduling model to optimize baggage transport. The objective of the optimization model is to minimize MAV operating cost while transporting baggage from the terminal to the aircraft without delay. To solve the proposed problem efficiently, a fast construction-merging heuristic algorithm is proposed based on property analysis of the feasible solutions. A series of case studies at Tampa International Airport were conducted to evaluate the performance of the proposed operational design and the heuristic algorithm.

3 A Continuous Approximation Model for Urban Electric Robotic Deliveries with Maintenance Costs

Joseph Y J Chow[1], Hai Yang[1], Tho Le[2], [1]New York University, Brooklyn, NY, [2]Purdue University, Lafayette, IN

With the rise in demand for local deliveries and e-commerce, robotic deliveries are being considered as more sustainable and efficient solutions. However, the deployment of such systems can be highly complex due to numerous factors involving stochastic demand, stochastic charging and maintenance needs, etc. We propose a continuous approximation model for evaluating service trade-offs that consider unique characteristics of sidewalk robots. Synthetic data as well as real world deployment data are used to calibrate such a model to evaluate potential deployment in neighborhoods in NYC.

Traveling Salesperson and Repairman Problems

Community Committee Choice Session

Session Chair: Albert Schrotenboer, Eindhoven University of Technology, Eindhoven, -, Netherlands

1 An Exact Method for the Time Window Assignment Traveling Salesperson Problem with Stochastic Travel Times

Sifanur Celik[1], Layla Martin[2], Albert Schrotenboer[1], Tom Van Woensel[2], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: a.h.schrotenboer@tue.nl

We consider optimization problems often modeled as stochastic programming problems with mixed binary and continuous first- and second-stage decision variables. This paper introduces Scenario Clustered Benders Dual Decomposition (SCBDD) as a general methodology for solving such stochastic programs. The method combines and generalizes Benders Dual Decomposition, Partial Benders Decomposition, and Scenario Clustering techniques and does so within a novel two-step decomposition along the binary and continuous first-stage decisions. We apply SCBDD to jointly assign time windows and determine a vehicle tour for stochastic travel times, i.e., optimally solving the Time-Window Assignment Traveling Salesperson problem. Extensive experiments show that SCBDD is superior to state-of-the-art approaches in the literature.

2 A Scalable and Adaptable Supervised Learning Approach for Solving the Traveling Salesman Problems

Zefeng Lyu, Andrew J. Yu, The University of Tennessee, Knoxville, Knoxville, TN

This paper addresses the challenges of scalability and generalization in learning-based approaches for solving TSPs. We propose a supervised learning approach that leverages local information to make predictions, using the concept of "anchors" to represent nodes that should connect to their nearest neighbors. Unlike previous approaches, our model relies solely on surrounding nodes for predictions, enabling it to handle large-scale instances without sacrificing accuracy. Experimental results show successful identification of anchors with high precision for both generated and TSPLIB instances. Integrating predicted anchors into established methods improves solution quality. Our approach demonstrates scalability and adaptability for solving TSPs.

3 The K Traveling Repairman Problem with Stochastic Service Requests

Thomas B. Cassidey[1], Iman Dayarian[2], [1]California State University, East Bay, Hayward, CA, [2]The University of Alabama, Tuscaloosa, AL

We investigate the problem of designing a set of routes to service a combination of deterministic and stochastic customers with known and unknown service request times at the beginning of an operational period, respectively. Our problem considers the routing of k service agents to minimize the expected total latency of customers in the system. We develop a branch and price approach to solve the problem. We present an analysis of the general expected latency calculation which allows for a novel recourse rule we call the *maximum wait-to time* and present a novel set of dominance rules. We perform a factorial experiment over numbers and types of customers as well as numbers of service agents. We find that our proposed approach outperforms both a greedy approach and an approach which uses only the point estimates of service request times and quantify the tradeoff with solution time.

Exploring the Intersection of Metaverse and AGI: Applications and Challenges

Community Committee Choice Session

Session Chair: Yuan Zhang, 1</sup

1 Through Many Faces: How Virtual Influencer Appearance Changes Impact User Engagement

Hongjun Ye[1], Yuan Zhang[2], Tianwen Du[3], Zhiya Zuo[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Memphis, Memphis, TN, [3]University of Georgia, Athens, GA, [4]City University of Hong Kong, Kowloon Tong, China. Contact: hongjun.ye@katz.pitt.edu

As digital humans, virtual influencers are fundamental to the emerging metaverse. Though easily modifiable by creators, should their appearance be changed? This study explores how altering a virtual influencer's appearance affects user engagement and examines the underlying mechanisms. This research not only guide creators in enhancing audience engagement but also contribute to discussions on identity, ownership, and accountability in the context of metaverse.

2 Open For U? The Effects of Openness on Initial Exchange Offering Multihoming

Zhiya Zuo[1], Jie Zhou[2], Xi Wang[3], Xiuhua Zhang[2], [1]City University of Hong Kong, Kowloon Tong, Hong Kong; [2]Harbin Engineering University, Harbin, China; [3]Central University of Finance and Economics, Beijing, China

Initial exchange offerings (IEOs) have emerged as a reliable blockchain startup fundraising model, with exchanges serving as intermediaries. However, exchanges' control over IEO projects can limit their growth. Multihoming - listing projects on multiple exchanges - offers advantages, including greater investor access and protection. Integrating the theoretical lens of legitimacy, resource-based view, and open innovation, this study explores the role of project openness in achieving multihoming, with implications for blockchain startups.

3 Does Collaboration Pay off for Individuals? Virtual Team Formation and Individual Performance

Yihan Deng[1], Zhiya Zuo[2], [1]City University of Hong Kong, Hong Kong, Hong Kong; [2]City University of Hong Kong, Kowloon Tong, China. Contact: yihandeng2-c@my.cityu.edu.hk

Crowdsourcing contest platform has been a prevalent channel for organizations to gain access to the wisdom of crowds for novel ideas effectively and efficiently, in which solution seekers launch complex tasks with monetary reward, and the users compete for the prize by sole participation or voluntary collaboration with other competitors. This study uncovers the effects and mechanisms through which team formation influences individual performance outcomes by conducting Difference-In-Differences (DID) with multiple time periods. We find that team formation positively affects an individual's performance. Heterogeneous effects manifest within specific subgroups defined by individual capital characteristics. Specifically, individuals with high-level capital outperform those with low-level capital when forming teams.

4 The Rise Of Generative AI Art: How Do Text-to-Image Models Affect Artist Productivity And Artwork Novelty?

Yumeng Miao, Qinglai He, Sung S. Kim, University of Wisconsin-Madison, Madison, WI, Contact: ymiao38@wisc.edu

Generative AI models have transformed work and occupations. While emerging literature has started exploring generative models and their societal impacts, little research explores text-to-image models and how they affect artwork creation using data from real-world settings. We seek to quantify the impacts of DALL-E 2 on artist productivity and their artwork novelty by analyzing data from an online artist community using difference-in-differences analyses. We measure artwork novelty regarding two essential image elements: subject and style. Our results indicate that DALL-E 2 boosts user productivity and encourages users to explore more distinct artistic styles in image creation. However, DALL-E 2 shows no influence on image subjects. The effects vary among artists with distinct characteristics. We also conduct secondary analyses to obtain deeper insights.

5 When Digital Meets Reality: Examining the Impact of Featuring Digital Humans Alongside Real Ones

Zhiya Zuo[1], Yuan Zhang[2], Tianwen Du[3], Hongjun Ye[4], [1]City University of Hong Kong, Kowloon Tong, China; [2]University of Memphis, Memphis, TN, [3]University of Georgia, Athens, GA, [4]University of Pittsburgh, Pittsburgh, PA, Contact: tianwen.du@uga.edu

Virtual influencers are digital humans that often blend virtuality with reality. Drawing from identity theories and user engagement literature, we analyzed the impact of featuring these influencers alongside real humans on social media. By examining audience reactions to this phenomenon, our research findings provide insights into what transpires when the digital and the real world converge.

1 Distributionally Robust Airport Ground Holding Problem Under Wasserstein Ambiguity Sets

Haochen Wu, University of Michigan, Ann Arbor, Ann Arbor, MI

The airport ground holding problem seeks to minimize flight delay costs due to airport capacity reductions. However, the critical input of future airport capacities is often difficult to predict, presenting a challenging yet realistic setting. Even when airport capacity predictions provide a distribution of possible capacity scenarios, such distributions may themselves be uncertain (e.g., due to distribution shifts, or due to mis-specification of an underlying assumed parameterized distribution). To address the problem of designing airport ground holding policies under distributional uncertainty, we formulate and solve the airport ground holding problem using distributionally robust optimization (DRO). We address the uncertainty in the airport capacity distribution by defining ambiguity sets based on the Wasserstein distance metric. We propose reformulations which integrate the ambiguity sets into the airport ground holding problem structure. Faced with the problem that the Wasserstein distance of two probability distributions is non-convex, we introduce a conditional distribution to represent the joint distribution of the empirical distribution and an arbitrary distribution in the ambiguity set. Based on the Wasserstein ambiguity set, we use the Lagrangian dual function and the duality theorem to derive the deterministic equivalent formulation of distributionally robust single airport ground holding problem(dr-SAGHP). We also extend the dr-SAGHP to distributionally robust multi-airport ground holding problem(dr-MAGHP) and discuss dicretization properties of the proposed models, which demonstrate the existence of the worst-case distribution of the dr-SAGHP & dr-MAGHP and the performance of dr-SAGHP & dr-MAGHP with discretized support. We discuss comparisons (via numerical experiments) between ground holding policies and optimized costs derived through the deterministic, stochastic, and distributionally robust airport ground holding problems. Our experiments show that the dr-MAGHP outperforms the stochastic MAGHP and deterministic MAGHP when there is a significant difference between the empirical airport capacity distribution and the realized airport capacity distribution. As shown in Figure 1, when the radius of the Wasserstein ambiguity set is 0.5, the dr-MAGHP has the lowest expected total delay cost for each sample size compared with that of d-MAGHP and s-MAGHP. We note that DRO can be a valuable tool for decision-makers seeking to design airport ground holding policies, particularly when the available data regarding future airport capacities are highly uncertain.

2 Estimating Airport Leakage with Connected and Automated Vehicle Adoption

Shriya Karam, Massachusetts Institute of Technology, Boston, MA

Through the 2021 $1.2 trillion Bipartisan Infrastructure Law, The U.S. Department of Transportation aims to create and sustain equitable and accessible intercity transportation systems. However, in accessing the intercity transportation system through airports, individuals' ability to access airports through a reliable ground transportation mode may inhibit their travel ability. Using a cohort-based optimization approach, we determine the optimal allocation of a limited supply of buses to serve an airport from a particular bus station by maximizing accessibility for low and high income census tracts. The findings of the study indicate that incorporating financial disadvantage impacts the allocation of transit which thus provides a framework for examining the impact of ground access improvements on accessibility for low and high income groups.

Artificial Intelligence in Clinical Decision Supports

Community Committee Choice Session

Session Chair: Samie Tootooni, Loyola University Chicago, Maywood, IL

1 Rapid Diagnosis of Stroke Through EMS Data

Samie Tootooni[1], Grant Hiura[1], Paula de la Pena[1], Nafiseh Mollaei[1], Daniel Heiferman[2], Oguz Akbilgic[3], [1]Loyola University Chicago, Maywood, IL, [2]Edward-Elmhurst Health, Naperville, IL, [3]Wake Forest University, Winston-Salem, NC, Contact: mtootooni@luc.edu

Timely triage and transport to an appropriate stroke center are crucial for providing life-saving treatments for stroke patients. Early identification of stroke patients is crucial for EMS teams to transport them to the most appropriate health center, which may sometimes involve traveling a greater distance. Our goal in this study is to develop a machine learning model, using retrospective EMS data, to detect stroke during the early stage of EMS care. By analyzing the geographic disparity factors, we will also identify how patients from underrepresented areas are disproportionately affected by delays in stroke diagnosis and treatment, and how our developed AI solution can help address these disparities.

2 Mitigating Emergency Overcrowding Using Machine Learning and Simulation

Abdulaziz Ahmed[1], Khalid Y. Aram[2], James Booth[3], Brittany Lindsey[4], [1]University of Alabama Birmingham, Birmingham, AL, [2]Emporia State University, Emporia, KS, [3]UAB Medicine-University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham Health System, Birmingham, AL

Full capacity protocol (FCP) is a tool proposed by the American College of Emergency Physicians (ACEP) to mitigate emergency department (ED) overcrowding.

However, this tool is reactive as it depends on real-time values of patient flow measures (PFM). In this project, we study the possibility of making FCP proactive by predicting PFM using machine learning. Then, we build discrete event simulation (DES) models to assess the effectiveness of the proactive FCP by comparing it with a reactive FCP. The proactive FCP will be integrated into a clinical decision support system to be used by the hospital management.

3 Inherent Test Variability As A Limit For Model Accuracy. Predicting Cochlear Implant Eligibility Using Routine Hearing Test Data.

Santiago Romero-Brufau, Mayo Clinic, Brookline, MA

In this session we will discuss common pitfalls when training machine-learning algorithms for clinical decision support, and how to avoid them. They will be exemplified with a recent project at Mayo's Department of ENT predicting cochlear implant eligibility using the results of routine audiograms. Eligibility was based on two separate clinical tests. Our final model achieved an accuracy of 87% (Sensitivity: 90%; precision: 80%) Our discussion will include: tailoring accuracy metrics to the clinical context and intended use; reformulating models that may seem insufficiently accurate.

Robust and Fair Machine Learning in The Presence of Distribution Shifts

Community Committee Choice Session

Session Chair: Sina Baharlouei, University of Southern California, Los Angeles, CA

1 A Stochastic Alternating Balance K-Means Algorithm for Fair Clustering

Suyun Liu[1], Luis Nunes Vicente[2], [1]Amazon.com Services LLC, Sunnyvale, CA, [2]Lehigh University, BETHLEHEM, PA

In the application of data clustering to human-centric decision-making systems, the clustering outcome might discriminate against people across different demographic groups, leading to unfairness. A natural conflict occurs between the clustering cost and the balance representation of all demographic groups across the clusters, leading to a nonconvex and nonsmooth bi-objective optimization problem. To determine the complete trade-off between these two competing goals, we design a novel stochastic alternating balance fair k-means (SAfairKM) algorithm, which consists of alternating classical mini-batch k-means updates and group swap updates. Our numerical experiments show that the proposed SAfairKM algorithm is robust and computationally efficient in constructing well-spread and high-quality Pareto fronts both on synthetic and real datasets.

2 Understanding New Tasks Through the Lens of Training Data via Exponential Tilting

Subha Maity, University of Michigan, Ann Arbor, MI, Contact: smaity@umich.edu

Deploying machine learning models on new tasks is a major challenge due to differences in distributions of the train (source) data and the new (target) data. However, the training data likely captures some of the properties of the new task. We consider the problem of reweighing the training samples to gain insights into the distribution of the target task. Specifically, we formulate a distribution shift model based on the exponential tilt assumption and learn train data importance weights minimizing the KL divergence between labeled train and unlabeled target datasets. The learned train data weights can then be used for downstream tasks such as target performance evaluation, fine-tuning, and model selection. We demonstrate the efficacy of our method on Waterbirds and Breeds benchmarks.

3 Domain Adaptation Meets Individual Fairness, and They get Along

Debarghya Mukherjee, Boston University, Boston, MA, Contact: mdeb@umich.edu

Many instances of algorithmic bias are caused by distributional shifts. For example, machine learning (ML) models often perform worse on demographic groups that are underrepresented in the training data. In this paper, we leverage this connection between algorithmic fairness and distribution shifts to show that algorithmic fairness interventions can help ML models overcome distribution shifts, and that domain adaptation methods (for overcoming distribution shifts) can mitigate algorithmic biases. In particular, we show that (i) enforcing suitable notions of individual fairness (IF) can improve the out-of-distribution accuracy of ML models under the covariate shift assumption and that (ii) it is possible to adapt representation alignment methods for domain adaptation to enforce individual fairness.

Equity, Fairness in Digital Systems

Community Committee Choice Session

Session Chair: Brittany Green, 1</sup
Session Chair: Nehir Tanyel, University of Cincinnati

1 Systematic Differences in Graders in Automated Hiring Solutions: A Machine Learning Fairness Approach

Mike H. M. Teodorescu[1], Nailya Ordabayeva[2], Marios Kokkodis[3], Abhishek Unnam[4], Varun Aggarwal[4], [1]University of Washington, Seattle, WA, [2]Dartmouth College, Chestnut Hill, MA, [3]Boston College, Chestnut Hill, MA, [4]SHL, New Delhi, India

Organizations routinely utilize natural language processing combined with other machine learning (ML) tools to assess prospective employees through automated resume classification based on pre-codified skill databases. The rush to automation can however backfire by encoding unintentional bias against groups of candidates. We run two experiments with human evaluators from two different countries to determine how cultural differences may affect hiring decisions. We use hiring materials provided by an international skill testing firm which runs hiring assessments for Fortune 500 companies. The company conducts a video-based interview assessment using machine learning, which grades job applicants automatically. We find that systematic differences can exist across human graders and that some can be reversed by algorithms if accounted for at training time.

2 AI Oversight to Promote Fairness in Finance: A Win-Win for Lenders and Borrowers

Amber Young, Wenwen Ding, University of Arkansas, Fayetteville, AR

Lending firms rely on artificial intelligence systems to determine credit worthiness. These systems draw on ‘big data’ from diverse sources and may systematize cultural biases. To combat bias, firms can implement oversight strategies such as ‘fairness through unawareness’, ‘demographic parity’, and ‘equalized opportunity.’ Using the data of a Chinese lending firm, we developed four models (Wide & Deep, Light GBM, XG Boost, and linear regression) to predict repayment. We identified rural borrowers as at-risk based on the weight of predictor variables. We then implemented the strategies above to determine which interventions enhanced fairness in loan approval outcomes for rural borrowers. We found that the Wide & Deep model promoted such fairness to a greater extent than the less sophisticated models. While the interventions reduced wrongful denials of rural loan seekers when applied to the less sophisticated models, results for rightful approvals were mixed. In some cases, interventions applied to the Wide & Deep model resulted in less just decisions for rural loan seekers. Notably, we found that most of the interventions would result in net gains for the firm. Our study indicates that carefully chosen and contextually appropriate fairness interventions could offer a beneficial outcome for both lenders and loan seekers, potentially reducing bias and resulting in financial gains. However, the effectiveness of these interventions can be model-dependent, underscoring the need for a nuanced approach in their implementation.

3 Till Tech Do Us Part: Betrayal Aversion and Its Role in Algorithm Use

Cameron Kormylo[1], Idris Adjerid[1], Sheryl Ball[1], Can Dogan[2], [1]Virginia Tech, Blacksburg, VA, [2]Radford University, Radford, VA, Contact: ckormylo@vt.edu

Failing to follow expert advice can have significant consequences. One potential mechanism that restricts the acceptance of expert advice is betrayal aversion, or the strong dislike for the violation of trust norms. This study explores whether the introduction of algorithms in place of human experts can attenuate betrayal aversion and lead to higher rates of advice seeking. We answer this question through an experimental financial market where there is an identical risk of betrayal from either a human or algorithmic advisor. We find that the willingness to utilize human experts is significantly reduced by betrayal version, while no betrayal aversion is exhibited towards algorithmic experts. The resulting unwillingness to take the advice of the human expert leads to a 20% decrease in subsequent earnings, while no loss in earnings is observed in the algorithm condition.

4 Longitudinal Examination of Bias and Generative AI on Online Labor Markets

Brittany Green, University of Louisville, Louisville, KY

While online labor markets (OLMs) provide many benefits including flexibility and data driven AI matching systems, gender and other social biases have been shown on OLMs, and research demonstrates AI can also perpetuate bias. Recently, generative AI systems have been used to provide profile recommendations to freelancers to increase their chances of getting noticed by AI ranking systems and employers on the platform. To help design OLMs that minimize the detrimental impact of biases on marginalized social groups, we investigate generative AI systems and its role in empowering or furthering bias for marginalized groups. We focus on investigating the long-term effects of this system using an agent-based simulation model, since bias is not static over time or independent of AI systems.

5 Exploring the Emancipatory and Hegemonic Potential of Social Media in Facilitating Connective Grief

Nehir Tanyel, University of Cincinnati, Cincinnati, OH, Contact: tanyelin@mail.uc.edu

Devastating subsequent earthquakes struck 12 major cities in southeastern Turkey on February 6, 2023, leaving 13.5 million people in need of assistance. As social media has been instrumental in crisis response, this study explores its role in facilitating the process of long-term crisis response such as collective grief in the aftermath of a humanitarian disaster. Specifically, we examine the impact of social media on shaping collective identity and mobilizing for collective action, with a particular focus on the upcoming elections. Through a case study of the Kahramanmaras earthquake in Turkey, our study sheds light on the potential contributions of social media to the theoretical understanding of whether social media could be an emancipatory or hegemonic technology during the collective grief process, and how it can influence social and political transformation.

Advanced Data Analytics for Reliability and Maintenance

Community Committee Choice Session

Session Chair: Jaesung Lee, Texas A&M University, College Station, TX

Session Chair: Akash Deep, University of Wisconsin - Madison, Stillwater, OK

Session Chair: Congfang Huang, UW Madison, Madison, WI

1 Distributional Robust Partially Observable Markov Decision Processes Optimization with Distance-Based Uncertainties

Yisha Xiang[1], Tong Li[2], [1]University of Houston, Housy, TX, [2]University of Houston, Houston, TX

In this paper, we consider distributional robust partially observable Markov decision processes (DR-POMDP). We prove that the optimal value still has the piece-wise linear and convexity property under some assumptions of the uncertainty sets. We further adapt the heuristic search value iteration (HSVI) algorithm to solve the proposed DR-POMDPs. Computational studies are conducted to investigate the performance of the DR-POMDP.

2 Need-Based Sampling for Machine Learning with Application to All-Terminal Network Reliability Assessment Leveraging a Quantum Computing Approximation

Seyyed Farid Hashemian[1], Jose Azucena[2], Haitao Liao[1], [1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas-IE Department, Fayetteville, AR, Contact: sfhashem@uark.edu

Since the effort of calculating the exact all-terminal reliability grows exponentially, approximation methods are often applied. The performance of such data-driven models is highly dependent on the selected training samples. In this work, we consider using additional samples to augment the observations used to fit a model and develop a method for effective improvement through active learning under a budget constraint. Moreover, we implement an algorithm based on quantum computing to approximate the desired all-terminal network reliability and leverage this estimation as an input to our surrogate model used in our active learning scheme.

3 Strata Design In Stochastic Simulations With Multivariate Inputs

Jaeshin Park[1], Young Myoung Ko[2], Sara Shashaani[3], Eunshin Byon[4], [1]University of Michigan - Ann Arbor, Ann arbor, MI, [2]Pohang University of Science and Technology, Pohang, Korea, Republic of; [3]North Carolina State University, Raleigh, NC, [4]University of Michigan, Ann Arbor, MI, Contact: jaeshin@umich.edu

Stratified sampling is one of the powerful variance reduction methods for analyzing system performance, such as reliability, with stochastic simulation. It divides the input space into disjoint subsets, called strata, to draw samples from each stratum. Strata design faces the curse of dimensionality and data scarcity as the input dimension increases. We analytically derive the optimal stratification structure that minimizes the estimation variance for univariate problems. Further, reconciling the optimal stratification into decision trees, we devise a robust algorithm for multi-dimensional problems.

4 Privacy-Preserving Location Scale Regression Based on Differential Privacy Approach

Jiewen Sheng, Xiaolei Fang, North Carolina State University, Raleigh, NC, Contact: jsheng4@ncsu.edu

Data privacy protection is an important yet challenging topic in industrial federated learning. In this talk, we present (log)-location-scale (LLS) regression models that can achieve epsilon-differential privacy based on the functional mechanism. We specifically discuss models whose response variable follows several most common distributions in the LLS family: Smallest Extreme Value, Weibull, Logistic, and Loglogistic. Numerical studies have demonstrated that the proposed approach can effectively provide privacy protection while maintaining a relatively high accuracy of the regression model.

5 Component-Wise Markov Decision Process for Solving Condition Based Maintenance of Large Multi-Component Systems with Economic Dependence

Vipul Bansal, University of Wisconsin - Madison

Condition-based maintenance of multi-component systems is a prevalent engineering problem due to its effectiveness in reducing the operational and maintenance costs of the system. However, developing the exact optimal maintenance decisions for the large multi-component system is computationally challenging, even not feasible, due to the exponential growth in system state and action space size with the number of components in the system. To address the scalability issue in CBM of large multi-component systems, we propose a Component-Wise Markov Decision Process and an Adjusted Component-Wise Markov Decision Process to obtain an approximation of the optimal CBM decision policy for large heterogeneous systems. Further, extensive numerical studies demonstrate the effectiveness of component-wise solutions for solving large multi-component systems.

Emerging Machine Learning in Manufacturing and Operations

Community Committee Choice Session

Session Chair: Jia Liu, 1</sup

1 Enhancing Patient Similarity Learning with a Graph Generative Model for Multiple Chronic Conditions

Julian Carvajal Rico, Adel Alaeddini, The University of Texas at San Antonio (UTSA), San Antonio, TX, Contact: julian.carvajal@utsa.edu

Chronic diseases present a substantial healthcare challenge, particularly when dealing with Multiple Chronic Conditions (MCCs). In this context, we present a generative model that effectively utilizes individual patient-level risk factors and existing conditions to tackle the intricacies of optimizing graph representations for MCCs. Furthermore, we harness the potential of Graph Neural Networks (GNNs) derived from these representations to comprehend the intricate progression of MCCs. Our method's validity is established through its application to a dataset from the Cameron County Hispanic Cohort (CCHC), encompassing five chronic conditions and ten patient-level risk factors.

2 Wind Power Forecasting Based on Spatial-Temporal Graph Convolution Network with Limited Engineering Knowledge

Luo Yang, Kaibo Wang, Tsinghua University, Beijing, China. Contact: yangluo18@mails.tsinghua.edu.cn

Wind power forecasting is of crucial importance to improve the reliability of wind power systems. Extensive sensors installed on the wind turbine can collect multivariate time series of various variables in the turbine. The correlation between some variables can be described based on engineering knowledge. In this work, we propose a hierarchical multivariate time series forecasting based on spatial-temporal graph convolution network (HMTGCN) to forecast the wind power by taking full advantage of engineering knowledge.Spatial-temporal graph neural networks are utilized to extract features from subsystems of turbine and a graph convolution network integrates these features to perform prediction. The performance of the proposed method is evaluated by the real-life wind power dataset, and the results prove the effectiveness and superiority of the proposed method.

3 Process-Informed Gaussian Process Regression for Thick Layer Quality Assessment in Large-Scale Metal Additive Manufacturing

Cesar Ruiz[1], Qiang Huang[2], [1]University of Oklahoma, Norman, OK, [2]University of Southern California, Los Angeles, CA

Large-scale metal additive manufacturing (LMAM) is gaining popularity for sustainable on-demand near-net shape fabrication of complex parts. However, LMAM-built parts suffer from significant distortion due to unstable high-temperature deposition processes. Predictive models are being developed to predict and control LMAM geometric accuracy. These methods rely on accurate product qualification, which is challenging due to high surface roughness, layer remelting, and out-of-plane layer displacement. To enable accurate layer segmentation, we propose an efficient Gaussian process regression algorithm to identify layer boundaries by leveraging knowledge of idealized layers and geometry of previous layers. Numerical and experimental studies validate the effectiveness of the proposed Gaussian process segmentation algorithm in assessing layer quality.

4 A Federated Data Fusion-Based Prognostics Model for Applications with Incomplete Signals

Madi Arabi, Xiaolei Fang, North Carolina State University, Raleigh, NC, Contact: sarabi@ncsu.edu

Two of the most significant analytical challenges when constructing prognostic models for real-world industrial applications include missing data and limited training samples. Missing data means degradation signals are incomplete (i.e., some observations are missing, or the data are irregularly sampled due to varying sampling intervals), and limited training samples implies there are not enough historical samples for modeling training. This paper proposes a federated prognostics model, which allows multiple users to jointly construct a failure time prediction model using their incomplete data while keeping each user's data local and confidential. Numerical results verify effectiveness of introduced methods.

5 Clustering Raman Spectrum Data via Heterogeneity Extraction from Sequential CP Decomposition

Shenghao Xia, Jian Liu, University of Arizona, Tucson, AZ, Contact: jianliu@email.arizona.edu

Raman spectrum fluence has been used to evaluate the quality of products from the ultraviolet curing process. Traditional Raman spectrum analysis methods are ineffective due to sampling uncertainty and process uncertainty. In this research, an unsupervised learning method is proposed to investigate the curing process and the process variation by clustering Raman spectrum data. CP decomposition is adapted to extract both homogeneous and heterogeneous features from noisy Raman Spectrum data of a sample of cured products. Based on heterogeneous features, products are clustered to indicate physical process variation. The effectiveness of the proposed method is demonstrated with a case study.

Session Chair: Raghav Gnanasambandam, Virginia Tech, Blacksburg, VA

1 Provable Convergence of Tensor Decomposition-Based Neural Network Training

Bo Shen, Chenyang Li, New Jersey Institute of Technology, Newark, NJ, Contact: bo.shen@njit.edu

In this research, a holistic framework is proposed for tensor decomposition-based NN training by formulating TT decomposition-based NN training as a nonconvex optimization problem. This problem can be solved by the proposed tensor block coordinate descent (tenBCD) method, which is a gradient-free algorithm. The global convergence of tenBCD to a critical point at a rate of O(1/k) is established with the Kurdyka Łojasiewicz (KŁ) property, where k is the number of iterations. The theoretical results can be extended to the popular residual neural networks (ResNets). The effectiveness and efficiency of our proposed framework are verified through an image classification dataset, where our proposed method can converge efficiently in training and prevent overfitting.

2 Diffusion Implicit Model-Enabled Ultrasound Images Analysis to Advance Tumor Treatment

Emmanuel Yangue, Oklahoma State University, Stillwater, OK

Enabling effective drug delivery is an important field in cancer treatment studies that has witnessed tremendous growth and technological advancements over the years. However, the current biomedical imaging technologies used in this field, such as MRI and CT scans, although accurate, are expensive and sometimes may expose patients to radiation and potential side effects. This work presents an approach using a diffusion implicit model to analyze real-time ultrasound images, which are more affordable and accessible than other imaging technologies. The current results suggest a potential for using this approach for data augmentation and segmentation for ultrasound image applications.

3 Multi-Laser Scanning Planning and Scheduling Optimization for Large Scale Metal Additive Manufacturing

Yuxin Yang[1], Lijing Yang[2], Yu Jin[3], [1]Binghamton University, Binghamton, NY, [2]University of Southern California, Los Angeles, CA, [3]Binghamton University, Binghamton, NY

Metal additive manufacturing (AM) is gaining significant attention for large-scale end-product fabrication, but the limited efficiency hinders its implementation. Concurrent AM with multiple independently driven lasers is a promising technique for rapid fabrication of large metal products. To maximize fabrication efficiency while ensuring quality for multi-laser AM processes, an optimization problem is proposed for multi-laser scanning planning and scheduling. The goal is to minimize the makespan while considering the factors that may affect the quality of metal parts as constraints, such as special geometric features and inter-hatch travel time. A deep reinforcement learning model is structured to solve this NP-hard problem. Numerical studies are conducted to demonstrate the effectiveness of the proposed methods.

4 Bayesian Inference for Survival Prediction of Childhood Leukemia

Yuning Cui, University of Okalhoma, Norman, OK, Contact: Yuning.Cui-1@ou.edu

Childhood Leukemia is the most common type of cancer among children. The painful morality and mobility rates catalyze researchers to perform predictive modeling for childhood Leukemia. Existing survival predictions rely on a single best model. However, the prediction from a single model is brittle with model uncertainty neglected, leading to serious ethical and economic consequences. Therefore, in this paper we predict patient-specific survivals for childhood Leukemia through Bayesian inference to account for model uncertainty. Experimental results indicate that the proposed model is robust and accurate in patient-specific survival predictions. Moreover, the accurate predictions can also help clinicians track the contribution of multiple clinical attributes, thereby enabling well-informed intervention and timely medical care for childhood Leukemia.

Natural Resource Optimization in Heavy Industry

Community Committee Choice Session

Session Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO

1 Predicting Roll Force at a Continuous Casting Steel Mill

Edikan Udofia, Colorado School of MInes, Golden, CO

We develop regression model to improve prediction of roll forces in a large, hot-roll steel mill at industrial scale. Based on real-world plant data, we derive information from a constitutive physical model and include variable transformations, variable selection and model comparisons. We show how our model can help inform mill best practice in their scheduling operations.

2 A Heuristic for Design and Dispatch of Distributed Energy Systems

James Grymes[1], Alexander Zolan[2], Alexandra M. Newman[3], Dinesh Mehta[4], [1]United States Military Academy, West Point, West Point, NY, [2]National Renewable Energy Laboratory, Austin, TX, [3]Colorado School of Mines, Golden, CO, [4]Colorado School of Mines, Golden, CO

The adoption of distributed energy resources that incorporate renewable energy and storage technologies is growing, partly due to significant reductions in the cost of photovoltaic systems. However, modeling these systems often require complicated mathematical expressions. We present a *Matheuristic* for solving these non-convex mixed-integer linear programs. Our methodology yields objective function value improvements over the traditional optimization solvers across multiple test cases for practical time limits.

3 Optimizing Haul Trucks Maintenance Scheduling in Open Pit Mines

Bart Maciszewski[1], Jose Santiago Rodriguez Osorio[2], Anuraj Grewal[1], Christine Viljoen[1], Amber Mckay[1], Ervin Balleza[1], Andrew Milne[1], [1]Imperial Oil, Calgary, AB, Canada; [2]ExxonMobil, Houston, TX, Contact: bart.m.maciszewski@exxonmobil.com

We present a problem of scheduling maintenance for heavy haul trucks in an oil sands mine. The trucks require periodic preventive maintenance based on operating hours and in addition to break-in work. There is a need to schedule close to due dates while grouping activities to minimize the number of truck visits to the shop. Activities need to be performed on compatible bays and need to respect the amount of available resources. We formulate the problem as a special case of the Dual Constrained Flexible Job Shop Problem (DCFJSP) with a preprocessing step to group orders. We solve and compare performance using constraint programming and MIP. We show how the model has uncovered important business insights and improves over current approaches.

4 Bilevel Optimization for Unconventional Field-Wide Constrained Oil Production

Benjamin Spivey, Keith Zorn, Neil Adair, Amr El-Bakry, Brock Argyle, ExxonMobil Technology and Engineering Company, Spring, TX

Oil and gas production can be optimized by adjusting well choke valves and artificial lift to increase field-wide oil and gas flowrates within production constraints. For unconventional production, a field-wide model may be needed to represent how operations decisions affect field-wide production constraints. A field-wide model-based optimization problem can become computationally challenging to solve and maintain due to the large number of wells, steep decline curves, and continuously changing infrastructure. This paper describes a bilevel optimization architecture that separates field-wide pipeline network optimization from well-level optimization to make maintaining model accuracy more feasible and to reduce computational time.

Representation of Hydrogen in Capacity Expansion Modeling

Community Committee Choice Session

Session Chair: Brian Sergi, 1</sup

1 Techno-Economic Analysis of Hydrogen Storage in Wind and Solar Electricity Systems

Jacqueline A. Dowling, California Institute of Technology, Pasadena, CA

We analyzed the tradeoff between capital cost reductions and efficiency improvements of hydrogen conversion and storage in different electricity systems with varying levels of dispatchable fossil power and otherwise-curtailed wind and solar generation. In the systems featuring abundant zero-cost electricity (resulting from wind and solar generation exceeding mean demand), hydrogen storage systems were not highly sensitive to an efficient utilization of otherwise-curtailed power, but they were sensitive to capital cost reductions. Our results suggest that innovation priorities for hydrogen storage technologies should differ depending on the characteristics of the electricity system in which the technology is utilized, with some cases placing greater value on technology cost reductions and in other cases efficiency improvements.

2 On the Representation of Hydrogen Supply and Demand for Policy Analysis

John Bistline, 1</sup

Hydrogen consumption and production raise computational challenges for energy system optimization models, given their cross-sector dynamics and power system interactions for electrolytic hydrogen pathways. This talk will highlight recent model advances in representing end-use demand for hydrogen and supply-side technological options, highlighting how model representations of supporting policies can alter hydrogen's projected role. Motivating examples will focus on two recent U.S. policies—incentives in the Inflation Reduction Act (IRA) and proposed power plant performance standards.

3 Hydrogen in the Reeds Model

Brian Sergi, National Renewable Energy Laboratory, Golden, CO, Contact: bsergi@nrel.gov

This presentation will provide an overview of the current hydrogen representation in the Regional Energy Deployment System (ReEDS) model, a capacity expansion model used for long-term planning of the U.S. power sector. The presentation will include a discussion of the formulation of key modeling features, such as storage costs and constraints, electrolyzer operations, coupling with intersectoral demand, and policy incentives. Discussion on results will center on the impact of different formulations on hydrogen deployment in the context of pathways to a zero-carbon system, and on current challenges for modeling hydrogen.

4 The Impact of Spatial Resolution on the Optimal Planning of Net-Zero Hydrogen Supply Chains

Alissa Ganter, Paolo Gabrielli, Giovanni Sansavini, ETH Zurich, Zurich, Switzerland. Contact: aganter@ethz.ch

Low-carbon hydrogen plays a key role in the decarbonization strategies of hard-to-abate industries. However, the widespread use of hydrogen is currently hampered by the lack of hydrogen supply chains, and by the uncertainty of optimal production pathways in different geographical conditions and at different spatial scales. We investigate the optimal planning of hydrogen supply chains to decarbonize hard-to-abate industries in Europe. We focus on the impact of spatial resolution on the preferred hydrogen production technologies and hydrogen supply chain structure. Our findings highlight the importance of spatial resolution to reliably design net-zero hydrogen supply chains that rely on large shares of spatially distributed renewable resources.

GO Competition Performers

Community Committee Choice Session

Session Chair: Richard Paul O'Neill, ARPA-E, Silver Spring, MD

1 Scaling Security Constrained Optimal Power Flow to Multi-Timestep

Constance Crozier[1], Javad Mohammadi[2], Kyri Baker[3], [1]Georgia Tech, Atlanta, GA, [2]The University of Texas at Austin, Austin, TX, [3]University of Colorado Boulder, Boulder, CO

This talk will cover the approach of the Electric Stampede team in Challenge 3 of the ARPA-E Grid Optimization (GO) competition. The focus will be on the challenges of adapting the team's previous code to accommodate the multiple time step format of Challenge 3 - which includes 18-48 times more variables than the previous formulation.

2 GravityX: The Last Challenge

Hassan Hijazi, LANL, NM

In this talk, we will go over the Challenge 3 modeling and solution methods used by the GravityX team. This will include time decomposition and convexification approaches. We will discuss lessons learned and future research directions.

3 Experiences In Solving Multi-period UC-ACOPF In GO Competition

Andy Sun[1], Matthew Brun[2], Dirk Lauinger[3], Thomas Lee[4], Xin Chen[5], [1]MIT, Cambridge, MA, [2]Operations Research Center, MIT, Cambridge, MA, [3]MIT, Cambridge, MA, [4]Massachusetts Institute of Technology, Cambridge, MA, [5]Texas A&M University, College Station, TX, Contact: sunx@mit.edu

In this talk, we will present our experiences of participating in the ARPA-E's GO competition, especially the Third Challenge on solving large-scale problems of multi-period unit commitment, AC optimal power flow, and branch switching. We will discuss the challenges posed by such problems in the operation and short-term planning of electric power systems. Some efforts in developing effective algorithms and computational packages will be discussed.

4 Heuristics for the GO Competition

Daniel Bienstock, Columbia Univ, NY

We describe the approach used in last year's and this year's GO competition. Joint work with Richard Waltz.

Advanced Learning and Optimization for Carbon-Neutral Electricity

Community Committee Choice Session

Session Chair: Xin Chen, 1</sup

Session Chair: Luo Xu, 1</sup

1 Toward Net Zero Emissions by Optimizing Building Setpoints: A Graph Neural Network-Based Deep Reinforcement Learning Approach

You Lin, Green Daisy, Leslie Norford, Jeremy Gregory, Audun Botterud, Massachusetts Institute of Technology, Cambridge, MA

Building energy consumption from HVAC systems causes around 28% of global energy related carbon emissions. In this study, a setpoint optimization model is proposed to reduce carbon emissions using a graph neural network-based deep reinforcement learning (DRL) algorithm considering thermal exchanges among various zones within buildings. By intelligently scheduling the day-ahead temperature setpoints and adjusting the real-time setpoints, DRL-based controllers can optimize setpoints while reducing carbon emissions and considering thermal comfort of occupants. Testing on MIT campus buildings demonstrates the effectiveness of the proposed model in reducing energy consumption and carbon emissions.

2 Quantitative Opportunity Costs Of Demand Response In Real-time Markets: A Multi-parametric Programming Approach

Kiyeob Lee[1], Dustin Kenefake[1], Le Xie[1], Efstratios Pistikopoulos[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M Energy Institute, College Station, TX

This paper presents security constrained economic dispatch and demand response through the lens of multi-parametric programming (MPP). The goal is to leverage MPP to provide valuable system and market information in terms of demand, which is necessary to address scarcity pricing and price forecasting mechanisms. In electricity markets, self-interested market participants are coordinated by system operators through price signals, namely locational marginal price (LMP). The proposed approach enhances this coordination by providing tangible incentives, such as an enumeration of all possible LMP values. To solve the proposed MPP problem, various algorithms are introduced to understand the computational complexity and scalability. All algorithms are evaluated for numerous test systems, and detailed case study is performed on a synthetic Texas 2000-bus grid.

3 Carbon-Aware Optimal Power Flow

Xin Chen[1], Andy Sun[2], Na Li[3], Wenbo Shi[4], [1]Texas A&M University, College Station, TX, [2]MIT, Cambridge, MA, [3]Harvard University, Cambridge, MA, [4]Singularity Energy, Somerville, MA, Contact: xinch512@mit.edu

Decarbonization of the electricity sector is essential to achieve carbon neutrality. To enable effective decarbonization decision-making, this paper proposes the carbon-aware optimal power flow (C-OPF) method as the theoretical foundation. Built upon the classic optimal power flow (OPF) technique, this proposed C-OPF method incorporates carbon flow equations, constraints, and carbon-related objective components to co-optimize power flow and carbon flow. In particular, this paper proposes reformulation approaches to handle the issues of undetermined power flow directions and bilinear terms. Numerical simulations demonstrate the characteristics and effectiveness of the C-OPF method.

4 Learning to Optimize Macro-Energy Systems

Filippo Pecci, Amarasinghage T. Perera, Jesse D. Jenkins, ZERO Lab, Princeton University, Princeton, NJ

Due to the need for high temporal and spatial resolution, optimization-based planning models for macro-energy systems are often slow. This prevents planners from exploring the full range of parameter uncertainties and policy scenarios. Although supervised learning has been used to speed-up optimal power flow, optimal sizing of energy technologies, and optimal planning of urban energy systems, it has not been applied to macro-energy system planning models, taking into account generation and transmission capacity expansion, and system operation. We propose a supervised learning architecture to approximate solutions of macro-energy system planning models, where investment and operation decisions are jointly optimized to minimize total cost, subject to physical, economical, and policy constraints.

Optimization and AI in Environment and Sustainability

Community Committee Choice Session

Session Chair: Wenquan Dong, University of Tennessee-Knoxville, Knoxville, TN

1 Nationwide Network Design for Circular Biomass-to-Bioenergy and Biofuel with Carbon Capture and Conversion

Rui Zhou, University of Tennessee, Knoxville, knoxville, TN

Biomass-bioenergy and biofuel have great potential in alternative renewable energy production and carbon reduction. Biomass can be converted into various bioenergy and biofuels via fermentation, pyrolysis, gasification, or combustion with carbon capture and storage. In this paper, we evaluate the techno-economic feasibility and the environmental impacts of those conversion technologies for the primary terrestrial and aquatic biomass feedstocks with biochar recycling and develop a programming model to incorporate spatial and techno-economic data for the renewable bioenergy and biofuels supply chain network optimization. The model economically optimizes the geographic distribution and scale of biomass resources, conversion refineries, and the primary fuel consumers in the United States for a 20 years life span.

2 Exploring Nutritional Equity in Food Bank Supply Chains

Nowshin Sharmile[1], Lauren Berrings Davis[2], [1]North Carolina A&T State University, Greensboro, NC, [2]North Carolina A&T State University, Greensboro, NC, Contact: nsharmile@aggies.ncat.edu

This project aims to optimize the foodbank supply chain while considering the nutritional quality, storage requirements, and equity of the food available for distribution. The Healthy Eating Research Guideline is incorporated into our research to encourage a better understanding of nutritious foods in the foodbank distribution network.

3 A Heuristic Solution to the Single Depot Electric Vehicle Scheduling Problem

Taner Cokyasar[1], Omer Verbas[1], Amir Davatgari[2], Abolfazl Kouros Mohammadian[2], [1]Argonne National Laboratory, Lemont, IL, [2]University of Illinois Chicago, Chicago, IL, Contact: omer@anl.gov

Transit is the backbone of the transportation sector that not only mitigates traffic congestion and environmental impact but also provides equity through an affordable mobility service. Transit electrification has an utmost importance to achieve global net-zero economy goals. In this study, we revisit a decades-old single depot vehicle scheduling problem (SDVSP) to address the operational constraints bus electrification brings in. To this end, we follow a two-stage modeling approach: In the first stage, we solve an SDVSP model to form vehicle blocks, and we solve a block chaining problem in the second stage. An analysis conducted using this solution framework found that electric vehicle range plays a key role in determining the fleet size.

Managing Resources in Marketplaces

Community Committee Choice Session

Session Chair: Deniz Akturk, University of Chicago Booth School of Business, Chicago, IL

Session Chair: Ozan Candogan, University of Chicago, Chicago, IL

1 Managing Resources for Shared Micromobility: Approximate Optimality in Large-Scale Systems

Deniz Akturk[1], Ozan Candogan[2], Varun Gupta[3], [1]Washington University in St. Louis Olin School of Business, St. Louis, MO, [2]University of Chicago, Chicago, IL, [3]University of Chicago Booth School of Business, Chicago, IL

We consider the problem of managing resources in shared micromobility systems (bike-sharing and scooter-sharing). An important task in managing such systems is periodic repositioning/recharging/sourcing of units to avoid stockouts or excess inventory at nodes with unbalanced flows. We consider a discrete-time model: each period begins with an initial inventory at each node in the network, and then customers (demand) materialize at the nodes. Each customer picks up a unit at origin node and drops it off at a randomly sampled destination node given origin-specific probability distribution. We introduce a mean-field approximation and prove that the mean-field optimal policy is asymptotically optimal. We then provide an algorithm to compute a near-optimal policy for the mean-field system. Using micromobility data, we show the strong performance of our algorithm.

2 Driver Pre-Allocation Problem via Transfer Payment

Bomin Bian[1], Zhenyu Hu[1], Long He[2], JUN JIANG[1], [1]National University of Singapore, Singapore, Singapore; [2]George Washington University, Washington

We consider a driver pre-allocation problem faced by an on-demand platform that earns commission from trips. To maximize the expected profit, the platform provides monetary incentives to pre-allocate drivers to potential demand locations. Given incentives, the drivers' choice behaviors are captured by the multinomial logit (MNL) choice model that endogenizes other drivers' choices via the probability of matching with a demand. We show that the drivers' equilibrium choice probability exists, and the platform's problem and the optimal incentive are independent of the platform's commission rate. Moreover, computationally, the profit maximization problem can be reformulated as an exponential cone program (ECP). Finally, we conduct numerical studies using real data from a taxi operator in Singapore to demonstrate the solution and discuss managerial implications.

3 An Analysis of Hierarchical Randomized Experiments with Network Inference

Yiming Jiang, He Wang, Georgia Tech, Atlanta, GA, Contact: yjiang463@gatech.edu

We consider designing randomized experiments under network interference. The goal is to estimate the global average treatment effect, which compares outcomes under the counterfactuals that all or no units are treated, without knowing the magnitude of the spillover effect between the treatment and the control groups. We analyze a hierarchical experiment design that simultaneously runs both a completely randomized experiment and a cluster-based randomized experiment. We show that this design allows for an unbiased estimate of the global average treatment effect, and bound the variance of the estimator by a clustering problem. Using a simple clustering algorithm, the hierarchical estimator achieves better efficiency than the state-of-the-art cluster-based experiment designs.

4 On the Supply of Autonomous Vehicles in Open Platforms

Daniel Freund[1], Ilan Lobel[2], Jiayu (Kamessi) Zhao[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]New York University, New York, NY, Contact: kamessi@mit.edu

Autonomous vehicle (AV) technology may fundamentally change the transportation landscape. Due to the high cost of AV hardware, the most likely path to widespread AV use is via open platforms that sustain high-utilization, outsource the high capital burden, and complement the network with human drivers who join as individual contractors (ICs). In my talk, I present a supply chain game between a platform, an outside AV supplier, and the ICs. Such a setting is subject to the risk of AV underutilization as the platform needs to maintain a sufficiently high IC utilization to keep them engaged. In a decentralized supply chain, this can have a disastrous effect on supply chain efficiency, which can be alleviated through contracting solutions.

AI for a Better World

Community Committee Choice Session

Session Chair: Leonard Boussioux, MIT, Operations Research Center, Cambridge, MA

Session Chair: Cynthia Zeng, Massachusetts Institute of Technology, Cambridge, MA

1 How to Solve the United Nations' Sustainable Goals in 5 Minutes

Leonard Boussioux, MIT, Operations Research Center,

Cambridge, MA

We present a transformative approach to solving the United Nations Sustainable Development Goals using Generative AI, focusing specifically on its potential to create innovative solutions for sustainable, circular economies. We compared the efficacy of human-driven innovation with AI-generated solutions by initiating a crowdsourcing challenge attracting solvers from diverse backgrounds worldwide and employing GPT-4 with calibrated prompts. From 1,885 evaluator-solution pairs, our results indicated comparable quality between human and AI-generated solutions. Interestingly, while human ideas were perceived as more novel, AI solutions demonstrated superior environmental and financial value. Overall, we set the stage for a multimodal, integrative approach, where human-AI collaboration can lead to actionable solutions across the 17 goals.

2 Catastrophe Insurance: An Adaptive Robust Optimization Approach

Cynthia Zeng, Massachusetts Institute of Technology, Cambridge, MA

Climate change leads to more frequent and costly natural disasters worldwide. In light of this, insurance can play a pivotal role in supporting recovery and incentivizing investments in hazard mitigation. In this talk, I will present our work on an Adaptive Robust Optimization (ARO) framework for catastrophe insurance premium pricing, applied to flood insurance using data from the US National Flood Insurance Program (NFIP). To the best of our knowledge, this is the first work to use an ARO approach to set disaster insurance premiums. These premiums are designed to protect against both historical flooding risks and forward-looking forecasted risks obtained through machine learning models, thus incorporating the elevated risks posed by climate change. Our research demonstrates that a data-driven optimization approach can lead to a more efficient and fair insurance scheme. This talk is intended to extend an open invitation on how we can incorporate new technologies to improve our financial instruments and aid in climate adaptation.

3 Road Speed Prediction in Developing Regions: Leveraging Data Scarce GPS Trajectory Data, Weather and Satellite Information

Valentijn Stienen[1], Dick Den Hertog[2], Joris Wagenaar[1], Joann de Zegher[3], [1]Zero Hunger Lab, Tilburg University, Tilburg, Netherlands; [2]University of Amsterdam, Amsterdam, Netherlands; [3]MIT Sloan, Cambridge, MA

In developing, data scarce, environments, inaccurate digital road networks pose significant challenges for the use of analytics. Travel time/speed information is crucial but often unknown, especially in developing regions where the speed may also depend on weather conditions. Existing methods for speed prediction are inadequate due to the inaccuracy or unavailability of data. This paper introduces a novel deep learning approach that utilizes GPS trajectory data and satellite imagery to predict average travel speeds for roads under specific circumstances (time of day and recent weather). A case study conducted in collaboration with the organization PemPem demonstrates the effectiveness of the proposed method in predicting road speeds.

Optimization of Logistics Operations for Autonomous Drones and Collaborative Robots

Community Committee Choice Session

Session Chair: Sharan Srinivas, University of Missouri, Columbia, MO

1 Human-Robot Teaming for Intralogistics Operations in Dynamic Environments

Shitao Yu[1], Surya Ramachandiran[2], Sharan Srinivas[1], [1]University of Missouri, Columbia, MO, [2]Penn State University

To serve increased customer orders and expectations, warehouses seek to optimize their order picking and improve responsiveness. In this study, we propose a Collaborative Human-Robot Order Picking System, where the pickers are only responsible for the pick and place operations, while the robots undertake the transportation tasks. Further, we propose Interventionist and Select-Interventionist algorithms to serve the dynamic incoming customer orders. Unlike most existing dynamic approaches, these strategies allow updating the pick list during the picking cycle of a robot. Our results show that the collaborative system consistently outperforms the traditional picking strategy. Further, the interventionist approach resulted in the lowest tardiness and completion time, while the select-interventionist approach ensured that the workers traveled the least.

2 Maximizing Service Level in Drone Transportation Networks: A Robust Scenario-Based Model for Battery-Swapping Station and Hub Location

Nima Golghamat Raad, University of Missouri, Columbia,

MO, Contact: nima.golghamatraad@mail.missouri.edu
Drones will revolutionize point-to-point transportation, including commercial, medical, emergency, and food supplies. However, their limited flight range and the unique challenges of aerial transportation necessitate novel approaches to the network design of charging/battery-swapping stations. To address these challenges, this research introduces a stochastic scenario-based model for locating battery-swapping stations and drone hubs. It considers uncertain factors like service demand, payload weight, and wind conditions and maximizes the service level. The model is efficiently solved using the sample average approximation (SAA) technique and a hybrid metaheuristic algorithm that combines the shortest path method with Augmented Large Neighborhood Search. Numerical experiments confirm the competitiveness and effectiveness of the proposed approach.

3 Route-Sequence Decisions for Truck-Drone Delivery System Considering En Route Operations

Teena Thomas[1], Sharan Srinivas[2], Chandrasekharan Rajendran[3], [1]Indian Institute of Technology Madras, Chennai, India; [2]University of Missouri, Columbia, MO, [3]IIT Madras, India, Chennai, India. Contact: annateenathomas@gmail.com
This study considers a single-truck multi-drone delivery system with en route drone launch and recovery operations. An optimization model is proposed to minimize the total delivery time, addressing truck routing and truck-drone scheduling decisions. A model variant is proposed to minimize the vehicle operating costs. The model can optimally solve problem sizes of up to 20 customers in less than 500s. A two-phase relax-and-fix with recouple-refine-and-optimize heuristic is designed to solve large size problems. A multi-truck model variant is also developed with a deep learning enabled clustering and routing solution technique. Computational experiments are conducted for problem sizes of up to 100 customers. The results ensure great savings in delivery completion time and vehicle operating costs for the respective variants, with the inclusion of en route operations.

Towards More Environmental Friendly Operations

Contributed Session

Session Chair: Fuzhen LIU, The Hong Kong Polytechnic University, Hong Kong, China

1 Risk Tradeoffs in Supplier Selection: A Discrete Choice Experiment

Behnam Fahimnia[1], Andrew Collins[1], Brent Motitz[2], [1]The University of Sydney, Darlington, Australia; [2]Pennsylvania State University, State College, PA
This paper investigates how supply managers evaluate environmental and social sustainability relative to cost and supply diversification. We engaged 217 practicing supply managers in a discrete choice experiment to calculate their willingness to pay for and trade-off between location diversification, environmental sustainability, and social sustainability. Managers were willing to incur slightly higher costs for suppliers with better environmental and social performance, but more importantly they were willing to substitute environmental performance for social performance. Managers were willing to pay more for increased geographic diversification of the suppliers, even if adding diversification resulted in poorer environmental performance.

2 Design of Logistics Infrastructure in Support of Naval Operations with use of Ammonia-Based Fuel

Jing Wang[1], Nathan Huynh[1], Josh Allen[2], Qing Hui[2], Roger A. Dougal[3], William E. Mustain[4], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]University of South Carolina, Columbia, SC, [4]University of South Carolina, Columbia, SC
One of the U.S. Navy’s energy goals is to demonstrate and then deploy a “Great Green Fleet,” which will include ships and aircraft using alternative sources of energy. One such energy source is ammonia. A challenge with switching to using ammonia for fuel is reduced range. This study aims to assess the viability of utilizing ammonia as fuel to support naval operations. To this end, a mixed integer non-linear programming model is developed to determine ship routes taking into account factors such as ship speeds, refueling time, and the non-linear relationship between fuel consumption and the ship’s speed. The objective of the model is to minimize cost. To solve this model, a particle swarm optimization-based algorithm is developed. Preliminary results from several hypothetical fuel logistics scenarios are presented.

3 Stay or Move? the Impact of Environmental Regulation on Supply Chain Reconfiguration

Ruolei Liu[1], Yuxiao Ye[1], Di Fan[2], Baofeng Huo[1], [1]Tianjin University, Tianjin, China; [2]Hong Kong Polytechnic University, Hong Kong, China. Contact: lrlei@tju.edu.cn

Whether and how environmental regulation influence supply chain networks is theoretically ambiguous and warrants an empirical analysis. We empirically study the impact of the stringency of environmental regulation on firms' supply chain dynamic adjustment using firm-level panel data. Our results show a negative relationship between environmental regulation and supply chain involvement. Also, the main negative effect is moderated by several factors. These results are robust across many tests. These findings shed new light on how firms use supply chain to arbitrage across institutional environments.

4 Complementary or Substitutive Effects? A Resource-based Perspective on Green Manufacturing and Operational Efficiency

Fuzhen Liu[1], Ni Huang[2], Kee-hung Lai[1], [1]The Hong Kong Polytechnic University, Hong Kong, China; [2]University of Miami, Coral Gables, FL, Contact: fuzhen02.liu@connect.polyu.hk

The trade-off between environmental friendly policies and efficiency gains challenges the widespread adoption of green manufacturing. The existing literature has yet to reach a consensus on the operational efficiency of green manufacturing adoption. Drawing upon a resource-based view, this study examines the influence of green manufacturing on operational efficiency and the moderating role of organizational and technological characteristics on the said relationship. Based on a two-stage difference-in-differences analysis on 18,297 firm-year observations, this research adds new insights into the operations management (OM) literature by uncovering the complementary role of organizational characteristics and the substitutive role of technological characteristics on the link between green manufacturing and operational efficiency.

2023 MCDM Junior Researcher Best Paper Award

Award Session

Session Chair: Roman Słowiński, Poland

1 The use of the Success-Based Decision Rule to Support the Holistic Evaluation Process in Fitradeoff

Lucia Reis Peixoto Roselli[1], Adiel Teixeira De Almeida[2], [1]Center for Decision Systems and Information Development, Federal University of Pernambuco, Recife, Brazil; [2]Universidade Federal de Pernambuco, Recife PE, Brazil

The paper proposes the Success-Based Decision Rule (SBDR) to support the holist evaluation within the decision process with the FITradeoff method. The aim of this rule has been to assist the analyst in the advising process with Decision-Makers (DMs) concerning the holistic evaluation performed with graphical and tabular visualizations. Therefore, using this rule, the analyst can advise DMs to use or not use visualizations to express dominance relations between alternatives during the holistic evaluation. This rule transforms the FITradeoff Decision Support System. The Success-Based Decision Rule (SBDR) has been constructed using the probability of success and its standard deviation following the Bernoulli distribution.

2 A Novel Picture Fuzzy Critic & Regime Methodology: Wearable Health Technology Application

Elif Haktanır Aktaş[1], Cengiz Kahraman[2], [1]Bahcesehir University, Istanbul, Turkey; [2]Istanbul Technical University, Istanbul, Turkey. Contact: elif.haktaniraktas@eng.bau.edu.tr

Picture fuzzy sets (PFSs) are one of the most promising extensions of ordinary fuzzy sets with three parameters, namely positive membership, neutral membership, and negative membership, for defining the membership status of an element to a set. CRiteria Importance Through Intercriteria Correlation (CRITIC) & REGIME methods are recently developed multi criteria decision making (MCDM) methods for calculating the criteria weights and ranking alternatives, respectively. CRITIC method determines the criteria weights by using the values in the decision matrix. REGIME method is a compensatory MCDM method employing superiority and guide indices, superiority identifier and impacts, and REGIME matrices. In this paper, an integrated CRITIC & REGIME methodology is developed for the first time by using single-valued PFSs in order to use the advantage of PFSs in handling ambiguity and impreciseness. The main contribution of our study is to demonstrate theoretically and practically how to transform superiority and guide indices, superiority identifier and impacts, and REGIME matrices to the PF environment. A new interval valued Relative Magnitude Index scale and an original Percentile Rank under Vagueness function have been developed. The developed methodology is applied to the selection problem of wearable health technology (WHT). Comparative and sensitivity analyses are presented. These analyses show that CRITIC & REGIME methodology produces very effective and valid results, and unlike the other methods, it shows slight ranking differences due to the statistical-based calculations it contains.

Session Chair: Chunjie Zhao, Clark University, Worcester, MA

1 Is It the Way to Go for a Cleaner Environment? Lessons from Renewable Portfolio Standard
Chunjie Zhao[1], Anqi Wu[2], Ramanath Subramanyam[3], [1]Clark University, Worcester, MA, [2]Florida International University, Miami, FL, [3]Universality of Illinois Urbana-Champaign, Champaign, IL, Contact: ChuZhao@clarku.edu
Role of government policy in pursuing sustainable development has received increasing attention. Different types of policy design along with the firm's emission policy, play a crucial role in mitigating greenhouse gas (GHG) emissions. This paper utilizes a combination of data from the Carbon Disclosure Project (CDP) and the Renewable Portfolio Standard (RPS) policy to examine the causal effects of state-level policies and firm-level GHG emissions. By employing a staged difference-in-differences methodology, we have found a negative connection between policies and emissions. Furthermore, we have observed that states with lower and more progressive targets have the potential to achieve even lower emissions. These findings have significant implications for environmental regulations and public policies targeting emissions in firms operating in the United States.

2 Factors Affecting the Relationship Between Inspections and Quality Outcomes in the Pharmaceutical Industry
Zach Wright[1], John Gray[1], In Joon Noh[2], [1]Fisher College of Business, The Ohio State University, Columbus, OH, [2]Penn State University, University Park, PA, Contact: wright.2482@osu.edu
Regulatory inspections play an important role in maintaining acceptable quality standards for manufacturers in many industries. Contextual heterogeneity leaves it unclear as to when regulatory inspections will be most effective in driving quality improvement. This study aims to explore the effect of inspections on quality outcomes as well as moderating factors that influence this relationship.

3 Impact of Foodtech Platforms on Food Insecurity
Sandeep Srinivas[1,2], [12]University of Illinois at Urbana Champaign, Champaign, IL
Food insecurity is a serious problem globally, including in developed nations such as the US. One sustainable solution to the problem is - food recovery - which connects excess food to people in need. Although food recovery is traditionally done by food banks, a few for-profit "foodtech" platforms have recently emerged in this space. In this paper, we study the impact of one such platform, which works with supermarkets to provide an alternate sales channel for food that is near expiry. We find a statistically significant reduction in food insecurity in the local area after the platform introduction. The results are robust to alternate identification

strategies and subsample analyses. Our results establish a new mechanism in the push to reduce food insecurity - through for-profit businesses by leveraging technology, emphasizing the importance of sustainable business models.

4 Health Insurance and Labor Productivity in Us Manufacturing: Evidence from Medicaid Expansion

Yasaman Asayesh, Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN, Contact: yasaman@umn.edu

Medicaid expansion program aims to improve healthcare access for Americans by reducing eligibility constraints and widening government-sponsored insurance coverage. However, the economic implications of this large-scale public health intervention are controversial. This study investigates the impact of Medicaid expansion on labor productivity in the manufacturing industry. Furthermore, the study explores variations in the aforementioned impact based on a range of socioeconomic and health factors.

Redistricting

Community Committee Choice Session

Session Chair: Soraya Ezazipour, Oklahoma State University, Stillwater, OK

1 Fairness and Graph Algorithms for Political Redistricting

Rahul Swamy[1], Douglas M. King[2], Sheldon Jacobson[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]U of Illinois at Urbana-Champaign, Urbana, IL, [3]UIUC, Urbana, IL, Contact: shj@illinois.edu

Political districting in the United States is a decennial process of redrawing the boundaries of congressional and state legislative districts. Fairness in political districting has been an important topic of subjective debate, with district plans affecting a wide range of stakeholders, including voters, candidates, and political parties. This talk covers Mixed Integer Programming formulations for fairness-based redistricting.

2 A New Metric For Evaluating Political Redistricting Plans

Brendan Ruskey, Lawrence V. Snyder, Lehigh Unversity Department of Industrial Engineering, Bethlehem, PA, Contact: bjr221@lehigh.edu

Every 10 years in the United States, lawmakers partition the citizens of each state into groups of roughly equal population in what is called a "redistricting plan". These districts are expected to be geographically compact, and should not unfairly disadvantage members of any demographic group or political party. In this project, we first propose a metaheuristic to create new redistricting plans from a previously proposed plan, improving its performance in one or more objectives. We then propose a metric for comparing the proposed plan against those generated by our metaheuristic. In the context of legal challenges to redistricting plans, our proposed metric could be used to show that a plan may be unfit for use in future elections by demonstrating that making small changes to the plan's district boundaries leads to significant improvement in one or more objectives.

3 Political Districting to Optimize the Polsby-Popper Compactness Score

Pietro Belotti[1], Austin Buchanan[2], Soraya Ezazipour[2], [1]Polytechnic University of Milan, Milan, Italy; [2]Oklahoma State University, Stillwater, OK, Contact: sezazip@okstate.edu

In the academic literature and in expert testimony, the Polsby-Popper score is the most popular way to measure the compactness of a political district. Given a district with area A and perimeter P, its Polsby-Popper score is given by $(4 \pi A)/P^2$. This score takes values between zero and one, with circular districts achieving a perfect score of one. In this paper, we propose the first mathematical optimization models to draw districts with optimum Polsby-Popper score. Specifically, we propose new mixed-integer second-order cone programs (MISOCPs), which can be solved with existing optimization software. We investigate their tractability by applying them to real-life districting instances in the USA. Our techniques could be used by plaintiffs when seeking to overturn maps that dilute the voting strength of minority groups.

4 Multi-Balanced Redistricting and Within-Cycle Malapportionment in Computational Redistricting

Daryl Robert Deford, Washington State University, Pullman, WA, Contact: daryl.deford@wsu.edu

Tools from discrete optimization have become increasingly important for analyzing graph-based formulations of political redistricting. Given a partition of a state into a set of geographic units, such as census blocks or voting precincts, a districting plan becomes a labelled partition of the associated dual graph formed by connecting vertices representing adjacent units with the property that each induced subgraph is connected. Performing optimization in this context requires operationalizing legislative text and exploring complex Pareto frontiers. In this talk I will discuss recent work that considers multiple relevant population columns in an attempt to address natural within-cycle vote dilution. This includes theoretical bounds on worst-case behavior of partitioning methods and empirical optimization on data from the 2020 census.

Service Science and Information Systems

Community Committee Choice Session

Session Chair: Yeongin Kim, Virginia Commonwealth University, Glen Allen

Session Chair: Seonjun Kang, VCU, Richmond, VA

1 Cross-Platform Comparison of Feature Differences and Their Effects on Content Production with Cryptocurrency Rewards

Tong Wu[1], Yeongin Kim[2], Tae Hun Kim[3], Stacie Petter[4], [1]Western Kentucky University, Bowling Green, KY, [2]Virginia Commonwealth University, Glen Allen, VA, [3]Ajou University, Suwon, Korea, Republic of; [4]Wake Forest University, Winston-Salem, NC

This paper aims to generate a systematic understanding of how various features on cryptocurrency reward-based social media platforms enhance user engagement in content production. This paper adopts technology affordance theory as the theoretical lens to analyze the effects of two main feature differences – cryptocurrency reward features and social interaction features – on user engagement across five cryptocurrency reward-based social media platforms. By utilizing difference-in-differences and propensity score matching methods, the findings suggest that platforms offering multiple cryptocurrencies and flag features are more likely to increase user engagement in posting production. However, offering cryptocurrency rewards for comments and providing a downvote feature to users can result in a decrease in posting production on these platforms.

2 Effects of Decentralization on Blockchain-Based Digital Platform Market Capitalization

Rongen Zhang, Baylor University, Waco, TX

Decentralization is a core principle for blockchain, but its overall effect remains controversial and inconclusive. Although Chen et al. (2021) proposed an inverted-u shape effect of decentralization, we still have insufficient theoretical understanding of different aspects and its mechanism. We introduce two unique decentralization dimensions—physical and development—and propose the mediating role of governance engagement, measured by proposal quantity and topic diversity. Analyzing historical data from 7 PoW blockchain platforms (2015-2020), we uncover distinct effects of decentralization aspects on platform market capitalization and partial mediation by governance engagement. This study contributes to the emerging blockchain literature and highlights the crucial mediating role of decentralized governance for blockchain platform designers.

3 User Engagement in Hyperlocal Content and Its Economic Contribution to Local Businesses

Myungsun Lee, Tae Hun Kim, Ajou University, Suwon, Korea, Republic of. Contact: micle619@ajou.ac.kr

People use mobile/social media platforms to share location-based information with others in real time. Such hyperlocal content impacts the economy by updating nearby users on local businesses. This research first addresses what motivates users of a social media platform, Nextdoor, to engage in sharing hyperlocal content on local businesses and related local events in New York City. The locational amount of content crowdsourced by nearby users and its user interaction density, the location-based numbers of comments on and reactions to each content are measured to address hyperlocal user engagement. Second, we propose the local economic consequences of such hyperlocal user engagement for restaurant and lodging businesses specifically. We discuss how hyperlocal user engagement contributes to the financial and marketing success of local businesses around urban areas.

Developing and Managing Social Media Platforms and Networks

Community Committee Choice Session

Session Chair: Alice Jang, Virginia Tech, Blacksburg, VA

1 Knowledge Digitization and Causal Knowledge Analytics

Yuanyuan Song, University of Georgia

Scientific progress requires building upon exponentially expanding foundations, and this problem of synthesizing ideas across manifold publications needs a more efficient

methodology. While Google Scholar accelerates the discovery of possibly pertinent research, these approaches do not encode knowledge, and scholars have to extract the core knowledge from the results of their search. The failure to digitally encode knowledge inhibits the growth of many fields. As casual and process models are the foundation of scientific reasoning, the Theory Research Exchange (T-Rex) project is developing causal knowledge analytics methods that enable researchers to code causal and process models as graphs and synthesize the literature exhaustively and speedily. We invite scholars to discuss the next generation of methodologies for the analytics and synthesis of knowledge.

2 The Impact of Hyperbole on Product Sales in Short Video Platforms

Yutong Han[1], Bowen Yin[1], Fei Ren[1], Bin Gu[2], [1]Peking University, Beijing, China; [2]Boston University, Boston, MA, Contact: hanyutong19@pku.edu.cn

While short video has become popular in social media platforms, how to design video content to promote product sales still remains unclear. This study proposes a novel content strategy of utilizing hyperbole in short videos and investigates its potential for driving product sales. Hyperbole, which involves exaggerating multimodal features, can stimulate interest and capture the audience's attention, but may also negatively affect credibility if perceived as misleading. The study employs machine learning algorithms to measure multimodal hyperbole, and then assesses its impact on actual sales data. The findings indicate that hyperbole has a positive impact on sales conversion, particularly for products with lesser-known brands and influencers with lower indegree. This study contributes to the literature on advertising content and online purchase behavior.

3 The Effects of Quote Retweet on Subsequent Posting Behavior and Morality Expression on Social Media

Yan Wu[1], Qianzhou Du[1], Xiaohui Zhang[2], John Zhang[2], [1]Nanjing University, Nanjing, China; [2]Arizona State University, Tempe, AZ

Users are increasingly engaged in online discussions on social media platforms, while previous studies rarely explore their impacts on users' behaviors. To address this gap, guided by the Threshold model and Self-justification theory, we proposed a research model on the impact of online discussion on users' behaviors on social media. Utilizing data from Twitter, we empirically examined the positive effects of quote retweeting a tweet related to the topic of immigration policies and border issues on users' subsequent topic-related posting behaviors and morality expression. This impact is found to be strengthened among users with higher threshold levels or larger behavior-opinion inconsistency. Our findings have both theoretical and practical implications for social media platforms.

4 Leveraging Large Language Models (LLMs) for Effective Online Deliberation via Persuasion

Hazel Hyeseung Kang, Boston University, Boston, MA, Contact: hazelk@bu.edu

The rise of user-generated content on social media challenges productive and inclusive online deliberations, leading to echo chambers, polarization, and a lack of exposure to alternative viewpoints. We identify optimal argumentation schemes for online persuasion using Walton's compilation of existing persuasion literature from Cicero and Aristotle. Using ChangeMyView's dataset, we conduct a field experiment to establish causality, seeking to reduce polarization and facilitate opinion change. Our research has managerial implications for designing moderation strategies on social media platforms. Methodologically, our study contributes insights into optimal prompting techniques of large language models, including state-of-the-art LLMs such as GPT-3.5.

Emerging Themes in Product/Innovation Management

Community Committee Choice Session

Session Chair: Sina Khorasani, 1</sup
Session Chair: RAMAZAN Kizilyildirim, UCL, LONDON, United Kingdom
Session Chair: Ersin Korpeoglu, University College London, London, United Kingdom

1 Towards an Understanding of Nanostores' Operations, as Organized Retailers Expand

Syd Hashem Alavi[1], Glen M. Schmidt[2], [1]University of Utah, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, Contact: syd.alavi@utah.edu

Nano-stores are small, privately owned, and operated grocery outlets common in emerging economies. The expansion of modern organized chain retail stores is challenging these traditional outlets. Using a survey and statistical analysis of sales databases, we study nanostores' operation in this market dynamic.

2 When Does Culture Outperform Formal Incentives in Innovation? A Culture Evolution Theory Approach

Konstantinos Ladas[1], Christoph H. Loch[2], Stylianos Kavadias[1], [1]University of Cambridge, Cambrige, United Kingdom; [2]Cambridge University, Cambridge, United Kingdom. Contact: s.kavadias@jbs.cam.ac.uk

Peter Drucker once famously remarked, "culture eats strategy for breakfast." We develop a Culture Evolution Theory (CET) model to compare top-down incentives for innovation with a bottom-up culture (where innovation ideas are imitated but the idea generators are given recognition by other employees) in a company that operates under competition. In this model, culture is a more robust environment for innovation. Moreover, we discuss how the CET modelling approach can address other problems in innovation and operations management.

3 The Value of Private Feedback in Trial-and-Error Innovation Contests

Zhi Chen[1], Zhenyu Hu[2], Yufei Zhu[3], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]National University of Singapore, Singapore, Singapore. Contact: e0253756@u.nus.edu

Providing interim feedback is common practice In innovation contests. In this paper, we study the effect of private feedback on innovation in multi-agent and multi-stage trial-and-error innovation contests. Prior literature has shown that in ideation projects, giving private feedback may not always be conducive to innovation, as compared to the case of no feedback. In contrast, we find that in trial-and-error projects, giving private feedback always improves both quantities and qualities of innovation.

4 Dynamic Development Contests

Sina Khorasani[1], Ersin Korpeoglu[2], Vish Krishnan[3], [1]University of Dayton, Dayton, OH, [2]University College London, London, United Kingdom; [3]University of California-San Diego, La Jolla, CA, Contact: skhorasani1@udayton.edu

We derive optimal dynamic development contests with enriched rank-based incentives and carefully-tailored information design that can help organizations leverage their suppliers for their development projects while seeking to minimize project lead time by stimulating competition among them.

Innovative Endeavors: Assessment, Creation, Funding, and Breakup

Community Committee Choice Session

Session Chair: Moren Levesque, York University, Toronto, ON, Canada

1 Opportunity Judgment and Entrepreneurship Policy

Jacqueline Csonka-Peeren[1], Norris Krueger[2], [1]IBM, Toronto, ON, Canada; [2]Entrepreneurship Northwest, Boise, ID, Contact: jcsonka@uwaterloo.ca

An entrepreneur must assess an opportunity despite having a lack of information. Because of this lack of information, exact probabilities for success or loss cannot be known; this lack of information creates a condition of ambiguity. Although operational research methods to help with decision making under condition of risk are ubiquitous, entrepreneurs make decisions under condition of ambiguity. Theoretical development of research methods for attitude to ambiguity has led to two novel scores, "ambiguity-sum" and "ambiguity-ratio". We present a framework comprised of these scores to help inform policy supporting entrepreneurship and model the impact of this policy on entrepreneurship. We further describe how this research method can be extended to opportunity judgment between two opportunities.

2 Designing Reward Structure for Crowdfunding Campaigns

PARAM PAL SINGH Chhabra[1], Manpreet Singh Hora[2], Karthik Ramachandran[2], [1]University of Alberta, Edmonton, AB, Canada; [2]Georgia Institute of Technology, Atlanta, GA, Contact: param.chhabra@ualberta.ca

Rewards are crucial for the success of a campaign in reward-based crowdfunding. However, creators adopt hit and trial approach to design the reward structure. In this study, we empirically investigate the association between reward structure design and the campaign's performance to make recommendations for creators.

3 I Think We Should See Other People: Exploring Biotech-Pharma Partnership Breakups Following Successful Drug Launches

Pierre Gautreau[1], Moren Levesque[2], Annapoornima Subramanian[3], Vareska van de Vrande[4], [1]York University, Toronto, ON, Canada; [2]York University, Toronto, ON, Canada; [3]National University of Singapore, Costa Mesa,

CA, [4]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands. Contact: gautreau@schulich.yorku.ca
Using a comprehensive database of new drug development projects, we investigate whether successful drug launches within an established pharmaceutical firm's portfolio influence the likelihood of the big pharma sustaining its partnerships with biotech start-ups. We also consider whether this influence is moderated by drug types or drug development phases.

4 New Venture Creation: The Role of Proprietary Resources

Moren Levesque[1], Saul Estrin[2], Andrea Herrmann[3], Tomasz Mickiewicz[4], Mark Sanders[5], [1]York University, Toronto, ON, Canada; [2]London School of Economics, London, United Kingdom; [3]Radboud University, Nijmegen, Netherlands; [4]Aston University, Birmingham, United Kingdom; [5]Maastricht University, Maastricht, Netherlands
New ventures trade off between being innovative and scaling up revenues or reaching the point that enables market valuation (speed-to-market) quickly. We present a formal model that illustrates why such tradeoffs arise. Then, we analyze 331 ICT ventures that completed the venture creation stage, using an empirical method that accounts for unobserved heterogeneity across ventures. This approach allows us to identify a strong tradeoff between innovativeness and speed-to-market, but the tradeoff is weaker between revenue levels and speed. We also find that proprietary resources (founder equity and founder labor) are the main drivers of new ventures' multidimensional success. Our results suggest that access to these resources can present a key bottleneck in the innovation process and explain the unexplained variation in venture creation efficiency across new ventures.

Data Analytics in Manufacturing Industry

Community Committee Choice Session

Session Chair: Dohyun Kim, 1</sup

1 Process Parameters Optimization Using Neural Inversion

Ki Jeong Choi[1], Dohyun (Norman) Kim[2], [1]Myongji University, Yongin-si, Korea, Republic of; [2]Myongji University, Yong-In, Korea, Republic of
Effective control of process parameters such as pressure and temperature significantly impacts manufacturing yield. However, process parameters are typically adjusted based on the judgments of experienced experts, which can introduce uncertainty and potentially lead to significant issues. Therefore, we propose a novel approach that utilizes neural inversion to optimize manufacturing process parameters. Neural inversion tracks how specific patterns in process parameters affect characteristics, thereby enhancing manufacturing precision, efficiency, and advancing product quality and stability.

2 Prioritized Group Sparse Autoencoder

Jae Heon Jeong[1], Jisu Woo[1], Dohyun (Norman) Kim[2], [1]univ. myung-ji, Yong-in, Korea, Republic of; [2]Myongji University, Yong-In, Korea, Republic of. Contact: lhe339@mju.ac.kr
Autoencoder is an artificial neural network architecture designed to learn a compressed representation of data. However, a drawback of conventional autoencoders is that they require the utilization of all input variables. In this research, we aim to perform data compression by exclusively using the variables that are crucial for representing the data. Moreover, when dealing with pre-grouped input variables, our approach involves prioritizing the essential group and selecting the necessary variables within that group, resulting in an optimized compressed representation of the data.

3 Domain Invariant and Contrastive Representation for Sleep Dynamics

Seungyeon Lee, The Ohio State University, Columbus, OH
Sleep staging is a key challenge in diagnosing and treating sleep-related diseases. Many deep learning methods have been proposed for automatic sleep staging, but they face several challenges including the heterogeneity of patients' underlying health conditions and the difficulty modeling complex interactions between sleep stages. In this paper, we propose a neural network architecture named DREAM to tackle these issues. DREAM consists of (i) a feature representation network that generates robust representations for sleep signals and (ii) a sleep stage classification network that explicitly models the interactions between sleep stages in the sequential context at both feature representation and label classification levels.

4 Enhancing Prediction Model in Semiconductor Manufacturing Dataset: A Transformer with Statistical Feature-based Embedding

GyeongTaek Lee, Rutgers University/Department of Industrial System Engineering, Piscataway, NJ

In the realm of semiconductor manufacturing, the rapid advancement of process technology has led to swift changes in the process recipe. Consequently, amassing an extensive volume of sensor data has become a challenge. Despite the impressive performance exhibited by recent deep learning models in tasks like fault detection and virtual metrology, it is difficult to apply the models in the field due to model capacity. To address this, this research introduces a Transformer-based predictive model designed to function effectively even with a limited quantity of sensor data. The novel approach involves transforming sensor data into embeddings based on statistical features. Empirical evaluation on an actual semiconductor manufacturing dataset demonstrates that the proposed model enhances predictive performance compared to previous models. The proposed method can be utilized in real-world scenarios where only a small amount of data is available.

5 Reliability Prediction and Control of Semiconductor Chips Using Mass Production Burn-In Data

Kilsoo Kim, Soheon Choi, Eunji Lee, Nohseok Park, Ilsang Park, Samsung Electronics, Hwaseong, Korea, Republic of. Contact: ks1.kim@samsung.com

It is very important to predict the probability of field failure and control before semiconductor chips are shipped to customers. To this end, sampling-based product reliability tests are being additionally conducted after burn-in test. However, this way has several problems such as large statistical error due to a lack of sample quantity compared to what is required to check a very low defective rate and high evaluation costs due to scrap of samples tested. This paper presents the field failure prediction model using mass production burn-in data. Next, this work describes how to set the product control limits for abnormal lot considering a field failure risk. Finally, the real case study is included to illustrate our proposed procedures.

Community Committee Choice Session

Session Chair: Sophie Zhai, 1</sup

1 On the Influence of Online Conversations - a Human Dignity Perspective

Sophie Zhai, Heshan Sun, University of Oklahoma, Norman, OK

Digital platforms are becoming an increasingly integral part of everyday life. In this study, we introduce the concepts of embedded conversational intentions and digital dignity. We examine how online communications from information senders can impact the digital dignity of information receivers. Using user-generated videos and comments, we construct a model to demonstrate the relationship between embedded conversational intentions and human digital dignity. As well, we contribute to the literature on using information and communication technologies to build a bright society.

2 Discovering Supply Chain Issues from Sec 10-K Reports Through Topic Modeling

Kara Li Liu, Zhu(Drew) Zhang, University of Rhode Island, Kingston, RI

IT firms are more driven by the supply-side economy regarding customized products or services and compatible operations. Managers seek to identify major issues and accelerate the interaction with their suppliers due to the dynamics of supply chains in recent years. However, it is challenging for IT firms to identify those issues from the great number of unstructured texts. In this study, we utilize topic modeling, a text-mining approach, to analyze SEC filings of IT firms and discover topics associated with supply chain issues. Our study contributes to the application of topic modeling approach in supply chains. The findings provide insights into supply chains from the IT industry and improve managers' decision-making.

3 Now You See It, Now You Don't: Leveraging Transient Content Alongside Permanent Content to Foster Social Media Engagement

Lucy Shen[1], Byungyeon Kim[2], Elie Ofek[1], [1]Harvard Business School, Boston, MA, [2]University of Minnesota, Minneapolis, MN, Contact: lushen@hbs.edu

This study explores whether influencers can enhance follower engagement by differentiating permanent content (Posts) and transient content (Stories), which is viewable for only 24 hours, in the context of Instagram. We find that influencers publish Stories that are lower visual quality than and topically different from Posts. Followers respond positively to this distinction. Higher similarity in Posts correlates with more likes on Posts, while lower similarity between Posts and Stories also leads to higher engagement. This suggests that influencers can boost engagement by strategically dividing their content, publishing consistent, professional content to permanent channels and sharing authentic, personal content to transient channels.

4 Corporation Between Brands and Influencers in Livestream

Jingyun Hu, Clemson University, Clemson, SC, Contact: jhu3@clemson.edu

The matching problem is a pervasive issue examined within empirical industrial organization field. Hitsch(2010) use the Gale-Shapley algorithm to predict stable matches in dating market. Similar to dating market, the livestream market operates on the principle of matching firms with suitable influencers for product promotion. Douyin the social media platform, the chinese version of Tiktok has established a dedicated space for influencers and brands to connect and collaborates on promotion activities through "JuLiangXingTu". What I doing is get 411 influencers who have over 10 million influencers and their livestream performance, product performance, and their price fee for promotion. My model is to use historical livestream performance and current price, to solve the matching problem if firm want to find a big influencer in Douyin.

Applications in Market Design

Community Committee Choice Session

Session Chair: Ashu Thakur, 1</sup

1 Optimal Liver Exchange with Equipoise

Alex Chan, Harvard University, Cambridge, MA

The practical and ethical needs of liver exchange is different from kidney exchange, a new mechanism is proposed. Instead of just maximizing the number of exchanges, clinicians prioritize liver transplant candidates with the highest medical urgency as measured by MELD score first. Donation of the right liver lobe is five-fold riskier than the left lobe for the donor. An exchange that involves donors giving different lobes is deemed unfair. Existing mechanisms are not suited to identify optimal matchings for the organ exchange problem that needs to flexibly meet a finite exchange cycle-length constraint, accommodate indifferences in preferences, maximize transplants for highest priority patients and keep risk balanced for donors. The proposed mechanism yields optimal allocations, respects balanced donor risk, maximizes priority and is incentive compatible.

2 An Empirical Framework for Waitlists with Endogenous Priority: Evaluating the Heart Transplant Waitlist

Kurt Sweat, Stanford, CA

Waitlists that prioritize specific agents to achieve certain policy goals are common in practice, but policy makers often use endogenous characteristics of agents to assign waitlist priority. I study the heart transplant waitlist in the United States where the treatment that a patient receives is used to assign waitlist priority. Policy makers recently changed the prioritization in an attempt to reduce waitlist mortality by assigning higher priority to patients receiving specific treatments associated with high waitlist mortality. I document a significant response to waitlist incentives and demonstrate that this has had an effect on observed survival. I develop an empirical framework to evaluate the life-years gained by a patient from entering a waitlist with a given design. The model is used to evaluate the recent change to the heart transplant waitlist.

3 Evolution of Institutional Designs: Theory and Empirics

Ashutosh Thakur, National University of Singapore, Singapore, Singapore. Contact: adthakur@nus.edu.sg

In many organizations, members need to be assigned to certain positions, whether these are legislators to committees, executives to roles, or workers to teams. In such settings, the design of the assignment procedure becomes an institutional choice that is influenced and agreed upon by the very members being assigned. Will these agents seek to reform the assignment procedures by voting in favor of some alternative allocation over their current allocation? I explore this question of institutional stability by bringing together matching theory and social choice. I introduce institutional stability under majority rule and juxtapose it with other voting rules an organization might use to resolve internal conflict. The theoretical insights are used empirically to explain the historical evolution of assignment procedures of elite civil servants to states in India.

4 Matching with Costly Interviews: The Benefits of Asynchronous Offers

Akhil Vohra, University of Georgia, GA

We analyze the welfare implications of costly interviewing in a model of worker-firm matching. Centralized matching leads to coordination issues in the interview stage. Each firm must incorporate the externality imposed by the interview decisions of the firms ranked above it when deciding on its interview list. As a result, low-ranked firms often fail to interview some candidates that ex-ante have high match quality. A decentralized setting with exploding offers generates, at a minimum, the same welfare as a centralized system. Total welfare is maximized with a system that ensures firms interview and match in sequence, clearing the market for the next firm. Such asynchronicity reduces interview congestion. This can be implemented by encouraging top firms to interview and match early and allowing candidates to renege on offers.

Machine Learning for Heterogeneous Data Fusion

Community Committee Choice Session

Session Chair: Hyunsoo Yoon, Yonsei University, Seoul, Korea, Republic of

1 A Patch-Wise Fault Diagnosis Framework with Self-Supervised Learning in Limited Data Scenarios

Beomgyo Shin, Hyunsoo Yoon, Yonsei University, Seoul, Korea, Republic of. Contact: beomgyo.shin@yonsei.ac.kr

Fault diagnosis plays an important role in industrial settings. Recently, deep learning-based methods have shown promising results in this area. However, acquiring a significant number of labeled data for real-world industrial scenarios poses a challenge. This study proposes a self-supervised learning approach for diagnosing faults in unlabeled signal data. The proposed method extracts feature vectors from signals through self-supervised learning techniques and employs clustering algorithms for fault type classification, eliminating the need for extensive fine-tuning. Experimental results demonstrate exceptional performance in predictive clustering on entirely unlabeled data and robustness against variations in fault type ratios and noise levels.

2 An Explainable Deep Neural Network for Extracapsular Extension Identification in 3d Head and Neck Cancer Computed Tomography Images

Haifeng Wang, Mississippi State University, Mississippi State, MS

Extracapsular extension (ECE) is a strong predictor of patients' survival outcomes with head and neck cancer. In this study, a gradient-weighted class activation mapping (Grad-CAM) technique is proposed to guide the deep learning algorithm to focus on the regions that are highly related to ECE. The proposed framework includes an extractor and a classifier. In the joint training process, informative volumes of interest (VOIs) are extracted by the extractor without labeled lymph node region information, and the classifier learns the pattern to classify the extracted VOIs into ECE positive and negative. The results were compared with different existing models and further confirmed by a clinic study. The presence or absence of ECE has been analyzed and correlated with ground truth histopathological findings.

3 Pseudo Supervised Metrics: Evaluating Unsupervised Image to Image Translation Models in Unsupervised Cross-Domain Classification Frameworks

Firas Al-Hindawi, Arizona State University, Tempe, AZ, Contact: falhinda@asu.edu

Unsupervised cross-domain classification frameworks were developed to handle the data domain shift problem by utilizing unsupervised image translation models. For lack of annotations, it is not possible to use traditional supervised metrics to evaluate these translation models to pick the best-saved checkpoint model. In this work, we introduce Pseudo Supervised Metrics, designed specifically to support unsupervised cross-domain classification applications contrary to other typically used metrics such as the FID which was designed to evaluate the model in terms of the quality of the generated image from a human-eye perspective. Our method outperforms the FID, is robust, explainable and highly correlated with the true supervised metrics.

4 Semi-supervised Domain Adaptation Via Statistics Invariant Adversarial Training

Yu Jun Yang, Hyunsoo Yoon, Yonsei University, Seoul, Korea, Republic of. Contact: diddbwns1025@yonsei.ac.kr

Rotating machinery is pivotal in industry. However, the substantial domain gaps hinder cross-machine adaptation. In light of this challenge, we propose a cross-machine semi-supervised domain adaptation framework for real-world scenarios. Conventional statistical features from sensors notably contribute to inter-machine domain gaps. To address this, we design a domain-invariant framework diverging from the statistical features. This effectively mitigates inter-machine domain gaps originating from distinct machines, enhancing performance with few target labels.

Emerging Topics in FinTech Empirical Research

Community Committee Choice Session

Session Chair: Tian Lu, Arizona State University

1 Inclusive Decision Making Via Contrastive Learning And Domain Adaptation

Xiyang Hu, Carnegie Mellon University, Pittsburgh, PA

Achieving inclusiveness in decision-making is of utmost importance for advancing social justice and mitigating inequality. This is especially critical in high-stakes decisions, where decisions can have profound and long-lasting effects on individuals. In this study, we propose to leverage contrastive learning and domain adaptation to improve inclusion in algorithmic decision-making. We empirically examine our method in a high-stakes micro-lending context. We propose a new Transformer-based sequential loan screening model with self-supervised contrastive learning and domain adaptation to achieve this objective. Our experiment results show that our model significantly promotes the inclusiveness of funding decisions, while also improving loan screening accuracy and lender profit.

2 Understanding the Drivers of Digital Assets Investment: An Investigation of Sustainable Cryptocurrencies

Wenya Shen, Arizona State University, Tempe, AZ

Cryptocurrency is a decentralized digital asset that has recently gained growing attention from researchers and practitioners. Increasingly, the high energy consumption from mining PoW-based coins has raised concerns and debates on creating harmful environmental impacts. The rise of environmental concerns has led to the introduction of more environmental-friendly crypto coins using the proof-of-stake (PoS) consensus mechanism. This study aims to investigate the drivers of sustainable cryptocurrency investment and adoption.

3 Unmasking Inequality In The Virtual Realm: A Study Of Skin-tone Bias In The Cryptopunks Market

(Selena) Sungeun Han, Arizona State University, Tempe, AZ, Contact: sungeunh1024@gmail.com

The metaverse offers lifelike personal and business experiences through the integration of VR/AR, and other advanced technologies. Despite of positive benefits of it, there are emerging concerns related to data privacy and the ethical implications of avatar representation. This research project explores the potential bias in the digital collectible market and its impact on DEI in the metaverse. Digital collectibles are often used for expressing self-identity (e.g., avatars), and transferring value across platforms in the metaverse. This research will specifically examine racial and gender discrimination in this market and how they could potentially lead to intentional or unintentional colorism and sexism in the metaverse. The goal is to better understand the implications of DEI and develop strategies to promote inclusive governance in this emerging digital space.

4 Concrete Achievements and Coherent Plans: Linguistic Properties in Initial Coin Offerings (Icos)

Ziyi Xiong, Yan Chen, Rong Liu, Chihoon Lee, Stevens Institute of Technology, Hoboken, NJ, Contact: rliu20@stevens.edu

Initial Coin Offerings (ICOs) have emerged as an innovative crowdfunding method for technology start-ups. Effective communication between start-ups and investors is critical to the fundraising success. We draw on construal level theory to examine business roadmaps, an important but often overlooked type of disclosures for ICOs. We suggest that achievements and plans in the roadmap differ in hypothetical distances, tend to trigger mental construals at different levels, and thus should be communicated through different linguistic features. Our empirical results show that fundraising performance is positively associated with the concreteness of achieved activities and the coherence of planned activities. Furthermore, the concreteness of achieved activities has a greater impact on older projects, and the value of coherent plans increases with market sentiment.

Novel Analytics and Machine Learning Approaches with Manufacturing Applications

Contributed Session

Session Chair: Golnoush Javan, University of Toledo, Toledo, OH

1 Global Sensitivity Analysis of Input Uncertainties in the Thermal Fluid Model of Metal Additive Manufacturing

Amanda Giam, National University of Singapore, Singapore, Singapore. Contact: amandagiam@u.nus.edu

Computational multi-physics models play an integral role in Laser Powder-Bed Fusion (L-PBF) metal additive manufacturing as they streamline the qualification cycle of the L-PBF products. However, the models involve a large number of input factors with uncertainties, and incur high computational cost. Thus we focus on a preliminary screening experiment via global sensitivity analysis to reduce input dimensionality, and guide the construction of a surrogate model. We demonstrate the effectiveness of the Elementary Effects method with space-filling trajectories in characterizing input uncertainties in the thermal-fluid model, providing valuable physics-based insights, and identifying the most influential inputs. This facilitates factor fixing and targeted follow-up experimentation with Latin Hypercube Sampling, achieving efficient resource allocation.

2 Machine Learning Applications in Predicting Solder Joint Characteristic Life: A Comparative Analysis

Seyed Soroosh Alavi[1], Daniel F. Silva[2], [1]Auburn University, Auburn, AL, [2]Auburn University, Auburn, AL, Contact: sza0147@auburn.edu

This research explores the use of machine learning (ML) in predicting the characteristic life of solder joints, typically estimated through time-consuming, costly empirical methods. ML models offer the potential to consolidate diverse test conditions into a single, universal model by using data from isothermal aging and thermal cycling tests on solder joints obtained from past research at Auburn University. A comparative analysis between ML and empirical modeling reveals comparable accuracy, with the ML model demonstrating cost and time efficiencies. Results suggest that the application of ML in this area is promising, providing a streamlined, cost-effective approach for solder joint life prediction.

3 Data-Driven Predictive Maintenance in Counter Pressure Casting Process

Jaebong Cho[1], Jihoon Nam[2], Minjoo Park[1], [1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]Pohang University of Science and Technology, Pohang, Korea, Republic of. Contact: jaycho00@postech.ac.kr

Counter pressure casting (CPC) is a process technology used to manufacture aluminum automotive parts, where the mold is filled by having a slight pressure differential. Predictive maintenance of CPC equipment is crucial to avoid quality degradations such as air entrapment and porosity inside the parts. The operating conditions characterized by high temperature and pressure, coupled with the inaccessibility of internal components hinder the adaptation of pre-emptive management. This study proposes an autoencoder-based operational anomaly detection method for the data-driven CPC equipment maintenance to address this challenge. The result looks promising, expecting that the manufacturers may achieve the reduction of maintenance costs and improved quality of the parts by adapting the predictive maintenance methods.

4 Text Mining in Manufacturing: A Systematic Literature Review

Golnoush (Julie) Javan[1], Nima Molavi[2], [1]University of Toledo, Toledo, OH, [2]California State University, San Bernardino, San Bernardino, CA, Contact: sjoreim@rockets.utoledo.edu

With the emergence of cyber-physical manufacturing systems, the manufacturing industry has generated one of the largest shares of data in recent years and is projected to grow significantly in the upcoming years, according to IDC. Structured data makes up a small portion of the total, while the majority consists of semi-structured and unstructured data like text documents. Text mining (TM) can be used to extract information from manufacturing unstructured data; however, comprehensive reviews of TM applications in manufacturing are limited. This study systematically reviews articles published on TM applications in manufacturing, analyzing prime application fields, identifying key challenges, and proposing future research directions. The findings inform the research community about the novel TM applications in manufacturing and research opportunities.

Big Data Methods and Applications to Finance

Community Committee Choice Session

Session Chair: Agostino Capponi, Columbia University, New York, NY

1 A Matrix Balancing Perspective on Choice Modeling

Zhaonan Qu, Stanford University, Stanford, CA

This paper studies some optimization aspects of choice modeling, a popular subject in econometrics and social choice. For a broad class of choice and ranking models based on Luce's choice axiom, we show that the associated maximum likelihood estimation problems are equivalent to a classic matrix balancing problem with target row and column sums. This perspective allows us to unify existing algorithms in the choice modeling literature as special instances or analogs of the celebrated Sinkhorn's algorithm. We then resolve an open problem by characterizing the linear rate of convergence of Sinkhorn's algorithm for non-negative matrices in terms of the algebraic connectivity. Lastly, we provide a discussion on the interesting trade-off between computational and statistical efficiencies of maximum likelihood estimation in the context of choice models.

2 Bridge the Gap Between Financial Engineering and Finance Communities: Opportunities and Challenges Led by Big Data

Mao Ye, Cornell University, Ithaca, NY

The big data revolution creates many opportunities for collaboration between the OR/Financial Engineering and finance communities. As a researcher in the finance community, I would like to discuss several potential topics that may benefit from collaboration with the OR/Financial Engineering community, such as high-frequency trading, algorithmic trading, quantitative investing and regulations of trading algorithms.

3 Optimal Transport and Risk Aversion in Kyle's Model of Informed Trading

Ibrahim Ekren, Florida State University, Tallahassee, FL

We establish connections between optimal transport theory and the dynamic version of the Kyle model, including new characterizations of informed trading profits via conjugate duality and Monge-Kantorovich duality. We use these connections to extend the model to multiple assets, general distributions, and risk-averse market makers. With risk-averse market makers, liquidity is lower, assets exhibit short-term reversals, and risk premia depend on market maker inventories, which are mean reverting. We illustrate the model by showing that implied volatilities predict stock returns when there is informed trading in stocks and options and market makers are risk averse. Based on joint work with Kerry Back, Francois Cocquemas and Abraham Lioui.

Economics and Computation I

Award Session

Session Chair: Yeganeh Alimohammadi, Stanford University, Stanford, CA

1 Welfare-Maximizing Pooled Testing

Francisco Marmolejo-Cossío[1], Simon Finster[2], Edwin Lock[3], Michelle González Amador[4], Evi Micha[5], Ariel Procaccia[1], [1]Harvard University, Boston, MA, [2]CREST-ENSAE & CNRS/ Université Grenoble Alpes, Grenoble, France; [3]University of Oxford, Oxford, United Kingdom; [4]UNU-MERIT & Maastricht University, Maastricht, Netherlands; [5]University of Toronto, Toronto, ON, Canada. Contact: fjmarmol@ seas.harvard.edu

In an epidemic, how should an organization with limited testing resources safely return to in-person activities after a period of lockdown? We study this question in a setting where the population at hand is heterogeneous in both utility for in-person activities and probability of infection. In such a period of re-integration, tests can be used as a certificate of non-infection, whereby those in negative tests are permitted to return to in-person activities for a designated amount of time. Under the assumption that samples can be pooled, the question of how to allocate a limited testing budget in the population to maximize the aggregate utility (i.e. welfare) of negatively-tested individuals who return to in-person activities is non-trivial, with a large space of potential testing allocations.

We show that non-overlapping testing allocations, which are both conceptually and (crucially) logistically more simple to implement, are approximately optimal, and we design an efficient greedy algorithm for finding non-overlapping testing allocations with approximately optimal welfare. In computational experiments, we highlight the efficacy and viability of our greedy algorithm in practice. To the best of our knowledge, we are also first to implement and provide causal evidence on the benefits of utility-weighted pooled testing in a real-world setting. Surprisingly, our pilot study at a higher education research institute in Mexico finds no evidence that performance and mental health outcomes of participants in our testing regime are worse than under the first-best counterfactual of full reopening without testing.

2 Finding the Right Curve: Optimal Design of Constant Function Market Makers

Mohak Goyal, Geoffrey Ramseyer, Ashish Goel, David Mazieres, Stanford University, Stanford, CA, Contact: mohakg@stanford.edu

Constant Function Market Makers (CFMMs) are a tool for creating exchange markets, have been deployed effectively in prediction markets, and are now especially prominent in the Decentralized Finance ecosystem. We show that for any set of beliefs about future asset prices, an optimal CFMM trading function exists that maximizes the fraction of trades that a CFMM can settle.We formulate a convex program to compute this optimal trading function. This program, therefore, gives a tractable framework for market-makers to compile their belief function on the future prices of the underlying assets into the trading function of a maximally capital-efficient CFMM.

Our convex optimization framework further extends to capture the tradeoffs between fee revenue, arbitrage loss, and opportunity costs of liquidity providers. Analyzing the program shows how the consideration of profit and loss leads to a qualitatively different optimal trading function.

Our model additionally explains the diversity of CFMM designs that appear in practice. We show that careful analysis of our convex program enables inference of a market-maker's beliefs about future asset prices, and show that these beliefs mirror the folklore intuition for several widely used CFMMs. Developing the program requires a new notion of the liquidity of a CFMM, and the core technical challenge is in the analysis of the KKT conditions of an optimization over an infinite-dimensional Banach space.

3 Fundamental Bounds on Online Strategic Classification

Saba Ahmadi[1], Avrim Blum[1], Kunhe Yang[2], [1]Toyota Technological Institute at Chicago, Chicago, IL, [2]UC Berkeley, Berkeley, CA

Strategic classification has received increasing interest over the years, where the understanding of how agents manipulate their observable features to gain advantageous classifications directly affects the effectiveness and fairness of the marketplace. We focus on the problem of online binary classification, where strategic agents can manipulate their observable features in predefined ways, modeled by a manipulation graph, in order to receive a positive classification. We show this setting differs in fundamental ways from classic (non-strategic) online classification. For instance, whereas in the non-strategic case, a mistake bound of ln|H| is achievable via the halving algorithm when the target function belongs to a known class H, we show that no deterministic algorithm can achieve a mistake bound o(Δ) in the strategic setting, where Δ is the maximum degree of the manipulation graph (even when |H|=O(Δ)). We complement this with a general algorithm achieving mistake bound O(Δ ln|H|). We also extend this to the agnostic setting, and show that this algorithm achieves a Δ multiplicative regret (mistake bound of O(Δ(OPT+ln|H|)), and that no deterministic algorithm can achieve o(Δ) multiplicative regret.
Next, we study two randomized models based on whether the random choices are made before or after agents respond and show they exhibit fundamental differences. In the first fractional model, at each round, the learner deterministically chooses a probability distribution over classifiers inducing expected values on each vertex (probabilities of being classified as positive), which the strategic agents respond to. We show that any learner in this model has to suffer linear regret. On the other hand, in the second randomized algorithms model, while the adversary who selects the next agent must respond to the learner's probability distribution over classifiers, the agent then responds to the actual hypothesis classifier drawn from this distribution. Surprisingly, we show this model is more advantageous to the learner, and we design randomized algorithms that achieve sublinear regret bounds against both oblivious and adaptive adversaries.

4 Robust Auction Design with Support Information

Jerry Anunrojwong, Santiago R. Balseiro, Omar Besbes, Columbia Business School, New York, NY

The seller wants to sell an item to n i.i.d. buyers and only the support [a,b] is known; a/b quantifies relative support information (RSI). The seller either minimizes worst-case regret or maximizes worst-case approximation ratio. We show that i) with low RSI, second-price auctions (SPA) is optimal; ii) with high RSI, SPA is not optimal, and we introduce a new mechanism, the "pooling auction" (POOL), which is optimal; iii) with moderate RSI, a combination of SPA and POOL is optimal. Under POOL, whenever the highest value is above a threshold, the mechanism still allocates to the highest bidder (just like SPA), but otherwise the mechanism allocates to a uniformly random buyer, i.e., pools low types.

5 Incentive Compatibility in the Auto-Bidding World

Yeganeh Alimohammadi[1], Andres Perlroth[2], Aranyak Mehta[3], [1]Stanford University, Stanford, CA, [23]Google, Mountain View, CA

Auto-bidding has recently become a popular feature in ad auctions. This feature enables advertisers to simply provide high-level constraints and goals to an automated agent, which optimizes their auction bids on their behalf. These auto-bidding intermediaries interact in a decentralized manner in the underlying auctions, leading to new interesting practical and theoretical questions on auction design, for example, in understanding the bidding equilibrium properties between auto-bidder intermediaries for different auctions.
In this paper, we examine the effect of different auctions on the incentives of advertisers to report their constraints to the auto-bidder intermediaries. More precisely, we study whether canonical auctions such as first price auction (FPA) and second price auction (SPA) are auto-bidding incentive compatible (AIC): whether an advertiser can gain by misreporting their constraints to the autobidder.
We consider value-maximizing advertisers in two important settings: when they have a budget constraint and when they have a target cost-per-acquisition constraint. The main result of our work is that for both settings, FPA and SPA are not AIC. This contrasts with FPA being AIC when auto-bidders are constrained to bid using a (sub-optimal) uniform bidding policy. We further extend our main result and show that any (possibly randomized) auction that is truthful (in the classic profit-maximizing sense), scalar invariant and symmetric is not AIC. Finally, to complement our findings, we provide sufficient market conditions for FPA and SPA to become AIC for two advertisers. These conditions require advertisers' valuations to be well-aligned. This suggests that when the competition is intense for all queries, advertisers have less

incentive to misreport their constraints.
From a methodological standpoint, we develop a novel continuous model of queries. This model provides tractability to study equilibrium with auto-bidders, which contrasts with the standard discrete query model, which is known to be hard. Through the analysis of this model, we uncover a surprising result: in auto-bidding with two advertisers, FPA and SPA are auction equivalent.

Optimization of Logistics Delivery Systems

Contributed Session

Session Chair: Vahid Eghbal Akhlaghi, Georgia Institute of Technology (H. Milton Stewart School of Industrial and Systems Engineering), Atlanta, GA

1 City Logistics in Megacities: The Two-Echelon Pickup-And-Delivery Problem with Time Windows and Deadlines

Muchammad Arya Zamal[1], Albert Schrotenboer[2], Tom van Woensel[1], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: m.a.zamal@tue.nl

This paper presents the Two-Echelon Pickup-and-Delivery problem with Time Windows and Deadlines (2E-PDPTW-D), a new and emerging routing variant addressing the operations of logistics companies connecting consumers and suppliers in megacities. The 2E-PDPTW-D integrates reverse flow, route flexibility, and vehicle time-synchronization aspects such as parcel time windows, satellite synchronization, and hub deadlines. A proposed matheuristic approach combines a set-partitioning model and an Adaptive Large Neighborhood Search (ALNS) to create cost-efficient vehicle routes satisfying all constraints. Computational studies in collaboration with a logistics service provider in Indonesia reveal that early pickup deadlines may require additional vehicles, emphasizing the need to consider the marginal costs of extra fleets for megacity logistics operations.

2 A Delivery Workers Assignment Problem for the Distribution of Goods in Urban Areas

Antonia Ilabaca, Germán Paredes-Belmar, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile. Contact: antonia.ilabaca.c@mail.pucv.cl

This paper addresses the delivery workers assignment problem with time-dependent and time windows constraints in urban areas for efficient distribution of goods. The purpose is determining routes for a set of vehicles that serves a set of demand points, taking characteristics of city logistics such as traffic congestion and distribution in different buildings. Unlike the traditional vehicle routing problem, our focus is on efficiently crew assignment for delivery vehicles. The crew composition can consist of drivers, delivery workers, or a multifunctional worker who perform both driving and delivery tasks. To solve this problem, we propose a mixed integer linear programming model that minimized the total transportation costs. The resulting set of efficient routes and crew vehicle assignments can support decision-making and improve customer service.

3 Load Balancing for Online Truck Routing

Tanvir Ibna Kaisar[1], Maged M. Dessouky[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: kaisar@usc.edu

In the absence of coordination, individual truck drivers act selfishly to minimize their travel time, resulting in a user equilibrium (UE) solution that is not necessarily system optimum (SO). In this study, we propose an algorithm that encourages collaboration among individual truck drivers. Route requests are received online from drivers who do not necessarily have the same value of time (VOT). The algorithm provides routing instructions and distributes the benefits of collaboration among the drivers resulting in a solution close to the SO solution. We provide some experimental results that showcase the effectiveness of our algorithm.

4 Combined People-And-Freight Delivery Problem with Request Incompatibility

Yu Syuan Chang, Chin Sum Shui, National Yang Ming Chiao Tung University, Hsinchu City, Taiwan. Contact: boice89821@gmail.com

In recent years, combined people and freight sharing systems are developed to have better vehicle utilization, but no study deals with the incompatibility among passenger and parcel requests (e.g., passengers with pets or parcels with odors). This study presents a variant of the combined people-and-freight delivery problem, formulated as a mixed integer linear programming problem, which aims to design a set of profit-maximizing routes for a heterogeneous fleet given a set of passenger and parcel requests while considering their compatibility and time windows. Numerical experiments demonstrate the effectiveness of the formulation in handling their incompatibility, while the cost of incompatibility is analyzed to offer managerial insights.

5 Optimizing Truck Fleet Scheduling for Fuel Deliveries

Vahid Eghbal Akhlaghi[1], Hongzhao Guan[1], Jason Lu[1], Pascal Van Hentenryck[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: vahid.eghbal@gatech.edu

In this paper, we optimize the delivery schedules for a fleet of trucks with specified availability time windows to meet fuel replenishment needs at various sites. A mixed-integer programming model is proposed, incorporating a two-stage optimization algorithm: firstly, ensuring sufficient deliveries to maintain site operations, and secondly, enhancing driver shift and truck utilization while minimizing total traveled distance. The problem is refined via techniques to make it computationally tractable. A case study in Estonia provides valuable insights, including cost savings, improved customer satisfaction, enhanced business resilience, and reduced fuel consumption and emissions. This approach offers a compelling alternative to current manual drag-and-drop tools, underscoring the potential for automation in fleet scheduling.

Stochastic Systems

Contributed Session

Session Chair: Vishwakant Malladi, Indian School of Business, Mohali, Punjab, India

1 Sojourn Times in Bernoulli Feedback Queues Subject to Disasters

George C. Mytalas[1], Michael A. Zazanis[2], [1]UTH, Lamia, Greece; [2]Athens University of Econ & Business, Athens, Greece. Contact: gmytalas@uth.gr

We consider a queueing system with batch Poisson arrivals andBernoulli feedback which is subject to disasters occurring according to an independent Poisson process. Each disaster is followed by a repair period. The server, when idle, takes repeated vacations of random length and, while the server is under repair or on vacation, disasters cannot occur. We analyze this system and obtain the Laplace transform of the system time distribution for a typical customer completing service. A special case where the system parameters follow the exponential distribution is provided.

2 Queue-Based Service-Level Estimation a Finite-Interval Lookahead Predictor for the Erlang-A Model with Customer Abandonment

Ling Zhang, Yunan Liu, Amazon Corporate LLC, Seattle, WA, Contact: lzhangn@amazon.com

In this article, we develop effective methodologies and algorithms for estimating the service-level (SL) for Amazon customer service contact center. Our SL metric is the fraction of all customer arrivals in an interval [0,T] experiencing a shorter-than-w waiting time (e.g., T=24 hours and w=60 seconds). Our algorithm predicts the SL in a forward-looking fashion using input parameters including the future demand forecast, future agent capacity, average handling time, average abandonment time and real-time queue information.

3 Markov Persuasion Processes With Endogenous Agent Beliefs

You Zu[1], Krishnamurthy Iyer[1], Haifeng Xu[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Chicago, Chicago, IL, Contact: zu000002@umn.edu

We consider a repeated persuasion setting where a long-lived sender persuades short-lived receivers by sharing payoff-relevant state information. The state transitions are Markovian conditional on the receivers' actions, and the sender seeks to maximize the long-run average reward by committing to a signaling mechanism. We analyze the setting where the receivers may have limited historical information and show that solving this problem requires solving a large non-linear program. To overcome this difficulty, we propose a robust history-independent signaling mechanism that is persuasive even when receivers have some historical knowledge, and it approximates the optimal payoff in settings where the receivers have no historical information.

4 T-Estimation of Controlled Markov Chains via Randomised Hellinger Distances Using Histograms

Imon Banerjee, Purdue University, West Lafayette, IN, Contact: ibanerj@purdue.edu

In this work, we estimate the transition functions "s" of a controlled Markov chains using histograms. We define a randomised Hellinger distance and prove that our estimator satisfies minimax risk bounds with respect to that distance. We produce a testing functional "T" to evaluate two distinct estimates of "s", and describe a model selection procedure for choosing the best estimator by representing it as a constrained minimisation problem. We then illustrate the applicability of our problem by providing oracle risk bounds for estimating the transition densities of an offline reinforcement learning (RL) algorithm with minimal assumption on the policy.

5 Modeling Inter-Temporal Correlation Between Stochastic Processes

Vishwakant Malladi, Indian School of Business, Mohali, Punjab, India. Contact: vishwakant_malladi@isb.edu

Inter-temporal correlation is present in multiple areas where the state of a process at one time affects the state of another later. Such examples can be found in queuing, disruption propagation, delay proliferation, etc. Given its prevalence, a convenient model for inter-temporal correlation could be advantageous to aid in managerial decision-making. We propose a new approach using time-subordinated Markov chains whereby inter-temporal correlation can be modeled in a mathematically tractable fashion. We also extend the approach to model propagation in networks. We demonstrate the applicability of our approach using examples from route optimization in road networks and delay propagation in airlines.

Optimization for Smart Grids

Contributed Session

Session Chair: Ali AlArjani, Prince Sattam Bin Abdulaziz University, AlKharj, Saudi Arabia

1 Effect of Optimally Pooling Diverse Wind Generation Sources on Resulting Operational Costs

Alexander Vinel[1], Chanok Han[2], [1]Auburn University, Auburn, AL, [2]Auburn University, AUBURN, AL

It is widely accepted that combining together geographically or technologically diverse energy sources can significantly reduce generation variability. Since variability directly translates into increased cost of wind and solar energy, being able to better understand ways to control it can be important. In previous efforts we have demonstrated that by a priori employing advanced optimization techniques (specifically, risk-averse portfolio modeling), it is possible to design energy generation portfolio that exhibits significantly lower intermittency and higher generation forecasting accuracy. In this talk we will discuss our efforts to model the extent to which this reduction in variability can directly translate to reduction in operational costs and grid efficiency.

2 Optimization Models for Residential Electricity Usage Under Net-Metering Programs in a Smart Grid

Shahab Sadri, Lihui Bai, University of Louisville, Louisville, KY, Contact: shahab.sadri@louisville.edu

This research aims to study residents' electricity consumption behavior and the resulting system-level consumption profile in a smart grid. We assume that each household is equipped with a system consisting of solar panels and battery storage and, under the net metering program, is allowed to sell excess electricity back to the grid. We study electricity consumption from two different perspectives. The System Optimal (SO) model minimizes the total system cost, while the User Equilibrium (UE) model describes the individual households' behavior in a Nash Equilibrium. Under certain convexity assumptions, we prove the existence and uniqueness of the solution. Numerical experiments using a simulated network and extensive sensitivity analysis will be reported.

3 Optimal Computation of Fixed Charges for Efficient Electricity Tariffs in Future Distribution Networks

Quentin Lété, Gabriela Hug, ETH Zürich, Zürich, Switzerland. Contact: qulete@ethz.ch

With the increasingly important role of distribution networks in the energy transition, electricity tariffs should evolve to become more cost reflective. This implies resorting more and more to fixed charges to recover residual network costs. At the same time, higher fixed charges increase the incentive of prosumers to go off grid while decreasing costs of DER will only increase the risk of grid defection in the future. In this work, we propose a model that endogenize the computation of fixed charges in distribution tariffs that accounts for the possibility of grid defection by prosumers in the network. Based on this framework, we propose illustrative results on small instances as well simulations on realistic cases, and comment on the implication of the increasing risk of grid defection for the design of distribution tariffs.

4 Biux2x2

Ali AlArjani, Prince Sattam Bin Abdulaziz University, AlKharj, Saudi Arabia. Contact: a.alarjani@psau.edu.sa

Wind energy plays a crucial component in the contest to fulfill environmental control objectives. Wind energy, on the other hand, will only be able to fulfill its essential importance if the wind turbines work efficiently. The paper aims to analyze the application of artificial intelligence (AI) algorithms in wind speed. In this paper, three network parameter optimization algorithms, AdaGrad, RMSprop, and Adam, are implemented and compared in the context of wind speed forecasting. This paper employs wind speed data obtained from Saudi Arabia. Mean absolute error (MAE), mean square error (MSE), root mean square error (RMSE), and R-squared are the four metrics used to assess performance. The experiment results show that the Adam algorithm outperforms the other optimization algorithms regarding forecasting accuracy and training time.

Case Competition

Award Session

Session Chair: Dessislava Pachamanova, Babson College, Wellesley, MA

1 Racial Bias in Automated Traffic Law Enforcement and the Price of Unjustness

Chrysafis Vogiatzis[1], Eleftheria Kontou[2], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Urbana, IL

This case study has been developed for students to practice their data analysis and optimization skills in a contemporary societal issue: that of injustice in automated traffic law enforcement. Specifically, this case study is for students of modern data analysis and statistical modeling courses that focus on hypothesis testing; it also has a component for students in optimization and mathematical modeling courses that focus on linear and network optimization. The case study has been used since Spring 2023 in two courses within the Industrial Engineering and Civil Engineering curricula.

2 Three Mountain Communications: Fairness Considerations for Workplace Task Allocation

Saurabh Bansal, Wei Wu, Rashmi Sharma, Penn State University, State College, PA

The case has two objectives: incorporating fairness considerations in managerial decision-making and introduce task allocation using optimization. The case focuses on a call center that faces the issue of daily task allocation. The current self-selection-based allocation has created friction among employees. The call center must develop an allocation model that is perceived to be fair by employees. Students believed the case provided them skills to combine modeling focused methods with qualitative considerations for workplace fairness. This case is based on an industry project with National.

3 Mobismile Bike-Sharing

Deniz Akturk[1], Ozan Candogan[2], [1]Washington University in St. Louis, St. Louis, MO, [2]University of Chicago, Chicago, IL

This case examines possible expansion strategies for a bike-sharing firm from an operations perspective. The case aims to guide readers in constructing a process flow diagram and illustrate how operational metrics identify critical drivers of cost, revenue, and depreciation. First, the case provides a historical overview and widely adopted revenue models in bike-sharing. Later, the case highlights the main cost items in the bike-sharing industry. These costs are then visualized through the Mobismile bike-sharing system, a hypothetical bike-sharing company operating in Chicago.

Machine Learning Models for Patient Readmission and Follow-up

Contributed Session

Session Chair: Lihui Bai, University of Louisville, Louisville, KY

1 A Hybrid Analytics Framework Toward Better Explanations: The Case of Survival After Lung Transplantation
Ali Bagheri[1], Mostafa Amini[1], Dursun Delen[2], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Tulsa, OK, Contact: ali.bagheri@okstate.edu
We propose a hybrid analytics framework for improving the interpretability of black-box ML models. Using a feature selection strategy, supervised and unsupervised learning, and explanation methods, our goal is to offer medical professionals a tool that, provides further insight into the most important factors involved in a prognostic or survival analysis and, also, adds flexibility to the development of effective clinical decision support systems. We apply the proposed framework to investigate the factors involved in patients' short- and long-term survival after lung transplantation. The results can assist in developing more effective indicators for lung allocation decisions, ultimately leading to improved transplantation benefits.

2 Multi-Stage Heart Failure Readmission Prediction
Xinyu Yao[1], George Huaien Chen[2], Karmel S. Shehadeh[3], Rema Padman[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Lehigh University, Bethlehem, PA, Contact: xinyuyao@andrew.cmu.edu
Hospital readmissions are burdensome for heart failure patients as well as the healthcare system. In this paper, we propose an interpretable model that predicts whether a patient will be readmitted to the hospital or die within 30 days after being discharged based on data available at different admission stages. Our model is an attention-based neural network model, where the features available at different time steps vary. We demonstrate our framework on heart failure admission data from a major health system, where we find that our proposed framework can achieve competitive prediction accuracy while identifying how the importance of features varies over stages.

3 Risk Factors Associated with Stroke Readmissions: A Systematic Literature Review
Eddah Mauti[1], Niyousha Hosseinichimeh[2], Vida Abedi[3], Ramin Zand[4], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Falls Church, VA, [3]Penn State College of Medicine, Hershey, PA, [4]Pennsylvania State University, Hershey, PA
Hospital readmissions impose a substantial burden on the healthcare system in the United States, costing Medicare about $26 billion per year. The Centers for Medicare and Medicaid Services defined readmission as an indicator of poor hospital care and has made reducing readmission rates a national healthcare reform goal. This study performs a systematic literature review to identify the risk factors associated with stroke readmissions between 30 days to 5 years. Web of Science and PubMed were searched for studies related to stroke readmissions, and 365 articles met the inclusion criteria. The study found stroke readmission risk factors and interventions to reduce stroke readmissions. The results of this study can assist in designing interventions to reduce stroke readmission.

4 Prediction of Unplanned 30-Day Readmission in Patients with Heart Failure Using Machine Learning
Sonia Jahangiri, Nasibeh Azadeh-Fard, Rochester Institute of Technology, Rochester, NY, Contact: sj1374@rit.edu
Heart failure (HF) is a major cause of US hospital admissions with high readmission rates. This study extracted HF patient data from the Nationwide Readmission Database (NRD). We employed machine learning techniques to develop a new prediction model for all-cause readmission within 30 days and in-hospital mortality. The model incorporated patient demographics, comorbidities, and utilized both traditional machine learning methods and neural networks for comparison.

5 Predicting and Managing Hypotension in Perioperative Medicine
Xiaoyu Chen[1], Lihui Bai[1], Guanghui Lan[2], Jiapeng Huang[3], [1]University of Louisville, Louisville, KY, [2]Georgia Institute of Technology, Atlanta, GA, [3]University of Louisville, Louisville, KY, Contact: lihui.bai@louisville.edu
Perioperative hypotension can cause postoperative complications such as renal insufficiency, myocardial injury, and increased mortality. Predicting hypotension prior to the episode and taking preventative measures early can be crucial to improving patient outcomes. In this paper, we use

both pre-operative and intra-operative medical record data to predict hypotension using Bayesian inference with mixed responses, and to optimize pre-operative and intra-operative decisions using decision analysis as well as reinforcement learning methods. Numerical results based on high-fidelity multi-parameter vital signs in the open source VitalDB database will be reported.

Managing Supply Chains during Pandemics

Contributed Session

Session Chair: Marta J Ventura, Penn State, State College, PA

1 Designing a Sustainable-Resilient-Responsive Supply Chain Network Considering Uncertainty in the Covid-19 Era

Amir Hossein Moadab[1], Ghazale Kordi[2], Mohammad Mahdi Paydar[3], Ali Divsalar[4], Mostafa Hajiaghaei-Keshteli[5], [1]Washington State University, Pullman, WA, [2]University of Helsinki, Helsinki, Finland; [3]Babol Noshirvani University of Technology, Babol, Iran, Islamic Republic of; [4]Babol Noshirvani University of Technology, Babol, Iran, Islamic Republic of; [5]Tecnologico de Monterrey, Puebla, Mexico. Contact: amirhossein.moadab@wsu.edu

COVID-19 has presented significant challenges to supply chains, making PCR testing a vital product during the pandemic. This paper proposes a multi-objective mathematical linear model to optimize a sustainable, resilient, and responsive supply chain for PCR diagnostic tests. The model aims to minimize costs, negative societal impact, and environmental impact, using a scenario-based approach with stochastic programming. The model is validated by investigating a real-life case study in one of Iran's high-risk supply chain areas. The proposed model is solved using the revised multi-choice goal programming method. Lastly, sensitivity analyses based on effective parameters are conducted to analyze the behavior of the developed MILP. To enhance the design of the supply chain network, this paper has considered various COVID-19 variants and their infectious rates.

2 Understanding Dynamics of Restaurant Foot-Traffic Recovery: A Case Study of the Covid-19 Pandemic

Mohsen Bahrami, Amir Tohidi, Alex Pentland, Massachusetts Institute of Technology, Cambridge, MA, Contact: bahrami@mit.edu

Considering the importance of the restaurant industry for economic stability, it is crucial to investigate factors associated with restaurants' disaster recovery. We utilize large-scale Mobility and Place datasets to study the temporal dynamics of restaurants' foot traffic in NYC and Boston MSA. We show that restaurants' customer education level has a negative association with their Recovery Index (RI), while there is a positive association between customer income level and restaurants' RI. The most important finding of our analyses is the significant negative association of customers' geographic diversity with restaurants' RI. This is counterintuitive, as many previous studies have shown that the diversity of customers can potentially help businesses. Finally, we show that restaurants which adapted mask mandates were more likely to recover faster.

3 Rethinking Supply Chain Trade-Offs to Face Pandemic Outbreaks: Current Decision Support Models and Insights for Future Directions

Suzan Alaswad, Zayed University, Abu Dhabi, United Arab Emirates. Contact: salaswa@gmail.com

The recent COVID-19 had severely impacted supply chains that companies are still recovering from the shock it caused to their supply chains almost four years after the pandemic first started. The pandemic has exposed many flaws in modern supply chains forcing companies to reassess their existing supply chain strategies. In this paper, we review current research on supply chain management during epidemics and discuss how pandemic outbreaks lead to the rethinking of supply chain decisions. We mainly analyze existing supply chain models deployed for epidemic control and assess them from the perspective of the new challenges imposed by COVID-19. We focus on decision support models and quantitative methodologies used in supply chain management pre- and post-COVID-19 and identify modeling gaps to address and improve response in future pandemics.

4 Efficient Vaccine Management in Response to Covid-19 and Emerging Infectious Diseases: An Integer Programming Approach with Discrete-Event Simulation

HyungJu Kim, Taesu Cheong, Korea University, Seong Buk gu, Seoul, Korea, Republic of. Contact: hjkim1013@korea.ac.kr

Efficient vaccine distribution and administration are critical during pandemics, but challenges exist. We propose an integer programming methodology based on the newsvendor model, validated by a discrete-event simulation and economic analysis. Our approach aims to increase efficiency and address issues surrounding vaccine wastage and missed opportunities. It can be applied to COVID-19 and other infectious diseases to improve vaccine management.

5 Structure Methodology for Optimizing Public Health and Economic Impact of Covid-19 Vaccination

Marta J Ventura, Penn State, State College, PA, Contact: mxv176@psu.edu

When vaccines became available, the limited logistics available to manage the manufacturing and distribution of vaccines led to new challenges. Such challenges involved increasing production capacity and distributing vaccines to medical facilities in different regions to reach herd immunity in a timely manner. We propose a mathematical framework that coordinates all the necessary activities for selecting the locations and capacities of temporary medical facilities that need to be installed, purchasing of single-dose and two-dose of vaccines by medical facilities in an orderly manner, and generating a vaccination timetable for residents. The mathematical framework also involves the computation of an effective time window for the minimum immunization time.

Advances in Delivery Service Operations

Contributed Session

Session Chair: Sunil Chopra, Northwestern University, Evanston, IL

1 Utilizing Crowdsourced Delivery Data for Chain Store Location Selection

Jiana-Fu Wang, Yu-Sheng Wu, National Chung Hsing University, Taichung, Taiwan. Contact: jfwang@dragon.nchu.edu.tw

The outbreak of COVID-19 epidemic has increased the usage of crowdsourced food deliveries. This research utilizes the delivery system-generated data at a chain store's end to measure each store's service boundary. Together with the Retail gravity model, the Huff model, the Central Place theory, and the information of local competitors and potential number of customers, we build a novel model for the chain store to evaluate potential locations for new stores.

2 Analysis the Factors of the Customer's Satisfaction and Importance of Delivery Applications

Jaejun Hwang, Hosun Rhim, Korea university, Seoul, Korea, Republic of. Contact: jjyw2648@naver.com

The delivery app market in South Korea continues to grow while competition among companies intensifies. This study explores the attributes that a competitive delivery app should have by utilizing IPA analysis on various attributes of delivery apps in Korea. By exploring attributes that are expected to further increase customer satisfaction, new directions for service development in related industries are presented.

4 Fast Food Stores with a Drive-Through Option Recovered from Covid-19, Stores Without Did Not

Sunil Chopra[1], Partha S. Mishra[2], Ioannis Stamatopoulos[3], [1]Northwestern University, Evanston, IL, [2]Kellogg School of Management, Northwestern University, Evanston, IL, [3]The University of Texas at Austin, McCombs School of Business, Austin, TX, Contact: s-chopra@kellogg.northwestern.edu

Comparing the foot-traffic data for popular fast-food customers before and after the COVID-19 pandemic, we empirically show that customer preference shifted from stores without a drive-through option to stores with one. In particular, we show that this shift in preference for a drive-through is consistent across the US. Moreover, we find evidence of signs of persistence in this shift in the future.

3 Integral Optimization of Robotic Mobile Fulfilment Systems

Lu Zhen[1], Zheyi Tan[1], René B.M. De Koster[2], Shuaian Wang[3], [1]Shanghai University, Shanghai, China; [2]Erasmus University-Rotterdam, Rotterdam, Netherlands; [3]Department of Logistics & Maritime Studies, Hong Kong Polytechnic University, Kowloon, Hong Kong, Kowloon, China. Contact: rkoster@rsm.nl

Parts-to-picker, robotic mobile fulfillment (RMF) systems are used in many e-commerce warehouses. Scheduling orders, robots, and storage pods in interaction with manual workstations is critical to obtaining high performance. This scheduling problem is complicated due to interactions between decisions. This paper models all such scheduling decisions in combination to minimize order fulfillment time. We conduct numerical experiments based on a real-world case to validate the model and solutions. Our model provides near optimal solutions for instances with 14 workstations, 400 orders, 300 stock-keeping units (SKUs), 160 pods, and 160 robots, within four minutes. We use our model to obtain different managerial and design insights.

1 Distributionally Robust Optimization: The Science of Underpromising and Overdelivering

Daniel Kuhn, Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland

Many decision problems in science, engineering and economics are affected by uncertain parameters whose distribution is only indirectly observable through samples. The goal of data-driven decision-making is to learn a decision from finitely many training samples that will perform well on unseen test samples. This learning task is difficult even if all training and test samples are drawn from the same distribution—especially if the dimension of the uncertainty is large relative to the training sample size. Wasserstein distributionally robust optimization (DRO) seeks data-driven decisions that perform well under the most adverse distribution within a certain Wasserstein distance from a nominal distribution constructed from the training samples. It has a wide range of conceptual, statistical and computational benefits. Most prominently, the optimal decisions can often be computed efficiently, and they enjoy provable out-of-sample and asymptotic consistency guarantees. This talk will highlight two recent advances in Wasserstein DRO. First, we will develop a principled approach to leveraging samples from heterogeneous data sources for making better decisions. In addition, we will prove the optimality of linear policies in Wasserstein distributionally robust linear-quadratic control problems with imperfect state observations, and we will show that these policies can be computed efficiently using dynamic programming, Kalman filtering and automatic differentiation.

Incorporating Artificial Intelligence into Healthcare Workflow: Models and Insights

Tutorial Session

Session Chair: Ebru Korular Bish, University of Alabama, Tuscaloosa, AL

1 Incorporating Artificial Intelligence into Healthcare Workflow: Models and Insights

Tinglong Dai, Michale Abràmoff, Johns Hopkins University, Baltimore, MD

Artificial intelligence (AI) is poised to revolutionize healthcare delivery in the United States and around the world. As AI becomes an integral part of the healthcare workflow, it will change the way we model and analyze healthcare delivery and upend the paradigm that has dictated how operations research and management science researchers interact with healthcare practitioners. In this tutorial, we demonstrate how the integration of AI into the healthcare workflow will require a new set of models to guide rapidly changing healthcare practices, measure productivity gains in the industry, and reduce disparities in access to care. These models must be based on a thorough understanding of the variables that influence physician buy-in and patient acceptance. While medical AI promises to learn and adapt based on user interactions and data, the development, validation, and approval process also requires the creation of new models that generate useful insights. Finally, we discuss barriers and opportunities related to incentive design and ethical considerations for AI in healthcare.

Technology Tutorial

1 The New OROps: Build More Decision Models, Not More Decision Tools

Sebastian Quintero, Nextmv, Bogato, Colombia. Contact: sebas@nextmv.io

Decision models save money. Decision tools save time. For decades, realizing business value from decision algorithms and operations research has often been hindered by the challenges with model definition, solver setup, testing, deployment, and collaboration. It's time for decision optimization technology to get out of its own way. Inspired by MLOps and software development approaches, a new platform is providing collaborative, opinionated tooling that empowers teams to move faster with less confusion and more access to the decision technology ecosystem. In this tech tutorial, we'll explore these tools and workflows and their impact on accelerating algorithm development cycles from months to weeks or less.

2 JD.com Uses Advanced Analytics to Enhance Supply Chain Capability

Zuo-Jun Max Shen, University of California Berkeley, Berkeley, CA, Contact: maxshen@berkeley.edu

Supply chain leaders have continuously tried to expand and enhance capabilities by using advanced techniques and analytics. JD.com, the largest retailer in China based on revenue, is committed to an intelligent, integrated, and resilient supply chain that creates value for all players within the retail ecosystem. Despite challenges in the complex and sophisticated retail supply chain, JD.com has strengthened its supply chain agility, and attained shared value by focusing on supply chain efficiency, supply chain resilience, and reducing supply chain uncertainty and volatility. This speech will help you to uncover more supply chain capabilities using advanced techniques with real-world cases adopted by JD.com.

Advances in Data-Driven Operations

Community Committee Choice Session

Session Chair: Ruihao Zhu, Cornell University, Ithaca, NY

1 Robust Auction Design with Support Information

Jerry Anunrojwong, Santiago R. Balseiro, Omar Besbes, Columbia Business School, New York, NY, Contact: jerryanunroj@gmail.com

The seller wants to sell an item to n i.i.d. buyers and only the support [a,b] is known; a/b quantifies relative support information (RSI). The seller either minimizes worst-case regret or maximizes worst-case approximation ratio. We show that i) with low RSI, second-price auctions (SPA) is optimal; ii) with high RSI, SPA is not optimal, and we introduce a new mechanism, the "pooling auction" (POOL), which is optimal; iii) with moderate RSI, a combination of SPA and POOL is optimal. Under POOL, whenever the highest value is above a threshold, the mechanism still allocates to the highest bidder (just like SPA), but otherwise the mechanism allocates to a uniformly random buyer, i.e., pools low types.

2 Offline Pricing Analytics With High-dimensional Covariates

Mabel C. Chou[1], Jingren Liu[2], Hanzhang Qin[2], [1]National University of Singapore, SG, SG, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: hzqin@nus.edu.sg

We consider a feature-based offline pricing problem, where a firm needs to make a pricing decision to maximize its expected revenue. We employ a semi-parametric partially linear structure with shape-restricted constraint to model the empirical demand. We develop a Three-Step Semi-Parametric Estimation method to make data-driven pricing decisions. From a non-asymptotic perspective, we derive finite sample regret bounds, showcasing the efficacy of our data-driven pricing policy even under potential misspecification of the demand model. Moreover, when the demand model is well specified, we provide the explicit sample size guarantee to achieve near-optimal revenue. The effectiveness of the method is further validated through numerical experiments.

3 Temporal Fairness in Learning and Earning: Price Protection Guarantee and Phase Transitions

Ruihao Zhu[1], Qing Feng[1], Stefanus Jasin[2], [1]Cornell University, Ithaca, NY, [2]University of Michigan, Ann Arbor, MI, Contact: ruihao.zhu@cornell.edu

Motivated by the prevalence of "price protection guarantee", which helps to promote temporal fairness in dynamic pricing, we study the impact of such policy on the design of online learning algorithm for data-driven dynamic pricing with initially unknown customer demand. Under the price protection guarantee, a customer who purchased a product in the past can receive a refund from the seller during the so-called price protection period in case the seller decides to lower the price. We consider a setting where a firm sells a product over a certain time horizon. For this setting, we characterize how length of price protection period, can affect the optimal regret of the learning process. Our results reveal the surprising phase transitions of the optimal regret with respect to M.

4 Managing Perishable Inventory Systems With Positive Lead Times: Inventory Position Vs. Projected Inventory Level

Jinzhi Bu[1], Xiting Gong[2], Huanyu Yin[2], [1]The Hong Kong Polytechnic University, Hong Kong, China; [2]The Chinese University of Hong Kong, Hong Kong, China. Contact: xtgong@cuhk.edu.hk

We consider periodic-review perishable inventory systems with a fixed product lifetime and positive replenishment lead times. Demands are satisfied by on-hand inventories of different ages following a general issuance policy. Unsatisfied demand can be either backlogged or lost. The objective is to minimize the long-run average holding, penalty, and outdating costs. We study a simple class of projected inventory level (PIL) policies, which raises the expected on-hand inventory upon each order arrival to a constant level. Among other results, we prove that the best PIL policy is asymptotically optimal with large unit penalty costs under a large class of demand distributions. Our numerical study shows that it performs very well in these systems.

5 Posterior Sampling for Continuing Environments

Wanqiao Xu[1], Shi Dong[2], Benjamin Van Roy[1], [1]Stanford University, Stanford, CA, [2]Microsoft, Mountain View, CA, Contact: wanqiaox@stanford.edu

We develop an extension of posterior sampling for reinforcement learning (PSRL) that is suited for a continuing agent-environment interface and integrates naturally into agent designs that scale to complex environments. The approach, continuing PSRL, maintains a statistically plausible model of the environment and follows a policy that maximizes expected □-discounted return in that model. At each time, with probability 1-□, the model is replaced by a sample from the posterior distribution over environments. For a choice of discount factor that suitably depends on the horizon T, we establish an O(□ S√(AT)) bound on the Bayesian regret, where S is the number of environment states, A is the number of actions, and □ denotes the *reward averaging time*, which is a bound on the duration required to accurately estimate the average reward of any policy.

Delayed Incentives and Digital Competition

Community Committee Choice Session

Session Chair: Serdar Simsek, The University of Texas at Dallas, Richardson, TX

Session Chair: Guang Li, Queen's University, Kingston, ON, Canada

1 Does Size Matter for Loyalty Points Redemptions?

Yang Chen, Anton Ovchinnikov, Nicole Robitaille, Smith School of Business, Queen's University, Kingston, ON, Canada. Contact: chen.y@queensu.ca

Prior research finds that redeeming loyalty points is associated with increased customer loyalty. However, numerous economic, behavioral, and psychological theories suggest that redemption size might matter, although the specific predictions are often conflicting. With a large proprietary data set from a major loyalty program (LP), we study the effect of redemption size on long-term loyalty. We find that size does matter in redemptions, so does the size metrics and prior redemption behaviors. Small redemptions are sometimes associated with increased loyalty, whereas medium redemptions are most consistently associated with increased loyalty. Large redemptions, however, can backfire. Our findings suggest that encouraging the right redemption size may increase LP revenue, and firms should actively manage redemption as a key control lever in revenue optimization.

2 Dual Value of Delayed Incentives

Bharadwaj Kadiyala[1], Serdar Simsek[2], Ozalp Ozer[3], [1]University of Utah, Salt Lake City, UT, [2]The University of Texas at Dallas, Richardson, TX, [3]Amazon, Richardson, TX

Gift card (GC) promotions reward customers who spend on regularly priced products with a promotional GC which can be redeemed by customers towards a future purchase at the retailer. Using a regression-discontinuity design, we causally investigate the impact of GC promotion on whether and how the promotion impacts customer purchase behavior. We find that GC promotion increases sales by 21.84% and 29.18% among customers with 4-month and 13-month purchase recency. A significant portion of these incremental sales are due to the advertisement effect of the promotion. GC promotion also changes the concentration of sales distribution as customers seek out niche product categories and high-end brands. Customers also spend more while redeeming their gift card, thus validating the dual value of delayed incentives.

3 Loyalty Currency and Mental Accounting: Do Consumers Treat Points like Money?

Freddy Lim[1], So Yeon Chun[2], [1]INSEAD, Singapore, Singapore; [2]INSEAD, Singapore, France. Contact: freddy.lim@insead.edu

We study how consumers decide to pay with loyalty points or money, and how their attitudes toward points and their payment choices are related to their point earning sources and characteristics. We develop a model of consumers' payment choices and estimate it on airline loyalty program data. We find that mental accounting, subjective perceived value, and reference exchange rate of points play important roles, and consumers' primary points earning source and total earning level are jointly associated with their attitudes toward points and money. We propose a probabilistic segmentation of consumers and show how a firm can implement pricing policies to efficiently target and influence consumers' payment choices through counterfactual analyses.

4 How Resilient are Warehouse Clubs to Digital Competition? The Role of Retail Agglomeration

Xiaodan Pan[1], Guang Li[2], Martin Dresner[3], Benny Mantin[4], [1]Concordia University, Montreal, QC, Canada; [2]Queen's University, Kingston, ON, Canada; [3]University of Maryland-College Park, College Park, MD, [4]University of Luxembourg, Luxembourg, Luxembourg

As digital commerce grows, traditional brick-and-mortar retailers confront challenges to stay resilient. Our study examines the effect of ecommerce on these entities, focusing on warehouse clubs. We analyze customer traffic data sourced from Costco, the leading WC chain in the U.S., to understand the relationship between retail clusters and ecommerce on customer visits. Findings show that dense clusters of general and narrow-range merchandise boost foot traffic. However, less dense areas, especially near rivals, see a decline. General merchandise ecommerce has a more negative impact on footfall than narrow-range ecommerce. These online activities disrupt the previous positive correlation between merchandise clusters and foot traffic. The study highlights the need for adept navigation of the evolving retail landscape to ensure future success.

Demand Modeling and Price Optimization in Retail and Hospitality Industries

Community Committee Choice Session

Session Chair: Andrew Vakhutinsky, Oracle Labs, Burlington

1 Demand Estimation with Missing Data on Covariates: Imputation-Based Approach

Sanghoon Cho[1], Danhyang Lee[2], Andrew Vakhutinsky[3], [1]Texas Christian University, Fort Worth, TX, [2]University of Alabama, Tuscaloosa, AL, [3]Oracle Labs, Burlington

Discrete choice modeling is widely used in academia and industry to understand customer demand. However, practical data collection often provides only records of purchased products, which poses challenges for demand estimation. In industries like hotels, booking records typically include purchased rooms and their associated features and prices, while the prices and features of non-purchased rooms are not observed. This limits the applicability of discrete choice models unless imputation techniques are employed. To tackle this issue, we propose a novel method that simultaneously estimates the parameters of our demand model and imputes the prices of unsold products using our incomplete data. We demonstrate the effectiveness of our approach using a real hotel transaction dataset.

2 Assortment Design in Online Grocery Retail

Renjun Hu, University of Michigan, Ann Arbor, MI, Contact: renjunhu@umich.edu

Despite the growth of online grocery delivery in recent years, most supermarkets have not turned the growth into profitability. One reason is the high picking and delivery cost with a low margin. The advancement of the micro-fulfillment center (MFC) is promising to improve efficiency in picking operations but it has two limitations. First, the capacity is limited and can handle a subset of items sold at a supermarket. Second, cart abandonment prohibits an online grocer from only selling a limited selection of items. Considering these, a retailer must carefully choose which items are sold online and which items are picked from an MFC. In this research work, we consider the assortment decision for online groceries under the cart abandonment model fulfilled by MFCs. We provide an efficient and adaptive formulation that jointly optimizes the MFC and online assortment.

3 Multiple Discrete Choice Models with Copula: An Application to Hotel Standby Upgrades

Ovunc Yilmaz[1], Andrew Vakhutinsky[2], Ruxian Wang[3], Zifeng Zhao[4], [1]University of Colorado Boulder, Boulder, CO, [2]Oracle Labs, Burlington, [3]Johns Hopkins University, Carey Business School, Kensington, MD, [4]Mendoza College of Business, University of Notre Dame, Notre Dame, IN, Contact: ovunc.yilmaz@colorado.edu

Hotels often offer a set of upgrades to their guests right after the booking, and guests can request multiple of these upgrades. Since classical discrete choice models only allow one alternative per customer, we develop a novel multiple-discrete choice model that allows customers to choose more than one alternative and use copula to account for the potential dependence between the choices. We test this model in an industry partner's booking and upgrade data set and offer some insights on the price optimization for this setting.

4 Segmentation Framework for Personalizing Shopping Experience for Online Retail Shoppers

Pratik Mital[1], Liz Luo[2], Allison Feldman[2], [1]Amazon,

Atlanta, GA, [2]Amazon, Jersey City, NJ, Contact: mitalp@amazon.com

Segmenting customers into appropriate groups helps businesses provide better customer experience and gain more revenue. Deciding how to segment customers is highly dependent upon the experience being provided. In this work we tackle the problem of identifying shoppers who share similar purchasing behavior with other shoppers in order to provide personalized product recommendations to them while shopping. We first highlight the limitations of clustering based approaches for our use case and then propose a propensity score based framework to segment customers. We also propose new metrics to evaluate the performance of our approach.

Frontiers of Algorithmic RM

Community Committee Choice Session

Session Chair: Vahideh Manshadi, Yale University, New Haven, CT

Session Chair: Rad Niazadeh, Chicago Booth School of Business, CHICAGO, IL

1 The Prophet Inequality With Buyback

Pranav Nuti[1], Farbod Ekbatani[2], Rad Niazadeh[3], Jan Vondrak[1], [1]Stanford University, Stanford, CA, [2]Chicago Booth School of Business, Chicago, IL, [3]Chicago Booth School of Business, CHICAGO, IL, Contact: pranavn@stanford.edu

Motivated by applications with overbooking and compensation fees upon service denial, we initiate the study of the prophet inequality problem with buyback. In the vanilla prophet inequality, we observe realizations of random variables in an online fashion, and we have to (irrevocably) accept one of the realizations with the goal of maximizing the expected value of our pick. In the prophet inequality with buyback, acceptances are no longer irrevocable. Instead, they can be cancelled at the cost of a fixed multiple f of the realization accepted. In this talk, I will elaborate upon some recent progress towards designing optimally competitive online algorithms for this problem, progress that has resulted in an improvement over a competitive ratio of 1/2 for all choices of the parameter f.

2 Non-Stochastic CDF Estimation Using Threshold Queries

Princewill Okoroafor, Vaishnavi Gupta, Robert Kleinberg, Eleanor Goh, Cornell University, Ithaca, NY

We present an algorithm to estimate the empirical distribution of a scalar-valued data set, when the data are adversarially generated and the algorithm can only ask a limited number of threshold queries about each data point rather than observing it directly. This problem models scenarios where a seller is experimenting with prices to estimate the distribution of consumers' willingness to pay. Our main result quantifies the sample complexity of estimating the empirical CDF of a sequence of numbers, up to an additive error, using one threshold query per sample. The complexity depends only logarithmically on n, extending previous results for noisy binary search to the more challenging setting where noise is non-stochastic. We also characterize the minimum number of simultaneous threshold queries required by deterministic CDF estimation algorithms.

3 Mobility Data in Operations: The Facility Location Problem

Yiding Feng, Ozan Candogan, University of Chicago, Chicago, IL, Contact: yidingfeng2021@u.northwestern.edu

The recent large scale availability of mobility data, which captures individual mobility patterns, poses novel operational problems that are exciting and challenging. Motivated by this, we introduce and study a variant of the facility location problem where each individual is endowed with two locations (hereafter, her home and work locations), and the connection cost is the minimum distance between any of her locations and its closest facility. We design a polynomial-time algorithm and show its approximation ratio is between 3.073 and 3.103. We show that there exists no polynomial-time algorithm with approximation ratio 2 – ?. We further extend our results and analysis to the model where each individual is endowed with K locations. Finally, we conduct numerical experiments over both synthetic data and US census data and evaluate the performance of our algorithms.

4 Secretary and Matroid Secretary Problems with Unknown Number of Candidates

Junhui Zhang[1], Patrick Jaillet[2], [1]MIT, Cambridge, MA, [2]M.I.T., Cambridge, MA

We study variants of the secretary and matroid secretary problems where the number of candidates N is random with distribution p.

For the secretary problem, we show that 1) when p is known, the optimal single-threshold strategy succeeds w.p. at least P^*/e, where P^* is the maximum probability of success among all strategies; 2) when N≤n and n is known,

or E[N]≤μ and μ is known, there are simple strategies which succeed w.p. Ω(1/log(n)) or Ω(1/log(μ)) respectively; 3) if p is uniformly sampled among distributions supported on {1,...,n}, there is an algorithm which succeeds w.p. at least $2/e^2$ with high probability.
For the rank-k matroid secretary problem where the size of the ground size N is random and satisfies $\underline{n}$≤N≤n, we provide a $\Omega((\log(n/\underline{n})\log(\log(k)))^{-1})$-competitive algorithm. We also apply our techniques to prophet inequalities and online LP where the time horizon is random.

Queueing Theory and Applications

Community Committee Choice Session

Session Chair: Daniela Hurtado-Lange, William & Mary, Williamsburg, VA

1 Fork-Join Queues with Redundancy

Chutong Gao, Northwestern University, Evanston, IL, Contact: chutonggao2026@u.northwestern.edu

We consider an n-server fork-join queueing system with redundancy; in this system, n i.i.d. copies of each incoming job are sent to each of the n servers, with k copies required for job completion. We introduce an equivalent two-station tandem queue, in which the service-time distributions in the two stations are dependent, and derive the stability condition for that system. Further, the tandem queue can be represented as a quasi-birth-and-death (QBD) process, so that its stationary distribution can be efficiently computed via matrix-geometric algorithms. We also propose an algorithm to construct the generator of the QBD when the number of copies k is larger than 2, for which the generator has a complex form. Finally, we employ the QBD representation to solve an optimal-design problem.

2 Control of High-Dimensional Reflected Brownian Motion

Baris Ata[1], J. Michael Harrison[2], Nian Si[1], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]Stanford University, Stanford, CA, Contact: baris.ata@chicagobooth.edu

Motivated by applications in queueing theory, we consider the control of Reflected Brownian Motion in the d-dimensional positive orthant. A system manager chooses a drift vector a(t) at each time t based on the history of Z, and the cost rate at time t depends on both Z(t) and a(t). In our initial problem formulation, the objective is to minimize expected discounted cost over an infinite planning horizon, after which we treat the corresponding ergodic control problem. We develop and illustrate a simulation-based computational method that relies heavily on deep neural network technology. For test problems studied thus far, our method is accurate to within a fraction of one percent, and is computationally feasible in dimensions up to at least d = 30.

3 Staff Sharing Under Uncertainty

Yuting Yuan, William & Mary, Williamsburg, VA

As the coronavirus pandemic exacerbates staff shortages, we propose a two-stage staff-sharing rule that effectively utilizes expensive capacities when the uncertainty in demand (e.g., patient arrivals to hospitals during the pandemic) is high. By representing a centralized service system with a queueing model consisting of several units, we derive the optimal sharing policy under the stochastic fluid approximation and quantify the performance gap between the sharing policy and a benchmark policy that staffs each unit independently. A case study using hospital data is provided to demonstrate the practical implementation of the staff-sharing strategy. The simulation results suggest that capacity sharing could have reduced annual Emergency Department costs for three hospitals by at least half a million dollars.

4 Efficient Algorithm For Transient Analysis Of Cox/M/m Queues

Daniela Hurtado-Lange[1], Pengyi Shi[2], [1]Northwestern University, Evanston, IL, [2]Purdue University, West Lafayette, IN

Cox processes have shown to be accurate models for patients arriving to hospitals during the pandemic and crime rates, among others. Due to its doubly stochastic nature, efficient algorithms for transient analysis of queues with Cox arrivals are limited. Existing work mainly focuses on steady-state analysis of queues with periodic arrival rates, infinitely many servers, or the many-server asymptotic regime. In this work, we focus on non-periodic arrival rates and analyze the number of jobs in the system X(t) in Cox/M/m queues with finite m. We develop an efficient algorithm to compute the transient pmf of X(t) and show that our approach is flexible and accurate in terms of the load, the number of servers, and the value of t. We also show that our algorithm provides an accurate pmf when the future arrival rate is unknown but needs to be predicted via some forecast models.

Advances in Queueing Theory

Community Committee Choice Session

Session Chair: Martin Zubeldia, University of Minnesota, Minneapolis, MN

1 Steady-State Limit of a Particle System with Mean-Field Interaction

Alexander Stolyar, University of Illinois at Urbana-Champaign, Urbana, IL

We consider a system of *n* particles, moving forward in jumps on the real line. The jump sizes are i.i.d. The instantaneous jump rate of a particle depends on its location rank w.r.t. other particles. This is a model of peer-to-peer synchronization. Under very mild conditions, we prove that, as *n* becomes large, the limit of steady-states is such that the empirical distribution of particle locations evolves as a deterministic traveling wave. As ingredients of the proof, we obtain uniform steady-state moment bounds and a convergence to mean-field limit result.

2 Reinforcement Learning Algorithms for Queueing Systems

Lei Ying, The University of Michigan, Ann Arbor, Ann Arbor, MI

In this talk, I will present a new reinforcement learning algorithm for queueing networks.

3 The Benefits of Partial Priority

Mor Harchol-Balter, Isaac Grosof, Vanshika Chowdhary, Carnegie Mellon University, Pittsburgh, PA, Contact: harchol@cs.cmu.edu

We introduce the idea of a partial priority queue, where class 1 jobs have only partial priority over class 2 jobs. Specifically, whenever the server is free, it runs a job of class 1 with probability q and class 2 with probability 1-q. Here q can range from 0 to 1. In this talk we discuss analysis and applications for the partial priority queue.

4 Dynamic Routing in Queuing Networks via Differentiable Discrete Event Simulation

Ethan Che[1], Jing Dong[2], Hongseok Namkoong[2], [1]Columbia Business School, New York, NY, [2]Columbia University, New York, NY

Consider the problem of dynamically allocating jobs to servers in general multi-class multi-pool queuing networks. We develop a generic framework for policy optimization in these systems by modeling the environment as a discrete event simulation. This modeling approach can flexibly handle non-stationary and non-Markovian arrivals and services, requires only samples of these events, and accommodates batch parallelism with GPUs. Although these systems lack differentiability, we borrow tools from the machine learning literature to obtain pathwise gradients of performance metrics with respect to the routing actions, which enables the application of gradient-based algorithms for policy optimization. We derive a pathwise policy gradient algorithm and a gradient-based model-predictive controller which outperforms standard policies and is highly scalable.

Learning and Decision Making with Network Data

Community Committee Choice Session

Session Chair: Yeganeh Alimohammadi, Stanford University, Stanford, CA

1 Uniqueness of Low-Depth Neighborhoods and Implications for Learning in Networks

Miklos Racz, Northwestern University, IL

I will discuss recent progress on local canonical labeling algorithms on sparse random graphs and randomly perturbed graphs. I will also discuss implications of these results to average-case and smoothed analysis of graph isomorphism, as well as graph reconstruction problems.

2 On the Impact of Mass Screening for SARS-CoV-2 Through Self-Testing in Greece

Kimon Drakopoulos, University of Southern California, Data Sciences and Operations, Los Angeles, CA

We study the self-testing COVID-19 mass screening program that was implemented in Greece, involving large, susceptible populations taking tests routinely and pre-emptively so as to enable early detection of infections. Using a novel compartmental model we quantify the effectiveness of the program in curbing the COVID-19 pandemic. Conservative estimates indicate that the program reduced the reproductive number by 4%, hospital admissions by 25% and deaths by 20%, which translated into approximately 20,000 averted hospitalizations and 2,000 averted deaths between April-December 2021. Self-testing mass screening programs are efficient interventions with minimal social and financial burden, thus they are invaluable tools to be considered in pandemic preparedness.

3 Optimal Information Disclosure to Maintain Safe Activity Levels

Sohil Shah[1], Saurabh Amin[1], Patrick Jaillet[2], [1]MIT, Cambridge, MA, [2]M.I.T., Cambridge, MA, Contact: sshah95@mit.edu

We investigate the dynamic disclosure of information in non-stationary environments. A planner iteratively discloses information about the efficacy of an immunizing booster that stochastically evolves over time amid long-run spread of disease. Each time period, a heterogeneous mass of agents decide whether they should obtain the booster shot, and then whether to remain isolated or active. The planner's objective is to ensure that the active population remains above a minimum threshold each period. Greedy disclosure minimizes information disclosed subject to the planner maximizing the likelihood of achieving the active population threshold in the current period. We show that greedy disclosure becomes optimal in finite time for settings where the population's belief over the booster's efficacy becomes more pessimistic than the belief required in the long-run.

Learning and Control for Stochastic Systems

Community Committee Choice Session

Session Chair: Debankur Mukherjee, ISyE Georgia Tech, Atlanta, GA

1 Learning to Schedule in Multiclass Many-Server Queues with Abandonment

Yueyang Zhong[1], John R. Birge[2], Amy R. Ward[1], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]University of Chicago, Chicago, IL, Contact: yzhong0@chicagobooth.edu

We consider a learning variant of a canonical scheduling problem in a multiclass many-server queue with abandonment with general service time and patience time distributions (GI/GI/N+GI). The objective is to minimize the long-run average class-dependent expected linear abandonment costs when the distributional and parameter information are a priori unknown. We evaluate the performance by means of regret against the benchmark aμ rule with parameter knowledge. We propose a Learn-Then-Schedule algorithm over T periods, which is composed of a learning phase where statistical estimators of the parameters are formed, and an exploitation phase where an empirically learned aμ rule is followed. It is shown that the smallest achievable regret is $\Omega(\log T)$, and our proposed algorithm achieves a regret upper bound of $O(\log T)$, which matches the lower bound.

2 Control Policies for Telehealth: Connecting Patients to Doctors

Mark E. Lewis[1], Jamol Pender[2], Shuwen Lu[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, [3]Cornell University, Ithaca, NY, Contact: mark.lewis@cornell.edu

We consider a clearing system model for moving patients through a minute clinic equipped with a triage station, the potential for service to be completed with a nurse practitioner (NP) and the possibility of accessing a doctor through telehealth. After initial triage, in some cases, the NP needs to decide whether or not they prefer to connect with a general practitioner. We provide cases in which the optimal control follows intuition and show heuristics perform well when the optimal control is too complicated for implementation.

3 Asymptotic Product-Form Steady-State for Multiclass Queueing Networks with Static-Buffer-Priority Service Policies in Multi-Scale Heavy Traffic

Jim Dai[1], Lucy Huo[2], [1]Cornell University & CUHK-Shenzhen, Ithaca, NY, [2]Cornell University, Ithaca, NY

We establish that when subjected to a multi-scale heavy traffic condition, the stationary distribution of the scaled queue length vector process in multiclass queueing networks, operating under static-buffer-priority service policies, converges to a product-form limit. This convergence is achieved under the assumption of uniform moment bounds. Each component in the product form follows an exponential distribution.

Socially Responsible Operations Decision

Community Committee Choice Session

Session Chair: Amy Williams, Irvine, CA

Session Chair: L. Robin Keller, University of California, Irvine, Corona del Mar, CA

1 Informing Socially Responsible Operations Decision with Stated Choice Data

Katherine Silz-Carson, Air force Academy, CO

Data about consumers' stated choices can sometimes provide useful information to inform socially responsible operations decision-making. However, some aspects of socially responsible operations have characteristics that resemble markets for public goods. In these settings, data about consumer choices can sometimes provide biased information and lead to sub-optimal decisions. This paper discusses potential problems with the validity of consumer choice data in various choice settings, the implications for socially responsible operations decision-making, and potential avenues for new research on consumer choices in these settings.

2 Behavioral Analysis Of Needs Reporting And Fund Allocation In Humanitarian Response

Bengisu Urlu[1], Karen L. Donohue[2], [1]INSEAD, Fontainebleau, France; [2]University of Minnesota, Minneapolis, MN, Contact: bengisu.urlu@insead.edu

When a disaster strikes, an accurate assessment of required funds for the response is crucial to utilize scarce resources for the greatest good. Humanitarian organizations (HOs) evaluate the needs of the crisis-affected population and report the required amount of funds for the response. Donors then allocate their budget based on these reports. In this study, we explore how environmental factors, such as the nature of private information, level of competition, and varying budget levels, influence HOs' reports and their display of trustworthy behavior. We also examine donor responses to these reports and their impact on humanitarian outcomes.

3 Environmentally Conscious Consumers and Retail Purchasing and Returning Behavior

Amy Williams[1], L. Robin Keller[2], [1]University of California, Irvine, Irvine, CA, [2]University of California, Irvine, Corona del Mar, CA

Product returns are environmentally taxing due to the transportation, repackaging, and waste costs accumulated by a returned item. Surprisingly, our first lab study found that more environmentally conscious participants are more likely to purchase multiple sizes of the same item at once and, consequently, return more frequently. Next we modeled this behavior analytically and confirmed that this purchasing behavior is, in fact, less environmentally friendly, in more cases. Through this analysis, we identified ways in which retailers might be able to curb this behavior: by offering more transparency around what will happen to a returned product. We then tested this in a second lab study and found that providing more transparency around what happens to a returned product does significantly reduce environmentally costly customer purchase habits.

Understanding and Disrupting Illegal Supply Chains

Community Committee Choice Session

Session Chair: N. Orkun Baycik, Boston University, Boston, MA

1 Nation's Fight Against Illegal Fishing: A Research Agenda for OR/OM Community

Canan Gunes Corlu, N. Orkun Baycik, Alyssa Pierson, Greg McDaniel, Boston University, Boston, MA, Contact: canan@bu.edu

Illegal, Unreported, and Unregulated (IUU) fishing destroys our environment, economy, and society. It allows other illegal activities such as human trafficking and drug trafficking to take place in the ocean and onshore. The goal of this talk is to present the operational aspects of IUU fishing networks and discuss research opportunities for OM/OR scholars in fighting against these illegal activities.

2 Interdiction of Wildlife Trafficking Supply Chains: An Analytical Approach

Emily C. Griffin[1], Aaron Ferber[2], Burcu B. Keskin[3], Bistra Dilkina[4], Meredith Gore[5], [1]Babson College, Babson Park, MA, [2]University of Southern California, Los Angeles, CA, [3]University of Alabama, Tuscaloosa, AL, [4]USC, Los Angeles, CA, [5]University of Maryland, College Park, MD

Illicit Wildlife Trade (IWT) is a serious global crime that negatively impacts biodiversity, human health, national security, and economic development. Many flora and fauna are trafficked in different product forms. We investigate a network interdiction problem for wildlife trafficking and introduce a new model to tackle key challenges associated with IWT. We incorporate vital issues unique to IWT, including the need for training and difficulty recognizing illicit wildlife products, the impact of charismatic species and geopolitical differences, and the varying amounts of information and objectives traffickers may use when choosing transit routes. We present solutions for several key IWT supply chains using realistic data from conservation research, seizure databases, and international reports.

3 When or Meets the Street: Interdicting Interdependent Human Trafficking Networks
Felipe Aros-Vera, Ohio University, Athens, OH, Contact: aros@ohio.edu
This presentation will walk the audience through the challenges of implementing Network Interdiction Models (NIMs) in the real world. Starting from a solid theoretical foundation, NIMs promise to deliver new tools in the fight against Human Trafficking (HT). However, the implementation of such tools can be a great challenge when: data are unavailable, police enforcement does not see the value, and academics are seen as a liability more than a help. Funded by DOJ, the authors embarked on providing technology and methods to the Cuyahoga HT Task Force in its daily efforts to crack down on modern slavery in the streets of Cleveland.

4 Classification Methods for Decision Making in Illegal Drug Trafficking Networks
N. Orkun Baycik, Boston University, Boston, MA
This study focuses on a machine learning application in deciding law enforcement actions against illegal drug trafficking activities. In such illegal supply chains, there may be different types of criminals such as drug manufacturers, drug dealers, and drug users. Law enforcement may choose to arrest the "known" criminals as soon as they identify that they are indeed a criminal. On the other hand, they may decide to "target" them for a period of time with the goal of accessing higher ranked criminals. By using classification methods, our goal is to develop approaches to assist in this decision-making process. Computational experiments compare the resulting decisions with the optimal decisions.

Data Driven Approaches in Social and Sustainable Operations

Community Committee Choice Session

Session Chair: Somya Singhvi, USC Marshall School of Business, Los Angeles, CA
Session Chair: Amrita Kundu, McDonough School of Business, Georgetown University

1 Optimal Design of Default Donations
Scott Rodilitz, UCLA Anderson School of Management, Los Angeles, CA
Nonprofit organizations commonly use *default* suggested donations to increase fundraising revenues, but they often determine these default options in an ad hoc way. Towards optimizing the design of nonprofits' default donation menus, we present a modeling framework where prospective donors have an ideal donation amount (determined by a concave utility function) and also derive a small utility gain from selecting a default option. We first characterize the optimal personalized default menu when the nonprofit has full information about the donor, including their ideal donation amount. We then take a competitive analysis approach and assess the maximum achievable revenue gain in the absence of personalization. For such settings, we also present a dynamic program to efficiently solve for the optimal default menu.

2 Towards Global, General-purpose Geographic Location Encoders
Konstantin Klemmer, Microsoft Research New England, Cambridge, MA
Geospatial data is common across a wide range of disciplines and modeling tasks, e.g. in ecology or urban analytics. Location features are often not readily available and need to be obtained via individual data collection and fusion. This opens the opportunity for a new class of "foundation models": global, general-purpose geographic location encoders, which provide vector embeddings summarizing the characteristics of a location for convenient usage in downstream tasks. I propose training such a location encoder using multi-spectral Sentinel-2 satellite data. I show that the trained encoder can be used for a broad range of predictive out-of-domain tasks like house price prediction and animal recognition. I then systemically compare this model to existing location encoders, ranging from models trained on natural images or semantic context to large language models.

3 Sustainable Sourcing Enhances Product Durability: Evidence Fromleadacid Batteries for Electric Three Wheelers in Bangladesh
Amrita Kundu[1], Erica Plambeck[2], Qiong Wang[3], [1]McDonough School of Business, Georgetown University, Washington, DC, [2]Stanford University, Stanford, CA, [3]University of Illinois Urbana-Champaign, Champaign, IL
We empirically assess the impact of informal recycling practices on product quality and durability of lead acid batteries (LABs). With increase in adoption of green technologies and due to weak regulatory capacity, informal recycling of LABs has become rampant in developing countries. In Bangladesh, 2 out of 3 children suffer from lead exposure, largely due to informal recycling of used LABs in

"open-pit bhattis". Our analysis of a large LAB manufacturer's warranty claim and lead sourcing data suggests that informal recycling of lead in the circular economy for LABs significantly decreases the quality and durability of batteries, resulting in direct warranty costs and indirect conformance quality costs for the manufacturer. This economic motivation for manufacturers to source sustainably can be used as a lever to increase formal recycling in developing countries.

4 A Data-Driven Approach to Improve Artisans' Productivity: Empirical Evidence from India

Divya Singhvi[1], Somya Singhvi[2], Xinyu Zhang[3], [1]New York University, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA, [3]New York University Stern School of Business, New York, NY

Despite their vital role in rural economy, artisanal supply chains continue to be plagued by low productivity and the highly fragmented nature of their upstream. This study presents research conducted in close collaboration with a leading exporter of handmade rugs in India, aimed at improving artisans' productivity in distributed supply chains. We provide robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity. Our analysis also suggests that this impact is heterogeneous, with visits to more complex rugs, and visits that are more consistent, leading to maximum productivity gains. To capitalize on these insights, we propose a novel predict-then-optimize framework for optimizing supervisor visits in the supply chain and we see significant productivity improvement from extensive numerical analysis.

Decision-making in a Contested Environment

Community Committee Choice Session

Session Chair: Stephen Donnel, Air Force Institute of Technology, WPAFB, OH

Session Chair: Carson Long, Air Force Institute of Technology (AFIT), Dayton, OH

1 Indiscriminate Disruption of Conditional Inference on Multivariate Gaussians

William Caballero[1], Alexander Fisher[2], Matthew LaRosa[1], Vahid Tarokh[2], [1]United States Air Force Academy, United States Air Force Academy, CO, [2]Duke University, Durham, NC

The multivariate Gaussian distribution is a fundamental probabilistic model underpinning myriad applications and, given recent advances in adversarial machine learning, it is important to revisit how a malicious actor may corrupt inference relying upon it. Therefore, we consider an attacker who wishes to disrupt a decisionmaker's conditional inference by corrupting a set of evidentiary variables while also maintaining attack plausibility. In this setting, we consider both whitebox and greybox conditions such that the attacker has complete and incomplete knowledge about the decisionmaler's distribution, respectively. The problems are shown to reduce to quadratic and stochastic quadratic programs. We derive proofs that explore the problems' structure. Benchmarking showcases the impacts of these attacks on multiple, realistic case studies.

2 A Stackelberg Framework for Disrupting Coordinated, Multi-Asset Routing and Sequential Servicing of Demand

Stephen Donnel, Air Force Institute of Technology, Dayton, OH

Complex, contested routing inspired the development of a bilevel multiple asset sequential routing problem. Wherein the lower-level route to minimize the total sum of final delivery of the penultimate asset type required at all demand nodes as the upper-level, given a limited budget for arc disruptions, seek to maximize the same objective. A Greedy Construction Heuristic finds an initial solution strategy by incrementally adding delaying actions. Two simulated-annealing-inspired solutions attempt to improve this initial solution. In the first, delaying actions are shifted, with predominantly random decisions. The second adjusts solutions by moving an action affecting routing least to an area where the current route is most affected.

3 A Multi-Objective, Bilevel Programming Methodology to Identify Transportation Distribution Network Vulnerabilities

Carson Long, Air Force Institute of Technology (AFIT), Dayton, OH

Transportation of material over ground distribution networks is subject to both man-made and natural disruptions. This research sets forth a multi-objective bilevel linear program to identify, quantify, and characterize network vulnerabilities for a defender solving a multi-objective material routing problem, given an adversary conducting a limited number of arc-specific, spatiotemporal attacks driven by competing objectives. Examining an instance comprised of real-world network topology, this research examines the efficiency of

NSGA-II to search the upper-level decision space and identify high quality solutions, subject to the defender's lexicographic prioritization over its multiple objective functions.

4 Preventing Double-Counting in Data Fusion: A Network Topology-Based Approach

Sangeeth Panthakkal Das, Alexander Nikolaev, University at Buffalo, Buffalo, NY, Contact: spanthak@buffalo.edu

Double-counting, or data incest, may occur when nodes (sensors) of a decentralized communication network make estimates based on shared signals forwarded with no overheads: when the same signals reach the nodes via multiple paths, such duplication leads to wrong estimation and waste of resources. This work introduces loop-graph based protocols that prevent double-counting, minimizing the network-wide communication delay and nodes' energy expenditures.

Responding Climate Crisis with Data-Driven OM

Community Committee Choice Session

Session Chair: Ilgin Dogan, University of California, Berkeley, Berkeley, CA

Session Chair: Zuo-Jun Max Shen, University of California Berkeley, Berkeley, CA

1 Optimal Maintenance and Inspection Policy for Power Grids

Abolfazl Taghavi[1], Reza Ahmadi[2], Sriram Dasu[3], [1]UCLA Anderson School of Management, Los Angeles, CA, [2]UCLA, Los Angeles, CA, [3]University of Southern California, Los Angeles, CA

Wildfires have a significant impact on the environment, society, and infrastructures. During the last decades, the behavior of wildfires has changed significantly and become more severe. In addition, climate change and wildland-urban interface expansion made the wildfire problem even more challenging than it was in the past. As a result, wildfire management is becoming significantly important in the US and other countries. In 2018, PG&E, the largest utility company in California, almost went bankrupt because of igniting the campfire. Since then, utility companies have initiated several programs to reduce the fire ignition probability across their power grid, including maintenance and inspection of the power grid elements. In this project, we present an optimal inspection and maintenance policy for the utilities' power grid.

2 Do Noisy Customer Reviews Discourage Platform Sellers? Empirical Analysis of an Online Solar Marketplace

Herbie Huang[1], Nur Sunar[1], Jayashankar M. Swaminathan[2], Rahul Roy[1], [1]UNC Kenan-Flagler Business School, Chapel Hill, NC, [2]University of North Carolina Chapel Hill, Chapel Hill, NC

For this project, we collaborated with one of the largest online solar marketplaces in the U.S. that connects potential solar panel adopters with installers. We empirically study how the review dispersion affects a seller's activity level and the number of matches in an online marketplace with active sellers.

3 Estimating and Incentivizing Imperfect-Knowledge Agents with Hidden Rewards: An Example from Green Energy Aggregators

Ilgin Dogan[1], Zuo-Jun Max Shen[2], Anil Aswani[3], [1]University of California, Berkeley, Berkeley, CA, [2]University of California Berkeley, Berkeley, CA, [3]UC Berkeley, Berkeley, CA, Contact: ilgindogan@berkeley.edu

As opposed to many principal-agent models, incentive providers in practice often cannot observe the reward realizations of incentivized agents. This information asymmetry challenges principal to consistently estimate agent's unknown rewards and steer its choices by solely watching their actions - which becomes even more challenging when these actions carry the selfish agent's learning uncertainty. We explore this practically relevant scenario of repeated adverse selection game within a multi-armed bandit framework and design: i) a consistent estimator for agent's rewards from a bounded continuous space, ii) a low-regret adaptive incentive policy inducing incentive compatibility. We prove finite-sample concentration of our estimator and a rigorous regret bound of the proposed policy - supported by our numerical results for green energy aggregator contracts.

4 Estimating the Impact of Climate Change: An Empirical Analysis of Smart Thermostat Data

Saed Alizamir[1], Michael Blair[1], Shouqiang Wang[2], [1]Yale University, New Haven, CT, [2]The University of Texas at Dallas, Richardson, TX, Contact: saed.alizamir@yale.edu

Using a rich micro-level dataset, we empirically analyze smart thermostat data to understand the relationship between households' thermostat settings and their ambient environment. We combine a variety of methodological tools including Dynamic Linear Models, random effects, and Bayesian Statistics, to develop models for short- and long-term behavior. Using established models we create realistic estimates of future weather conditions under a variety of climate change scenarios. We combine these scenarios with our statistical model to estimate the impact of climate change. Specifically, we predict future household behavior and investigate the resulting changes in consumption. The insights derived from our research provide a valuable framework to evaluate and design interventions such as smart nudging or demand response management programs.

Emerging Topics in Behavioral Service Operations

Community Committee Choice Session

Session Chair: Stephen Leider, University of Michigan, Ann Arbor, MI

Session Chair: Clare Snyder, University of Michigan - Ross School of Business, Ann Arbor, MI

1 Algorithm Reliance for Binary Classification Tasks: Implications for Fairness

Clare Snyder[1], Samantha Meyer Keppler[2], Stephen Leider[2], [1]Michigan Ross, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: claresny@umich.edu

Feedback plays a critical role in the way people use decision-support algorithms; people are averse to algorithms after seeing them err but may also learn from feedback over time when algorithms are helpful. But feedback from binary classification tasks is censored - true outcomes are only seen if an action is taken. For example, a lender can only know if a borrower will repay a loan if that loan is awarded. How will people use and learn about algorithms to make binary classifications? What implications does this have for algorithm design (i.e., about the false +/false - tradeoff)? We answer these questions with simulations and results from laboratory experiments. Our results have natural implications for algorithmic fairness, and we extend our work with a follow-up study on the consequences of “fair” algorithms for algorithm reliance, accuracy, and fairness outcomes.

2 Discretionary Task Under Operating and Peer Performance: Evidence from the Emergency Department

Diwas S. KC[1], Blair Liu[2], Bradley R. Staats[3], [1]Emory University, Atlanta, GA, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: Blair_Liu@kenan-flagler.unc.edu

This research examines operating factors affecting knowledge workers’ discretionary test ordering in an emergency department (ED), focusing on workload, remaining shift time, prior interactions, and relative peer performance. With data from a healthcare system’s ED in a major US city, we perform econometric analysis of over 50,000 patient observations over a year. The result shows workload and time remaining in shift significantly influence test ordering. Prior patient familiarity reduces test ordering, while relative peer performance also impacts this. The study highlights that an additional test decreases 30-day patient revisits but prolongs ED stays, offering managerial implications like standardizing test ordering, balancing workload and shift time, and incorporating past interactions and relative peer performance in staffing decisions.

3 Redesigning Shift Work to Incorporate Heterogeneous Worker Preferences

Harriet Jeon[1], Song-Hee Kim[2], Hummy Song[1], Kyeongsug Kim[3], Sangwoon Cho[3], Jeong Hee Hong[3], [1]The Wharton School, University of Pennsylvania, Philadelphia, PA, [2]Seoul National University, Gwanak-gu, Korea, Republic of; [3]Samsung Medical Center, Seoul, Korea, Republic of. Contact: hyjeon@wharton.upenn.edu

Shifts are the dominant way to work in many contexts requiring 24/7 coverage, including call centers, police departments, and hospitals. While the detriments of shift work are well-documented both at the individual and organizational levels, its deployment is often unavoidable given round-the-clock staffing needs. We explore a potential organizational lever—incorporating heterogeneous preferences over shift design—to mitigate ramifications of shift work in the context of acute care bedside nurses. Using survey, administrative, and shift data, we examine whether and the extent to which individual choice over dimensions of their shifts mitigates the impact of shift work on work (dis) satisfaction and turnover of nurses.

4 Incentive Design for Good Advice

Jing Li, Xiao Zhang, Fei Jia, Saint Louis University, Saint Louis, MO, Contact: fei.jia@slu.edu

Advice from those who have experience with a decision problem is often believed to be beneficial for decision making. However, if predecessors do not properly update their evaluation of decision options based on their experience, they may fail to pass the information obtained from their experience to their successors. This could lead to a worse outcome than in the absence of advice, since the entire group of decision-makers may herd on an inferior choice due to bad advice. We design (non-)monetary incentives to induce good advice in lab experiments. We also study the impact of risk preference on advice giving and taking behaviors. Our results shed light on how online advice/review systems could be improved.

HAS Distinguished Speakers Session

Community Committee Choice Session

Session Chair: Jonas Oddur Jonasson, MIT Sloan School of Management, Somerville, MA

Session Chair: Mariel Sofia Lavieri, University of Michigan, Ann Arbor, MI

1 Modeling to Inform Strategies for Disease Eradication: The Case of Guinea Worm Disease

Pinar Keskinocak[1], Hannah Smalley[1], Tyler Perini[2], Christopher Hanna[3], Yifan Wang[4], Julie L. Swann[5], Adam Weiss[6], [1]Georgia Tech, Atlanta, GA, [2]Rice University, Houston, TX, [3]Global Project Partners, Chicago, IL, [4]Georgia Institute of Technology, Atlanta, GA, [5]North Carolina State University, Raleigh, NC, [6]Carter Center, Atlanta, GA, Contact: pinar@isye.gatech.edu

In the 1980s, WHO declared commitments to globally eradicate Guinea Worm disease and Polio. The prevalence of these diseases has dramatically decreased, but eradication efforts faced many challenges during the endgame or "last mile." We built an agent-based simulation model to analyze the disease transmission of Guinea Worm disease among dogs in Chad. We analyzed intervention strategies, namely, tethering, Abate®, and a potential diagnostic test. Our results show that tethering and Abate need to increase above historical levels to achieve disease elimination, and suggest how best to target limited resources and reach elimination faster. A diagnostic test could be successful in conjunction with these interventions and support elimination efforts; benefits of a test rely heavily on dog selection, frequency, and education about the importance of tethering compliance.

2 Modeling the Impact of Community First Responders

Shane G. Henderson[1], Pieter van den Berg[2], Oceane Fourmentraux[3], Caroline Jagtenberg[4], Hemeng Li[5], [1]Cornell University, Ithaca, NY, [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]Rotterdam School of Management, Rotterdam, Netherlands; [4]NULL, NULL, [5]Cornell University, Ithaca, NY, Contact: sgh9@cornell.edu

Patient survival from out-of-hospital cardiac arrest (OHCA) can be improved by augmenting traditional ambulance response with the dispatch of community first responders (CFRs) who are alerted via an app. How many CFRs are needed, from where should CFRs be recruited, and how should they be dispatched? We use a combination of Poisson point process modeling and convex optimization to address the first two questions; the right areas from which to recruit are not always obvious, because CFRs recruited from one area may spend time in various areas across a city. We use a combination of dynamic programming and decision trees to answer the last question, balancing the goal of a fast response to the current patient with the need to avoid disengagement of CFRs that arises when multiple CFRs respond. A case study for Auckland, New Zealand demonstrates the ideas.

Bonder Scholars Session

Community Committee Choice Session

Session Chair: Katherine Adams, University of Wisconsin-Madison, Monona, WI

1 Personalizing Tuberculosis Treatment Adherence

Justin J. Boutilier[1], Jonas Oddur Jonasson[2], [1]University of Wisconsin - Madison, Madison, WI, [2]MIT Sloan School of Management, Cambridge, MA

Tuberculosis (TB) is a global health emergency and low treatment adherence among patients is a major barrier to ending the TB epidemic. The WHO promotes digital adherence technologies as facilitators for improving treatment adherence in resource-limited settings. We propose analytical tools to personalize TB treatment adherence support and demonstrate their potential using data from Kenya.

2 Planning a Personalized Community Health Worker Intervention for Diabetes Care in Low- and Middle-Income Countries

Katherine B. Adams[1], Justin J. Boutilier[2], Sarang Deo[3],

Yonatan Mintz[4], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin - Madison, Madison, WI, [3]Indian School of Business, Hyderabad, India; [4]University of Wisconsin Madison, Madison, WI, Contact: kbadams@wisc.edu

Diabetes is a global health priority that disproportionately affects low- and middle-income countries (LMICs). In addition to being home to almost 90% of people with undiagnosed diabetes, it is estimated that fewer than 10% of people with diabetes in LMICs receive guideline-based diabetes treatment. Several studies have demonstrated the feasibility of using Community Health Worker (CHW) programs to provide affordable and culturally tailored solutions for early detection and management of diabetes. We propose an optimization framework to personalize CHW visits to maximize glycemic control at a community-level while trading off screening and management decisions. We present structural and computational results using real data from India.

3 Interpretable Policy Design with Application to Hypertension Treatment Planning

Gian-Gabriel P. Garcia[1], Lauren N. Steimle[2], Wesley Javier Marrero[3], Jeremy Sussman[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Tech ISyE, Atlanta, GA, [3]Dartmouth College, Hanover, NH, [4]Michigan Medicine, Ann Arbor, MI, Contact: giangarcia@gatech.edu

Effective hypertension management is critical for mitigating the consequences of atherosclerotic cardiovascular disease. Despite their potential for improved health outcomes, model-based treatment recommendations may be clinically unintuitive, limiting their acceptance in clinical practice. Hence, we formulate and solve the *interpretable treatment planning problem,* which aims to generate a clinically intuitive and dynamic treatment policy that maximizes patient health outcomes. In a case study on hypertension treatment planning, our interpretable treatment policies achieve 3,246 quality adjusted life years per 100,000 patients over clinical guidelines, are more intuitive than the optimal policy, and are less than 0.5% worse than the optimal policy.

4 Mass Vaccination Scheduling: Trading off Infections, Throughput, and Overtime

Shanshan Luo, Steven Shechter, University of British Columbia, Vancouver, BC, Canada. Contact: shanshan.luo@sauder.ubc.ca

Mass vaccination is essential for epidemic control, but long queues can increase infection risk. We focus on scheduling arrivals at mass vaccination sites to minimize a tri-objective function of infection risk, throughput, and overtime. Leveraging multi-modularity results from a related optimization problem, we construct a solution algorithm and find that our model-based policy significantly outperforms an equally-distributed, equally-spaced schedule. We also discuss managerial insights regarding the optimal schedule's structure and compare it to the well-known "dome-shaped" policies in appointment scheduling problems.

Data-driven Healthcare Operations

Community Committee Choice Session

Session Chair: Paola Martin, Indiana University, Bloomington, IN

Session Chair: Diwakar Gupta, University of Texas, Austin, TX

1 Health Service Delivery: Does Robot-Assisted Surgery Play a Role?

Sung Joo Kim, Jianing Ding, Susan F. Lu, Purdue University, West Lafayette, IN, Contact: kim3245@purdue.edu

We investigate the role of an emerging AI-based clinical treatment method, robot-assisted surgery (RAS), in transforming the healthcare delivery. As an advanced technique to help diminish the human physical and intellectual limitations in surgeries, RAS is expected to but has not been empirically proven to improve clinical performance. In this study, we first examine the effect of RAS on clinical outcomes, controlling physicians' self-selection behavior in choosing whether or not to use RAS treatment methods. In particular, we focus on the accessibility of RAS and explore how physician and patient heterogeneity affect the adoption of the RAS method, including learning and using RAS. Investigating the decision making process on RAS implementation in both learning and using stages, we show the synergy of RAS implementation in alleviating healthcare racial disparity.

2 Learning from Unfolding Dynamics: Forecast-Driven Adaptive Scheduling in Multi-Service Non-Stationary Queues

Sohom Chatterjee, Youssef Hebaish, Hrayer Aprahamian, Lewis Ntaimo, Texas A&M University, College Station, TX

We consider the problem of scheduling scarce resources in multi-service queues with time-varying demand. As arrivals unfold, future estimates may shift, necessitating a schedule

update. Our approach combines optimization techniques with a novel forecasting method that learns from evolving dynamics, enabling the creation of adaptive policies. The auto-regressive model incorporates period-dependent trends and lagged orders, calibrated via a sub-optimization problem. The model can handle limited data, making it an attractive alternative to data-hungry methods. This is complemented by a tractable reformulation scheme, utilizing a pointwise transient approximation approach to reduce wait times. Through a case study on Texas A&M's counseling center, we illustrate the benefits of our methodology in enhancing students' access to vital mental health services.

3 Towards a New Kidney Transplant Allocation System

Elijah Pivo[1], James Alcorn[2], Dimitris Bertsimas[3], Sarah Booker[2], Keighly Bradbrook[2], Thomas Dolan[2], Nikolaos Trichakis[1], [1]MIT, Cambridge, MA, [2]UNOS, Richmond, VA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: elipivo@gmail.com

We worked with the Organ Procurement and Transplantation Network (OPTN) Kidney Transplantation Committee to develop a new national kidney allocation policy, with the goal of making allocation more efficient and more equitable. We deployed a high-speed algorithm that enabled thousands of simulations, a powerful interactive web-based policy analysis tool, and advanced analytics for policy design using optimization. At the time of writing, four policies created with our methods are advancing towards becoming national policy. Compared to current policy, simulation results show significant gains in fairness metrics with no loss in utility metrics. We anticipate that by applying modern analytics, the transplantation system can produce fairer and better outcomes for patients.

44 Hotspots for Emerging Epidemics: Multi-Task and Transfer Learning over Mobility Networks

Mehmet Ahsen[1], Sebastian Souyris[2], Ujjal Kumar Mukherjee[3], Shuai Hao[4], Anton Ivanov[1], Sridhar Seshadri[5], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]University of Illinois, Urbana-Champaign, Champaign, IL, [4]University of Illinois Urbana-Champaign, Champaign, IL, [5]University of Illinois, Champaign, IL

A new data-driven framework proposes identifying significant infection diffusion locations, known as hotspots, for effective epidemic mitigation like COVID-19. The framework employs advanced analytical methods, including interpretable long short-term memory models, multi-task learning, and transfer learning. It considers within- and across-location mobility as the primary driver of infection diffusion within a network of connected locations. Transfer learning from past influenza transmission data enhances infection diffusion and hotspot detection. Comparisons with infection load-based and state-wide lockdown policies demonstrate that the hotspot-based approach can reduce new infections by up to 21% while achieving performance similar to a state-wide lockdown. By incorporating transfer learning, hotspot prediction accuracy improves by 53.4%.

Primary Care Treatment Allocation and Scheduling

Community Committee Choice Session

Session Chair: Alba Olivares Nadal, 1</sup

Session Chair: Daniel Adelman, University of Chicago, Booth School of Business, Chicago, IL

1 Optimizing Treatment Allocation to Maximize the Health of a Population

Daniel Adelman[1], Alba Olivares-Nadal[2], [1]University of Chicago, Booth School of Business, Chicago, IL, [2]University of New South Wales, New South Wales, Australia. Contact: dan.adelman@chicagobooth.edu

We use MDPs to model the task of optimally allocating treatment amongst patients while fulfilling capacity constraints. The complexity of such a problem may be very high because healthcare populations may be large enough that gathering information of the current status of each patient and tracking the evolution of their covariates is untenable. To address this challenge we develop the so-called measurized theory, which allows to model MDPs that optimize the distribution of treated and untreated patients instead of dealing with identifed patients. This abstraction transforms a complicated problem into an intuitive formulation and sets the stage for delivering clinically implementable solutions.

2 Primary Care Continuity, Frequency, and Regularity Associated with Reduced Medicare Spending

Dilara Sonmez[1], Dan Adelman[1], George Weyer[2], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]The University of Chicago Medicine, Chicago, IL, Contact: dsonmez@chicagobooth.edu

Reducing Medicare expenditures is a key objective of Medicare's transition to value-based reimbursement models. Improving access to primary care is seen as an important way to reduce expenditures, yet less is known about how primary care visits should be organized to maximize patient-level savings. This retrospective cohort study aims to examine the relationship between outcomes (savings in Medicare expenditures, risk-adjusted number of emergency department visits, and risk-adjusted number of hospitalizations) and the primary care practice patterns (visit frequency, regularity, and continuity of care).

3 Robust Appointment Scheduling with Waiting Time Guarantees

Carolin Isabel Bauerhenne, Rainer Kolisch, Andreas S. Schulz, Technical University of Munich, Munich, Germany. Contact: carolin.bauerhenne@tum.de

Appointment scheduling under uncertainty encounters a fundamental trade-off between capacity utilization and customer waiting times. Most existing approaches tackle this trade-off using a weighted sum approach, resulting in a low consideration of individual waiting times and thus customer dissatisfaction. In contrast, we study how to maximize capacity utilization while guaranteeing acceptable waiting times. Therefore, we derive a mixed-integer linear program in a robust optimization framework. We prove that the general problem is NP-hard and present optimal polynomial-time scheduling and sequencing rules for special cases. A case study with real data from a large radiology demonstrates that our approach not only guarantees acceptable waiting times but, compared to existing weighted-sum approaches, can also reduce costs incurred by idle time.

Causal Inference in Healthcare

Community Committee Choice Session

Session Chair: Kevin Smith, University of Michigan, Ann Arbor, MI

1 Estimating Activity and Sleep Goals for Bipolar Disorder Patients

Sidian Lin, Soroush Saghafian, Jessica M. Lipschitz, Harvard University, Cambridge, MA

The development of mobile health technologies gives rise to the possibility of long-term monitoring for chronic diseases such as mental disorders. In this study, we focus on bridging causal inference and offline reinforcement learning to give better treatment suggestions to bipolar disorder patients. We also share some insights on how to translate causal inference and offline RL techniques to the complex real-world data. Given that mood transitions widely exist in most mental disorders, such design can be easily applied to other mental illnesses where new policies can be learned and evaluated in a more accurate and safer way.

2 Out-of-Distribution Generalization in Health

Aahlad Puli, [1</sup]

Machine learning models can speed up diagnosis from radiological images which in turn can improve patient outcomes or reduce treatment-cost. However, models built on a fixed dataset from one hospital are known to lose performance, sometimes catastrophically, when deployed at a different hospital due to dependance on unstable correlations . We employ insights from causality to couple the data generating processes in training and in deployment into a family of distributions. We develop Nuisance-Randomized Distillation (NuRD) to build models that enjoy performance guarantees on every member of the family. NuRD builds representations that separate the spurious and non-spurious signals in the covariates and predicts the labels with non-spurious ones. NuRD improves test performance on Pneumonia and Cardiomegaly detection from chest X-rays.

3 Federated and Transfer Learning to Estimate Causal Effects of Underrepresented Populations

Larry Han[1,2], Yi Zhang[3], Sharon-Lise Normand[4], Rui Duan[1], [1]Harvard University, Boston, MA, [2]Northeastern University, Boston, MA, [3]Harvard University, Cambridge, MA, [4]Harvard Medical School, Boston, MA, Contact: larryhan@g.harvard.edu

Federated or multi-site studies can improve the power to estimate treatment effects for patient subgroups, but privacy constraints often preclude the sharing of patient-level data. We develop a novel causal inference framework to incorporate information from *multiple sites* and *multiple populations* to make inferences on the causal effect for an underrepresented target population of interest. Our method leverages *transfer learning* and *federated learning* to data-adaptively incorporate summary-level information from source populations and sites. In extensive simulations, we show that the proposed method substantially improves the estimation accuracy of treatment effects for underrepresented target populations. We illustrate our method through a study of surgical outcomes for congenital heart defects across all 120 congenital heart centers in the U.S.

4 Optimal Interpretable Sequential Decision Making

Kevin Smith, Siqian Shen, Brian T. Denton, Industrial and Operations Engineering, University of Michigan, Ann Arbor, MI, Contact: kvbsmith@umich.edu

In healthcare domains, experiments are often impractical or impossible. Therefore, models developed using accurate cause and effect relationships are crucial to achieve optimal policies; moreover, the interpretability of such policies is particularly important in the healthcare domain to achieve clinical buy in and successful implementation. Achieving these dual goals of accuracy and interpretability using models built based on observational data is challenging due to sources of confounding. In this presentation we discuss relevant factors in estimating accurate and interpretable policies in the context of health decisions making. We present a case study in the context of health interventions to motivate the importance of these considerations.

Operations Management Downstream in the Supply Chain: Empirical Research Applications

Community Committee Choice Session

Session Chair: Elliot Rabinovich, Arizona State University, Tempe, AZ

Session Chair: Lina Wang, The Pennsylvania State University, State College, PA

Session Chair: Stanley Lim, Michigan State University, East Lansing, MI

1 Omnichannel Grocery Retail: Fulfillment Revenue Models and Operational Impact

Stanley Lim[1], Elliot Rabinovich[2], Rui Sousa[3], Park Sungho[4], [1]Michigan State, Lansing, MI, [2]Arizona State University, Tempe, AZ, [3]Catholic University Portugal, Porto, Portugal; [4]Seoul National University, Seoul, Korea, Republic of. Contact: elliot.rabinovich@asu.edu

We examine empirically the use of alternative fulfillment revenue models in omnichannel grocery retail and their effects on revenue, consumer purchasing behavior, and costs. we draw from these effects to develop prescriptive analyses on improvements to these revenue models. Our analyses are informed by a collaboration with a national grocery retail chain with store operations and direct-to-consumer deliveries across hundreds of urban and rural markets in their home country.

2 Do Virtual Showrooms Payoff? Evidence From A Quasi-experiment

Sina Golara[1], Nasim Mousavi[2], Subodha Kumar[3], Jesse Bockstedt[2], [1]Georgia State University, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]Fox School of Business, Temple University, Philadelphia, PA

With increasing consumer interest in "research online, purchase offline" (ROPO), automobile dealerships retailers have increasingly introduced virtual showrooms. Yet research is not conclusion on how this strategy affects retailer performance. Notably, the pre-sale information revealed in virtual showrooms can attract more customers or encourage free-riding and hurt performance. We document a strong and positive effect following virtual showroom roll-out by analyzing a sample of 20,372 U.S. dealerships over 16 months using difference-in-difference and matching methods. Interestingly, we find different types of competition (within- and between-brand) moderate this effect in opposite ways. We also find a complementary relationship between online reputation and virtual showrooms, where "stars" rise even further post-adoption of this service.

3 Assessing the Impact of Brand-Level ESG Violations on Sales

Yao Chen[1], M. Serkan Akturk[1], Rakesh Reddy Mallipeddi[2], Arvind Mahajan[3], [1]Clemson University, Clemson, SC, [2]Th Ohio State University, Columbus, OH, [3]Texas A&M University, College Station, TX

Employing retail transaction data and firm-level environmental, social, governance (ESG) information, our research investigates the impact of firms' ESG violations on their operational performance. We show that ESG violations lead to decreased sales for brands. Furthermore, store location and customer demographics moderate the relationship between ESG violations and brand sales. We also conduct several robustness analyses to make sure that our results are consistent.

4 Modeling Drivers' Choices in a Crowdsourced Delivery System

Lina Wang[1], Stanley Lim[2], Elliot Rabinovich[3], [1]The Pennsylvania State University, State College, PA, [2]Michigan State University, East Lansing, MI, [3]Arizona State University, Tempe, AZ, Contact: lkw5428@psu.edu

Using a dynamic discrete choice model, we empirically evaluate the choices crowdsourced drivers make when selecting bundles of delivery work on a last-mile delivery platform. The results show the tradeoffs between effort and payout in terms of bundle attributes in drivers' decision-making process. In the counterfactual simulations, we consider how the platform can better incentivize drivers to choose bundles that require more effort.

5 C2C e-Commerce Platform Trust from the Seller's Perspective Based on Institutional Trust Theory and Cultural Dimension Theory

Yulu Sun[1], Haoyan Sun[2], Qixing Qu[1], [1]University of International Business and Economics (UIBE), Beijing, China; [2]Lehigh University, Allentown, PA, Contact: 438024837@qq.com

With the development of e-tailing in C2C e-commerce platforms, the issue of trust loss from sellers has worsened. How to improve their trust is urgent for platform. Based on institutional trust theory, we intend to examine the direct effects of cultural factors on platform trust, the moderating effects of structural assurances, and the relationships among cultural factors. We collected and analyzed 2,970 valid responses from individual sellers on Taobao. The results reveal that uncertainty avoidance is negatively associated with platform trust, while masculinity and long-term orientation are positively associated with platform trust. Significant associations are also found among cultural factors. Website quality and institutional guarantee weaken the correlation between uncertainty avoidance and platform trust, while security system strengthens it.

MSOM Student Paper Competition Session 2

Award Session

Session Chair: Ersin Korpeoglu, University College London, London, United Kingdom

1 UMOTEM: Upper Bounding Method for Optimizing over Tree Ensemble Models and its Applications

Leann Thayaparan, Massachusetts Institute of Technology, Cambridge, MA

2 Sequential Search with Acquisition Uncertainty

Cagin Uru, Duke University, Durham, NC

We study a variation of the classical Pandora's problem in which a decision-maker (DM) sequentially explores alternatives from a given set and learns their values while trying to acquire the best alternative. The variations in the model we study are (i) alternatives randomly become unavailable during exploration and (ii) the DM's ability to acquire a remaining alternative is uncertain and depends on a chosen offer price. Such acquisition uncertainties arise in many applications, including housing search, hiring problems, and e-commerce, but greatly complicate the search problem. We develop simple greedy policies based on static sequencing and a single threshold value. We show that our policies (a) are asymptotically optimal in high multiplicity regimes with many alternatives and (b) obtain at least 1-1/e ≈ 63.2% of the optimal value under a broad set of conditions.

3 The Impact of Social Nudges on User-Generated Content for Social Network Platforms

Zhiyu Zeng, Washington University in St. Louis, St. Louis, MO

To tackle the underprovision of user-generated content, we develop an intervention that leverages peer recognition. Via two field experiments (N=1,671,766) conducted on a video-sharing social network platform, we reveal that receiving peer recognition not only immediately boosts users' video production by 13.21% but also increases users' likelihood of giving recognition to others by 15.57%. Such effects last several days and are bigger when the recognition sender and recipients have a stronger tie. Our social network model, combined with the experimental data, shows that estimating and optimizing the overall impact of peer recognition on production over the entire platform requires accounting for its diffusion and over-time effects.

Empirical Healthcare Operations

Community Committee Choice Session

Session Chair: Mohamad Soltani, University of Alberta, Edmonton, AB, Canada

1 Role of Monetary Incentives and Process Improvement in Improving Timeliness of Childhood Immunization

Sarang Deo[1], Sisir Debnath[2], Ashish Sachdeva[3], Abhishek Shreevastava[3], Puja Roy[3], Harish Kumar[3], [1]Indian School

of Business, Hyderabad, India; [2]Indian Institute of Technology, Delhi, India; [3]Indian School of Business, Hyderabad, India. Contact: sarang_deo@isb.edu

Vaccine preventable diseases continue to be major causes of child deaths in low-and-middle income countries despite increased vaccination rates. A key factor behind this phenomenon is delayed immunization potentially due to lack of explicit incentives for timeliness and complex workflows that make it difficult for frontline workers to assess delays. We conducted a field trial in the Indian state of Bihar to assess the effectiveness of a package of interventions (including automating workflow, additional incentives and reminder calls to parents) on the timeliness of first two sets of vaccines delivered after birth. We found that the fraction of infants receiving all the vaccines within stipulated time window increased from 41% to 62% and the fraction of infants getting all the recommended vaccines in the first two sets also increased from 55% to 75%.

2 Emergency Care Access vs. Quality: Uncovering Hidden Consequences of Fast-Track Routing Decisions

Shuai Hao[1], Yuqian Xu[2], Zhankun Sun[3], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [3]City University of Hong Kong, Kowloon, Hong Kong

We utilize a two-year dataset from two hospital EDs in Alberta, Canada, and adopt an instrumental variable (IV) approach to quantify the impact of the FT routing decisions on patient outcomes. Based on the empirical findings, we propose a multi-class queueing model to derive the optimal routing policy and then utilize a data-calibrated simulation to compare the performance of different routing policies. Our empirical findings call for immediate attention from healthcare practitioners to carefully balance the trade-off between the access to emergency care and the quality of care. Using the estimated effects of FT routing decisions on patient outcomes for different patient groups, we also propose potentially implementable routing policies for hospital EDs

3 The Impact of Primary Care Regularity on Health Outcomes

Yingchao Lan[1], Vishal Ahuja[2], Aravind Chandrasekaran[3], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]Southern Methodist University, Dallas, TX, [3]The Ohio State University, Columbus, OH, Contact: yingchao.lan@unl.edu

The role of continuity of care is acknowledged in the healthcare delivery where patients seen by the same providers develop social ties that allows for increase in trust in their relationships. [illegible]

4 Ed Experiment in Displaying an Algorithmic Wait Time Prediction

Danqi Luo, UC San Diego, San Diego, CA, Contact: d1luo@ucsd.edu

In a hospital that aims to have fewer patients leave the Emergency Department without being seen by a physician (LWBS), we field-tested two approaches for displaying an algorithmic prediction of low-acuity patients' wait time to see a physician. The first approach is the prediction rounded to a multiple of 10 minutes, and the second is an interval designed to communicate that the wait time could be even 20 minutes longer. Relative to the control with no wait time information, both approaches significantly reduce the likelihood of LWBS, with the interval approach being more effective. Improved waiting satisfaction, as indicated by our incentivized satisfaction survey of ED patients, and a higher anticipated wait time with the interval approach, indicated by our online experiment, may contribute to these effects.

FinTech Innovation in Supply Chain

Community Committee Choice Session

Session Chair: Panos Kouvelis, Washington University in St. Louis

Session Chair: Yunzhe Qiu, Washington University in St. Louis, St. Louis, MO

1 Multiperiod Joint Inventory and Pricing Decisions for Substitutable Products with Nonstationary Data

Jing-Sheng (Jeannette) Song[1], Zhengliang Xue[2], Xiaobei Shen[3], [1]Duke University, Durham, NC, [2]IBM Research Center, Ardsley, NY, [3]University of Science and Technology of China, Hefei, China. Contact: fayshen@ustc.edu.cn

We study optimal inventory-pricing decisions for substitutable products with backlogging and nonstationary data over a finite planning horizon. We characterize the optimal integrated policy, and establish conditions under which the optimal base-stock levels decrease in the overstock levels. The property enhances computation significantly. We construct exact algorithms to compute the optimal policy and computationally efficient heuristics. Our policy and algorithms enable companies to develop prescriptive analytics for multi-product dynamic inventory-pricing decisions with nonstationary costs and demand. We numerically show how the heuristics dynamically influence demands of substitutable products based on their inventory status, which can increase profit substantially, especially when overstock levels are high in a volatile environment.

2 The Theory of Supply Chain Resilience: From Mechanics to Supply Chain Finance

Yunzhe Qiu[1], Dongwei Xie[2], [1]Peking University, Beijing, China; [2]Peking University, Beijing, China. Contact: qiuyunzhe@pku.edu.cn

Our work presents the intrinsic mechanism of the firms' resilience in the supply chain under risk shocks from the perspective of Mechanics. We first analyze the firm's resilience in response to risk and specify the elasticity and plasticity intervals depending on its constrained capital structure and the optimal inventory and financing decisions of facing upstream and downstream risks. We extend the theory of resilience to a bilateral supply chain where trade credit or buyer financing contracts are available. We analyze the individual resilience and entire supply chain resilience and give measures to improve the resilience of the firm and the supply chain. We find that the chain's resilience depends on the weaker participant but can be improved via supply chain finance contracts by balancing the financial resilience between two participants.

3 Financial Hedging For A Data-Driven Newsvendor Selling New Products

Yulong Huang[1], Shaochong Lin[2], Frank Y. Chen[3], Quan Yuan[1], [1]Zhejiang University, Hangzhou, China; [2]The University of Hong Kong, Hong Kong, China; [3]City University of Hong Kong, Tat Chee Avenue, Hong Kong. Contact: yulohuang@zju.edu.cn

We study a data-driven joint inventory and financial hedging problem in a risk-averse newsvendor setting for a new product. Historical data on similar products and financial markets are available for the firm. We consider the impact of product features and return rates of financial assets on product demand and explore the use of financial derivatives to hedge against profit risk. A data-driven approximation procedure based on historical data is proposed, which is consistent and asymptotically optimal. Experiments indicate that financial hedging always benefits the firm when integrated with inventory hedging as long as the firm exhibits sufficient risk aversion, which contradicts the theoretical problem. We also find that financial hedging may regularize the data-driven model, but it may also mitigate the positive impact of risk-averse constraint regularization.

4 Sourcing Under Supply Uncertainty: Impact of Tariff and Shipping Cost

Yulan Amanda Wang[1], Guang Xiao[2], Jingwen Xu[3], Lei Chen[4], [1]The Hong Kong Polytechnic University, Hung Hom, Hong Kong; [2]Hong Kong Polytechnic University, Hung Hom, Hong Kong; [3]The Hong Kong Polytechnic University, Hong Kong, Hong Kong; [4]Jinan University, Guangzhou, China

In this study, we consider a three-tier decentralized global supply chain that consists of a buyer, a reliable supplier located outside a free trade area, an unreliable supplier situated within a free trade area, and a logistics service provider (LSP) that transports products from suppliers to the buyer. We consider different combinations of trade agreements and tariff calculation schemes: First, based on who shall bear the tariff and shipping cost, the buyer and supplier can undertake one of the following three trade agreements: Ex Works (EXW), Delivered at Place (DAP), or Delivered Duty Paid (DDP). Second, depending on the basis of dutiable value on which the tariff is calculated, two tariff calculation schemes, i.e., Free on Board (FOB) and Cost Insurance Freight (CIF), are considered. We characterize each member's preference for the aforementioned tariff agreements.

Socially Sustainable Service Operations

Community Committee Choice Session

Session Chair: Qiuping Yu, Georgetown University/ Georgia Tech, Washington, DC

Session Chair: Xiaoxuan Hou, University of Washington, Seattle, WA

1 The Impact of Scheduling Quality on Worker Turnovers: Evidence from a national Restaurant Chain in the U.S.

Qiuping Yu[1], Haonan Zhang[2], [1]Georgetown University, Washington, DC, DC, [2]University of Washington-Seattle, Seattle, WA, Contact: qiuping.yu@georgetown.edu
Just-in-time scheduling in service industries offer unique advantages for restaurant and retail stores to match labor supply to customer demand. However, this scheduling practice can lead to insufficient, inconsistent, and unpredictable schedules for employees. Such irresponsible schedules could lead to employees' voluntary turnover. We empirically examine the causal effect of irresponsible scheduling on part-time employees' voluntary turnover decision under a restaurant setting. We conclude that perceiving insufficient working hours and earnings, volatile and unpredictable schedules significantly contribute to turnover.

2 Leapfrogging for Last-Mile Delivery in Health Care: Drone Delivery for Blood Products in Rwanda

Harriet Jeon[1], Claudio Lucarelli[1], Jean Baptiste Mazarati[2], Donatien Ngabo[3], Hummy Song[1], [1]The Wharton School, University of Pennsylvania, Philadelphia, PA, [2]University of Global Health Equity, Kigali, Rwanda; [3]Ministry of Health, Rwanda, Kigali, Rwanda. Contact: hummy@wharton.upenn.edu
The access to and quality of health care, especially in hard-to-reach areas, are challenges for many countries. Traditional solutions improve geographic connectivity through incremental and costly infrastructure investments. Radical technological innovations may allow leapfrogging to directly improve access to quality medical care. Using data from Rwandan public hospitals, we examine whether adopting drone delivery technology improves operational and health outcomes. We find that adopting drone delivery leads to a substantial reduction in on-hand inventory, wastage, and inpatient mortality for patients with post-partum hemorrhage (PPH). Additional analyses suggest that the drone delivery system exhibits a leapfrogging effect.

3 The Effect of Fair Workweek Laws on Worker Schedules and Store Performance

Caleb Kwon, Ananth Raman, Harvard Business School, Boston, MA
Fair Workweek laws aim to help workers by entitling them to additional compensation from their employers when their schedules are unilaterally adjusted on short notice. Despite having been implemented in seven jurisdictions, little is known about their impact on worker schedules and employment. In this paper, we use a difference-in-differences strategy surrounding the enactment of Chicago's Fair Workweek Ordinance to study its effects on scheduling and employment-related outcomes. Consistent with the objectives of Chicago's Fair Workweek law, we estimate a significant increase in the amount of notice provided to employees for their shifts. Importantly, this increase in advance notice is not accompanied by commonly expressed concerns about Fair Workweek laws, such as job loss, hiring reductions, or decreased scheduled hours or shifts for employees.

4 Too Good to Go: Combating Food Waste with Surprise Clearance

Luyi Yang[1], Man Yu[2], [1]University of California, Berkeley, Berkeley, CA, [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong
We study a novel clearance mechanism of perishable goods to reduce food waste and increase store profit.

Platforms and Multichannel Operations: Incentive of Decision Makers

Community Committee Choice Session

Session Chair: Jaelynn Oh, University of Utah, Salt Lake City, UT

1 Food Ordering and Delivery: How Platforms and Restaurants Should Split the Pie

Jaelynn Oh[1], Chloe Kim Glaeser[2], Xuanming Su[3], [1]The University of Utah, Salt Lake City, UT, [2]University of North Carolina at Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [3]University of Pennsylvania, Philadelphia, PA, Contact: jaelynn.oh@eccles.utah.edu
Food ordering and delivery platforms generate online demand for restaurants and deliver food to customers. In return, restaurants pay the platform a commission, typically a percentage of the order amount. We study the commission contract between the food delivery platforms and restaurants. We find inefficiencies in the food commission contract which is widely used in the practice and propose a new contract which can eliminate the inefficiencies.

2 Favorable Risk Selection in Medicare Advantage: The Effect of Allowing Non-Medical Services

Woonam Hwang[1], Jonas Oddur Jonasson[2], Heikki Peura[3], [1]University of Utah, Salt Lake City, UT, [2]MIT Sloan School of Management, Somerville, MA, [3]Imperial College

Business School, London, United Kingdom. Contact: woonam.hwang@eccles.utah.edu
Social determinants of health (SDOH)---such as health-related knowledge and behaviors---account for a significant part of health outcomes. The provision of non-medical services that affect SDOH, however, traditionally falls outside the purview of healthcare providers, resulting in little integration with healthcare delivery. The US CHRONIC Care Act seeks to ameliorate this situation, allowing Medicare Advantage (MA) insurers to offer an expanded range of non-medical supplementary services, with the goal that this integration will improve health outcomes. We develop a game-theoretical model to study the impact of this policy change on decisions and outcomes for beneficiaries and MA insurers.

3 Managing User-Generated Content Platforms
Ruize Ma[1], Yunke Mai[2], Bin Hu[3], [1]Dalian University of Technology, Dalian, China; [2]University of Kentucky, Lexington, KY, [3]University of Texas at Dallas, Dallas, TX, Contact: rzma@mail.dlut.edu.cn
The popularity of user-generated content (UGC) platforms enable professional creators to earn a living by sharing the platform's advertising revenue. UGC platforms need to effectively manage the growth of both creator and user bases and its own profitability with its dynamic promotion, advertising and revenue sharing decisions. We comprehensively analyze a UGC platform and characterize its optimal operating policies and show that the platform's advertising and revenue sharing strategies differ in early, intermediate and late stages. We also analyze alternative monetization models such as sponsored contents and tipping.

4 Offline Returns for Online Retailers via Partnership
Soo-Haeng Cho[1], Leela Aarthy Nageswaran[2], Elina Hwang[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Washington, Seattle, WA, [3]University of Washington-Foster School of Business, Seattle, WA
Online shoppers often prefer to return items to stores than to mail them back. We study the newly emerging business practice where an online retailer and a store retailer partner to offer customers a store return option. Our results show that store and online retailers who offer differentiated products have incentives to partner, as in the case of the return partnership between Everlane and Cost Plus World Market. Interestingly, return partnerships may also feature retailers who offer similar products as in the case of Amazon-Kohl's. In this case, online customers' migration to store returns ensures a store retailer's incentive to partner while the incentive of an online retailer is also assured when store visits are not too convenient.

Innovations in Retail Operations

Community Committee Choice Session

Session Chair: Soraya (Nadia) Fatehi, The University of Texas at Dallas, Richardson, TX

1 Estimating the High-Dimensional Correlation Structure in Transportation Demand for Robust Service Network Design
Joline Uichanco[1], Amitabh Sinha[2], [1]University of Michigan, Ross School of Business, Ann Arbor, MI, [2]Amazon, Seattle, WA, Contact: jolineu@umich.edu
Amazon operates its own freight transportation network (i.e., fleet of trailers, consolidation terminals) in order to ship packages from fulfillment centers to customer locations. To incorporate flexibility, models for network design must explicitly consider uncertainty in the transportation demands, a high-dimensional random vector. However, estimating the high-dimensional correlation structure with limited data is extremely challenging. In this talk, we propose using Principal Component Regression (PCR) to estimate transportation demands as a linear function of lower-dimensional primitive factors. We then propose a factor-based uncertainty set for transportation demands that can be used in robust network design models. We conduct computational experiments to demonstrate the value of using our approach in service network design.

2 Reducing Food Waste Through Early Adoption of Supply Transparency Technology
N. Bora Keskin, Chenghuai Li, Jing-Sheng (Jeannette) Song, Duke University, Durham, NC, Contact: chenghuai.li@duke.edu
Motivated by the rapid development of digital technologies that allow fresh-produce retailers to track the conditions of their supplies in real-time, this paper studies whether an early adopter advantage exists in a competitive retail market and the impact of mergers. Considering a duopoly facing freshness-dependent demand, we show that an early adopter can achieve greater profit growth due to the spillover-capture effect when the retail margin is low and/or the market-expansion effect when consumer utility is boosted by the technology adoption. Under certain conditions, early adoption can also lead to a greater reduction in food waste or a greater increase in consumer surplus. Furthermore,

sometimes the monopoly can have a higher level of adoption than duopoly in the presence of uncertainty-transmission motive, leading to increased demand fill rate or less food waste.

3 Expanding into On-Demand Markets with "Airbnb of Warehousing"
Soraya (Nadia) Fatehi, Anyan Qi, The University of Texas at Dallas, Richardson, TX, Contact: Soraya.Fatehi@UTDallas.edu
Despite the potential benefit of capturing more demand, few firms offer on-demand fulfillment services due to operational challenges. One emerging solution to address these challenges is the "Airbnb of Warehousing (AW)." The AW allows a firm to flexibly tap into excess capacities of independent warehouse providers closer to its on-demand markets, which enables the on-demand fulfillment services without long-term commitments or high upfront costs. We investigate how a firm should utilize the AW to expand into its on-demand markets. We study the firm's problem under scenarios where the firm has access to the AW option, and the firm (i) knows the demand parameters of its on-demand markets or (ii) has no or limited knowledge about its on-demand markets. Our proposed policies help retailers expand into their untouched on-demand markets efficiently and flexibly via the AW.

4 Like Attracts Like: Optimal Assortment on a Platform
Hakjin Chung[1], Myeonghun Lee[1], Hyun-Soo Ahn[2], [1]Korea Advanced Institute of Science and Technology, Seoul, Korea, Republic of; [2]University of Michigan, Ann Arbor, MI, Contact: hakjin.chung@kaist.ac.kr
Online marketplace platforms have become a major pillar of the retail industry, providing consumers with convenient access to many products and providing sellers with the ability to reach a vast customer base. However, high commission fees and intense competition drive some sellers off their respective platforms. We study the platform's problem of determining the assortment and fee policies when sellers can decide whether to join or not based on self-interests. We find that the optimal assortment is strikingly homogeneous, including all sellers who are similar in traffic and product attractiveness and filling the rest of the assortment by selecting a few sellers below the band. Compared to a uniform fee, an individualized fee results in a wider range of sellers, as the platform can incentivize some high-traffic sellers to stay while squeezing more revenue from a few others.

1 Science-Based Targets: Empirical Analysis of Carbon Reduction Commitments by Global Firms
Donghyun Choi[1], Abhinav Shubham[2], Manpreet Singh Hora[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: manpreet.hora@scheller.gatech.edu
A growing number of firms are joining Science-Based Target (SBT) initiatives and are pledging to set carbon reduction or net-zero targets. We identify the antecedents of setting SBTs. Merging the historical SBTs with firm-level financial and environmental performance data, our findings unravel insights on antecedents and consequences.

2 Optimal Hour-Ahead Commitment and Storage Decisions of Wind Power Producers
Emre Nadar[1], Ece Cigdem Karakoyun[2], Harun Avci[3], Woonghee Tim Huh[4], Ayse Selin Kocaman[2], [1]Bilkent University, Ankara, Turkey; [2]Bilkent University, Ankara, Turkey; [3]Northwestern University, Evanston, IL, [4]University of British Columbia, Vancouver, BC, Canada. Contact: emre.nadar@bilkent.edu.tr
We study the energy commitment, generation and storage problem for a wind farm paired with a battery. We model this problem as a Markov decision process and characterize the optimal policy structure. We implement our structural results into a heuristic solution method that yields near-optimal solutions within a few minutes.

3 Quality Costs of Fuel Efficiency Improvements in the Automobile Industry
Donggyu Jeon[1], George Ball[1], Gil Souza[2], [1]Operations and Decision Technologies, Kelley School of Business, Indiana University, Bloomington, IN, [2]University of Tennessee Knoxville, Knoxville, TN, Contact: djeon93@indiana.edu
In this study, we empirically examine the impact of firms' efforts to improve the environmental performance of a vehicle (measured as MPG) on product quality (measured as the number of quality complaints reported) in the automotive industry. We provide operational and strategic managerial implications of improving sustainability on product quality.

4 Does Less Information Result in More? The Role of Information About Circular Economy Strategies in Take-Back Programs for Clothing

Erin Mckie[1], Anna Saez de Tejada Cuenca[2], Vishal Agrawal[3], [1]The Ohio State University, Columbus, OH, [2]IESE Business School, Barcelona, Spain; [3]Georgetown University, Washington, Contact: asaezdetejada@iese.edu

Retailers are increasingly sponsoring take-back initiatives to facilitate the recycling and reuse of secondhand clothing. To stimulate the return of goods, retailers share information about disposal-related circular economy strategies and offer consumers a small incentive in exchange for used clothing items. The effects of different approaches are unknown yet are postulated to have significant implications on retailers' ability to collect used clothing items. Through three online and laboratory experiments involving over 3,500 subjects, we test how consumers' likelihood to return their used garments is affected as the degree of information transparency and reward level is manipulated. Our results suggest that significant gains can be achieved by offering modest rewards and strategic disclosures of circular economy business model information.

Statistical Methods for Operations

Contributed Session

Session Chair: Lan Gao, University of Tennessee Knoxville, Knoxville, TN

1 Robust Statistical Methods for Adversarial Attack Mitigation in Federated Learning

Mohammad Mahdi Ahmadi, The University of Arizona, Tucson, AZ

This study investigates the application of robust statistical methods to address the impact of adversarial attacks in machine learning models. Specifically, we explore the effectiveness of these methods in federated learning settings. By comparing the results to centralized machine learning, both in the absence and presence of adversarial attacks, we aim to assess the robustness and reliability of the proposed techniques. Our findings shed light on the potential of robust statistical methods to mitigate the adverse effects of adversarial attacks in federated learning.

2 Transformer-Based Unsupervised Anomaly Detection with Multivariate Time Series

Soomin Lee[1], Juheon Kwak[2], Wonkeun Jo[1], Sungsu Lim[1], Dongil Kim[2], [1]Chungnam National University, Yuseong-gu, Daejeon, Korea, Republic of; [2]Ewha Womans University, Seodaemun-gu, Seoul, Korea, Republic of. Contact: sxxmin.lee@g.cnu.ac.kr

Anomaly detection is one of the most important tasks in various industries. For multivariate time series (MTS), anomaly detection methods have been proposed by considering characteristics such as frequency and trend. We propose a novel transformer-based unsupervised anomaly detection model for MTS. The proposed method considers both time and frequency domains. The proposed model for anomaly detection includes independent modules to decompose the signal and extract information in the time and frequency domains. The experiments employing four benchmarks resulted that our method outperformed several benchmark methods, which was promising enough to warrant further study on various domains.

3 Data-Driven Quickest Change Detection Using Wasserstein Uncertainty Sets

Liyan Xie, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: xieliyan@cuhk.edu.cn

We study online change detection problems under known pre-change distribution, while only information about the post-change distribution is through a set of samples. This post-change data is used in a data-driven minimax robust framework, where an uncertainty set for the post-change distribution is constructed using the Wasserstein distance. The robust change detection problem is studied in an asymptotic setting where the mean time to false alarm goes to infinity. It is shown that the density corresponding to the least favorable post-change distribution is an exponentially tilted version of the pre-change density and can be calculated efficiently. A Cumulative Sum (CuSum) test based on the least favorable distribution is proposed and proved asymptotically optimal. The results are extended to the case where the post-change distribution contains multiple scenarios.

4 Distance Correlation Can Enhance Understanding of Recurrent Neural Networks for Time Series Forecasting

Christopher Salazar, University of Washington, Seattle, WA, Contact: salezara@uw.edu

Our current understanding of how recurrent neural networks (RNN) learn time series forecasting is limited. We adapt a statistical dependency measure, called distance correlation, to investigate the non-linear relationships of

RNN activation layers with the variables of interest such as prediction time horizon and lag characteristics. We conduct a series of experiments that show RNNs learn auto-regressive time series well but struggle with data exhibiting heteroscedasticity. We also generate heatmaps to show a visual representation of RNN activation layers at various time epochs and for different network architectures. We believe our approach can be useful to characterize the effectiveness of other neural networks in the future.

5 Thompson Sampling with Discrete Support

Lan Gao[1], Xueru Zhang[2], Wei Zheng[3], [1]University of Tennessee Knoxville, Knoxville, TN, [2]Purdue University, West Lafayette, IN, [3]The University of Tennessee Knoxville, Knoxville, TN, Contact: lgao13@utk.edu

Thompson sampling is a popular algorithm for multi-armed bandit problems, but its Bayesian posterior update can be computationally expensive for complex reward distributions. Recently, prior discretization has been proposed to address this issue. In this paper, we propose a new prior discretization method that guarantees the same regret rate without requiring the unrealistic assumption that the true parameter is within the discrete prior support. Moreover, we introduce a modified posterior update approach that further improves the performance of discrete prior Thompson sampling. We prove that the accumulated regret is bounded by O(log(T)) with high probability. In addition, we conduct numerical experiments to validate our theoretical analysis and demonstrate the performance of our proposed algorithm.

Session Chair: Daniel De Roux Uribe, Carnegie Mellon, PA

1 Approximation Algorithms for Stochastic Orienteering Problems

David Aleman, University of Waterloo, Waterloo, ON, Canada

An instance of knapsack stochastic orienteering (SKO) consists of a complete rooted metric graph. Each node is associated with a job with correlated random processing time and reward. These random variables are independent across different vertices. We are given two budgets B and W. A solution to SKO without cancellations consists of a rooted path of total length at most B that visits a sequence of vertices in a possibly adaptive fashion. When a vertex is visited its corresponding job is executed non-preemtively. The reward of a completed job is collected if the sum of completion times of vertices processed so far is at most W. The goal is to maximize the total expected reward. In SKO with cancellations we are can cancel a job at any given timestep without collecting its reward. We provide LP based approximation algorithms for these problems. This is a joint work with Chaitanya Swamy.

2 Burer-monteiro Method For Low-rank Sum-of-square Certification

Shixuan Zhang[1], Greg Blekherman[2], Mauricio Fernando Velasco[3], Rainer Sinn[4], [1]Texas A&M University, College Station, TX, [2]Georgia Institute of Technology, Atlanta, GA, [3]Universidad de los Andes, Bogota, Colombia; [4]Leipzig University, Leipzig, Germany. Contact: shixuan.zhang@tamu.edu

To certify a sum of k squares on a real projective variety, one can minimize the distance of the sum of squares of k linear forms from it in the space of quadrics. This is known as the Burer-Monteiro method in semidefinite optimization. When k is smaller than the dimension of linear forms, the certification problem can be applied in low-rank semidefinite relaxation of polynomial optimization. We discuss the existence of spurious local minima in this nonconvex optimization problem with some characterization based on the properties of the underlying real projective variety. We also propose efficient algorithms to avoid such spurious local minima.

3 Second Order Cone Approximations for a Graph Latency Problem

Daniel de Roux, Carnegie Mellon University, Pittsburgh, PA, Contact: dderoux@andrew.cmu.edu

We consider an information dissemination problem in an undirected graph where sources inform correspoding sinks and constantly updates their information. The goal is to keep every sink in the graph as freshly informed as possible of their correspoding source. We work under a synchronous information spreading model in which any node can communicate with at most one neighbor at each time, thus forming a matching over which information is transmitted at each step. We introduce a problem in minimizing the maximum latency of sources and sinks. We give an algorithm to solve the problem on trees and then we propose a second order cone program to approximate the solution of the problem in general graphs. We prove that a solution of

this program can approximate the original problem within polylog factors. Finally, we show that the solution obtained is both locally and globaly periodic.

4 A Linearization Proposal for the Redundancy Allocation Problem

Isis Lins, Lavínia Araújo, Caio Maior, Márcio Moura, Universidade Federal de Pernambuco, Recife, Brazil. Contact: lavinia.mendes@ufpe.br

The Redundancy Allocation Problem (RAP) is a common NP-hard nonlinear problem in Reliability Engineering. The aim is to increase reliability while adhering to budget and quantity limits for subsystem components. (Meta-)heuristics commonly address it, while exact linear methods still need to be explored. This study proposes an approximate linear formulation of RAP for series-parallel configuration, for which the failure of a single subsystem leads to system failure. The proposed formulation minimizes the failure probability of the least reliable subsystem and the product of subsystems' probabilities as a proxy to maximizing system reliability. In addition to applying exact linear programming, this formulation also allows using quantum optimization algorithms that require quadratic, binary, and unconstrained problems.

5 Delving into the Heart and Soul of Matrix Optimization: A New Perspective to Spectrally Constrained Models

Casey Garner, University of Minnesota, Minneapolis, MN, Contact: garne214@umn.edu

At first glance, matrix optimization might appear equivalent to optimizing over simple column vectors in Euclidean space; however, when we consider constraining the spectrum of a matrix, we realize this perspective is woefully inadequate hiding much richness and veiling numerous challenges. In this talk, we shall discuss a novel framework for spectrally constrained matrix optimization which allows general constraints on the spectrum, moving well beyond traditional constraints such as positive semidefiniteness, and present new algorithms for handling highly non-convex matrix optimization problems.

Novel Applications of Discrete Optimization

Community Committee Choice Session

Session Chair: Diego A. Moran, Universidad Adolfo Ibañez, Santiago, Chile

1 Risk-Averse Dynamic Antibiotic Time Machine Problem

Burak Kocuk, Deniz Tuncer, Sabanci University, Istanbul, Turkey. Contact: burak.kocuk@sabanciuniv.edu

Given a treatment length and a set of antibiotics, antibiotic time machine problem aims to maximize the probability of reversing the mutations that lead to antibiotic resistance. This problem can be modeled as a Markov Decision Process. Due to the seriousness of the issue, obtaining risk averse solutions would be a reasonable approach. We formulate a risk-averse MILP model for this problem with scenarios in which the risk is measured using conditional value-at-risk. We propose a risk-averse scenario decomposition algorithm, which partitions the scenario set into group subproblems. We construct lower and upper bounds based on the optimal values and solutions of the group subproblems. We enhance the standard algorithm with improved cuts by exploiting the special structure of the problem. We conduct computational experiments with real data and obtain promising results.

2 Optimal Unlabeled Set Partitioning with Application to Risk-Based Quarantine Policies

Jiayi Lin[1], Hrayer Aprahamian[1], Hadi El-Amine[2], [1]Texas A&M University, College Station, TX, [2]George Mason University, Fairfax, VA, Contact: jiayilin@tamu.edu

We consider the problem of partitioning a set of items into unlabeled subsets so as to optimize an additive objective. Under an arbitrary objective, this class of problems is known to be an NP-complete combinatorial problem. We study this problem under a broad family of objectives characterized by elementary symmetric polynomials, which are "building blocks'' to symmetric functions. By analyzing a continuous relaxation of the problem, we identify conditions for a more tractable network flow reformulation that can be solved in polynomial-time. We show that a number of results from the literature arise as special cases of our proposed framework, highlighting its generality. Our case study, which is an application of quarantining heterogeneous populations using real COVID-19 data, reveals significant benefits that underscore the importance of data-driven policies.

3 Uncovering Multiple Collective Tendencies in Preference Data: A Split Consensus Kemeny Aggregation Approach with Polyhedral Enhancements

Romena Yasmin, Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ, Contact: ryasmin@asu.edu

The present work is focused on developing principled aggregation methods that challenge the assumption of a single underlying ground truth for preference data. The objective is to identify multiple latent subgroups with conflicting preferences present within a set of subjective evaluations. To achieve this objective, we employ the mixed integer programming formulation of the Split Consensus Kemeny Aggregation (SC-KA) model. In order to establish a heuristic algorithm, we explore the relationship between the SC-KA model and the K-means clustering algorithm. Additionally, we present a polyhedral approach to enhance the computation of the proposed heuristic. This approach exploits valid inequalities that can be generated from the correspondence between weak order polytopes and preference structures to refine the characterization of the solution space.

4 Optimization Methods for Experimental Design

Rodolfo Carvajal[1], Diego A. Moran[2], Burak Kocuk[3], Jacqueline Meza[4], [1]Universidad Adolfo Ibáñez, Viña del Mar, Chile; [2]Universidad Adolfo Ibañez, Santiago, Chile; [3]Sabanci University, Istanbul, Turkey; [4]Universidad Adolfo Ibáñez, Santiago, Chile

Given a number of observations, each of them having some attributes of interest (e.g. if the observations are people, the attributes could be: height, weight, age, etc.), a fundamental question in experimental design is to partition the observations into statistically equivalent groups. This is crucial, for instance, in clinical trials when studying the effectiveness of a new medical treatment for which the observations are separated into two groups: the treated group and the control group. In this talk, we review some optimization approaches to solve this problem and present novel conic mixed-integer programming models whose solutions outperform the ones obtained by the methods proposed in the literature.

Influence and Design in Network Games

Community Committee Choice Session

Session Chair: Ceyhun Eksin, Texas A&M University, College Station, TX

1 Information Design for Unknown Quadratic Games

Ceyhun Eksin[1], Furkan Sezer[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M University- College Station, Chicago, IL, Contact: eksinc@tamu.edu

The talk discusses the problem of designing information structures in incomplete information games when the designer does not know the game payoffs exactly. This is a common situation in many real-world settings, where the game payoffs are often uncertain due to various factors such as incomplete information, imperfect modeling, or unknown parameters. We propose a robust optimization approach to address this problem. Specifically, we consider information design for the setting when the unknown payoff parameters are adversarially chosen. We develop a tractable SDP formulation given quadratic payoffs, Gaussian signal distributions, and ellipsoid perturbations. Numerical experiments show that the designer would choose to hide information about the state to the players as its uncertainty about the players' payoffs increases.

2 Information Design in Channel Capacity and Delay Constrained Settings

Emrah Akyol, SUNY, Binghamton, NY

This work is concerned with the quantization setting where the encoder and the decoder have misaligned objectives. While the unconstrained variation of this problem has been well-studied under the theme of information design problems in Economics, it becomes more appealing with a constraint on the cardinality of the message space. We first motivate the problem via a toy example demonstrating the strategic quantization problem's intricacies, explicitly showing that the quantization resolution can change the nature of optimal encoding policy and the iterative optimization of the decoder and the encoder mappings may not converge to a local optimum solution. We develop a gradient-descent based solution and present numerical results that demonstrate strategic quantization features that differentiate it from its classical counterpart.

3 Information Design for Non-Bayesian Agents in Repeated Non-Atomic Games

Ketan Savla, University of Southern California, Los Angeles, CA

Consider the following repeated routing game. In every round, a state is i.i.d. sampled from a publicly known distribution, which influences latency functions. The planner makes private route recommendations to participating agents, constituting a fixed fraction, according to a publicly known signaling strategy. These agents choose to obey or not according to satisficing regret cumulative over all participating agents. The other agents adopt myopic best response to a calibrated forecast of the decisions of participating agents. We show that, for parallel networks, if the planner's strategy satisfies the obedience condition, then, almost surely, the link flows are asymptotically consistent with the induced Bayes correlated equilibrium.

4 Algorithmic Collective Action in Machine Learning

Eric Mazumdar, Caltech, Pasadena, CA

We initiate a principled study of algorithmic collective action on digital platforms that deploy machine learning algorithms. We propose a simple model of a collective interacting with a firm's learning algorithm in which the collective pools the data of participating individuals and instructs them how to modify their own data to achieve a collective goal. We investigate this model in several learning-theoretic settings. In each setting, we come up with strategies and characterize success as a function of the collective's size. We validate our results by conducting experiments on a skill classification task involving freelancer resumes and a classier trained on top of a BERT-like language model. Altogether, our results support the conclusion that algorithmic collectives of exceedingly small size can exert significant control over a platform's learning algorithm.

Constrained Stochastic Optimization

Community Committee Choice Session

Session Chair: Xin Jiang, 1</sup

Session Chair: Qi Wang, Lehigh University, Bethlehem, PA

1 Stochastic Zeroth-Order Riemannian Derivative Estimation and Optimization

Shiqian Ma[1], Jiaxiang Li[2], Krishnakumar Balasubramanian[3], [1]Rice University, Houston, TX, [2]UC Davis, Davis, CA, [3]University of California, Davis, Davis, CA, Contact: sqma@rice.edu

In this talk, we consider stochastic zeroth-order optimization over Riemannian submanifolds. Our main contribution is to propose estimators of the Riemannian gradient and Hessian from noisy objective function evaluations, based on a Riemannian version of the Gaussian smoothing technique. The proposed estimators overcome the difficulty of the non-linearity of the manifold constraint and the issues that arise in using Euclidean Gaussian smoothing techniques when the function is defined only over the manifold. We use the proposed estimators to solve Riemannian optimization problems in different settings, and analyze the oracle complexity of our algorithms for obtaining appropriately defined epsilon-solutions. Our complexities are independent of the dimension of the ambient Euclidean space and depend only on the intrinsic dimension of the manifold.

2 Exact and Inexact Subsampled SQP Method for Equality Constrained Stochastic Optimization

Jiahao Shi[1], Albert Solomon Berahas[1], Raghu Bollapragada[2], [1]University of Michigan, Ann Arbor, MI, [2]The University of Texas at Austin, Austin, TX

In this paper, we propose a subsampled second order algorithms for solving equality constrained optimization problems in which the objective is defined by the expectation of a stochastic function and constraint functions are deterministic. We use line search methods in the algorithm and present the local and global convergence results. To fill the gap of the step size selection scheme in the analysis, we modify the algorithm with a new proposed line search condition. Finally, we develop an inexact algorithm to reduce computational cost.

3 On the Almost-Sure Convergence of the Iterates and Lagrange Multipliers in a Stochastic SQP Method

Frank E. Curtis, Xin Jiang, Qi Wang, Lehigh University, Bethlehem, PA, Contact: xjiang@lehigh.edu

Stochastic sequential quadratic optimization (SQP) methods for solving continuous optimization problems with nonlinear equality constraints have attracted attention recently. However, for a certain recently proposed class of such methods that is built upon the stochastic-gradient methodology from the unconstrained setting, convergence guarantees of the iterates and Lagrange multiplier estimates have been limited to convergence-in-expectation guarantees. This is in contrast to the unconstrained setting in which stronger almost-sure convergence results can be proved for stochastic-gradient-based methods. In this talk, we present new almost-sure convergence guarantees for the iterates and the Lagrange multipliers generated by a stochastic SQP algorithm.

4 A Stochastic-Gradient-Based Interior-Point Algorithm for Solving Smooth Bound-Constrained Optimization Problems

Frank E. Curtis[1], Vyacheslav Kungurtsev[2], Daniel Robinson[1], Qi Wang[1], [1]Lehigh University, Bethlehem, PA, [2]Czech Technical University in Prague, Prague, Czech Republic. Contact: qiw420@lehigh.edu

A stochastic-gradient-based interior-point algorithm for minimizing a continuously differentiable nonconvex objective function subject to bound constraints is presented, analyzed, and demonstrated. The algorithm is unique from other interior-point methods for solving smooth nonconvex optimization problems since the search directions are computed using stochastic gradient estimates. It is also unique in its use of inner neighborhoods of the feasible region--defined by a positive and vanishing neighborhood-parameter sequence--in which the iterates are forced to remain. With a careful balance between the barrier, step-size, and neighborhood sequences, the proposed algorithm converges in both deterministic and stochastic settings. The numerical experiments show that the algorithm can outperform a projected-(stochastic)-gradient method.

Fleet Planning and Operation in the Era of Connected, Autonomous, Shared and Electric Vehicles

Community Committee Choice Session

Session Chair: Zhaocai Liu, National Renewable Energy Laboratory, Golden, CO
Session Chair: Xinwu Qian, University of Alabama, Tuscaloosa, AL

1 Battery Swapping and Management System Design for Electric Trucks Considering Battery Degradation

Yanling Deng[1], Zhibin Chen[1], Pengyu Yan[2], Renxin Zhong[3], [1]New York University Shanghai, Shanghai, China; [2]University of Electronic Science and Technology of China, Chengdu, China; [3]Sun Yat-sen University, Guangzhou, China

This study focuses on the optimal design of a Battery swapping station (BSS) system that exclusively serves an electric truck (ET) fleet offering dedicated-line transportation services. By explicitly incorporating the battery degradation effect, we develop a mathematical model to determine the optimal configuration of the BSS system to minimize the total system cost including the fixed investment cost and the battery lifecycle cost. A battery charging management strategy is then proposed to reduce the battery degradation cost. Numerical experiments show that the system design model can well capture the trade-off between the one-time battery purchase cost and the long-term battery degradation cost; and the battery charging management strategy significantly reduces the battery degradation cost, resulting in a more cost-efficient BSS system.

2 Equitable Deployment of Wireless Charging Lanes in Transportation Networks

Ziqi Song, University at Buffalo, The State University of New York, Buffalo, NY

Electric vehicles are increasingly being acknowledged as a key instrument in achieving sustainable transportation, with the potential to significantly diminish emissions and air pollution. To facilitate this shift towards EVs and overcome their current limitations, it is imperative for governments to invest in public charging infrastructure, thereby extending the travel range of EVs and alleviating concerns related to range anxiety. However, given budgetary constraints, the development of such public refueling stations must be both cost-effective and equitable. In light of this, we propose a future where EVs proliferate, and governmental agencies begin to incorporate wireless charging lanes within regional road networks. The objective is to maximize societal welfare while ensuring an equitable distribution of the benefits derived from these charging lanes.

3 GTFS-Data Based Electric Bus System Energy Consumption Estimation and Planning

Zhaocai Liu, National Renewable Energy Laboratory, Golden, CO, Contact: zhaocai.liu@nrel.gov

This presentation talks about our recent works on electric bus system energy consumption estimation and planning. We first developed a data-driven machine learning based modeling framework for electric bus energy consumption estimation. A machine learning model is trained using real-world bus operation data to predict electric bus energy consumption. We then developed a General Transit Feed Specification (GTFS) data based user-friendly workflow to help transit agencies adopt the machine learning energy consumption model in electric bus fleet planning and operation.

4 Modular Vehicles Can Reduce Greenhouse Gas Emissions for Departure Flight Baggage Transportation

Zhiwei Chen[1], Xiaopeng Li[2], Xiaowei Shi[3], Xiaobo Qu[4], [1]Drexel University, Philadelphia, PA, [2]University of Wisconsin, Madison, Madison, WI, [3]University of Michigan, Ann Arbor, Ann Arbor, MI, [4]Tsinghua University, Beijing, China

Modular vehicle (MV) is an emerging transportation technology that allows vehicles to adjust their capacity flexibly by assembling or disassembling identical detachable units. This innovative technology offers us a new perspective to decarbonize the aviation sector, as it holds promise for reducing GHG emissions in flight baggage transportation. To investigate this possibility, this study proposes an MV operation paradigm and a corresponding "greenest" MV scheduling problem that aims to minimize MV-relevant GHG emissions while transporting baggage from the terminal to the aircraft without delay. A series of case studies at the Tampa International Airport were conducted to evaluate the performance of the proposed MV operation and the construction-merging heuristic.

1 Sample-Based Online Generalized Assignment Problem with Unknown Poisson Arrivals

Zihao Li, Hao Wang, Zhenzhen Yan, Nanyang Technological University, Singapore, Singapore. Contact: hao_wang@ntu.edu.sg

We study an online Generalized Assignment Problem where we need to allocate online items to offline bins. Online items follow independent Poisson processes with unknown arrival rates. Each online item will either be packed into a bin which will deduct the bin's capacity by the item's demand and generate a reward, or be rejected upon its arrival. The reward and demand depend on the bin and item, and the demand and capacity are D-dimension vectors. Our goal is to maximize the total reward. We provide sample-based algorithms utilizing pre-existing offline data and sequentially revealed online data for a simplified online matching setting and the original setting. We present parametric competitive ratios and analyze the effect of offline data, planning horizon, and dimension. Finally, we demonstrate the effectiveness of our algorithms numerically.

2 Information Basis In Dynamic Robust Optimization

Ningji Wei[1], Peter Zhang[2], [1]Texas Tech University, Lubbock, TX, [2]Carnegie Mellon University, Pittsburgh, PA

Constant and affine policies are commonly used for approximating optimal policies in multistage robust optimization. The former is computationally efficient, while the latter often provides policies with desirable performance. In this work, we examine a natural transition between the two policy families and identify two types of sparsity associated with the concepts: information filters and information bases. Based on this, we develop an algorithm to construct a certain type of policies on-the-fly to obtain a near-optimal affine policy using a small-sized information basis. We prove that the performance of the policy obtained from this algorithm converges exponentially to the optimal affine policy. Then, we demonstrate its run-time efficiency via computational experiments.

3 A Branch-and-Cut Algorithm for Distributionally Robust Chance-Constrained Programs with a Finite Support

Hamed Rahimian, Soumya Pathy, Clemson University, Clemson, SC, Contact: hrahimi@clemson.edu

In this talk, we study a distributionally robust optimization approach to chance-constrained stochastic programs to hedge against uncertainty in the distributions of the random parameters. We assume that there are a finite number of scenarios to represent the uncertainty and model the distributional ambiguity with a polyhedral set. We propose a decomposition-based algorithm to solve the resulting problem, and showcase our results for ambiguity sets formed via moment-based constraints, total variation distance, and Wasserstein distance.

4 Robust Design of Critical Supply Chains

Hao Hao[1], Peter Zhang[1], Erica R. Fuchs[1], Ningji Wei[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Texas Tech University, Lubbock, TX, Contact: haohao@andrew.cmu.edu

The challenge of balancing resiliency and efficiency with limited resources in critical supply chains requires a principled approach. To this end, we propose a two-stage supply chain design model under uncertainty. Our model captures the trade-off between cost and robustness under worst-case supply and demand disruptions; as well as the multiple time scales of resiliency building and contingency planning. Specifically, the model optimizes for the risk-mitigating first-stage network design and resource allocation that maximize the total profit under both common uncertainty and extreme events. We deploy affinely adjustable robust optimization (AARO) formulations to our problem. We provide theoretical support for (near) optimality of this method and demonstrate its tractability through numerical studies on semiconductor and pharmaceutical supply chains.

Continuous Labor Planning for Ultra-Fast Delivery at Amazon

Community Committee Choice Session

Session Chair: Martin Savelsbergh, ISyE Georgia Tech, Darlington, Australia

1 Continuous Labor Planning Overview
Roman Levkin, Thomas Fillebeen, Amazon, Seattle, WA
Given the volatility in labor supply and customer demand, Amazon supply chain businesses can benefit from a blended fixed and flexible under-the-roof labor workforce. Fixed associates, working a reoccurring shift pattern week-over-week, enable the business to lock a baseline capacity with a certain guarantee early. Flexible associates, picking up on-demand shifts each week, allow business to accommodate volatility. To facilitate blended workforce planning at scale, we introduced the Continuous Labor Planning (CLP) suite of decision support tools. CLP posts on-demand shifts from 3 weeks to 2 hours ahead of operations trading off improving forecast accuracy and decreasing associate acceptance probabilities. This enables scheduling to staff as close as possible to actual labor demand, which reduces costs.

2 Labor Plan Optimization for Under-the-Roof Operations at Amazon
Zeynep Sargut, Amazon, Bradenton, FL, Contact: zeyneps@amazon.com
An under-the-roof (UTR) associate at an Amazon Ultra-Fast delivery site can work on multiple processes such as inbound and outbound, where each process has its own tasks with corresponding deadlines. A labor plan translates the most recently task forecasts from different processes into a blueprint of how many associates are needed at each process at each time for a given operating period. To create an operationally feasible and cost-effective labor plan, an optimization model is proposed where the costly time-periods, available shifts, time-dependent productivity rates, priorities of processes, associate transfer times between processes, and target process buffers are considered. The optimal labor plan forms the basis for the creation of associate shifts and directly impacts labor planning cost.

3 Shift Creation and Modification for Under-the-Roof Operations at Amazon
Ramon Auad, Amazon, Atlanta, GA
Shift modifications and incremental postings are foundational to run a seamless and cost-effective under-the-roof operation at Amazon. We present an optimization-based modular system to create and modify associate shifts in response to variability in demand and supply. In case of higher-than-expected demand, the system fills gaps between the labor plan and existing associate shifts by recommending either the creation of incremental flexible shifts or the extension of existing ones. Conversely, when demand is lower than expected, it reduces existing shift hours by recommending voluntary time off opportunities. The system ensures that scheduled shifts are aligned with labor requirements, thereby minimizing costs and maximizing customer and associate experience.

4 Continuous Shift Release for Amazon's Ultra-Fast Delivery Business
Hadi Panahi[1], Thomas Fillebeen[2], Roman Levkin[2], [1]Amazon, St. louis, MO, [2]Amazon, Seattle, WA
Continuous labor planning (CLP) leverages incremental on-demand shift postings for flexible associates at multiple planning horizons prior to the operation day. Once shifts are posted, flexible associates can choose their preferred shifts.

The amount of required labor hours at a given planning horizon is determined by demand forecast accuracy and the likelihood of associates selecting shifts. Posting shifts early benefits from higher likelihood of shifts acceptance while posting late takes advantage of a more accurate demand forecast. Continuous Shift Release (CSR) is an optimization model which determines the shift release cadence by planning horizon while respecting business service level agreements.

5 Fulfillment Capacity Allocation for Ultra-Fast Delivery at Amazon

Saba Neyshabouri, Amazon

In ultra-fast delivery, customer promise windows that overlap share fulfillment capacity. In particular, high speed promise windows that overlap with the flexible ones compete for shared capacity. To make this capacity allocation decision, the capacity allocation engine (CAE) maximizes capacity utilization while maximizing delivery fee revenue. It has an offline component that sets order distribution targets and an online component that seeks to meet these targets. CAE can be extended to close the loop on the continuous labor planning by connecting the signals from labor supply, and managing the promise window availability to increase demand.

Learning in Transportation Network Modeling: Session I

Community Committee Choice Session

Session Chair: Zhichen Liu, University of Michigan, ANN ARBOR, MI

1 Wardrop Equilibrium Can be Boundedly Rational: A New Behavioral Theory of Route Choice

Jiayang Li, Zhaoran Wang, Marco Nie, Northwestern University, Evanston, IL, Contact: JiayangLi2024@u.northwestern.edu

In transportation, it is widely believed that Wardrop equilibrium (WE) has a relatively weak behavioral underpinning. To strengthen this foundation, one must reckon with bounded rationality, which was typically accompanied by a modification of WE. Here we show that giving up perfect rationality need not force a departure from WE. On the contrary, WE can be reached in a routing game played by boundedly rational travelers. We achieve this result by developing a day-to-day model called cumulative logit (CULO), which assumes routes are valued based on the accumulative cost received in the past. We prove the convergence of CULO toward WE under mild conditions. Our theory thus upholds WE's role as a benchmark. It also resolves the theoretical challenge posed by Harsanyi's instability problem by explaining why equally good routes at WE are selected with different probabilities.

2 Modeling Multi-modal Curbside Usage In Dynamic Networks: A Computational Graph Approach

Jiachao Liu[1], Sean Z. Qian[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: jiachaol@andrew.cmu.edu

The proliferation of emerging mobility technology prompts an explosive growth in demand for ride-hailing services and on-demand deliveries, transforming curb spaces into valuable but unprecedentedly oversaturated public infrastructure. It is critical to analyze the system-level impacts associated with multi-modal curb usage and to understand the interactions among curb users to facilitate optimal curb management. Our study proposes a curb-aware network modeling framework that encapsulates the route choice, competition, and interactive effect among various curb users and embeds the curb usage dynamics and associated network impact into the mesoscopic dynamic network loading model. Emerging curb usage data is used to calibrate the framework with other multi-source data via a computational graph approach. Two networks are used to test our proposed framework.

3 A Unified Framework for End-to-End Transportation Network Equilibrium Modeling

Zhichen Liu, University of Michigan, ANN ARBOR, MI

This study aims to develop a unified end-to-end framework for building transportation network equilibrium models from empirical data. The framework unifies the use of model-based and model-free approaches for representing supply/demand-side modeling components and directly learns them and the equilibrium state from data. Specifically, it uses computational graphs with learnable parameters to approximate unknown modeling components and embeds them in a variational inequality (VI) that enforces user equilibrium conditions. By minimizing the differences between the estimated and observed travel times, the parameters for supply/demand-side components are simultaneously estimated. Theoretically, the proposed framework can approximate target link times with infinitely small errors if the VI is well-posed.

4 Revitalizing Bottleneck Models: Integrating Calibratable Schedule Delay Disutility from a Queuing and Machine Learning Perspective

Mohammad Abbasi, Xuesong Zhou, Arizona State University, Tempe, AZ, Contact: mohammad_abbasi@asu.edu

This talk discusses the limitations of bottleneck models in transportation planning and proposes an approach to address these issues. It explores the use of polynomial fluid queues to improve the understanding of traffic dynamics at oversaturated bottlenecks. By integrating different modeling approaches, including macroscopic analytical formulations and mesoscopic queue vehicular fluid models, the speaker aims to capture the complex relationship between dynamic demand, supply, and congestion. The approach is demonstrated through case studies conducted in congested corridors of cities like New York, Los Angeles, and Phoenix, using real-world data. The talk emphasizes how traditional models can be enhanced with machine learning techniques to tackle modern transportation planning challenges such as eco-routing and eco-arrival control.

Optimizing Service Facilities to Improve Freight Transportation Operations

Community Committee Choice Session

Session Chair: Adrian Hernandez, Northwestern University, Evanston, IL

1 Delivering Efficiency: Joint Optimization of Parcel Locker Location and Configuration Considering Vehicle Routing and Flexible Delivery Alternatives

Lissa Melis, Vikash V. Gayah, Andisheh Ranjbari, Penn State University, University Park, PA, Contact: lissa.melis@uantwerpen.be

To respond to the growing challenge of the last-mile delivery of goods, the use of parcel lockers has been widely proposed as an alternative to home deliveries. When a carrier wants to use company-owned parcel lockers, three decisions need to be made: the number of lockers provided, the location of the lockers and the internal configuration and capacity of the lockers. An optimization problem that combines these decisions with vehicle routing and alternative delivery strategies (home or locker delivery), has not yet been investigated in the literature. We will therefore introduce Parcel Locker Location-Configuration-Routing Problem with Flexible Delivery alternatives. As a solution method, we propose an adaptive large neighborhood search heuristic that considers both the carrier's and customer's perspective. We will conclude with some managerial recommendations.

2 Optimal Extreme Fast Charging Station Investment with Renewable Energy Generation and Storage

Ridvan Aksu, Mesut Yavuz, University of Alabama, Tuscaloosa, AL, Contact: myavuz@cba.ua.edu

Extreme Fast Charging (xFC) stations are key to widespread adoption of electric vehicles in commercial transportation due to the high energy demand of Medium and Heavy Duty (MD/HD) freight vehicles. Due to intense power requirement of xFC, power grids struggle to keep up with the demand. We analyze utilizing renewable energy generation and energy storage systems for a viable investment plan for such a station. Based on DCFC station design for an uncertain operation environment we optimize the station investment plan through the generation and storage capacities, as well as the energy storage policy.

3 Multi-Stage Stochastic Optimization of Intermodal Freight Transportation: A Case Study of the U.S. Southwest Supply Chain

Sarita Rattanakunuprakarn[1], Mingzhou Jin[2], [1]University of Tennessee, Knoxville, TN, [2]University of Tennessee, Knoxville, Knoxville, TN, Contact: srattan3@vols.utk.edu

Freight supply chains in the United States face significant and persistent challenges, including traffic congestion, extended drayage time, workforce shortages at ports, warehouses, and among truck drivers, as well as social and environmental concerns. We study an inbound supply chain problem within the U.S. Southwest region, employing mixed-integer stochastic programming to minimize transportation costs under demand uncertainty. The first-stage decision determines long-term strategies for optimal logistics centers equipped with intermodal facilities to improve accessibility to railroad systems. The sub-problem stages are formulated as network flow problems to determine transportation operations for a one-year period. This includes determining the optimal routing and the assignment of the number of goods to be loaded onto railcars and trucks.

4 Enhancing Infrastructure Network Resilience Under Uncertainty: A Network Completion Strategy

Mohamad Darayi, The Pennsylvania State University--

Great Valley, Malvern, PA, Contact: mud415@psu.edu

The functionality of infrastructure networks is threatened by disruptive events that can disable the networks' capacity. This research proposes a simulation-based optimization model to allocate budget under uncertainty to enhance network resilience via network hardening and/or network completion strategies. The proposed model is implemented in a stylized case study of Pennsylvania's freight transportation network.

5 Locating and Sizing Refueling Facilities to Support Freight Rail Decarbonization

Adrian Hernandez[1], Max Ng[2], Pablo Luis Durango-Cohen[2], Hani S. Mahmassani[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL

The decarbonization of energy intensive transportation services with cyclic operations on expansive networks (e.g., freight rail, trucking, and intercity bus services) presents significant challenges. We present a flexible framework, consisting of two components, to address the problems of locating and sizing service facilities on existing networks. We extend nominal flow-based facility location models to account for repositioning rolling stock along cyclical trajectories to enable periodic service. For these, we present a formulation for point-to-point service and a formulation which considers intermediate O-D flow capture (i.e., chained trips). We also present a minimum cost network flow model to determine optimal energy sourcing strategies. We illustrate these formulations on an example corridor and a portion of the US rail network.

Predictive and Constraint based Learning Techniques with Business Applications

Community Committee Choice Session

Session Chair: Neta Rabin, Tel-Aviv University, Tel-Aviv, Israel

Session Chair: Gonen Singer, Bar-Ilan University, Ramat Gan, Israel

1 A Hybrid Cost-Sensitive Machine Learning and Optimization Models for the Resource-Constrained Classification Problem

Gonen Singer[1], Lior Rabkin[1], Matan Marudi[1], Itay Margolin[2], [1]Bar-Ilan University, Ramat Gan, Israel; [2]Intuit, Tel-Aviv, Israel. Contact: gonen.singer@biu.ac.il

Resource-constrained classification tasks are common in real-world applications such as allocating tests for disease diagnosis and hiring decisions when filling a limited number of positions. We propose a comprehensive analytic framework for scenarios that, in addition to including multi-class classification problems with misclassification costs, also have constraints on the number of classified samples of classes due to resource limitations. To classify samples under the constraints, the framework uses a probability matrix generated by a trained cost-sensitive classifier as the input for an optimization model with a minimum cost objective and resource allocation constraints. To illustrate its effectiveness and applicability, the framework with a cost-sensitive neural network was applied in the context of a medical resources allocation case study.

2 Utilizing Machine Learning Methods for Improving the Readiness of the Fire and Rescue Authority

Neta Rabin[1], Gonen Singer[2], Yaniv Leucher[1], Elan Zamler[3], Michael Belinsky[3], [1]Tel-Aviv University, Tel-Aviv, Israel; [2]Bar-Ilan University, Ramat Gan, Israel; [3]Israel National Fire and Security Authority, Rishon Lezion, Israel

Fire fighting services employ historical and online datasets for prediction of fires, improving preparedness and risk analysis. In Israel, this field is still in its initial stages, and although the Fire Authority holds large amounts of data, a system that transforms this data into practical insights does not exist. In this work, we fuse internal datasets together with information from external sources in order to identify typical patters that increase the risk for fires and patterns that are associated with response to hazards. We focus on dimension reduction methods for pattern recognition and prediction methods, such as XGBoost and kernel based regression for forecasting future hazards per district.

3 Optimizing Flow Shop Scheduling with Shift Constraints: A Genetic Algorithm Approach

David Freud, Amir Elalouf, Bar-Ilan University, Ramat Gan, Israel

Our study introduces a new variation of the classic flow shop scheduling problem (FSSP) by imposing “shift constraints” where machines are only permitted to begin processing a job if they can complete it within a given and defined shift duration. We use a genetic algorithm that integrates an encoding scheme, selection and crossover operators, a mutation operator, and a fitness function. Our findings indicate that the genetic algorithm yields better results than the NEH algorithm, a commonly used benchmark across various instances.

4 Design for Explainability: A New XAI Method Based on Design of Experiments

Irad Ben-Gal, David Steinberg, Aviv Notovich, Tel-Aviv University, Tel Aviv, Israel. Contact: bengal@tauex.tau.ac.il

We propose a new Design for Explainability (DFX) methodology that for a given trained Machine Learning (ML) model; a feature training set; and a list of potential features interactions generates a Design of Experiments (DOE) plan to measure the importance or the effect of features, while estimating selected high-order features' interactions, with a lower computational cost than the SHAP.Experiments show that DFX and SHAP are equivalent in approximately 80% of the cases in identifying the top 10% of the most affecting features, while the DFX utilize on average 1.05% of the number experiments that are required by SHAP.

5 Spatio-Temporal Time-Series Forecasting Using an Iterative Kernel-Based Regression

Ben Hen[1], Neta Rabin[2], [1]Tel Aviv University, Israel; [2]Tel-Aviv University, Tel-Aviv, Israel

Spatio-temporal time-series forecasting is relevant in various domains like epidemiology or economics. Kernel-based regressions, which capture non-linear data-function relationships, provide simple and efficient forecasting models. In this work, we propose a kernel-based iterative regression model that utilizes multiscale kernels to fuse data from various spatial locations and improve the accuracy of time-series forecasting. The model resembles deep learning ideas but is easy to implement and effective for small datasets. Experimental results for forecasting solar energy, epidemiology infections, and fire event forecasts show that the proposed model outperforms existing techniques.

1 Flying High with Improved Data: How an Instructor Training Workshop Boosting Pilot Competency Assessment

Qingyin Ge, NUS IORA, Singapore, Singapore

Data informativeness is crucial for effective decision-making. In the context of pilot competency evaluation within an international airline, under a discrete grading scale from 1 to 5, we observed limited variation in grading, with grades being dominated by '3' (83%) and '1' or '5' rarely used (<0.1%). Instructor interviews revealed varied interpretations of the grading rubric, particularly the ambiguous '3'. The lack of specificity could lead to uniform yet potentially spurious grading patterns, adversely affecting trainee development and the integrity of the airline training system. Our research tackles a salient issue in pilot training: the tendency of instructors to default to a constant, neutral grade, thereby hindering the granularity and usefulness of feedback. More specifically, we ask: Can information sharing sessions for instructors trigger more varied and informative grading behavior? We hypothesize that this intervention raises informativeness of pilot competence assessments, thereby enhancing the grading efficacy. Our research combines Abadie's synthetic control method and the multi-period DiD approach to estimate the causal effect of information sharing workshops on instructors' grading patterns. The former method is applied for pre-treatment fit, the latter for treatment effect detection. Furthermore, our study serves as a pioneering exploration of evaluator behaviors and grading bias within the aviation sector.

2 The Terminal Airspace and Sequencing and Scheduling Problem (TASSP): An Optimization Approach

Wayne Ng, Singapore University of Technology and Design, Singapore, Singapore

The terminal airspace is crucial for aviation operations. It handles incoming and outgoing aircraft at airports. Efficient management of this airspace is essential for safety and reducing operational challenges. Proper sequencing and scheduling of aircraft are important to minimize delays, fuel consumption, and emissions. While runway sequencing and scheduling have received attention, optimizing aircraft sequencing in previous waypoints leading to the runways has been overlooked. Air Traffic Controllers (ATCs) need to intervene before aircraft reach the runway to ensure desired sequencing. This involves speed control, utilization of holding stacks, and vectoring techniques. In this research, we propose an integrated optimization approach that utilizes matheuristic algorithms to optimize runway aircraft sequencing and decisions in the terminal airspace, including aircraft speeds, utilization of holding stacks, and vectoring. We evaluate the algorithm using data from the congested terminal airspace of Changi Airport in Singapore. Our proposed algorithm employs an iterative process that combines a Linear Programming (LP) model with a Genetic

Algorithm, enabling the rapid generation of feasible solutions (within 1 second) and convergence to near-optimal solutions in approximately 10 minutes. To the best of our knowledge, this is the first algorithm that incorporates holding and vectoring decisions using optimization methods. When compared to commercial microsimulation models like Airtop, our proposed algorithm is capable of providing similar solutions within seconds. Furthermore, when left to optimize the runway sequence, the algorithm outperforms the ad-hoc routines from Airtop, resulting in significantly reduced delays. We address the Terminal Airspace Sequencing and Scheduling Problem (TASSP) as an optimization challenge. Our modeling approach represents the terminal airspace as a graph, with nodes representing intersections or holding stacks, and links denoting the aircraft paths. We optimize the continuous variable of time taken for each link, which encompasses aircraft speed or additional time resulting from vectoring. Nodes with holding patterns account for the time spent in holding. The objective is to minimize the overall flight time for aircraft traveling to and from the runway, while always adhering to the minimum separation standards (e.g. from ICAO).

3 Learning in the Airspace for Combinatorial Network Routing

Xiyitao Zhu, University of Illinois Urbana-Champaign, Champaign, IL

In aircraft trajectory planning, information about weather conditions in the airspace is critical, because planners utilize such information to decide what trajectory an aircraft could take to reduce its travel cost. However, in current practice, the information collection is spatially and temporally sparse. Specifically, aircraft usually herd onto traveling through well-used paths, so the updated weather information is limited to only a few sections of the airspace. In other words, other sections are mostly unsampled and potentially useful information about these less-traveled sections gets outdated quickly as weather changes dynamically over time. These information-related shortcomings leave great potential for improvement in aircraft trajectory planning and necessitate a better information collection process. In the best interest of the Federal Aviation Administration (FAA), one proposed way to address such shortcomings is to use en-route aircraft as sensors to sample the airspace and collect near-real-time information while traveling. That means, certain aircraft could be used to explore the less sampled airspace and collect information for other aircraft to exploit for future routing decisions to minimize the total travel costs in the aviation system. The exploration-exploitation trade-off is first addressed in the multi-armed bandit (MAB) framework. Existing works have analyzed different variants of MAB. Particularly in the airline routing setup, the uncertainty structure of wind conditions in the airspace by an Ornstein-Uhlenbeck process and proposes different algorithms with performance guarantees applied to airline networks with disjoint paths that do not share any common arcs in the corresponding graph. Yet, the airline routing network has a natural combinatorial structure. Our work tries to extend this scope by incorporating the combinatorial consideration and seek to design sampling strategies/algorithms that take advantage of the combinatorial structure of the problem. We also propose a new algorithm and we are working on upper bounding its regret. The results would not be limited to the airline network routing problems; they are also applicable to general bandit setups with spatial-temporal correlation and combinatorial structures, which haven't been studied before.

Generative AI, Content Creation, and Platforms

Community Committee Choice Session

Session Chair: Hong Zhang, University of Texas at Dallas, Richardson, TX

1 Designing A Personalized Generative Framework Towards Better Content Creation Strategy

Hong Zhang[1], Hongchang Wang[2], Amit Mehra[1], Zhiqiang Eric Zheng[3], [1]University of Texas at Dallas, Richardson, TX, [2]University of Texas at Dallas, Allen, TX, [3]University of Texas-Dallas, Richardson, TX

While the emergence of generative AI tools boosts content production, it lacks the ability to align with market preferences in the sense that the content generated by AI may not necessarily be appreciated by humans as intended. Further, current generative AI falls short of customizing content creation based on creators' experiences. This paper develops a personalized generative framework to assist creators in adopting better creation strategies with improved content sales. Toward that end, we incorporate GPT3 with a reinforcement learning reward model to make AI aligned with content-sale objectives. This architecture is further augmented by higher rewards when the contents generated by GPT3 don't deviate too much from the creator reference model in order to realize content personalization. We subsequently evaluate the framework in a non-fungible token (NFT) market.

2 Generative AI, Human Creativity, and Art

Eric Zhou, Dokyun Lee, Boston University, Boston, MA, Contact: ebzhou@bu.edu

This research examines the impact of Generative Artificial Intelligence (AI) on human creativity and its implications for content production. With the advent of AI algorithms capable of generating music, digital artworks, code, and stories, the line between human and machine-generated creativity has become blurred. As generative AI continues to evolve, it's essential to understand its effects on creative production and the perception of creative artifacts. Using data from an online Art sharing platform, the study focuses on three research questions: the influence of generative AI on human creative production, its role in enabling more innovative content, and its impact on creative expression and artistic content.

3 What's in a Name? the Impact of Artist Names in Image Generator Prompts

Jason Bell, Oxford University, Oxford, United Kingdom. Contact: jason.bell@sbs.ox.ac.uk

Widely accessible Generative AI has the potential to accelerate creativity, but also raises questions about the economics of art, intellectual property, and control of data. Generative image models are typically trained on datasets which include work from artists who did not give consent. End users often use artist names to replicate particular styles, which has already led to lawsuits. We examine the effects of artist names in image prompts. We use both a vision transformer and a choice model estimated on conjoint data. We demonstrate a means of conservatively estimating the impact of artist names in image prompts on preferences and willingness-to-pay. More broadly we offer insights into data sourcing for generative AI.

4 Large Language Model In Creative Work: The Role Of Collaboration Modality And User Expertise

Zenan Chen[1], Jason Chan[2], [1]University of Minnesota-Twin Cities, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: chen6029@umn.edu

Large Language Models (LLMs) are rapidly being adopted by businesses to assist users in a wide range of open-ended tasks, including ones that require creativity. We conducted an experiment where we task both expert and non-expert users to write an ad copy with and without the assistance of LLMs. We compare two ways of working with LLMs: (1) using LLMs as "ghostwriters," which assume the main role of content generation task and (2) using LLMs as "sounding boards," to provide feedback based on human-created content. Our results show that the two human-LLM collaboration modalities can have very different outcomes. Using LLMs as sounding boards yields an overall positive effect, by enhancing the quality of the resultant ad copies, especially for non-experts. However, using LLMs as ghostwriters did not provide significant benefits and is in fact detrimental to expert users.

Machine Learning Meets Discrete Optimization

Community Committee Choice Session

Session Chair: Stefano Gualandi, Princeton
Session Chair: Thiago Serra, Bucknell University, Lewisburg, PA

1 The Bemi Stardust: A Structured Ensemble of Binarized Neural Networks

Stefano Gualandi[1], Ambrogio Bernardelli[1], Simone Milanesi[1], Hoong Chuin Lau[2], Neil Yorke-Smith[3], [1]University of Pavia, Pavia, Italy; [2]Singapore Management University, Singapore, Singapore; [3]Delft University of Technology, Delft, Netherlands

Binarized Neural Networks (BNNs) are receiving increasing attention due to their lightweight architecture and ability to run on low-power devices. The state-of-the-art for training classification BNNs restricted to small dataset is based on Mixed Integer Programming. This paper proposes the BeMi ensemble, a structured architecture based a single BNN for each possible pair of classes and applying a voting scheme to predict the final output. The training of a single BNN is achieved by a MIP model that optimizes a lexicographic multi-objective function. We computationally validate our model using the MNIST and Fashion-MNIST datasets. While previous approaches achieve an average accuracy of 51.1% on the MNIST dataset, our approach achieves an average accuracy of 61.7% when trained with 10 images per class and 76.4% when trained with 40 images per class.

2 Optimizing Objective Functions from Trained Relu Neural Networks

Georgia Perakis[1], Asterios Tsiourvas[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: atsiour@mit.edu

In recent years, practitioners and academics have been increasingly incorporating machine learning models in data-driven optimization problems for decision-making. We introduce scalable algorithms that enable the integration of ReLU networks into data-driven optimization problems. Our algorithm takes advantage of the piecewise linear structure of ReLU neural networks and reduces the initial mixed-integer optimization problem (MIP) into several easy-to-solve linear optimization problems (LPs) through sampling. We demonstrate that the algorithm achieves a locally optimal solution from the first iteration, and we present a precise bound on the number of samples required for computing an optimal solution. We validate the performance of the proposed algorithms by conducting extensive numerical experiments with synthetic and real-world data.

3 Getting Away with More Network Pruning: From Sparsity to Geometry and Linear Regions

Junyang Cai[1], Khai-Nguyen Nguyen[1], Nishant Shrestha[2], Aidan Good[1], Ruisen Tu[1], Xin Yu[3], Shandian Zhe[3], Thiago Serra[1], [1]Bucknell University, Lewisburg, PA, [2]Bucknell University, Lewisburg, [3]University of Utah, Salt Lake City, UT, Contact: thiago.serra@bucknell.edu

One surprising trait of neural networks is the extent to which their connections can be pruned with little to no effect on accuracy. But when we cross a critical level of parameter sparsity, pruning any further leads to a sudden drop in accuracy. This drop plausibly reflects a loss in model complexity, which we aim to avoid. In this work, we explore how sparsity also affects the geometry of the linear regions defined by a neural network, and consequently reduces the expected maximum number of linear regions based on the architecture. We observe that pruning affects accuracy similarly to how sparsity affects the number of linear regions and our proposed bound for the maximum number. Conversely, we find out that selecting the sparsity across layers to maximize our bound very often improves accuracy in comparison to pruning as much with the same sparsity in all layers.

4 Fitting Hyperplanes to Minimize the Quantile Error in Noisy Data Sets

John W. Chinneck[1], Paul Brooks[2], [1]Carleton University, Ottawa, ON, Canada; [2]Virginia Commonwealth University, Richmond, VA, Contact: chinneck@sce.carleton.ca

Given a noisy set of data points (general fit) or a set of data points and an outcome variable (regression fit), contaminated with outliers, the goal is to fit a hyperplane that minimizes the maximum error for some quantile of the data points, often 50% of the points. This is a difficult problem in statistics. Mixed-Integer Optimization (MIO) algorithms provide an exact solution for small data sets but do not scale well. We develop (i) fast heuristic methods, and (ii) an improved MIO that is more scalable and effective than the existing MIO formulation, especially in combination with initialization heuristics. We examine the effect of halting the MIO early. Also, since it is sometimes assumed that a quantile-error minimizing fit is a good fit to the complete set of inliers in a data set, we examine whether this is true.

5 Mending Neural Networks with Logic: Case Studies in Language Technology

Vivek Srikumar, The University of Utah, Salt Lake City, UT

Large language models command the state-of-the-art across natural language processing. But such models can be opaque monoliths whose behavior is difficult to control except via explicit supervision.

In this talk, I will present a new paradigm for training machine learning models using discrete knowledge rather than simple data supervision. This framework allows us to guide models to satisfy specific properties that are expressed in logic. Specifically, I will show how we can systematically compile declarative constraints into regularizers that guides model training. I will present experiments which show that adding such declarative knowledge gives models are not only more accurate, but also more self-consistent in their predictions.

Exploring Equity and Fairness in Public Services Administration

Community Committee Choice Session

Session Chair: Nathan Adeyemi, Northeastern University, Boston, MA

1 Disaggregating Power Outages From Disconnections: A Commonwealth Edison Case Study

Akua McLeod[1], Amritanshu Pandey[2], Destenie Nock[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Vermont, Burlington, VT, [3]Carnegie Mellon University, Pittsburgh, PA, Contact: aamcleod@andrew.cmu.edu

Power outages negatively impact household resilience and cause energy insecurity. Standard metrics measure reliability across an electric utility service territory, but miss the details of how outages are experienced by different demographic groups. We develop a new model for disaggregating power outages from disconnections in residential electricity consumption AMI data, using logistic regression. We then evaluate how the duration and frequency of outages change across zip codes with different demographics within the Commonwealth Edison service territory.

Leveraging this analysis, we provide more granular metrics for electricity reliability, thus highlighting gaps in energy accessibility, and informing equitable investment in electric distribution infrastructure.

2 Amplified Access for All: A Simulation and Metaheuristic Guided Approach to Psychiatric Inpatient Bed Redistribution

Nathan Adeyemi[1], Kayse Lee Lee Maass[2], [1]Northeastern University, Boston, MA, [2]Northeastern University, Boston, MA, Contact: adeyemi.n@northeastern.edu

This work aims to improve patient access to care by reallocating inpatient mental health beds, reducing long wait times in the Emergency Department (ED) for individuals with mental health crises. A simulation was developed involving over 140 healthcare provider locations to model patient trajectories from ED care to inpatient treatment. The simulation considers patient characteristics and hospital resources to determine a patient's final treatment location. Output statistics were used in a multi-objective optimization model to allocate psychiatric treatment beds across the state. Findings indicate improvements in key access metrics including reductions in patient treatment delay, travel distance for externally transferred patients, and the total number of patients treated, promoting equitable and efficient access to inpatient mental healthcare.

3 Heterogeneous Impact Of LIHEAP On Non-economic Measures Of Energy Consumption

Jaih Hunter-Hill, Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA

Standard metrics of success of the Low-Income Home Energy Assistance Program (LIHEAP) primarily focus on household energy burden reduction--failing to capture how the program changes household energy consumption patterns. Understanding these patterns can shed light into non-economic effects of LIHEAP program participation within households. We employ a Diff-in-Diff framework to analyze the impact of LIHEAP on energy consumption behavior. Leveraging this analysis, we provide insights into behavior shifts for LIHEAP funding recipients and offer suggestions for how vulnerable households shift energy usage following a reduction of financial burden.

4 A Simulation-Based Approach to Improve Equitable Housing Coordination in New York City

Yaren Bilge Kaya, Kayse Lee Lee Maass, Northeastern University, Boston, MA

This study uses simulation modeling to improve access to temporary public housing resources for runaway and homeless youth (RHY), a highly vulnerable population susceptible to human trafficking. By simulating a set of crisis and emergency shelters in New York City funded by a single governmental organization with demographic eligibility criteria, stochastic RHY arrival, impatient youth behavior, and a coordinator that determines which server pool RHY is routed to, we evaluate different queue routing strategies. Our simulation results suggest that changing the routing process can decrease the average wait time by one day and reduce the proportion of RHY abandoning shelters by 13%, providing a more efficient, equitable, and interpretable means of coordinating access to housing resources for RHY.

Multi-process Modeling, Monitoring, and Control in Smart and Connected Systems

Community Committee Choice Session

Session Chair: Chao Wang, University of Iowa, Iowa City, IA

1 Integration of Feedback and Feedforward Control in Laser Powder Bed Fusion

Rongxuan Wang, Chaoran Dou, Benjamin Bevans, Alex Riensche, Prahalada Rao, Amirul Islam Saimon, Zhenyu James Kong, Virginia Tech, Blacksburg, VA, Contact: rxwang@vt.edu

Laser powder bed fusion can fabricate complex geometries, but ensuring a high tolerance is challenging. The primary cause of the shape error is the melt pool size fluctuation due to heat accumulation. However, it is challenging to implement power compensation precisely because quantifying the heat accumulation in both part and local scales is computationally expensive. This work addresses this issue by integrating feedforward and feedback control on real-time laser power adjustment. The part-scale heat accumulation is considered by the FEA model. A heuristic method was used to suggest the printing temperature of each layer. The within-layer heat accumulation is regulated by a high-speed feedback laser power controller. The framework has been demonstrated on an open-source machine, and a high-resolution 3D scanner verifies the result.

2 Tensor-based Feedback Control for Local Structured High-dimensional Streaming Data Under Limited Control Capability

Zihan Zhang, Kamran Paynabar, Jianjun Shi, ISyE Georgia Tech, Atlanta, GA

This study introduces a tensor-based feedback control model for structured high-dimensional (LSHD) streaming data, addressing limitations of conventional control models. Unlike traditional models that often overlook local correlation structures, our approach leverages kernel distributions to capture local response auto-correlations and incorporates the practical knowledge of control actions. We propose a dynamic control strategy that determines optimal control locations to boost efficiency under resource constraints. The model effectiveness is confirmed through simulations and case studies.

3 Online Active Learning with Transfer Learning

Zengchenghao Xia, Chao Wang, University of Iowa, Iowa City, IA, Contact: zengchenghao-xia@uiowa.edu

Active learning guides design and modeling with high sampling costs, but current methods suffer cold-start problems. We use transfer learning to solve the cold-start problem by leveraging knowledge from related, data-rich processes. Specifically, we construct a multi-output Gaussian process (MGP) to model inter-process relationship. The MGP features i) a special covariance structure that characterizes inter-process relationship, and ii) an iterative online Bayesian framework for reducing computational load in parameter estimation. The inter-relationship captured by this novel MGP is then fed into the active learning using integrated mean-squared error as the objective. We provide theoretical justifications that the objective is non-increasing as we get more data. Numerical and real case studies are implemented to show the superiority of the proposed method.

4 The Agglomerative Attribute Grouping (AAG): A Nonparametric Subspace Analysis Method for Anomaly Detection, Forecasting and Clustering

Irad Ben-Gal[1], Dario Bacher[2], Morris Amara[1], Erez Shmueli[1], [1]Tel Aviv University, Tel-Aviv, Israel; [2]Tel-Aviv University, Tel Aviv, Israel

The agglomerative attribute grouping (AAG) is a new subspace analysis approach that looks for subspaces of highly correlative attributes. Such correlations can be used to improve the identification of abnormal data samples. The proposed AAG algorithm relies on a generalized multi-attribute measure (derived from information theory measures over attributes' partitions) for evaluating the "information distance" among various subsets of attributes. Extensive evaluation over real-world data sets demonstrates that in the vast majority of cases, AAG outperforms both classical and state-of-the-art subspace analysis methods for anomaly detection, forecasting, and clustering.

Knowledge Fusion for High-dimensional Data Modeling and Analysis

Community Committee Choice Session

Session Chair: Shancong Mou, Georgia Institute of Technology, Smyrna, GA

1 Knowledge-Driven Posterior Regularized Bayesian Neural Network with Aleatoric Uncertainty

Jiayu Huang, Yongming Liu, Hao Yan, Arizona State University, Tempe, AZ

Modelling uncertainties, epistemic and aleatoric uncertainty, is crucial for decision-making in various fields, as it allows us to quantify potential outcomes and risks. Epistemic uncertainty arises from a lack of knowledge or data and can be modelled using Bayesian Neural Networks (BNN). While aleatoric uncertainty, which is related to inherent randomness or variability, can provide more realistic uncertainty estimates that inform robust decision-making. Also, domain knowledge is commonly available in various fields and could improve the performance of BNNs. We propose to use posterior regularization and sampling methods to incorporate various types of knowledge constraints into BNN, considering aleatoric uncertainty. Our simulation and case studies demonstrate that the proposed model outperforms traditional BNNs without constraints.

2 Video Foreground Segmentation via Posterior Regularized Robust Bayesian Tensor Factorization

Shenghao Xia, Jian Liu, University of Arizona, Tucson, AZ,

Contact: shenghaoxia@arizona.edu

Video foreground segmentation is a critical step in detecting moving objects from the background in video processing. Tensor factorization has been used in foreground segmentation due to its mathematical convenience in processing complex high-dimensional data, such as color images and videos. However, traditional tensor factorization lacks the ability to incorporate domain knowledge on video properties and to explicitly consider the estimation uncertainty. In this research, a new Bayesian tensor factorization method is proposed to formulate the characteristics of the dynamic foreground as posterior regularization terms in an optimal estimation problem. A series of case studies have shown the performance improvement of the proposed model over benchmarks.

3 On the Statistical Power and Limit of Scientific Machine Learning

Yiping Lu, STANFORD, CA

I'll discuss the statistical limit of linear operator learning in this talk. We build the first min-max lower bound for this problem. The min-max rate has a particular structure where the more challenging parts of the input and output spaces determine the hardness of learning a linear operator. Our analysis also shows that an intuitive discretization of the infinite-dimensional operator could lead to a sub-optimal statistical learning rate. Then, I'll discuss how, by suitably trading-off bias and variance, we can construct an estimator with an optimal learning rate for learning a linear operator between infinite dimension spaces. We also illustrate how this theory can inspire a multilevel machine-learning algorithm of potential practical use.

4 Robust Learning for Unsupervised Fine-Grained Anomaly Detection

Shancong Mou, Georgia Institute of Technology, Atlanta, GA

Unsupervised Fine-grained anomaly detection is an important yet challenging problem, which has not been well addressed. Robust learning is able to achieve robust signal restoration under unknown corruptions. Therefore, it is a promising tool for achieving the fine-grained anomaly detection goal. However, current robust learning is mainly designed for image/functional curve data and relies on strong statistical assumptions of the signal component, which may limit its applications. In this talk, I will discuss the recent development of robust learning in addressing those limitations and its corresponding applications in unsupervised pixel-wise anomaly detection.

Pathway to Decarbonization of the Energy Sector

Community Committee Choice Session

Session Chair: Omer Karaduman, Stanford University, Cambridge, MA

1 Flattening Energy Consumption Curve by Direct Load Control Contracts

Ali Fattahi[1], Saeed Ghodsi[2], Sriram Dasu[3], Reza Ahmadi[4], [1]Johns Hopkins University, Baltimore, MD, [2]University of California, Los Angeles, Los Angeles, CA, [3]University of Southern California, Los Angeles, CA, [4]University of California Los Angeles, Los Angeles, CA, Contact: rahmadi@anderson.ucla.edu

Flattening Energy-Consumption Curves
by Monthly Constrained
Direct Load Control Contracts Direct load control contracts (DLCCs) are a class of incentive-based demand-response programs that allow utilities to assign "calls" to customer groups to reduce their energy usage by a pre-specified amount for a given length of time. We develop a hierarchical approximation approach, which consists of an annual problem and monthly problems, to solve the DLCC implementation problem effectively and in a reasonable amount of time.A large utility firm in California implemented our model and informed us that the additional reduction in cost was approximately 4%. Our sensitivity analysis reports the impact of managerial concerns on some policies to enhance customer experience, and provides insights for improving the features of DLCC contracts.

2 Optimization for Highly Decarbonized Clean Power Systems

Thomas Lee, Xin Chen, Andy Sun, Massachusetts Institute of Technology, Cambridge, MA, Contact: t_lee@mit.edu

In order to achieve high decarbonization, the US power grid needs significantly more wind, solar, and storage resources. Challenges remain as to how such systems can emerge, and be operated with high economic efficiency and low risk. The appropriate computational models for planning such a clean power system should balance sufficient levels of spatial, temporal, and scenario resolution. A large scale nodal-resolution power system planning model is developed, in order to study the investment and operations of optimal high-renewable systems in different regions of the US.

3 Quantifying the Likelihood of Imbalances from Variable Renewable Energy Sources: A Risk Scoring Methodology for Energy Generators

Andres F. Ramirez, Alberto J. Lamadrid, Lehigh University, Bethlehem, PA, Contact: anr422@lehigh.edu

We present a framework that integrates information from the output of the Security Constrained Economic Dispatch (SCED) and Security Constraint Unit Commitment (SCUC) to calculate a risk score for stakeholders in Electricity Systems. Simulations were conducted to evaluate the variability and sensitivity of the risk-scoring methodology. The score is sensitive to changes in the optimization models and can effectively identify high-risk generators. The risk score provides a quantitative measure of the likelihood that a generator will cause imbalances in the grid due to variability and uncertainty. The proposed framework was tested using real-world data from the New York system (NYISO), and the results showed that it can effectively identify high-risk generators.

Optimization under Uncertainty Applications for Electric Power Systems

Community Committee Choice Session

Session Chair: Hanbin Yang, cuhksz, Shenzhen, China

1 A Risk-Averse Maintenance and Operations Scheduling Model with Flexible Generation Under Wind Energy Uncertainty

Natalie Randall, Beste Basciftci, University of Iowa, Iowa City, IA

We propose a risk-averse contextual predictive maintenance and operations scheduling problem with flexible generation under wind energy uncertainty. We formulate the problem as a two-stage risk-averse stochastic mixed-integer program. Gaussian Process Regression is used to predict wind energy and is leveraged into the stochastic program through a conditional expectation. We solve this computationally challenging problem using a risk-averse progressive hedging algorithm. Our results show the impact of adopting a risk-averse approach compared to a risk-neutral one, and highlight the value of integrating flexible generation and contextual information that leads to cost-effective plans with less failures. The solution algorithm provides speed-ups compared to GUROBI and finds optimal solutions in most instances.

2 Multi-Period Power System Risk Minimization Under Wildfire Disruptions

Hanbin Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: hanbinyang@link.cuhk.edu.cn

Wildfire risk is increasing globally, posing a growing threat to power systems, with grid failures fueling the most destructive wildfires. In day-to-day operations, preemptive de-energization of equipment is an effective tool to mitigate the risk and damage of wildfires. However, such power outages have significant impacts on customers. This paper proposes a novel framework for planning preemptive de-energization of power systems to mitigate wildfire risk. We model wildfire disruptions as stochastic disruptions with random magnitude and timing and formulate a two-stage stochastic program. We develop a decomposition algorithm to generate adaptive shutoff plans before a disruption occurs. Our method reduces both wildfire damage costs and load-shedding losses over multiple periods, and our nominal plan is robust against the uncertainty model perturbation.

3 Uncertainty-Aware Power-Gas Infrastructure Planning Under Deep Decarbonization Scenarios

Rahman Khorramfar[1], Dharik Sanchan Mallapragada[2], Saurabh Amin[1], [1]MIT, Cambridge, MA, [2]MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, Contact: khorram@mit.edu

We consider a joint electricity power and natural gas infrastructure planning problem and propose stochastic programming (SP) and distributionally robust optimization (DRO) formulations that consider interannual variations in both energy demand and renewable energy supply, and account for the operational constraints of the joint system. We develop a computational approach that exploits the spatial correlation between electric power and natural gas demands both within and across load zones, resulting in a mixed-integer programming (MILP) formulation. We compare the resulting uncertainty-aware designs with the certainty equivalent problem for realistic power-gas systems in the U.S. New England region and highlight the importance of systematic modeling of inter-annual variability in demand and renewable energy supply.

4 A Framework For Balancing Power Grid Resiliency And Efficiency With Bi-objective Stochastic Integer Optimization

Ramsey Rossmann[1], Mihai Anitescu[2], Julie Bessac[2],

Michael C. Ferris[1], Mitchell Krock[2], Jim R. Luedtke[1], Line Roald[1], [1]University of Wisconsin-Madison, Madison, WI, [2]Argonne National Laboratory, Argonne, IL, Contact: rossmann2@wisc.edu

Designing a power grid that is both efficient on average and resilient to extreme weather events is a critical challenge. Traditional stochastic programming approaches to this are highly sensitive to sampling error due to the presence of low probability events with very high impacts. Stochastic programming also fails to account for system goals changing under extreme conditions. For example, when the power grid faces extreme weather the goal shifts to minimizing load shed, with little concern for cost. We present a bi-objective modeling approach that addresses these issues and illustrate it in the context of capacity planning in the electric grid. By having an objective that explicitly focuses on load shed in extreme temperature scenarios, we achieve better solutions with smaller sample sizes. We also show the importance of spatial correlation in temperature samples.

Game Theoretic Models of Energy Markets

Community Committee Choice Session

Session Chair: Joseph Edward Duggan, University of Dayton, Dayton, OH

Session Chair: Ramteen Sioshansi, Carnegie Mellon University, Pittsburgh, PA

1 Distributionally Robust Optimization for a Hybrid Power Plant Trading Electricity and Hydrogen

Andrea Gloppen Johnsen, Technical University of Denmark, Kongens Lyngby, Denmark

In this work we present a Distributionally Robust Optimization model for the optimal scheduling of a hybrid power plant comprised of a wind energy source and electrolyzer. The hybrid power plant can participate both in electricity and hydrogen markets, as well as ancillary service markets. However, it is also exposed to several sources of uncertainty, such as wind power production, market prices, and reserve activation. The proposed model is reformulated into a mixed-integer linear program to determine the optimal day-ahead power and reserve bids of the entire hybrid power plant. The model is applied to a case study in Denmark, part of the Synchronous grid of Continental Europe, and compared to both a deterministic and sample average approximation model.

2 Coordination of Operation of Shared Hydropower Reservoirs

Stein-Erik Fleten[1], Lennart Hagemann[2], Hossein Babazadeh[1], [1]Norwegian University of Science & Technology, Trondheim, Norway; [2]University of Duisburg-Essen, Essen, Germany. Contact: stein-erik.fleten@ntnu.no

Typical hydropower systems comprise several power plants along a river. These power plants often have different owners with distinct operating strategies, so there is a need for coordinating the release of production water from upstream reservoirs. We use optimization and complementarity models to analyze the case of an interesting coordination mechanism used in Sweden, where virtual individual reservoir levels and power swaps are elements that contribute to ensuring that the different owners can operate independently.

3 Strategic Sector Coupling? Market Power in Heat and Power Markets

Afzal Siddiqui[1], Sebastian Maier[2], [1]Stockholm University, Kista, Sweden; [2]University College London (UCL), London, United Kingdom. Contact: asiddiq@dsv.su.se

Decarbonisation of the power sector envisages vast uptake of variable renewable energy (VRE) technologies. Coupling between heat and power sectors via combined heat and power (CHP) plants could provide the flexibility needed to mitigate intermittent VRE output. However, firms with CHP plants could use the link between the two energy sectors to manipulate electricity prices. We use a bi-level model to investigate the incentives for such strategic behaviour. At the upper level, a firm with both heat-only and CHP plants determines its heat output and is constrained by power-market operations at the lower level. Such a strategic firm produces more (less) heat from its CHP (heat-only) plant vis-à-vis the social optimum in order to constrain its maximum power output. Thus, it uses its leverage to manufacture scarcity in the power market to boost the electricity price.

4 Underground Hydrogen Storage as a Tool for Enhancing Energy Security: An Economic Perspective for the German Case

Ange Blanchard, CentraleSupelec, Paris-Saclay University, Saclay, France. Contact: ange.blanchard@chaireeconomieduclimat.org

Hydrogen technology is essential for reducing emissions in sectors that are hard to decarbonize. In Germany, the demand for hydrogen is expected to double by 2035, and the majority of the supply will be imported. To address this issue, Underground Hydrogen Storage (UHS) is a potential solution that can lower production costs and enhance reliability. Our study assesses the value of UHS by analyzing its ability to leverage time arbitrage and its role in mitigating supply disruptions. We use a Stochastic Dual Dynamic Programming algorithm and a Markov Chain to account for the uncertainty surrounding renewable energy sources and potential supply shocks. By reducing the need for expensive hydrogen supply capacity, UHS facilities can serve as a hedge against supply risks, and political support in the form of subsidies or tenders is critical for UHS investment decisions.

Sustainable Supply Chains and Recycling

Community Committee Choice Session

Session Chair: Majid Alipanah, University of Arizona, Tucson, AZ

1 Sustainable Supply Chain for Recycling of Lithium-Ion Batteries in the United States

Majid Alipanah, Sunday Usman, Apurba Saha, Hongyue Jin, University of Arizona, Tucson, AZ, Contact: majidalipanah@arizona.edu

Recycling spent lithium-ion batteries (LIBs) has attracted lots of attention recently, due to the increasing demand for critical materials contained in LIBs, putting high pressure on their geological reserves. This study evaluated the potential of bioleaching technology as a sustainable solution for recycling spent LIBs. A supply chain model has been developed to include required upstream processes with the objective of maximize economic feasibility of the technology. The model has been applied for the U.S. and optimal supply chain configuration was identified, considering the main affecting factors on the economic viability of the technology. The economic viability of the technology was identified to be highly sensitive to the black mass price. The study also examined the non-cooperative scenarios where each tier tries to maximize its own profit.

2 To Donate or Not to Donate: Optimal Policies for Supermarket In-Kind Donations to Food Banks

Shabnam Salehi, Irem Sengul Orgut, Emmett John Lodree, University of Alabama, Tuscaloosa, AL

Food banks are non-profit organizations that collect donations from donors and distribute them to food insecure households through a network of charitable agencies. The quality of in-kind perishable donations received by food banks is a key factor in their operations and food distribution process. However, retailers, one of the major in-kind donors to food banks, may prefer to donate perishables as late as possible in hopes of selling the products, despite receiving a tax credit for the donated food. This study adopts the perspective of the supermarket with the goal of maximizing profit. We develop a decision model that identifies the best time for donating perishables. We find that, even in terms of retailers' profit, it is not always optimal to wait until the last minute to donate.

3 A Novel Optimization Model with Python Package for Controlling Harmful Algal Blooms in Lake Okeechobee

Ashim Khanal[1], Vahid Mahmoodian[2], Hadi Charkhgard[1], [1]University of South Florida, Tampa, FL, [2]USF, Tampa, FL, Contact: ashimkhanal@usf.edu

Our research aims to mitigate nutrient contamination in Lake Okeechobee, a large freshwater lake in the US, and its watersheds. Excessive nutrient pollution from fertilizers and various effluents has led to the proliferation of harmful algal blooms. Addressing this issue involves approaches like implementing preventative measures such as Best Management Practices (BMPs) to regulate nutrient loading and employing curative measures like Water Treatment Technologies (WTTs) to remove nutrients. Our study takes a comprehensive approach, utilizing a mathematical optimization model to minimize nutrient contamination. We optimize the choice and placement of BMPs and WTTs while considering uncertainties. Numerical analysis shows the effectiveness of our model in reducing contamination. We also offer a user-friendly Python package, 'NutrientRedOpt', in pip library.

4 The Impacts of Sustainable Supply Chain Strategies and Environmental Performance on Competitive Advantages

Yao-Te Tsai[1], Chia-Hui Yu[2], [1]National Kaohsiung University of Science and Technology, Koahsiung, Taiwan; [2]National Taipei University of Business, Taipei, Taiwan. Contact: yaottsai@nkust.edu.tw

Governments and international organizations have developed initiatives and commitments to address environmental issues. The key responsibility of business to society is to find a balance between environmental, social, and economic performance, and more and more companies are willing to reduce environmental pollution in their supply chain processes and become environmentally friendly. This study aims to examine the relationships between sustainable supply chain strategies, environmental performance, and competitive advantages. In addition, this study investigates the moderating effect of institutional pressures on the correlation between green supply chain strategies and competitive advantage.

Research on Innovative Platform Operations

Community Committee Choice Session

Session Chair: Ming Hu, University of Toronto, Minneapolis, MN

Session Chair: Zhoupeng (Jack) Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada

1 Mobile App Push Strategies on Consumer Engagement

Jiaru Bai[1], Qiang Gao[2], Zhuping Liu[3], [1]Stony Brook University, Stony Brook, NY, [2]Baruch College, City University of New York, New York, NY, [3]Baruch College, New York, NY, Contact: jiarub@uci.edu

Building on consumer behavioral theories, we hypothesize that mobile app push strategies should be based on consumers' spatial and temporal information. Leveraging unique large-scale consumer data on companies' push promotions and customers' responses from a mobile coupon platform, we calibrate a hidden Markov model to test and verify our conjectures.

2 Temporal or Spatial Pooling Solves Wild Goose Chase

Mingliu Chen[1], Ming Hu[2], [1]Columbia University, New York, NY, [2]University of Toronto, Toronto, ON, Canada. Contact: mc5006@columbia.edu

Wild Goose Chase is a phenomenon that may greatly hinder efficiencies in the ride-hailing context. A driver may drive a significant time for a pick-up but end up with a short ride. We propose implementing either temporal or spatial pooling to improve operational efficiencies in such systems. Under temporal pooling, an available driver is not immediately dispatched upon a rider's arrival but until a certain number of riders cumulated in the system. Then the driver is dispatched to pick up the closest one. In spatial pooling, drivers only pick up riders at certain locations instead of chasing them around the city. We show that both pooling mechanisms may greatly improve operational efficiencies. Furthermore, there exists an optimal rider density in temporal pooling, and the efficiency of spatial pooling critically depends on riders' disutility of traveling on foot.

3 Freelancers or Employees? A Field Experiment with a Food Delivery Platform

Wee Kiat Lee[1], Yao Cui[1], Qi Li[2], [1]Cornell University, Ithaca, NY, [2]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: liqi@cuhk.edu.cn

The ongoing debate surrounding the regulation of gig platforms to classify service providers as employees rather than freelancers has generated significant industry discussions. However, the potential impact of such a transition on the operational efficiency of gig platforms is largely unknown. In this paper, we adopt an operational perspective to examine this issue. We collaborate with a food delivery platform and implement a field experiment in which orders are randomly routed to freelancers and employees. Using the experimental results, we compare the job performance between freelancers and employees, and derive insights into how a platform should adjust its operational policies when it changes the recruitment status of service providers.

4 Dissecting Fake News: The Role of Novelty and Polarization in Information Diffusion

Senthil Veeraraghavan[1], Kenneth Moon[1], Yijing Zhang[1], Jiding Zhang[2], [1]University of Pennsylvania, Philadelphia, PA, [2]New York University Shanghai, Shanghai, China. Contact: yijingz@wharton.upenn.edu

This study examines the social dynamics of news sharing and its implication for misinformation and media slant. We aim to uncover the underlying economic motives that drive individuals to share news content on social media platforms such as Facebook. Specifically, we propose a method using NLP to quantify news novelty, factoring in its relation to a historical 'news pool' and exposure of similar stories over time and then study the role of novelty and surprise in sharing, and the influence of social tribalism.

Optimization for Social Good

Community Committee Choice Session

Session Chair: Jean Pauphilet, London Business School, London, United Kingdom

Session Co-Chair
Baizhi Song, London Business School, London, United Kingdom

1 Stability in Many-to-Many Matching of Refugees to Employment Opportunities via Integer Optimization

Marcela Vasconcellos, Andrew C. Trapp, Worcester Polytechnic Institute, Worcester, MA, Contact: msvasconcellos@wpi.edu

Millions of displaced persons are in vulnerable situations due to a lack of permanent solutions for their inclusion in host countries. We approach the challenge of finding formal employment for at-risk refugees by formulating a many-to-many matching problem using integer optimization. Stable matches are important for eliminating the envy that occurs when two players would prefer being matched to one another over their suggested match. We investigate the correctness and efficiency of existing and novel constraint inequalities that can serve to ensure stability in matching optimization models. We also explore their effect on the match quality in many-to-many scenarios. The proposed methods are tested on representative profiles of refugees and job opportunities.

2 Food Subsidies at the Base-of-the-Pyramid: Take-Up, Substitution Effects and Nutrition

Alp Sungu, Ali Aouad, Kamalini Ramdas, London Business School, London, United Kingdom. Contact: asungu@london.edu

We investigate the impact of consumer food subsidy programs on poor consumers' nutrient purchases and data-driven pathways to improve the efficacy of such programs. We conduct an experiment in an urban settlement in Mumbai, India. First, we open a subsidy store to mimic governments' food subsidy programs. Second, we equip local grocery stores with point of sale scanner devices and start a loyalty card program to track individuals' shopping baskets. By randomly assigning households to a subsidy program, we examine how government-like subsidies affect food shopping behaviour. Next, we exogenously vary the subsidized food. Based on estimates of the take-up rates, we uncover a tradeoff between the nutrient richness of different staples and their attractiveness to customers.

3 Optimizing the Path Towards Plastic-Free Oceans

Dick Den Hertog[1], Jean Pauphilet[2], Yannick Pham[3], Bruno Sainte-Rose[3], Baizhi Song[2], [1]University of Amsterdam, Amsterdam, Netherlands; [2]London Business School, London, United Kingdom; [3]The Ocean Cleanup, Rotterdam, Netherlands. Contact: bsong@london.edu

The rising plastic pollution in the oceans has considerable adverse effects on both ecosystems and economic activities. We partner with an NGO and build an optimization-based algorithm that optimizes the route of the plastic collection system to maximize its collection quantity under complex plastic dynamics. We model the problem as finding the longest path in a well-structured graph. The model can incorporate various operational constraints and be extended to larger decision spaces, such as joint planning of the route and the schedule of ship operations. One of the challenges is that plastic distribution is affected by the previous collection route. To solve this, we propose a search-and-bound type of method to efficiently search for the near-optimal solution. We validate our findings on historical ocean data and achieve more than 50% improvement over the current method.

4 Optimization of Ambulance Dispatch Decisions

Anton J. Kleywegt[1], Vincent Guigues[2], Victor Hugo Nascimento[3], [1]ISyE Georgia Tech, Atlanta, GA, [2]School of Applied Mathematics (EMAp), Fundação Getulio Vargas (FGV), Rio de Janeiro, Brazil; [3]Systems Engineering and Computer Science, UFRJ, Rio de Janeiro, Brazil. Contact: anton@isye.gatech.edu

Ambulance dispatch decisions affect response times to emergencies, quality of service provided by ambulances and crews, as well as distribution of ambulances in preparation for future emergencies. Ambulance dispatch decisions are made when an emergency call arrives and a decision is made which ambulance to dispatch, and when an ambulance completes a task and a decision is made where the ambulance should wait for the next dispatch. These decisions should take into account factors such as: (a) Ambulances and crews have different capabilities appropriate for different emergencies. (b) Different ambulances would provide different response times. (c) Available ambulances should provide good coverage for future emergencies. We propose a number of optimization models to support ambulance dispatch decisions, and compare their performance with methods from the literature.

Session Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

1 Supply Constraints and Housing Rental Market Equilibrium in the Sharing Economy: Evidence from the Airbnb Regulation

Guofang Huang, Jianing Li, Susan F. Lu, Qianli Xu, Purdue University, West Lafayette, IN

This paper analyzes the effects of a supply-constrained regulation on sharing platforms on the equilibrium of the housing rental market, including its quantity, price, and social welfare implications. Using the data from Airbnb, Zillow, and the United States Census Bureau, we examine how a supply-constrained regulation (specifically, the San Francisco's 2017 policy) on sharing platforms can balance the equilibrium of the housing rental market. Our analysis demonstrates that the supply-constrained regulation implemented in San Francisco is effective in reducing the supply of short-term sharing rentals and in reducing the equilibrium prices in the long-term rental market. Moreover, we find that the price effect is less pronounced in affordable housing segments compared to high-end housing segments.

2 Beyond The Average: Empirical Study Of Heterogeneity In Online Retail

Natalie Epstein[1], Santiago Gallino[2], Antonio Moreno[3], [1]Harvard Business School, Cambridge, MA, [2]University of Pennsylvania, Philadelphia, PA, [3]Harvard Business School, Boston, MA

The evolution from brick-and-mortar to online retail has increased service heterogeneity for consumers and cost-to-serve heterogeneity for retailers. In this paper, we show that service performance matters for customers' future purchasing behavior, that it can be a significant driver of operational costs, and the trade-offs between providing better service at higher costs.

3 Scaling Peer-to-Peer Marketplaces in Supply Constrained Markets Through Lease-to-Earn Contracts

Milind Sohoni[1], Neha Sharma[2], Achal Bassamboo[2], [1]Indian School of Business, Hyderabad, India; [2]Kellogg School of Management, Evanston, IL, Contact: mgsohoni@gmail.com

Peer-to-peer marketplaces find it hard to scale up in markets where there is low asset ownership, as in emerging markets, or markets with strict regulations such as New York City. To operate at a scale, many platforms in emerging markets finance assets through long-term leases and offer a share in revenue to users who rent out their assets, hence called lease-to-earn contracts. While such contracts have been effective in some markets, they have not met with success in some markets. In this paper, we find the optimal lease-to-earn contract and theoretically find the value of such contracts.

4 Evolution of Ride Services: From Ride Hailing to Autonomous Vehicles

Daehoon Noh[1], Tunay Tunca[2], Yi Xu[3], [1]University of California, San Diego, San Diego, CA, [2]Robert H. Smith School of Business, College Park, MD, [3]University of Maryland, College Park, MD, Contact: dnoh@ucsd.edu

In recent years ride service industry has been evolving rapidly driven by disruptive technologies such as mobile apps and autonomous vehicles (AVs). While decentralized Ride Hailing companies have gained significant market share in the past decade, vertically-integrated robotaxi services using emerging AVs are starting to enter the market. We model and analyze the competition between an AV-based ride service firm (AV) and a platform-based Ride Hailing firm (RH). We find that when customers are sufficiently patient, in competition, the RH firm predominantly gains the upper hand in the market even if it has a cost disadvantage. Surprisingly, entry of the AV firm into a market with an RH monopolist incumbent may reduce total vehicle supply. When customers are impatient, the entry of an inefficient AV firm may even lead to a decrease in social welfare.

Machine Learning to Inform Business Decisions

Contributed Session

Session Chair: Marc Goessling, Afresh Technologies, Jersey City, NJ

1 Improving Restaurant Sales Forecasting Using Weather Forecasting Data

Shikhar Prasad Acharya[1], Biniv Maskay[2], [1]University of North Texas at Dallas, Dallas, TX, [2]Loras College, Dubuque, IA

Forecasting sales in any restaurant is crucial for inventory management and scheduling of employee hours. Most traditional methods almost exclusively rely on time series analysis and utilize factors such as month of year, day of week, and time of day to forecast sales. We analyzed daily sales of a fast-food restaurant in central Iowa for 3 years by using machine learning algorithms XGBoost and SHAP.

Our study shows that adding weather forecast data from NOAA such as average temperature and precipitation as independent factors significantly improves the accuracy of sales forecasting in a restaurant. This can result in cost reduction through better inventory planning and scheduling of employee hours in restaurants.

2 Intelligent Decision Support System for Steel Market Analytics

Pyam Oveys[1], Mahima Naznin[1], Thomas Willerth[1], Sharan Srinivas[2], James Noble[2], Anthony Ross[2], Kihyung Kim[3], [1]University of Missouri, Columbia, MO, [2]University of Missouri, Columbia, MO, [3]University of Missouri, COLUMBIA, MO, Contact: mngnd@mail.missouri.edu

The price of steel is set by multiple market factors as well as domestic and international events resulting in high price volatility. As such, understanding the trends in steel pricing is crucial for making profitable procurement decisions. Through correlation and covariance analysis we have identified several new critical economic predictors that impact the price of steel. This data is then used in an interactive decision support system utilizing a visualization dashboard as well as a predictive model. Numerical experiments indicate our model, a blend of time series analysis, linear regression, and machine learning, can predict the price of steel with a high degree of accuracy up to 12 weeks in advance.

3 Grocery Demand Forecasting in the Presence of Weekly Advertised Promotions

Marc Goessling, Afresh Technologies, San Francisco, CA, Contact: marc.goessling@afreshtechnologies.com

A core requirement for successful grocery store ordering policies are accurate demand forecasts. The forecasts have to be probabilistic in nature and they have to cover multiple possible target horizons of different lengths. We present a practical system for this task based on a deep neural network. An additional challenge for grocery demand forecasting are frequently occurring price discounts. These can correspond to planned weekly advertised promotions or ad-hoc temporary price reductions for liquidation reasons. One of our findings is that price elasticity can vary drastically based on the type of grocery item, meaning that the corresponding sales-price curves have different steepness. We discuss how we incorporated price sensitivity into our forecaster and how it impacted forecast accuracy.

Behavioral Issues in Multiple Criteria Decision Making

Community Committee Choice Session

Session Chair: Jyrki Wallenius, Aalto University School of Business, Kirkkonummi, Finland

Session Chair: Kalyanmoy Deb, Michigan State University, East Lansing, MI

1 Multiple Objectives Cause Psychological Burden

Jyrki Wallenius[1], Matias Kivikangas[2], Julian Blank[3], Ville Harjunen[4], Pekka Malo[1], Eeva Vilkkumaa[1], Kalyanmoy Deb[5], Niklas Ravaja[6], [1]Aalto University School of Business, Espoo, Finland; [2]Aalto University School of Business, Espoo, Finland; [3]Michigan State University, East Lansing, MI, [4]Helsinki University, Espoo, Finland; [5]Michigan State University, Espoo, MI, [6]Helsinki University, Helsinki, Finland

We investigate a situation relevant for Multiple Criteria Decision Making (MCDM) as well as Evolutionary Multi-objective Optimization (EMO), where the decision-maker needs to make a series of choices between nondominated options characterized by multiple objectives (criteria, attributes, dimensions). We measure how different levels of difficulty — the number of decision-making dimensions (attributes, objectives) — influence the psychological burden in a laboratory study. We use psychophysiological, behavioral, and self-report methods to make potentially impacting conclusions.

2 Biases in Multiattribute Utility Analysis (MAUA)

Detlof von Winterfeldt, USC, Los Angeles, CA, Contact: detlof@aol.com

We discuss omission, weighting, and scaling biases in MAUA. We demonstrate how these biases, when uncorrected, can lead to serious distortions of the results of a MAUA.

3 Using Process Tracing to Study Consumer Multiattribute Choice

Ilkka Leppänen, Aalto University School of Business, Espoo, Finland. Contact: ilkka.j.leppanen@aalto.fi

We use a novel method of dynamic process tracing in a preference-based choice task among consumer products. The method is based on a motor response dynamics paradigm that is derived from evidence accumulation models where the decision process is represented as a process of noisy temporal integration of information. We demonstrate that this method can model not just the decision maker's preferences among different attributes, but also the internal components of processing related to attribute information. We also use this method to explore how internal processing is affected by display properties of the choice options.

4 Cognitive Operations: Models that Open the Black Box and Predict Our Decisions

Konstantinos Katsikopoulos, University of Southampton

Cognitive operations examines how people make decisions under risk and uncertainty in operational settings by opening the black box and specifying the cognitive processes that lead to human behavior. Drawing on economics, psychology and artificial intelligence, the book provides an innovative perspective on behavioral operations: It shows how to build optimization as well as heuristic models for describing human behavior and how to compare such models on various dimensions such as predictive power and transparency, and also discusses interventions for improving human behavior. This talk will be particularly valuable to academics and practitioners who seek to select a modeling approach that suits the operational decision at hand.

5 Empirical Studies to Compare Interactive Multiobjective Optimization Methods with Human Participants

Giovanni Misitano[1], Bekir Afsar[1], Johanna Silvennoinen[1], Ana Belén Ruiz[2], Francisco Ruiz[3], Kaisa Miettinen[4], [1]University of Jyväskylä, Jyväskylä, Finland; [2]University of Malaga, Malaga, Spain; [3]University of Malaga, Malaga, UT, Spain; [4]University of Jyvaskyla, Univ. of Jyvaskyla, Finland. Contact: giovanni.a.misitano@jyu.fi

Applying interactive multiobjective optimization (MOO) methods necessitates preference information from a decision maker (DM). Because of the active role of the DM, comparison of interactive methods must be planned carefully. Previous comparisons have been rare and irreproducible. We have developed a new, reproducible experimental design to compare interactive MOO methods with human participants. Utilizing a novel questionnaire, we measure the cognitive load experienced by DMs, their satisfaction with the solution process and the solution finally obtained. We also compare the methods' ability to reflect preferences and responsiveness to changes in the preferences. Our design enables a transparent comparison of interactive MOO methods.

Innovation, Regulation, and Humanitarian Logistics

Community Committee Choice Session

Session Chair: Wenqing Zhang, University of Minnesota Duluth, Duluth, MN

Session Chair: Muer Yang, University of St. Thomas, Minneapolis, MN

1 Exploring Benefits and Ethical Challenges in the Rise of Mhealth (Mobile Healthcare) Technology for the Common Good

Sameer Kumar[1], Panagiota Galetsi[2], Korina Katsaliaki[3], [1]University of St Thomas, Minneapolis, MN, [2]University of St Thomas, Thessaloniki, Greece; [3]International Hellenic University, Thessaloniki, Greece. Contact: skumar@stthomas.edu

This study reflects on proliferating ethical initiatives in healthcare industry while leveraging innovative digital technological infrastructures including use of mobile technology for health professionals. Using content analysis, smartphone apps for health professionals were classified based on type. Expanded CPM theory explain ethical

considerations of mHealth apps' selection based on existing privacy & trustworthiness features, giving emphasis to apps utilizing smart technologies. Future agenda include development of technologically advanced and responsible mHealth apps. Disease handbook/manual and differential diagnosis are most frequently appearing mHealth apps. Apps utilizing AI methods are still few with expectations for apps with more smart capabilities. Study offers multi-layered analysis of usefulness of health-diagnosis mobile apps.

2 Mitigating Probability Uncertainties in Prepositioning Relief Supplies a Scenario-Robust Approach

Muer Yang[1], Sameer Kumar[2], Xinfang Wang[3], Michael Fry[4], [1]University of St. Thomas, Minneapolis, MN, [2]University of St Thomas, Minneapolis, MN, [3]Georgia Southern University, Statesboro, GA, [4]University of Cincinnati, Cincinnati, OH, Contact: yangmuer@stthomas.edu

The high-level uncertainty inherent to humanitarian logistics requires resilient plans for prepositioning relief supplies. This paper seeks to accommodate both aleatoric and epistemic uncertainties related to humanitarian logistics decisions. The proposed two-stage stochastic models incorporate a f-divergence uncertainty region to improve their solutions' robustness against uncertainty in the estimated probability of scenarios. We conduct Monte Carlo simulation studies using a real-world case of hurricane preparedness in the Southeastern United States to demonstrate that our methods are effective in mitigating probability uncertainties, particularly when the estimation errors of the scenario probabilities are large.

3 New Tech and Carbon Tax

Wenqing Zhang, University of Minnesota Duluth, Duluth, MN

The adoption of green technologies by firms may provide benefits that do not exceed the costs of adoption many may seek alternate-green methods that can provide output that can achieve a satisfying level of strategic performance. We use a game-theoretic model to see how marketing sustainable practices through social media a!ect it.

4 How Does the Blockchain Affect the Online Channel Selection of Competitive Remanufacturing?

Wei Gu, Chen Wang, Shufen Dai, University of Science and Technology Beijing, Beijing, China

Under the dual effects of environmental protection and economic benefits, original equipment manufacturers (OEMs) have started product remanufacturing. OEMs are facing the online channel selection (agency, resale, dual channel) issue when considering the cannibalization effect of the remanufacturing product to the new product. This paper integrates the quality perception and green perception of the consumer into a Stackelberg model to study the impact of the blockchain application on online channel selection of the competitive products. The results indicate that whether blockchain technology can improve the total profitability of online channels depends on consumers' sensitivity to the blockchain. After adopting blockchain technology, OEMs are more inclined to sell competitive products online through a dual channel mode.

5 Overconfidence in Subscription-Based Services: An Experimental Study

Wei Gu, Jing Luo, University of Science and Technology Beijing, Beijing, China

This study investigates the impact of overconfidence on customers' preferences in a subscription-based service. Using bike sharing services as an example, we examine whether customers who overestimate their usage tend to choose a monthly subscription plan instead of pay-per-use. Additionally, we explore how the pricing strategy, specifically bundling the monthly membership with other products or services, affects customer behavior and exacerbates overconfidence. By conducting experiments, this study uncovers the factors that drive customers' payment decisions and highlights potential implications for businesses determining pricing strategies in subscription-based services.

Political Redistricting

Community Committee Choice Session

Session Chair: Maral Shahmizad, Oklahoma State University, Stillwater, OK

1 Redistricting Compromise with Distance Metrics and Midpoints

Kiera W. Dobbs[1], Ian Griffith Ludden[2], Douglas M. King[3], Sheldon H. Jacobson[4], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]University of Illinois Urbana-Champaign, Urbana, IL, [3]U of Illinois at Urbana-Champaign, Urbana, IL, [4]University of Illinois, Urbana, IL, Contact: kdobbs2@illinois.edu

We propose an optimization framework to facilitate compromise between two given district plans. Using the transfer distance metric on graph partitions, we formulate a mixed-integer linear program to determine a feasible (approximate) midpoint plan between two given plans. We also generalize this program to find any fractional point between the two given plans and present computational experiments.

2 Political Districting to Minimize County Splits

Maral Shahmizad, Austin Buchanan, Oklahoma State University, Stillwater, OK, Contact: maral.shahmizad@okstate.edu

When partitioning a state into political districts, a common criterion is that political subdivisions like counties should not be split across multiple districts. This criterion is encoded into most state constitutions and is sometimes enforced quite strictly by the courts. However, map drawers, courts, and the public typically do not know what amount of splitting is truly necessary. In this presentation, we provide answers for all congressional, state senate, and state house districts in the USA using 2020 census data. Our approach is based on integer programming. The associated codes and experimental results are publicly available on GitHub.

3 In Pursuit of Compact Majority-Minority Districts

Samuel Kroger[1], Hamidreza Validi[2], Tyler Perini[3], Illya V. Hicks[3], [1]Rice University, Houston, TX, [2]Texas Tech University, Lubbock, TX, [3]Rice University, Houston, TX, Contact: sak8@rice.edu

The Voting Rights Act, Section 2, enacts the creation of majority-minority districts to provide minority groups with the opportunity to elect representatives of their choice. The Voting Rights Act enumerates three conditions (“Gingles prongs”) which necessitate the creation of majority-minority districts. We proposes mixed integer programming (MIP) formulations and fixing procedures for identifying the number of majority-minority districts which can be made and producing compact majority-minority districting plans at county and tract levels. While compactness is usually considered as an objective in redistricting optimization formulations, we provide a framework for optimizers to capture it in constraints. This provides opportunities to pursue other crucial redistricting criteria (e.g., federal constitutional requirements) in the objective function.

4 Distrix and Fastmap: Addressing America’s Gerrymandering Problem with a Puzzle Book, Strategy Game, and Computer Algorithm

Matthew Petering, University of Wisconsin-Milwaukee, Milwaukee, WI, Contact: mattpete@uwm.edu

We describe three recent projects aimed at increasing the fairness of political districts in the USA. The Distrix Puzzle Book contains 90 brainteasers that challenge readers to draw election districts that are fair or rigged in favor of different parties. The award-winning Distrix game system introduces a new method for political redistricting in which political parties form election districts in a high-stakes game, one voting precinct at a time. The FastMap computer algorithm considers 15 redistricting criteria when creating maps of congressional, state legislative, and local election districts. It generated the most politically fair maps of Wisconsin’s legislative districts in 2020-2021 and the maps that best adhered to the Wisconsin Supreme Court’s “least change” ruling from Nov. 30, 2021. Our experiences with these projects are shared.

Data, AI, and Business Processes

Community Committee Choice Session

Session Chair: Brian Han, Gies College of Business, UIUC, Los Angeles, CA

1 Value of Autonomous Last-Mile Delivery: Evidence from Alibaba

Brian Han[1], Meng Li[2], Yanan Zhang[3], Lixia Wu[4], [1]Gies College of Business, UIUC, Los Angeles, CA, [2]University of Houston, Houston, TX, [3]Shanghai Jiaotong University, Shanghai, China; [4]Cainiao Smart Logistics Network Ltd., Hangzhou, China

This paper provides the first empirical evidence on consumer responses based on Alibaba’s recent implementation of autonomous last-mile delivery on university campuses in China. The study leverages customer-level data from three universities over three years, employing a difference-in-differences approach combined with matching to estimate the impact of autonomous delivery adoption on order quantities. We find that compared with self-pickup, consumers order significantly more after adopting autonomous last-mile delivery. The number of orders increased by 24% in the first three months and 18% during following months. The efficiency and flexibility of autonomous vehicles reduce consumers’ travel costs, driving long-term usage and increased sales. However, the value of autonomous delivery diminishes when a fee is charged.

2 The Value of Operational Transparency: Empirical Evidence from a Food Delivery Platform

Zhanzhi Zheng[1], Yuqian Xu[2], Bradley R. Staats[3], [1]UNC Kenan-Flagler Business School, Chapel Hill, NC, [2]UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: zhanzhi_zheng@kenan-flagler.unc.edu

Operational transparency permits service providers to build trust with customers. In July 2021, Zhejiang province published a regulation that online restaurants show real-time food preparation processes online. Using a novel data-set of restaurants we use this policy change to investigate how operational transparency impacts restaurants' business performance.

3 Crowd-Starting a Shared (Shuttle) Service with Customer Suggestions

Long He[1], Tu Ni[2], [1]George Washington University, Washington, DC, [2]National University of Singapore, Singapore, Singapore. Contact: longhe@gwu.edu

We consider a platform that offers a shared shuttle service by gathering customer suggestions in a "crowd-starting" manner, which provides valuable information about customer needs. However, this also poses a challenge in balancing service coverage and quality to meet customer needs. To address this, we propose a service design optimization model to maximize expected customer adoption where we use a preference list model to understand how customers will respond to different service attributes and how their suggestions inform these responses. We further apply our model to a shared shuttle service case study and discuss practical considerations in the service design process.

4 Robotic-Assisted Surgery: Are Experts Learning from Interactions with Machines?

Thomas Ware, Arizona State University, Tempe, AZ

Robotic-assisted surgery is an emerging minimally-invasive surgical innovation to augment surgeons' capabilities in the operating room. To develop a better understanding of the role of human collaboration with robots in operative settings, we study whether robotic-assisted surgeries lead to improved overall effectiveness by reducing intraoperative risks during the procedure. We test our hypothesis using panel regression with patient-level surgery data in collaboration with the Veterans Health Administration. We observe significant reductions in intraoperative risks, in comparison to surgeries utilizing only manual techniques. We contribute to the research on robotic-assisted surgery and, more importantly, information systems literature by describing the benefits of machine-enabled augmentation.

Social Media Analytics Best Student Paper Award

Award Session

Session Chair: Wenqi Shen, Virginia Tech, Blacksburg, VA

1 Chatbot in Disguise: How Non-Disclosing Agent Identity Spurs Strategic Behavior

Yu (Rain) Kan, Yifan Yu, Lin Jia, Yong Tan, University of Washington- Michael G. Foster School of Business, Seattle, WA

This study explores the impact of agent type (AI, ChatGPT, human, or undisclosed) on customers' strategic behavior and satisfaction in a two-round experiment. Findings indicate heightened strategic behavior and lower satisfaction in the non-disclosure group. This study uncovers dual pathways causing these effects and utilizes mediation analysis and policy tree methods, providing significant business insights.

2 Deep-Learning-Based Causal Inference for Large-Scale Combinatorial Experiments: Theory and Empirical Evidence

Zikun Ye[1], Zhiqi Zhang[2], Dennis J. Zhang[2], Heng Zhang[3], Renyu Zhang[4], [1]University of Washington, Seattle, WA, [2]Washington University in St. Louis, St. Louis, MO, [3]Arizona State University, Tempe, AZ, [4]The Chinese University of Hong Kong, Hong Kong, China

We develop a framework combining deep learning and double machine learning to estimate and infer the causal effect of any treatment combination of multiple treatments when observing only a small subset of treatment combinations. Our proposed framework exploits Neyman orthogonality and combines interpretable and flexible structural layers in deep learning. To empirically validate our method, we collaborated with a large-scale video-sharing platform and implemented our framework for three experiments involving three treatments where each combination of treatments is tested.

3 Are You Already Satisfied? The Heterogeneous Effect of Media User Generated Contents on Free and Paid Mobile Games: Evidence from YouTube Comments

Seungwook Jin, Keumseok Kang, KAIST, Daejeon, Korea, Democratic People's Republic of

This research examines how user-generated content (UGC) sentiment impacts mobile game sales using a dataset of 58,000 apps and YouTube comments. Findings show positive sentiment boosts paid-to-play game revenue, but decreases free-to-play revenue, indicating a substitutional effect. Sentiments affect various aspects of the revenue generation process, from downloads to long-term retention.

4 Intertemporal Spillovers in Consumer Experiences: Empirical Evidence and Service Design Implications

Abhishek Deshmane[1], Victor Martínez de Albéniz[2], Guillaume Roels[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]IESE Business School, New York, NY, [3]INSEAD, Fontainebleau, France

Experiences are influenced by the impact of previous activities. Through a model that separates inherent quality from individual satisfaction, positive and negative spillovers are disentangled. Our findings suggest scheduling the best activity in the middle for maximum utility and saving a "wild card" activity to recover from bad outcomes.

Innovative Operations

Community Committee Choice Session

Session Chair: Neda Mirzaeian, University of Texas at Dallas, Richardson, TX

1 The Impact of Exchangeable Sports Tickets on Customer Purchasing Behavior

Hayri Alper Arslan[1], Yao Cui[2], Ross Rotwein[3], Ovunc Yilmaz[4], [1]University of Texas at San Antonio, San Antonio, TX, [2]Cornell University, Ithaca, NY, [3]MountainStar Sports Group LLC, El Paso, TX, [4]University of Colorado Boulder, Boulder, CO

Using transactional data from a US professional sports company that owns a baseball and a soccer team, we investigate the impact of selling exchangeable tickets that provide fans flexibility to change the game they attend for a small additional fee. We find that the use of exchangeable tickets leads to significant changes in customers' purchase time and total spending.

2 Promoting Equity in Micro-Mobility Sharing Services

Sheng Liu[1], Long He[2], Wu Hao[3], [1]University of Toronto, Toronto, ON, Canada; [2]George Washington University, Washington, WA, [3]National University of Singapore, Singapore, Singapore

Public authorities subsidize and regulate micro-mobility sharing services to ensure mobility equity. However, the effects of such policies on equity, especially when service providers prioritize profits over fairness, are unclear. Our study focuses on two equity-related policies-subsidy policy and regulatory policy, and we analyze their impacts on service performance. Our study offers insights into the efficiency and effectiveness of different equity policies in micro-mobility sharing services.

3 Optimal Cardinal Contests

Goutham Takasi, University of Texas-Dallas, Richardson, TX, Contact: vgt170000@utdallas.edu

We study the optimal design of a crowd-sourcing contest in settings where the output is quantifiable - e.g., a data science challenge. This setting is in contrast to settings where the output can only be assessed qualitatively - e.g., designing a logo. The rapidly growing literature on the design of crowd-sourcing contests focuses on ordinal contests - these are contests where contestants' outputs are ranked by the organizer and awards are based on these ranks. Such contests are ideally suited for the latter setting (where output is qualitative). For our setting (quantitative output), it is possible to design cardinal contests where awards are based on the actual outputs and not on their ranking alone - thus, our space of contest designs includes ordinal contests but is much larger. We derive an easy-to-implement contest design for this setting and prove its optimality.

4 Modeling and Managing Curbside Ride-Hailing Drop-Offs

Neda Mirzaeian[1], Soo-Haeng Cho[2], Sean Z. Qian[2], [1]University of Texas at Dallas, Richardson, TX, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: neda.mirzaeian@utdallas.edu

We investigate the effect of ride-hailing drop-offs on morning commuting patterns, characterizing a user equilibrium for commuters. We develop a continuous-time traffic model that incorporates parking fees and traffic congestion. In this model, commuters make decisions regarding departure times from their residences and transportation mode options, choosing between personal vehicles and ride-hailing services. Additionally, the ride-hailing company (RHC) determines the ride-hailing fares. Our results reveal that, in an unregulated market, the RHC can control the market to maximize its profit, causing substantial congestion and increased system cost. We demonstrate that by adjusting downtown parking fees and imposing drop-off tolls, we can significantly reduce both the system cost and congestion levels. We illustrate our results using data from Pittsburgh.

Collaboration in Innovation

Community Committee Choice Session

Session Chair: Pascale Crama, Singapore Management University, Singapore, Singapore

1 Prototyping in New Product Development

Gaoyu Xie[1], Janne Kettunen[2], [1]George Washington University, Washington, DC, [2]The George Washington University, Washington, Contact: gaoyux@gwmail.gwu.edu

The study employs the binomial option pricing model to examine when it is optimal to develop a prototype under uncertainty in product development efforts. The analysis is conducted with decision-makers (DMs) who aim to maximize their mean-variance utility. The study shows that when the level of development uncertainty is low, prototyping is optimal as it helps to learn about market requirements, leading to product improvements. On the other hand, when development uncertainty is high, a prototype is useful as a screener, allowing DMs to selectively abandon unfavorable development outcomes. In contrast, under medium or extremely high levels of development uncertainty, the optimal decision is to abandon development. Overall, the study highlights the dual purpose of prototyping and its importance in dealing with development uncertainty.

2 Should We Renegotiate or Leave the Contract?

Sara Rezaee Vessal, France

The suppliers might sometimes develop a new product with inferior quality to the buyer's expectations. We model the possibility of conditional acceptance of such products by the buyer. Our goal is to track the effect of conditional acceptance on supplier incentives to exert product development efforts. We construct a non-cooperative sequential game with risk-neutral players and analyze their equilibrium strategies. We find that implementing the conditional acceptance policy indeed affects supplier incentives if the product is of relatively high value to the buyer. The effect direction depends on the cost of effort and project success probability.

3 R & D Consortia in Competitive Supply Chains

Gaoyan Lyu[1], Pascale Crama[2], Yi Xu[3], [1]Beijing Institute of Technology, Beijing, China; [2]Singapore Management University, Singapore, Singapore; [3]University of Maryland, College Park, MD, Contact: lgy@bit.edu.cn

R&D consortia, which coordinate R&D activities of their member firms, have been successful in many industries. We study a model with two competing supply chains each consisting of a manufacturer and a supplier. The manufacturers compete in the final product market, and can conduct R&D to reduce unit product costs of their final products. The R&D can be done in three different ways: by the two manufacturers independently, by them jointly in a horizontal R&D consortium, or by the supplier and the manufacturer jointly in each supply chain in two vertical R&D consortia. We find that as compared to independent R&D, both the horizontal consortium and the vertical consortia lead to higher R&D effort, wholesale prices, and output quantities in the supply chains. However, different supply chain parties' preferences over the two types of consortia are not necessarily consistent.

Community Committee Choice Session

Session Chair: Hootan Kamran, University of Toronto, Toronto, ON, Canada

1 Distance-Based Critical Node Detection for Strategic Vaccination Policies

Faraz Khoshbakhtian[1], Hamidreza Validi[2], Mario Ventresca[3], Dionne Aleman[4], Randy Giffen[5], Proton Rahman[6], [1]University of Toronto, Toronto, ON, Canada; [2]Texas Tech University, Lubbock, TX, [3]Purdue University, Lafayette, IN, [4]University of Toronto, Toronto, ON, Canada; [5]IBM Canada, St. John's, NL, Canada; [6]Eastern Health, St. John's, NL, Canada. Contact: faraz.khoshbakhtian@mail.utoronto.ca

Effective vaccination policies are vital for controlling infectious diseases. We formulate the vaccination problem as the distance-based critical node detection problem (DCNDP) and present a novel approach for optimal vaccination under budget constraints. We introduce a lightweight integer programming model for 2-hop DCNDP and a divide-and-conquer pipeline for near-optimal solutions on large networks. Applied to a simulated contact network of a Canadian province (>500K nodes) during COVID, our method reduces 2-hop connectivity by 84% with 20% vaccine coverage. We further enhance our approach by integrating granular agent-based pandemic modeling and machine learning to derive effective vaccination policies. Our framework can be adapted to different regions and can be used as a decision-making tool to enhance public health outcomes.

2 Prominent Methodologies for Examining the Resilience of Infrastructure Systems

Nazanin Tajik, Misissipi State University

The research establishes the nexus of standard vulnerability measures and the 17 prevalent network topologies, aiming to draw the effectiveness of these measures on different network topologies against different disruption scenarios. The research conducted empirical analyses on the network topologies under the most common disruption patterns, including local, random, targeted, and cascading disruptions. With different network sizes, The resulting body of knowledge illustrates the triangular connection between network topology, disruption patterns, and vulnerability measures efficiency.

3 Concurrent Restoration of Coupled Infrastructures

Shabnam Rezapour, Namrata Saha, Mohammadhadi Amini, Florida International University, Miami, FL, Contact: nsaha003@fiu.edu

Timely restoration of critical infrastructures (CIs) is mandatory to increase the resilience of communities against disruptive events. Due to the resource scarcity after disasters, the restoration of all disrupted components cannot be triggered simultaneously in CIs. In this paper, we develop a novel modeling and solution approach that enables us to generate a cooperative restoration plan for coupled CIs under decentralized decision-making structure and different levels of uncertainty.

Digital Society and Advanced Data Analytics: Innovations, Advancements, and Challenges

Community Committee Choice Session

Session Chair: Jiao Wu, Northern Illinois University, DeKalb, IL

Session Chair: Jiaxi Luo, Midwestern State University, Wichita Falls, TX

1 HOW TO MAKE VIDEOS MORE ATTRACTIVE? AN INVESTIGATION ON THE IMPACTS OF VIDEO FEATURES ON VIEWER ENGAGEMENT

Ying Wang[1], Jiao Wu[1], Jaeki Song[2], [1]Northern Illinois University, DeKalb, IL, [2]Texas Tech University, Lubbock, TX

This study investigates the factors contributing to active engagement for virtual influencer videos. By integrating the elaboration likelihood model and social identity theory, our proposed theoretical framework elaborates on the relationship between various features of influencer videos and engagement rates. Further, it demonstrates that video character types could moderate this relationship. We found that visual features such as brightness, colorfulness, and vividness have a more pronounced influence on engagement rates in animated character videos than in human-like character videos. In contrast, the content topics discussed in the videos exert a stronger influence on engagement rates in videos featuring human-like characters than in animated character videos.

2 Emotion and Ideology Factors on Persuasiveness of Online Petitions

Jiao Wu, Northern Illinois University, DeKalb, IL, Contact: jwu3@niu.edu

Victory Online petition helps the mass people to influence decisions and arouse broad attention. Different linguistic cues are found to influence the persuasiveness of the petition. In this work, we combine discrete emotional cues and political ideology cues. We developed an analytical model which illustrates the relationship between the discrete emotion cues and ideology cues with the success of the online petitions. The data were from Change. Org. Our results highlight the need to use objective data to reduce the drawbacks of survey methods. Also, the findings can be used to design and develop more efficient petitions.

3 Impact of Covid-19 on Consumer Sentiments in the Automotive Industry: A Text-Mining Approach

Jiaxi Luo, Midwestern State University, Wichita Falls, TX

The COVID-19 pandemic has significantly disrupted the automotive industry, especially due to semiconductor chip shortages. This situation raises two key questions: Has consumer sentiment during the automobile purchase process changed due to COVID-19? How do these sentiments influence their ratings of car dealerships? To tackle these queries, we employ a text-mining methodology coupled with an ordered probit regression analysis. Our findings reveal that post-COVID-19, the sentiment keyword "fast" positively impacts online dealership ratings. Conversely, "wait" negatively affects ratings. Interestingly, "willing" and "mess" have consistently negative effects on ratings, both pre and post-pandemic. This study offers a unique perspective on the evolving consumer sentiments in the automotive industry amid a global crisis.

4 Consistency Is Not Always Key: Text And Image Consistency Across Social Media Posts

Timothy Kaskela[1], Jaeki Song[2], [1]Oregon State University, Corvallis, OR, [2]Texas Tech University, Lubbock, TX

Social media platforms have provided an important lane of communication between corporations and consumers. There has been substantial research into engagement that occurs between corporations and consumers, but there are areas that need further examination. We build upon existing research on social media engagement and consistency to examine how two components of a social media post, text and complexity, can impact engagement through consistent messaging across consecutive posts for a single company. A pilot study is conducted in which 62,853 tweets and 19,997 images are collected from 8 different companies. We find that consistency of text leads to positive engagement, however consistency of image and the interaction between text consistency and image consistency have a negative effect on engagement. Planned further research and implications are then discussed.

Market Design for Social Impact, Applications and New Insights

Community Committee Choice Session

Session Chair: Michael L. Hamilton, University of Pittsburgh, Pittsburgh, PA

1 Two-Sided Assortment Optimization with Simultaneous and Sequential Matches

Ignacio Rios[1], Alfredo Torrico[2], [1]The University of Texas at Dallas, Richardson, TX, [2]Cornell University, Ithaca, NY

We study the two-sided assortment problem recently introduced by [Rios et al., 2022]. A platform must choose an assortment of profiles for each user in each period. Users can either like/dislike as many profiles as they want, and a match occurs if two users see and like each other, potentially in different periods. The platform's goal is to maximize the expected number of matches generated. We show that the problem is NP-hard, even if we consider two periods and only one-directional sequential matches. Given this, we focus on the case with two periods and provide algorithms and performance guarantees for different variants of the problem. We use data from our industry partner (a dating app in the US) to numerically show that the loss for not considering simultaneous matches in the second period when making first-period decisions is negligible.

2 Project 412Connect: Bridging Students and Communities

Alex DiChristofano[1], Michael L. Hamilton[2], Sera Linardi[3], [1]Washington University in St. Louis, St. Louis, MO, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Pittsburgh, Pittsburgh, PA

In this work, we investigate some of the challenges Black-owned businesses face. Taking into account dynamics specific to the Pittsburgh region, we determine that university students represent an under-utilized market for these businesses. We investigate the root causes for this inefficiency and design and implement a platform, 412Connect, to increase support for Pittsburgh Black-owned businesses from students in the university community. The platform operates by coordinating interactions between student users and participating businesses. Our platform design choices are aided by two simple, novel models for badge design and equity-orientated recommendations that may be of independent interest.

3 Eliminating Waste in Cadaveric Organ Allocation

Peng Shi, Junxiong Yin, University of Southern California, Los Angeles, CA, Contact: junxiong.yin@marshall.usc.edu

Many reforms have been or are currently being implemented to address the cadaveric organ wastage problem. However, we show that waste will still be a problem as long as the allocation mechanism continues to prioritize patients by their waiting times, which incentivizes patients to reject organs of reasonable quality now to wait for better offers in the future. By analyzing a theoretical model, we show that the necessary and sufficient conditions to eliminating waste are to disincentivize waiting by allocating over-demanded organ types only to the patients who recently signed up for transplantation, and to give the patients who are not allocated their ideal organs an opportunity to take another offer. However, such a policy may be contentious as it no longer prioritizes patients by waiting times. Moreover, it may reduce the welfare of the patients who are the most willing to wait.

4 Hyperlocal Food Sharing: Household vs Commercial Food Donation Channel

Ekaterina Astashkina[1], Masha Shunko[2], Haonan Zhang[3], [1]Ross School of Business, University of Michigan, Ann Arbor, [2]University of Washington, Seattle, WA, [3]University of Washington-Seattle, Seattle, WA, Contact: hzhang96@uw.edu

We utilize the proprietary dataset from the world's largest food sharing platform, which facilitates donation of soon-to-expire excess food generated by (i) households and (ii) food businesses (supermarkets, grocery stores, bakeries, etc.) to the households in need. The platform aims to reduce household- & commercial- food waste and alleviate hunger. We both analytically and empirically examine the impact of the introduction of the second (commercial) channel as opposed to just the household channel onto the donation activities performed by households. We characterize the equilibrium outcomes of the platform before (after) adding the commercial channel and characterize the optimal level of commercial channel intervention that boosts the demand for household channel and matching rates.

The Future of Federated Learning: Prospective Trends and Research Directions

Community Committee Choice Session

Session Chair: Brianna Mueller, University of Iowa, Iowa City, IA

1 New Federated Learning Algorithms for Deep Learning with Unbounded Smooth Landscape

Mingrui Liu, George Mason University, Fairfax, VA

The current analysis of federated optimization algorithms for training deep neural networks typically requires the landscape to be smooth. However, there is a class of deep neural networks which is inherently nonsmooth, with a potentially unbounded smoothness parameter. Examples include recurrent neural networks, long-short term memory networks, and transformers. It remains unclear how to design provably efficient federated optimization algorithms for training these neural networks.
In this talk, I will consider the federated deep learning setting in the presence of unbounded smoothness. I will introduce two new efficient algorithms for homogeneous and heterogeneous data respectively. The main result is that these algorithms provably enjoy linear speedup and require significantly fewer communication rounds.

2 Dynamic Ensemble Selection for Personalized Federated Learning: A Decentralized Approach Based on Peer-To-Peer Model Sharing and Adaptive Model Aggregation

Brianna Mueller, University of Iowa, Iowa City, IA

The heterogeneity of datasets in federated learning (FL) poses challenges in achieving robust model aggregation and generalization. To address such challenges, personalized FL methods have been proposed to tailor the learning process to each client's data distribution. In this context, we introduce a novel approach that leverages dynamic ensemble selection (DES), which not only offers personalized models for individual clients, but also delivers unique solutions for each test sample. Our proposed framework is based on peer-to-peer model sharing, where clients maintain a collection of models from all the participants in the network. The key to DES is adaptive model aggregation where the most competent classifiers are selected to predict the label of a specific test sample. This presentation will discuss the advantages of DES and share comparisons with existed methods.

3 On the Efficiency and Robustness of Federated Learning

Hongyi Wang, Carnegie Mellon University, Pittsburgh, PA, Contact: hongyiwa@andrew.cmu.edu

Federated learning (FL) offers a privacy-preserving collaborative learning solution, though it grapples with high communication costs and susceptibility to attacks. In this talk, Dr. Wang will initially present FedMA, which matches and averages hidden elements bearing similar signatures. FedMA surpasses widely-used FL algorithms, all while reducing communication overhead.
Subsequently, Dr. Wang will explore FL's robustness, emphasizing vulnerabilities to backdoor attacks and asserting that robustness to backdoors entails resilience to adversarial examples with guarantees. He will introduce edge-case backdoors, which trigger misclassifications on atypical inputs, potentially jeopardizing fairness across diverse ML tasks.

AI Generated Content (AIGC)

Community Committee Choice Session

Session Chair: Ting Li, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands

1 The Downfall of Q & A? How Large Language Modelers Affect Q & A: A Study on Stackexchange

Dominik Gutt, Martin Quinn, Erasmus University Rotterdam, Rotterdam, Netherlands. Contact: gutt@rsm.nl

Large Language Models (LLM) have attracted immense attention since the end of 2022. In this paper, we examine the effects of introducing the arguably most popular LLM, ChatGPT, on the user-generated content on Stackexchange. We find that subsequent to the introduction of ChatGPT, the number of questions posted to Stackexchange drastically decreased. This research contributes to the developing literature stream on the effects of generative artificial intelligence on platforms. Our findings also imply that LLMs may be drilling away their own foundation because they are partly trained on openly available data from Stackexchange.

2 Exploring the Impact of Suggestion Richness and Question Richness of Generative AI on User Creativity and Satisfaction

Hanwen Wang[1], Cheng Yi[1], Ting Li[2], [1]Tsinghua University, Beijing, China; [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands. Contact: wanghw22@mails.tsinghua.edu.cn

This study focuses on the collaboration between generative AI and humans in a design context, where AI can offer suggestions and ask questions to humans. We explore how the richness of AI-generated suggestions and questions, measured by the number of viewpoints contained, affects user engagement and creativity through the design process, and finally influences users' satisfaction with the final design. We posit that while greater suggestion richness can increase users' engagement, it may restrain human creativity due to an overreliance on AI. Moreover, based on cognitive load theory, we expect that question richness may mitigate the restraining effect of suggestion richness on creativity. Our hypotheses are tested in an experiment with a 2x2 factorial design. The study makes theoretical contributions to human-AI collaboration and provides practical implications.

1 A Biclustering Approach to Phenotype Prediction

Hieu Trung Pham, University of Alabama in Huntsville, Huntsville, AL

Phenotypic variation in plants is due to genetics (G), environment (E), and their interaction (GEI). GEI is critical in explaining why some genotypes perform well in different environments. In plant breeding, incomplete data is a challenge. We propose a new model of GEI effects that uses a two-way table of phenotype observations. Our analysis uses a biclustering algorithm that handles missing values, identifying homogeneous cells with no GxE interaction. We fit no-interaction models to predict phenotypes and draw insights into a cultivar's performance in unused test environments. Our method is validated on different plant species, showing superior performance.

2 Using Machine Learning to Identify the Initial Planting Date of Crops

Angela Avila, Jianzhong Su, University of Texas at Arlington, Arlington, TX

This study focuses on training a neural network to accurately predict the planting date of any given field by leveraging time series leaf area index (LAI) data. Specifically, we utilize LAI data collected in Bushland, TX over a span of 35 years as the basis for our model. Through a third-degree polynomial regression, the LAI time series growth of different crops is fitted, and the resulting coefficients are utilized to train a neural network, enabling estimation of the field's initial planting date. To enhance the effectiveness of the neural network training, our dataset is augmented by creating various third-degree polynomials that mimic the LAI growth patterns of crops. The preliminary data indicated the predictive Machine Learning Model can predict the planting dates of various crops.

3 Analyzing Data for Hyperspectral Images of Bacteria in Chickens

Ashley Alfred, Jianzhong Su, University of Texas-Arlington, Arlington, TX

This talk delves into the utilization of hyperspectral imaging technology for bacteria detection in chickens. We will discuss the adoption of innovative data analysis techniques to differentiate and classify bacterial strains in chicken tissue. The talk aims to highlight the potential of this non-invasive, rapid, and high-throughput tool in the poultry industry, emphasizing its role in enhancing food safety and quality. Our findings can pave the way for new approaches in pathogen identification, potentially revolutionizing the veterinary and food industry.

4 Using the K-Nearest Neighbor Algorithm to Predict Precipitation Based on Historical Data

Sean Guidry Stanteen, Jianzhong Su, University of Texas at Arlington, Arlington, TX, Contact: sean.guidrystanteen@mavs.uta.edu

This study explores the application of the K-Nearest Neighbor (KNN) algorithm for predicting precipitation patterns using historical data. The KNN algorithm is employed to analyze past weather data and identify similar patterns to forecast future precipitation events. The research aims to assess the effectiveness of the KNN approach in predicting precipitation, thereby providing valuable insights for meteorological forecasting, and improving our understanding of weather patterns. Results indicate promising potential for accurate and efficient precipitation prediction using the KNN algorithm.

1 Community/Committee'S Choice Submission

Yugang Yu, 1</sup

2 Fintech Expansion

Jing Huang, Texas A&M University, College Station, TX, Contact: jing.huang@tamu.edu

I study credit market outcomes with different competing lending technologies: A fintech lender that learns from data and is able to seize on-platform sales, and a banking sector that relies on physical collateral. Despite flexible information acquisition technology, the endogenous fintech learning is surprisingly coarse---only sets a single threshold to screen out low-quality borrowers. As the fintech lending technology improves, better enforcement harms, while better information technology benefits traditional banking sector profits. Big data technology enables the fintech to leverage data from its early-stage operations in unbanked markets to develop predictive models for expansion into new markets.

3 The Distributional Effects of "Fulfilled By Amazon" (FBA)

Garud Iyengar[1], Yuanzhe Ma[1], Thomas Rivera[2], Fahad Saleh[3], Jay Sethuraman[1], [1]Columbia University, New York, NY, [2]McGill University, Montreal, QC, Canada; [3]Wake Forest University, Winston-Salem, NC, Contact: ym2865@columbia.edu

We provide an economic model of an e-commerce retail platform (e.g., Amazon) that offers a fulfillment service (e.g., "Fulfilled By Amazon") to merchants that sell on its platform. We demonstrate that the introduction of such a service generates disparate impacts on the different platform participants. In particular, while such a service benefits low service quality merchants and consumers, it reduces welfare for high service quality merchants. We compare the economic implications of introducing the fulfillment service when it is optimally designed by the platform vs an independent logistics company. We show that the distributional welfare effects are more pronounced when the platform provides the fulfillment service thereby demonstrating the impact that dual ownership of the platform and fulfillment service has on participant welfare.

4 Advertising and Price Competition Under Consumer Data Privacy Choices

Kinshuk Jerath, Columbia Business School, New York, NY, Contact: kj2323@columbia.edu

Recent privacy regulations and firm policies endow consumers with the choice of whether to allow firms to use their personal data for marketing (and other) purposes. We consider a scenario with competing horizontally differentiated firms that advertise to heterogeneous consumers, through an ad platform. If a consumer opts in, she provides an imperfect signal of her type, based on which the ad platform can price ads, and the firms can target ads and prices. Consumers make privacy choices by considering their surplus utility from product consumption. Compared to a benchmark where all consumers are opted-in to data sharing, with privacy choices consumers' surpluses are weakly higher, the firms' profits are weakly lower, and the ad platform's profit is either lower or higher depending on the signal accuracy and extent of product differentiation.

1 Signaling Competition in Two-Sided Markets

Omar Besbes[1], Yuri Fonseca[1], Ilan Lobel[2], Fanyin Zheng[1], [1]Columbia University, New York, NY, [2]New York University, New York, NY

Consider a platform facilitating decentralized many-to-many matches between two sides. A key attribute of supply is how competitive it will be for demand to obtain the supply after the match. Should the platform reveal competition levels to potential demand? We answer this question empirically in the context of a labor platform. We partnered with a services marketplace which sells non-exclusively labor market leads to service workers. We propose and estimate a structural model in which workers internalize expected competition levels. Our counterfactual analysis finds that signaling competition significantly improves outcomes for market participants and may lead to a win-win situation for both the platform and agents depending on certain market characteristics.

2 A Nonparametric Framework for Online Stochastic Matching with Correlated Arrivals

Ali Aouad[1], Will Ma[2], [1]London Business School, London, United Kingdom; [2]Columbia University, New York, NY

The design of online policies for stochastic matching and revenue management settings is usually bound by the Bayesian prior that the demand process is formed by a fixed-length sequence of queries with unknown types, each drawn independently. This assumption of serial independence implies that the demand of each type, i.e., the number of queries of a given type, has low variance and is approximately Poisson-distributed. Thus, matching policies are often based on ``fluid'' LPs that only use the expectations of these distributions.

This paper explores alternative stochastic models for online matching that allow for nonparametric, higher variance demand distributions. We propose two new models, \Indep and \Correl, that relax the serial independence assumption in different ways by combining a nonparametric distribution for the demand with standard assumptions on the arrival patterns -- adversarial or random-order. In our \Indep model, the demand for each type follows an arbitrary distribution, while being mutually independent across different types.

In our \Correl model, the total demand follows an arbitrary distribution, and conditional on the sequence length, the type of each query is drawn independently. In both settings, we show that the fluid LP relaxation based on only expected demands can be an arbitrarily bad benchmark for algorithm design. We develop tighter LP relaxations for the \Indep and \Correl models that leverage the exact distribution of the demand, leading to matching algorithms that achieve constant-factor performance guarantees under adversarial and random-order arrivals. More broadly, our paper provides a data-driven framework for expressing demand uncertainty (i.e., variance and correlations) in online stochastic matching models.

3 Centralized Versus Decentralized Pricing Controls For Dynamic Matching Platforms

Omer Saritac[1], Ali Aouad[1], Chiwei Yan[2], [1]London Business School, London, United Kingdom; [2]University of Washington Seattle, San Francisco, CA

Motivated by recent regulations and increased public scrutiny on platform control, we analyze how pricing centralization affects online service platforms using a fluid model of dynamic two-sided matching. We explore outcomes from a fully centralized pricing system, where the platform sets the price, to a fully decentralized one, where suppliers set prices. Our research uncovers the structure of stationary market equilibria and resulting social welfare under various degrees of centralization. We find that in 'impatient' markets, centralized platforms yield higher social welfare, while in more patient markets, decentralized pricing approaches first-best outcomes. Semi-centralized pricing rules, offering some flexibility to suppliers in setting their prices, recover near-optimal outcomes in most market conditions.

4 Tightness Without Counterexamples: A New Approach and New Results for Prophet Inequalities

Jiashuo Jiang[1], Will Ma[2], Jiawei Zhang[3], [1]Hong Kong University of Science and Technology, New York, NY, [2]Columbia University, New York, NY, [3]New York University, New York, NY

Prophet inequalities establish tight performance ratios between online and offline allocation algorithms. We formulate the worst-case instance construction as an optimization problem, directly finding the tight ratio without two separate bounds. Our analysis involves identifying the structure in a new "Type Coverage" dual problem, providing a unified framework that derives new prophet inequalities and recovers existing ones. Our paper shows that Chawla et al.'s "oblivious" method is best-possible among all static threshold algorithms, and confirms a separation between the convergence rates of static and adaptive algorithms. Our framework also allows us to numerically illustrate the tight guarantee under any number of starting units, with guarantees for k>1 exceeding the state-of-the-art.

5 Equitable Stable Matchings Under Modular Assessment

Kemal Yildiz[1,2], Ahmet Alkan[3], [1]Bilkent University, Ankara, Turkey; [2]Princeton University, Princeton, NJ, [3]Sabancı University, Istanbul, Turkey. Contact: kemalyild@gmail.com

We propose a framework for addressing issues of equity and social welfare in the stable matching model. We first establish an equivalence between an ordinal condition and modular optimization on the lattice of stable matchings. This equivalence charts out a domain where equity or welfare criteria separate over individuals and appear as weights in optimization. We call the ordinal condition convexity and the domain modular. Convexity requires stable "mixtures" of matchings in a solution to also be in the solution. We next propose a novel class of equitability criteria called equity undominance and characterize the modular stable matching rules that are equity undominated. Notably, the modular stable matching rules provide for clear testable implications and a wide range of specifications allowing efficient optimization.

Modeling of Transportation Systems

Contributed Session

Session Chair: Elham Heydarigharaei, York University, Toronto, ON, Canada

1 Deep Learning and Machine Learning for Analyzing Risky Driving Behavior

Yihan Wang, Yanjing Wang, Ziru Wang, Clark University, Worcester, MA, Contact: jamieyihan@gmail.com

Aggressive driving behavior is the number one factor in road crashes, with 106,727 fatal crashes (55.7% of the total) involving one or more aggressive driving behaviors by drivers during a recent four-year period, according to the AAA Foundation for Traffic Safety. This paper aims to use deep learning and machine learning methods to analyze and understand risky driving behaviors. Our data comes from collecting accelerometer and gyroscope-based sensor information installed on cell phones. We train these models to effectively identify and classify risky behaviors such as aggressive driving, distracted driving, and speeding. The results of this study provide valuable insights into the factors that contribute to dangerous driving and allow us to develop proactive measures to enhance road safety and promote responsible driving habits.

2 Coins, Cards, or Apps: Impact of Payment Methods on Street Parking Occupancy and Wait Times

Sena Onen Oz[1], Mehmet Gumus[1], Wei Qi[2], [1]McGill University, Montreal, QC, Canada; [2]Tsinghua University, Beijing, China. Contact: sena.onenoz@mail.mcgill.ca

This study examines how different payment methods affect drivers' payment behavior, street parking occupancy and incurred wait. We develop an analytical model for the optimal payment amount and analyze payment patterns. The empirical findings indicate that drivers tend to pay less when they pay with cash or via mobile applications than with credit cards. To provide further guidance to municipalities, we simulate the street parking situation to verify the effects of each payment method and pricing on the parking occupancy and wait. The results show that using mobile payment apps leads to shorter waiting times and lower parking occupancy. Simulations also reveal the asymmetrical effects of price changes on occupancy and wait times. These findings highlight the potential benefits of mobile payments and price adjustments for improving street parking experiences.

3 Can Usage-Based Pricing Reduce Congestion?

Itai Ater[1], Adi Shany[1], Brad Ross[2], Eray Turkel[2], Shoshana Vasserman[2], [1]Tel Aviv University, Israel, Tel Aviv, Israel; [2]Stanford Graduate School of Business, Stanford, CA, Contact: eray.turkel.93@gmail.com

Municipalities around the world are increasingly adopting congestion pricing policies in order to curb road traffic. Despite the growing enthusiasm for congestion pricing by policymakers, there is limited rigorous evidence that such policies are effective at reducingthe number of cars on the road, and constituent concerns over inadvertent distributional consequences have slowed the adoption of these policies by years. We analyze a major field experiment testing the efficacyof congestion pricing fees in Israel. Our analysis of data shows that individuals cut their congestion-related driving in response to per-Km pricing. What kind of drivers change their behavior the most and what kinds of trips are reduced the most and what are the distributional implications? We will focus on heterogeneity in effects and implications on highway traffic density.

4 Emission-Based Signal Control Optimization on Arterials

Efthymia Kostopoulou, University of Massachusetts Amherst, Amherst, MA, Contact: ekostopoulou@umass.edu

The rapid increase of car ownership in recent decades has led to the increase of air pollutants in road networks, degrading the air quality and public health. Traffic signals are components of the urban networks able to be modified to promote efficiency and sustainability. This study develops real-time signal control system for a single intersection that is part of a signalized arterial, i.e., vehicles arrive in platoons. This system optimizes signal control timings by minimizing the emissions of auto and transit vehicles. The model can handle both oversaturated and undersaturated flow conditions, takings into account delays experienced from residual queues. The final mathematical model is a mixed integer linear model that is characterized by low computation times, sufficient to allow for real-time optimization and applicability in the real-world.

5 Traffic Assignment Under Crowd-Sensed Congestion Information

Elham Heydarigharaei[1], MohammadAmir Ahmadian Shahreza[1], Sina Bahrami[2], Mehdi Nourinejad[3], [1]York University, Toronto, ON, Canada; [2]University of Michigan, Ann Arbor, MI, [3]York University, Toronto, ON, Canada. Contact: eheydari@yorku.ca

Accurate travel time estimation is crucial for drivers when choosing between multiple route options. However, tools like Google Maps may neglect unexpected delays or driving conditions. Additionally, stationary sensors and cameras are not cost-effective alternatives. In contrast, crowdsensing provides accurate traffic information without requiring significant infrastructure investment. This study analyzes the trade-off between information accuracy and traffic congestion, considering the length of the prediction horizon. Our objective is to optimize crowdsensing systems and enhance decision-making for drivers seeking the shortest path.

Optimization of Layout and Stocking

Contributed Session

Session Chair: Abhijit Gosavi, Missouri University of Science & Technology, Rolla, MO

1 Optimal Wave Design in Fulfillment Centers - the Key to Faster Speed

Sai Anjani Kumar K V N, Gowtham Bellala, Rishabh Bhat, Sarvesh Desai, Vikas Goel, Flipkart internet private limited, Bangalore, India

Fulfillment centers (FC) of an e-tailer typically assign approved orders to waves (defined by a wave end or cut-off time). Orders that miss the earliest network connection during the order promise end up waiting idle at an FC for a long duration. The percentage of such orders is referred to as spillage. Reducing spillage results in an improved delivery speed leading to increased platform conversion. In this work, we study the problem of optimal FC wave design that minimizes spillage considering hourly order patterns, network, capacity and other operational constraints. Reducing spillage for a large network by manual choice of wave cut-offs is challenging and leads to suboptimal decisions. We propose an integer optimization model to optimize the wave design. The proposed model was used at a large e-commerce company in India that resulted in a 35% reduction in overall spillage.

2 Solving the Unequal-Areas Layout Problem: A Meta-Heuristic Approach for Retaining Dimensions

Joshua Adu Afari[1], Abhijit Gosavi[2], Robert Marley[1], [1]Missouri University of Science & Technology, Rolla, MO, [2]Missouri University of Science & Technology, Rolla, MO, Contact: jay22@mst.edu

The so-called unequal-areas layout problem has been widely studied under the aspect-ratio assumption that allows the department's dimensions to be *distorted* as long as its area remains the same. Distortion of the width can lead to conditions in which machines in a department may not fit in the space designed. In this presentation, we present a meta-heuristic approach in which the dimensions are *not* distorted, along with numerical results. The new approach seeks to minimize the so-called dead space between departments, but, unlike the aspect-ration approach, does *not* ensure it becomes zero.

3 Kitting Optimization Models to Support Line Stocking and Hybrid Robotic Operations

Amirreza Talebi[1], Theodore T. Allen[2], [1]The ohio state university, Columbus, OH, [2]Ohio State University, Columbus, OH, Contact: talebi.14@osu.edu

We propose part delivery and kitting optimization models of trade-offs with realistic cost numbers to support possible transitions in material handling. Part feeding methods such as line stocking, operator-kit packing, and hybrid robot-operator kit packing are included. An application at a major automotive manufacturer is used to illustrate the benefits.

4 Multi-Swap Simulated Annealing Algorithm for Order Batching and Sequencing Problem in a Sequential Zone Picking System

Jeongwon Park[1,2], Soondo Hong[1], [1]Pusan National University, Busan, Korea, Republic of; [2]Arizona State University, Phoenix, AZ

This study proposes a heuristic algorithm to optimize the order batching and sequencing problem (OBSP) in a sequential zone picking system. The proposed algorithm solves the OBSP with multiple 2-opt local searches to balance the workload across zones. For each iteration, the algorithm evaluates the total maximum workload in each time window and significantly improves the order picking performance of large-size warehouse systems in a short time. Simulation experiments demonstrate that the proposed algorithm outperforms existing methods in terms of solution quality and efficiency, making it a promising approach for real-world warehouse applications.

5 Vertical Product Location Effect on Sales: A Field Experiment in Convenience Stores

Zahra Jalali[1], Maxime Cohen[2], Necati Ertekin[3], Mehmet Gumus[2], [1]McGill University, Montreal, QC, Canada; [2]McGill University, Montreal, QC, Canada; [3]University of Minnesota, Minneapolis, MN

Most retailers use the eye-level location to enhance demand. Yet, little is know about what happens to products at other shelves when a product is moved to the eye-level. We study how changing vertical locations of products in a shelving unit impacts product sales and overall sales, and whether this effect varies across products. We conducted a 20-week field experiment at 6 C-stores. Our results show that the eye-level generates an additional 13.8% and 8.5% more demand compared to the stoop-level and the stretch-level. Yet, this increase comes at an expense of demand loss at other shelves, leading to pure substitution among products. We also find that the vertical location effect varies across products. Incorporating this heterogeneity into planogram optimization can increase profit by 3% at the focal retailer, a significant 36.4% improvement over using homogeneous effects.

Game Theory and Markov Systems

Contributed Session

Session Chair: Zhengqi Lin, Rutgers University, Jersey city, NJ

1 On Coin Flipping Games with Uncertainty in the Probability of Heads: Beyond Linear Kelly Betting Strategies

B. Ross Barmish[1], Anton V. Proskurnikov[2], [1]Robust Trading Solutions, LLC, Boxford, MA and University of Wisconsin, Madison, WI, [2]Politecnico di Torino, Torino, Italy. Contact: bob.barmish@gmail.com

In this paper we "robustify" Kelly's celebrated betting strategy for a game involving N flips of a biased coin with probability of heads p. Unlike the classical theory with p being perfectly known, we only assume that a subset P of [0,1] is specified for this probability. Whereas the classical Kelly strategy defines the size of all wagers to be the same fixed fraction of wealth along sample paths, our main result is that assurance of robustness with respect to P dictates use of a strategy which is nonlinear in nature yet can be computed efficiently. To our knowledge, nonlinear strategies have not been considered to date in the body of literature under consideration.

2 How the Mean Field Games Applied to Many Players Differential Games?

Kemal Gursoy, Rutgers University, Piscataway, NJ, Contact: kemalgursoy@netscape.net

The mean field game systems may be used to construct Nash equilibria for finitely many players differential games. In this work, a model will be introduced to support to find an approximate Nash equilibria for multiplayer games.

3 Transportation Distance Between Kernels and Approximate Dynamic Risk Evaluation in Markov Systems

Zhengqi Lin[1], Andrzej Ruszczynski[2], [1]Rutgers University, Newark, NJ, [2]Rutgers University, Piscataway, NJ

We introduce a distance between kernels based on the Wasserstein distances, study its properties, and propose a method for approximating solutions to forward-backward Markov systems. In addition, we establish the metric properties of the kernel distance and relate it to various modes of convergence in the space of kernels. We then propose a recursive approximation scheme for the forward system of a Markov system using the kernel distance and estimate the error of the risk evaluation by the errors of individual kernel approximations. We illustrate the results on stopping problems and well-known risk measures and we develop a particle-based numerical procedure with finite support sets. Finally, we apply the proposed approach to pricing an American basket option in a financial problem.

Energy Storage and Electricity Pricing in Smart Grids

Contributed Session

Session Chair: Ashfaque Mohib, Wichita State University, Wichita, KS

1 Energy Storage as Learning-Agents in Electricity Markets

Ningkun Zheng, Bolun Xu, Columbia University, New York, NY, Contact: nz2343@columbia.edu

The strategic behavior of energy storage in energy markets is crucial for market power mitigation and new market model development. While prior research has attempted to model strategic energy storage behaviors, these efforts have often been constrained by high computational costs and assumptions of perfect market clearing knowledge among energy storage participants. This study seeks to overcome these challenges by integrating a wholesale energy market simulation with a model-based machine learning energy storage bidding algorithm. This novel approach offers a more realistic representation of energy storage strategic behaviors in real-world scenarios.

2 Elucidating the Capabilities and Limitations of Long-Duration Energy Storage Modeling Approaches

Sourabh Dalvi, National Renewable Energy Laboratory, Denver, CO, Contact: sourabh.dalvi@nrel.gov

Energy storage deployment enables integration of variable renewable energy (e.g., wind, solar) in power systems. However, existing models for long-duration storage lack accurate representation. This study discusses challenges, limitations, and proposes improvements. Enhanced long-duration storage dispatch modeling can increase operational value by 4.3%-13.8% and capacity credit by 14%-33.7%. This represents significant cost-saving opportunities for US Independent System Operators. Three dispatch methods were assessed, favoring end volume targets. Further research is needed for improved methods and inclusion of extreme climate events in power system planning and operation.

3 Designing Efficient and Equitable Retail Rate for Distributed Energy Resources

Madalsa Singh[1], Bruce Cain[2], Ines Azevedo[1], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA, Contact: madalsa@stanford.edu

Rooftop solar and storage adoption with variable electricity retails that reflect marginal (energy) and fixed (network) costs of utility can play an important role in efficient and equitable decarbonization. Under net-energy metering, especially in states with high tariffs, adopters of solar and/or storage have been overcompensated for the surplus energy sold back. In this work, we test different retail rate formulations - two-part, tiered, and high peak-off peak time varying volumetric tariffs - under a net bill minimization decision making framework with flexible electrified load to understand adopter bill savings, utility net costs, and society's environmental surplus focused on distributional equity. Initial results indicate storage with solar provides benefits to both adopters and utility with time varying rates (for both volumetric and two-part tariffs)

4 Optimization Model for Grid Connected Photovoltaic and Battery Energy Storage System

Ashfaque A. Mohib[1], Mehmet Bayram Yildirim[2], Ehsan Salari[1], Al Tamimi[3], [1]Wichita State University, Wichita, KS, [2]Wichita State University, Wichita, KS, [3]Sunflower Electric Power Corporation, Wichita, KS, Contact: aamohib@shockers.wichita.edu

This paper proposes an optimization model for photovoltaic (PV) and battery energy storage systems (BESS) in a grid-connected electric network. The model considers the variability and uncertainty of solar energy generation resources and the available capacities for the battery storage systems to determine the best energy mix to meet the growing energy demands. A Mixed Integer Linear Programming (MILP) technique was used on experimental IEEE bus systems to determine the optimal solution for combining PV and BESS to reduce dependency on the electric grid system. Academic researchers and utility asset managers would benefit from the experimental results obtained from this research paper to gain better insights into achieving their sustainable energy growth requirements, given a limited budget over a planning horizon.

Doing Good with Good O.R. II

Award Session

Session Chair: Robert G. Randall, Princeton Consultants, Inc., Greenville, SC

Session Chair: Justin J. Boutilier, University of Wisconsin - Madison, Madison, WI

1 Community-engaged School District Design: A Stream-based Approach

Aysu Ozel, Northwestern University, Evanston, IL

Decades after Brown v. Board of Education, school districts are still struggling with equal access to education. To make decisions with equity at the core, community engagement in every aspect of district design is essential. In partnership with a school district, we revisit the district design problem with a focus on community co-design. We present a compact formulation incorporating multiple decisions simultaneously, providing an efficient way to have a community-centered process and discuss the critical role it played in a community initiative to address historic inequities.

2 Reducing Air Pollution Through Machine Learning

Leonard Boussioux[1], Cynthia Zeng[2], [1]UW Foster, MIT, Somerville, MA, [2]Massachusetts Institute of Technology, Somerville, MA

The work presents a data-driven approach to mitigate air pollution impact from industrial plants on nearby cities by linking operational decisions with weather conditions. Our method combines predictive machine learning models to forecast short-term wind conditions and prescriptive production level recommendations to minimize air pollution impact. We have successfully deployed our models at the OCP Safi site, the largest phosphate plant in Morocco. Our framework provides a pathway for sustainable industrial development by forgoing the trade-off between pollution and industrial activities.

3 Analytics for Societal Impact: Improving Access to Volunteers on Volunteer Match

Akshaya Suresh, Yale University, New Haven, CT

In collaboration with VolunteerMatch—the world's largest online platform for connecting volunteers with nonprofits—we designed and implemented a new recommendation algorithm called SmartSort that builds on ideas from online robust optimization while also incorporating unique aspects of nonprofit operations. Based on promising experimental results showing a statistically significant 8-9% increase in our metric for equity, VolunteerMatch has deployed SmartSort nationwide. We expect it to provide an additional 30,000 volunteer sign-ups annually to opportunities with limited access to volunteers.

4 Hartford HealthCare Improves Hospital Operations with Patient Outcome Predictions

Liangyuan Na[1], Kimberly Villalobos Carballo[2], [1]Massachusetts Institute of Technolgy, Cambridge, MA, [2]Massachusetts Institute of Technolgy-Operations Research Ctr, Cambridge, MA

In collaboration with Hartford HealthCare, we develop machine learning models predicting inpatient outcomes, i.e., 24hr/48hr discharge, ICU transfers, mortality and discharge dispositions (AUC 76%-93%). These predictions enable more discharges (10%-29%) and fewer 7/30-day readmissions (p-value <1e-3). We implement an automated pipeline displaying daily predictions with user-friendly software. Over 200 medical staff currently use our tool, resulting in a significant reduction in patient-average length of stay (0.67 days) and projected annual benefits of $55-$72 million for Hartford HealthCare.

1 Estimating and Visualizing Demand for Dockless Shared Micromobility Systems

Kyran Flynn, Brown University, Cambridge, MA

Shared micromobility, publicly available bikes and scooters, generate data governments can use to understand user demand and access in the city. However, the data can censor users' true starting locations and underestimate demand. This paper offers a novel and interpretable demand estimation model from trip data that models user arrivals as time and location dependent Poisson processes. We design an Expectation-Maximization algorithm to estimate the underlying parameters of this process along with efficient, publicly accessible visualization software to run the model and visualize its results.

2 Smoothed Analysis of Online Non-parametric Auctions

Naveeb Durvasula, University of California-Berkeley, Berkeley, CA

Online learning of revenue-optimal auctions is a fundamental problem in mechanism design without priors. Nevertheless, all existing positive results assume that the auctioneer optimizes over a parameterized auction class (e.g. pricings and auctions with reserves). This leaves behind a significant gap in our understanding of online-learnability of general non-parametric auction classes. We provide the first positive results for online learnability of a non-parametric auction class, for smooth adversaries (in the style of smoothed analysis in online learning) and the class of smooth auctions.

3 A Time-Discretized Mathematical Model and Heuristic for Breast Cancer Radiotherapy

Scholar Sun, University of Waterloo, Toronto, ON, Canada

Sliding window intensity-modulated radiation therapy is a cancer treatment method whereby a high-energy beam is modulated by a set of tungsten leaves that move unidirectionally across the beam field to irradiate cancerous tissue. We formulate a nonlinear mixed integer program to optimize the delivery of treatment wherein the optimal motion of the leaves is determined. Additionally, a heuristic that generates a high-quality feasible solution is proposed. We demonstrate that the solutions generated can be directly implemented in clinical treatment planning software to assist planners.

1 Everything Everywhere All at Once - Teaching Can-Dos with Concepts

Kelly Slaughter, TCU, Fort Worth, TX, Contact: kelly.slaughter@tcu.edu

How can students participate in experiential problem-solving without understanding the underlying concepts? How can students understand the underlying concepts without experiential opportunities? In this session I will share some examples of interweaving the "Can Do" with the Concept that creates a healthy confusion leading to student learning.

2 Beginning with the End in Mind when Integrating Predictive and Prescriptive Analytics

Matthew A. Lanham, Purdue University, Lafayette, IN

We demonstrate a new case example to help students learn how to bridge the gap when interfacing predictive analytics with prescriptive analytics. We advocate to teach students to think with the end in mind, one of Stephen Covey's seven habits for highly successful people, when designing and developing analytics solutions for decision-support. Our carpet manufacturing case example challenges the manufacturer to determine the optimal settings to achieve a retailer's specified stain resistance requirements. We demonstrate options in integrating the estimated predictive model via the baseline linear regression model into a formal optimization model, as well as considerations when the predictive model is non-parametric.

3 An Assessment Of Tools Used In Business Analytics Curricula And Applicability In Industry

Prakash Shrivastava, University of Texas at Dallas, Richardson, TX

This talk will summarize results of a survey about tools students learn in Business Analytics programs and tools they use in Industry. This talk would delineate opportunities for potential augmentation of program based on feedback from alumni and practicing business analysts.

4 Dealing with Imperfect Data

Stephen Robertson, Southern Methodist University, Dallas, TX

The dreaded words for a data analyst: "messy data." However, handling less than perfect data is an ever-present and inevitable challenge we must face. Imperfect data may come in a number of forms, including missing data, inaccurate data, duplicate data, unstructured data, inconsistent data, too much data, and more. An obvious goal is to clean such dirty datasets in a way that allows us to employ our standard statistical methodologies to produce reliable results and conclusions. In extreme cases where data cleansing options are limited, perhaps the best option is to develop a strategy that most effectively utilizes the good data while minimizing the impact of the imperfect data.

Such a strategy can take on different meanings in different situations, and we explore some of these strategies by considering examples of real data from various industries.

Optimization for Portfolio Selection

Contributed Session

Session Chair: Sheung Chi Chow, Australian National University, Canberra, Australia

1 Optimal Currency Portfolio with Implied Return Distribution in the Mean-Variance Model

Norio Hibiki[1], Yuta Hibiki[2], Takuya Kiriu[3], [1]Keio University, Yokohama, Japan; [2]Asset Management One Co., Ltd., Tokyo, Japan; [3]Osaka University, Osaka, Japan. Contact: hibiki@ae.keio.ac.jp

We construct an optimal currency portfolio using the implied return distribution in the mean-variance approach and examine the performance through a backtest. We estimate the implied expected spot return, implied volatility, and implied correlation from currency option price data, and propose a method of constructing a fully forward-looking optimal currency portfolio without historical data. We implement the backtest from January 2006 to October 2020 on a currency portfolio comprising seven currencies and US-dollar interest rate, and examine the usefulness of the proposed method. We find that the proposed method yields a higher performance than the conventional method in previous studies that use historical data.

2 Portfolio Optimization with Weight Constraints Derived from a Nonlinear Function (NF) Reflecting Macroeconomic Variables

Jihye Yang, Seongmoon Kim, Yonsei University, Seoul, Korea, Republic of. Contact: jihyeyang89@gmail.com

We propose the macro augmented portfolio selection models with weight constraints derived from a nonlinear function (“NF”) reflecting Baltic Dry Index, Interest rate, Money supply, and Inflation rate that are estimated based on an exponentially weighted moving average (EWMA) method. We assess the performance of the models with NF compared to that of the models with weight constraints derived from a linear function (“LF”) in 12 different stock markets. The experimental results demonstrate the models with NF outperformed those with LF as well as general benchmarks. We show that the portfolio selection models can be improved by the constraints derived from NF reflecting the major macroeconomic variables of our interest.

3 Modified Mean-Variance Analysis, Portfolio Optimization and Prospect Theory

Sheung Chi Chow, Australian National University, Canberra, Australia. Contact: sheung.chow@anu.edu.au

We consider the use of mean-variance (MV) analysis and portfolio optimization for investors with different preferences under prospect theory. We explore the relationship between these concepts and prospect theory, incorporating prospect stochastic dominance (PSD) to make the results widely relevant. It demonstrates how partial moments align with PSD and can be used to eliminate PSD-inefficient investments. Using partial moments, we also formulate a rule akin to the MV rule to rank investments according to different value functions under prospect theory. This rule can pinpoint PSD-efficient segments on the MV frontier, helping to identify the subset of MV portfolio choices that are both MV and PSD-efficient. Additionally, partial moments enable us to devise a portfolio optimization method for building a portfolio that surpasses a target investment in a PSD sense.

Stochastic Models on Pandemic Management

Contributed Session

Session Chair: Feifan Wang, Mayo Clinic, Rochester, MN

1 A Coupled Seir-Replicator Dynamics Model for Covid-19 Pandemic

Soham Das, Ceyhun Eksin, Texas A&M University, College Station, TX, Contact: soham.das@tamu.edu

In this work, we leverage a SEIR model coupled with replicator dynamics describing changes in population behaviors for forecasting the dynamics of the COVID-19 pandemic. We formulate forecasting of future epidemic states as a problem of estimating the game-theoretic incentive parameters that drive the dynamics of the coupled SEIR model. We find that given sample sequences of data on population infection states, hospitalization numbers, and standard approximations for disease parameters, one can derive a least-squares regression to estimate the incentive parameters. The estimates of these parameters are used to produce our forecasts, which we apply both to

synthetically generated data as well as actual hospitalization datasets from Texas and California. We find our forecasts obtain high performance in predicting hospitalizations in a 30 day horizon.

2 Modeling Preventive Behavior and Viral Characteristics on Disease Spread
Isabella Freitas[1], Pitu Mirchandani[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ
An agent-based model was developed to simulate the spread of disease (e.g. COVID-19) through a population. The primary objectives for this model were to include two major factors and assess how these factors impact disease spread. These two major factors are preventative populations behaviors and viral characteristics. Preventative behaviors include social distancing, masking, and vaccination. Viral characteristics include aspects of the disease which may impact its spread such as viral load. The outcome of this research is a model that can be used to assess how making changes to population behaviors can impact disease dynamics.

3 Dynamic Human Activity Recognition and Its Application in Healthcare
Feifan Wang, Hojjat Salehinejad, Mayo Clinic, Rochester, MN, Contact: wangfeifan86@gmail.com
Human activity recognition (HAR) using machine learning is a novel approach for sensing and detection of human activities, especially in healthcare systems. However, limited attention has been paid to human activity dynamics. In this study, a framework of dynamic human activity recognition (DHAR) is proposed based on a partially observable Markov Decision Process (POMDP) model. It is motivated by the potential inaccuracy of current HAR models in real-world environments. Given a set of HAR models available, the proposed method dynamically selects an HAR model, according to the observed human activities, to better recognize the next human activity. The simulation experiment is conducted and shows better performance of the framework than a single HAR model. This approach has potential in applications in healthcare, such as fall detection.

Health Care Resource Planning
Contributed Session
Session Chair: Silviya Valeva, Saint Joseph's University, Philadelphia, PA

1 Incorporating Sustainability in Cost-Effectiveness of Cancer Surveillance Programs
Gizem Nemutlu[1], Jagpreet Chhatwal[2], [1]Brandeis University, Waltham, MA, [2]Harvard Medical School, Mass General Hospital, Boston, MA, Contact: gnemutlu@brandeis.edu
Sustainability in healthcare is becoming a great concern as carbon emissions produced at healthcare facilities is significant. Cost-effectiveness analyses, commonly used in health outcomes research, do not take carbon footprint costs into account when identifying the most cost-effective intervention. MRI and CT as diagnostic tools are 33 and 17 times more costly than ultrasound per abdominal scan although, especially for low-risk groups, there may not be a significant difference in the health outcomes due to undergoing MRI/CT vs ultrasound. In this study, we consider the cost of carbon footprint in our cost-effectiveness analysis for liver cancer surveillance and summarize different surveillance protocols without sacrificing health outcomes.

2 Inventory Rationing During a Pandemic: Model and Applications
Benjamin Neve, Weber State University, Syracuse, UT, Contact: benjaminneve@weber.edu
The availability of real-time data showing dynamic regional healthcare needs skyrocketed during the pandemic, with several large organizations providing the data for free and in many forms. As such, better-informed inventory rationing decisions became possible at a higher level than ever before. During the COVID-19 pandemic, several instances of rationing occurred in the US healthcare system. We present a model that takes into account multiple rationing classes in a healthcare environment using simulation optimization, where parameters can be derived from near real-time, openly-available healthcare data. We also provide a simplified model that performs well in real-world settings and allows for applied customization under different governing policies.

3 ICU Networks Design with Step-Down Units
Silviya Valeva[1], Guodong Pang[2], Andrew J. Schaefer[2], [1]Saint Joseph's University, Philadelphia, PA, [2]Rice University, Houston, TX, Contact: svaleva@sju.edu
Intensive care units (ICU) care for some of the most critically ill patients within hospitals. Once ICU patients are stable enough, they can be moved to downstream units, making space for incoming critical patients. Types of downstream units vary based on staff training and level of care. While the most general type of downstream units are wards,

caring for stable patients before discharge, some hospitals utilize intermediate (or step-down) units that are able to care for semi-critical patients. We explore network design considerations based on utility-maximizing optimization models. We test and validate our proposed network topologies using large-scale multi-period simulation studies considering patient health evolution and transfer policies between various level of care units.

Online Decision Making Algorithms

Community Committee Choice Session

Session Chair: Jinglong Zhao, Boston University, Boston, MA

Session Chair: Mika Sumida, University of Southern California, Los Angeles, CA

1 Randomized Robust Price Optimization

Xinyi Guan, Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA, Contact: xinyi.guan.phd@anderson.ucla.edu

The robust multi-product pricing problem is to determine the prices of products to maximize the worst-case revenue taken over an uncertainty set of demand models. A tacit assumption is that the pricing decision is deterministic. We consider a randomized approach to robust multi-product pricing, where a decision maker specifies a distribution over potential price vectors to maximize its worst-case revenue. We analyze when a randomized price scheme performs as well as a deterministic price vector, and propose solution methods for obtaining an optimal randomization scheme over a discrete price set for the case where the demand model uncertainty set is convex or discrete, and show how these methods are applicable for common demand models. We numerically compare the randomized approach against the deterministic approach on a variety of synthetic and real problem instances.

2 Bidding in Multi-Unit Pay-as-Bid Auctions

Rigel Galgana[1], Negin Golrezaei[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, Contact: galganarigel@gmail.com

We consider the problem of learning how to bid in repeated multi-unit pay-as-bid auctions, which are prevalent in treasury or procurement auctions. In these auctions, a large number of (identical) items are allocated to the highest bidders who pay the sum of their winning bids. The complexity of solving this challenging combinatorial optimization problem serves as a major obstacle to market entry, especially for smaller firms. To improve market efficiency, we design computationally efficient, low-regret online learning algorithms for both the full information and bandit feedback bid optimization problems. Numerical simulations suggest that the resulting equilibrium yields optimal welfare.

3 Adaptive Neyman Allocation

Jinglong Zhao, Boston University, Boston, MA

Neyman Allocation is an omnipresent concept in designing social experiments and clinical trials. In this work, I present how to conduct Neyman Allocation in an adaptive fashion.

4 Maximum Optimality Margin: A Unified Approach for Contextual Linear Programming and Inverse Linear Programming

Chunlin Sun[1], Shang Liu[2], Xiaocheng Li[2], [1]Stanford University, Stanford, CA, [2]Imperial College Business School, London, United Kingdom. Contact: chunlin@stanford.edu

We study the predict-then-optimize problem where the output of a machine learning prediction task is used as the input of some downstream optimization problem, say, the objective function of an LP. We develop a new approach to the problem called maximum optimality margin which designs the machine learning loss function by the optimality condition of the downstream optimization. The max-margin formulation enjoys both computational efficiency and good theoretical properties for the learning procedure, and our new approach only needs the observations of the optimal solution in the training data rather than the objective function. The method and its analysis not only shed light on the generic problem formulation of inverse and contextual LP, but also draw implications for problems of utility modeling, choice modeling, and revealed preference.

Online Markets and Policy Design

Community Committee Choice Session

Session Chair: Zhen Lian, Cornell University, NEW YORK, NY
Session Chair: Faidra Monachou, Harvard University, Cambridge, MA

1 Fair Assortment Planning

Qinyi Chen[1], Negin Golrezaei[2], Fransisca Susan[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, Contact: qinyic@mit.edu

Many online platforms prioritize featuring items with the highest popularity or revenue when making assortment planning decisions. This, however, can lead to undesirable outcomes for the rest of the items, making them leave the platform and hurting the platform's long-term goals. Motivated by that, we introduce and study a fair assortment planning problem, which requires any two items with similar quality/merits to be offered similar outcomes. We propose a framework to find near-optimal solutions to this problem, using the Ellipsoid method and an approximate separation oracle to its dual. We then develop two approximate separation oracles, which result in a polynomial-time 1/2-approx. algorithm and a PTAS for the original problem. We conclude with a case study on the MovieLens dataset, which shows the efficacy of our algorithms and sheds light on the price of fairness.

2 Online Fair Allocation of Perishable Resources

Chamsi Hssaine, University of Southern California, Marshall School of Business, Los Angeles, CA

We consider a practically motivated variant of the canonical online fair allocation problem: a decision-maker has a budget of *perishable* resources to allocate over a fixed number of rounds. Each round sees a random number of arrivals, and the decision-maker must commit to an allocation for these individuals before moving on to the next round. The goal is to construct a sequence of allocations that is *envy-free* and *efficient*. We design an algorithm which takes as input (i) a prediction of the perishing order, and (ii) a desired bound on envy. Given the remaining budget, the algorithm uses forecasts of future demand and perishing to adaptively choose one of two carefully constructed guardrail quantities. We show that our algorithm achieves the optimal envy-efficiency Pareto frontier. We demonstrate its strong numerical performance using data from a partnering food bank.

3 Community/Committee'S Choice Submission

Hongyao Ma, Columbia University, New York, NY

4 Information Design In Ride-hailing

Feifan Zhang, Duke University, Durham, NC

Conventional wisdom in ride-hailing suggests that disclosing trip details to drivers hurts the platform, as drivers become selective about trips ("cherry-picking"). Still, recent shifts in regulations and labor are nudging platforms towards more transparency for drivers. To understand its implications, we analyze a platform with two levers on drivers: the pay, and the transparency of this pay. The platform faces uncertain demand, characterized by multiple demand scenarios. We find that, surprisingly, revealing full information is optimal, providing that the pay is set properly in each scenario. However, if the platform cannot dynamically adjust the pay, then full information can backfire, worse than not sharing any information at all. Our results highlight the intricate relationship between the information policy and the driver pay in ride-hailing.

1 Offline Feature-Based Pricing Under Censored Demand: A Causal Inference Approach

Zhengling Qi[1], Jingwen Tang[2], Ethan Xingyuan Fang[3], Cong Shi[2], [1]The George Washington University, D.C., [2]University of Michigan, Ann Arbor, MI, [3]Duke University, Durham, NC, Contact: tjingwen@umich.edu

We study a feature-based pricing problem with demand censoring in an offline setting. A firm is endowed with a finite inventory and faces a random demand. With the demand function unknown, the firm has access to a dataset consisting of quadruplets of historical covariates, inventory, price, and potential censored sales quantity. Our objective is to find the optimal pricing rule to maximize the expected profit. Through the lens of causal inference, we propose a novel data-driven algorithm motivated by survival analysis and doubly robust estimation. We derive a finite sample regret bound to justify the proposed offline learning algorithm. Thorough numerical experiments demonstrate our proposed algorithm performs robustly well, demonstrating the value of factoring in demand censoring for feature-based pricing.

2 Transfer Learning, Cross Learning and Co-Learning Across Newsvendor Systems

Lei Li, Purdue University, West Lafayette, IN

Decision making with limited data is challenging. We demonstrate that transfer learning can improve decision performance in the focal system by leveraging a well-trained solution using the ample data in a related system. We further propose cross learning by adapting the parametric solution of Operational Data Analytics for non-parametric decision making. The resulting decision significantly improves the performance of the focal system over the transfer-learned solution and is shown to be asymptotically optimal. When there are multiple related systems with limited data, we derive a co-learning solution shown to be asymptotically optimal for each involved system, as well as the aggregate system, by pooling the data from different systems. Our results underscore the role of statistical and structural knowledge in designing efficient decisions with limited data.

3 Government Policies to Incentivize Citizen Preparedness for Supply Disruptions

Xiaoyan Zhao, Venus Lo, Stephen Shum, City University of Hong Kong, Kowloon Tong, Hong Kong. Contact: venus.hl.lo@cityu.edu.hk

The public can suffer from significant loss due to inadequate preparation ahead of supply disruptions due to emergencies. Governments can minimize the impact of disruptions by encouraging the public to store supply at home as part of emergency preparation. We study a government's problem of incentivizing emergency preparedness. The government can implement a citizens-based incentive via a discount or coupon to reduce their cost of holding spare supply. Alternatively, the government can implement a retailer-based incentive by subsidizing the retailer's capacity during regular times so that citizens can easily acquire spare supply in advance. These incentives are effective under different circumstances. We present an approximation algorithm to find a hybrid policy. By combining the incentives, the hybrid policy incurs much lower social loss than a single policy.

4 On Dynamic Pricing with Covariates

Hanzhao Wang[1], Kalyan Talluri[2], Xiaocheng Li[1], [1]Imperial College Business School, London, United Kingdom; [2]Imperial College Business School, London, VT, United Kingdom. Contact: h.wang19@imperial.ac.uk

We consider the dynamic pricing problem with covariates under a generalized linear demand model: a seller can dynamically adjust the price of a product over a horizon of T, where the demand of the product is jointly determined by the price and an observable covariate vector $x_t\in\mathbb{R}^d$ through an unknown generalized linear model. In this paper we show a Thompson Sampling pricing algorithm, which is simple and efficient, has an $\tilde{O}(d\sqrt{T})$ regret upper bound without assuming any statistical structure on the covariates x_t (which can even be arbitrarily chosen). Furthermore, we extend the algorithm into the setting with inventory constraint.

5 Simple Policies for Joint Pricing and Inventory Management

Adam Elmachtoub[1], Harsh Tarak Sheth[2], Yeqing Zhou[3], [1]Columbia University, New York, NY, [2]Columbia IEOR, New York, NY, [3]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: y.zhou2@tue.nl

We study the fundamental joint pricing and inventory control problem, where the customers are price sensitive. In the continuous review infinite horizon setting, the optimal policy is known to be an (s, S, p) policy, and the optimal price changes for every inventory state. We consider policies with only a small number of prices offered and compare these policies to the optimal policy.

When customer valuations follow an MHR distribution, we provide policies with theoretical guarantees for revenue and costs. In the lost sales case, we show that there exists a single-price policy that achieves at least as much revenue as the optimal dynamic policy while incurring costs at most \sqrt{ln*eS**} times more. The cost ratio is improved to 1.225 when the valuation distribution is uniform. When backlogging is allowed, we show that a three-price policy can achieve similar guarantees.

Pricing and Simple Mechanisms for Combinatorial Allocation Problems

Community Committee Choice Session

Session Chair: Andres Cristi, Universidad de Chile, Santiago, Chile

1 A Constant Factor Prophet Inequality for Online Combinatorial Auctions

Jose Correa[1], Andres Cristi[2], [1]Universidad de Chile, Santiago, Chile; [2]Universidad de Chile, Santiago, Chile. Contact: andres.cristi.e@gmail.com

In online combinatorial auctions, m indivisible items are to be allocated to n agents who arrive online. Agents have random valuations for the different subsets of items, and the goal is to allocate the items on the fly so as to maximize the total value of the assignment. For the case where valuations are subadditive, we prove the existence of an O(1)-competitive algorithm, resolving a central open problem in the area. Our result is based on a novel but elementary sampling idea, which we call the Mirror Lemma. This lemma is essentially concerned with understanding algorithms for which the sets of allocated and unallocated items distribute equally. The other main ingredient is a nonstandard application of Kakutani's fixed point theorem. We will give an overview of the techniques and discuss implications for pricing mechanisms.

2 Mnl-Bandit in Non-Stationary Environments

Ayoub Foussoul, Columbia University, New York, NY

In this paper, we study the MNL-Bandit problem in a non-stationary environment and present an algorithm with worst-case dynamic regret of $O(\min{\sqrt{NTL}, N^{\frac{1}{3}}(\Delta^k_{\infty})^{\frac{1}{3}} T^{\frac{2}{3}} + \sqrt{NT})$. Here N is the number of arms, L is the number of switches and Δ^k_{∞} is a variation measure of the unknown parameters. We also show that our algorithm is near-optimal (up to logarithmic factors). Our algorithm builds upon the epoch-based algorithm for stationary MNL-Bandit in Agrawal et al., 2016. However, non-stationarity poses several challenges and we introduce new techniques and ideas to address these. In particular, we give a tight characterization for the bias introduced in the estimators due to non stationarity and derive new concentration bounds.

3 An Empirical Analysis of Optimal Nonlinear Pricing

Soheil Ghili[1], Russ Yoon[2], [1]Yale University, New Haven, CT, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: ykyoon@mit.edu

In "continuous choice" settings, consumers decide not only on whether to purchase a product, but also on how much to purchase. As a result, firms should optimize a full price schedule rather than a single price point. This paper provides a methodology to empirically estimate the optimal schedule under multi-dimensional consumer heterogeneity. We apply our method to novel data from an educational-services firm that contains purchase-size information not only for deals that materialized, but also for potential deals that eventually failed. We show that the optimal second-degree price discrimination (i.e., optimal nonlinear tariff) improves the firm's profit upon linear pricing by about 7.9%.

4 Component Pricing with a Bundle Size Discount

Zechao Li[1], Ningyuan Chen[2], Xiaobo Li[3], Chun Wang[4], [1]Tsinghua University, Beijing, China; [2]University of Toronto, Toronto, ON, Canada; [3]National University of Singapore, Singapore, Singapore; [4]Tsinghua University School of Economics and Management, Beijing, China

Firms selling multiple products usually adopt bundle pricing in their marketing strategy. We propose a simple and widely used bundling mechanism, referred to as component pricing with a bundle size discount (CPBSD), which sells bundles for the summed prices of the included products minus a discount based on the number of products purchased. Theoretically, we show that CPBSD attains the optimal profit asymptotically under mild conditions. Practically, we formulate a mixed-integer linear program to solve CPBSD and develop an approximation algorithm for efficiently solving it in large-scale problems. In numerical studies, we show that CPBSD outperforms other bundling mechanisms; especially for the high product heterogeneity, the high production costs, and the potential surplus provided by products that are negatively correlated with the product valuations.

5 On Online Contention Resolution Schemes For The Matching Polytope Of Graphs

MacRury Calum[1], Will Ma[1], Nathaniel Grammel[2], [1]Columbia University, New York, NY, [2]University of Maryland, Maryland, MD, Contact: cm4379@columbia.edu

Online Contention Resolution Schemes (OCRS's) represent a modern tool for selecting a subset of elements, subject to resource constraints, when the elements are presented to the algorithm sequentially. OCRS's have led to some of the best-known competitive ratio guarantees for online resource allocation problems, with the added benefit of treating different online decisions---accept/reject, probing, pricing---in a unified manner. We analyze OCRS's for resource constraints defined by graph matchings, a fundamental structure in combinatorial optimization. We improve the state of the art both in terms of algorithmic guarantees and impossibility results. Our algorithms directly improve the best-known competitive ratios for online accept/reject, probing, and pricing problems on graphs. Most notably, this includes the prophet matching problem with edge arrivals.

APS Special Session: Queueing Models for Today's Compute Centers

Award Session

Session Chair: Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA
Session Chair: Christina Lee Yu, Cornell University, Ithaca, NY

1 Queueing Models for Today's Compute Centers

Mor Harchol-Balter, Carnegie Mellon University, Pittsburgh, PA

Almost all queueing models assume that a job runs on a single server. But this one-server-per-job model is not a good representation of today's compute jobs.
A typical data center job occupies multiple cores concurrently for some fixed time. Unfortunately, very little is known about the performance of such "multiserver job" queueing models. We present the first results on response time for multiserver job models.
Other compute jobs, like database queries and many machine learning jobs, are malleable. They can run on *any* number of cores, where the job's speed is a function of the number of cores allocated to it. We present the first results on optimal core allocation algorithms for such parallel speedup jobs.
All results presented are very recent and are a testament to how open both these settings are. If you are looking for open problems to work on, this is a good talk for you!

Scaling Limits of Interacting Particle Systems

Community Committee Choice Session

Session Chair: Ruoyu Wu, Iowa State University, Ames, IA

1 Smoothness of Directed Chain Stochastic Differential Equations and Its Applications

Tomoyuki Ichiba, Ming Min, University of California Santa Barbara, Santa Barbara, CA

On a filtered probability space for the space of continuous functions, we shall consider a system of stochastic equations called directed chain stochastic differential equations for a pair of stochastic processes whose marginal distributions in the path space are identical and their joint distribution is uniquely determined by the system of equations with the distributional constraints. In this talk we discuss the smoothness of the solutions of the equations under some regular conditions and introduce its applications of such systems to the stochastic filtering problem and to the generative adversarial network problem in finance.

2 Longtime Behavior of Stochastic Waves on Metric Spaces and Their Genealogies

Wai-Tong (Louis) Fan[1], Yifan (Johnny) Yang[2], [1]Indiana University, Bloomington, IN, [2]Indiana University, Bloomington, IN, Contact: waifan@iu.edu

Stochastic reaction-diffusion equations are important models in mathematics and in applied sciences such as spatial population genetics and ecology. However, for many reaction terms and noises, the solution notion of these equations is still missing in dimension two or above, hindering the study of spatial effect on stochastic dynamics. In this talk, I will discuss a new approach, namely, to study these equations on general metric graphs and fractals. This enables us to assess in great detail the impact of spatial effect on the co-existence and the genealogies of interacting populations. We will focus on recent results on extinction/survival probability, quasi-stationary distribution, asymptotic speed and other long-time behaviors for stochastic reaction-diffusion equations of Fisher-KPP type.

3 Multi-Component Matching Queues in Heavy Traffic

Bowen Xie, Washington University in St. Louis, St. Louis, MO

We consider multi-component matching queue systems in heavy traffic consisting of K ≥ 2 distinct perishable components, which arrive randomly over time to their respective queues at high speed at the assemble-to-order station and wait until an instantaneous match or their patience runs out. For a sequence of such systems parameterized by n, when the arrival rates tend to infinity in concert as n ⍰ ∞, we obtain a heavy traffic limit of the appropriately scaled queue length vector characterized by a coupled stochastic integral equation with a scalar-valued non-linear term under mild assumptions. We demonstrate some crucial properties. Motivated by the cost structure of blood bank drives, we formulate an infinite-horizon discounted cost functional and show that the expected value of the cost for the nth system converges to that of the heavy traffic limit as n tends to infinity.

4 Weakly Interacting Jump Processes with Graphon Interactions

Ruoyu Wu, Iowa State University, Ames, IA

We consider systems of weakly interacting jump processes on heterogeneous random graphs and their large population limit. The interaction is of mean field type weighted by the underlying graphon. A law of large numbers result is established as the system size increases and the underlying graphons converge. The limit is given by a graphon particle system consisting of independent but heterogeneous nonlinear Markovian processes whose probability distributions are fully coupled. An application to individual-based epidemic models is discussed.

Ergodicity and Scaling Limits of Stochastic Networks

Community Committee Choice Session

Session Chair: Sayan Banerjee, 1</sup

1 Load Balancing in Parallel Queues and Rank-Based Diffusions

Sayan Banerjee[1], Amarjit Budhiraja[2], Ben Estevez[2], [1]UNC, Chapel Hill, Chapel Hill, NC, [2]UNC, Chapel Hill, Chapel Hill, NC, Contact: budhiraj@email.unc.edu

Consider a queuing system with K parallel queues in which the server for each queue processes jobs at rate n and the total arrival rate to the system is nK-v \sqrt{n} where v>0 and n is large. We study a family of rank-based routing policies in which O(\sqrt{n}) of the incoming jobsare routed to servers with probabilities depending on their ranked queue length and the remaining jobs are routed uniformly at random. Heavy traffic limit theorems, large time behavior and interchange of limits results are studied. Some comparisons with the classical join-the-shortest queue control policy are made.

2 Opinion Dynamics on Complex Networks: From Mean-Field Limits to Sparse Approximations

Mariana Olvera-Cravioto, UNC, Chapel Hill

In a world of polarized opinions on many cultural issues, we propose a model for the evolution of opinions on a large complex network. Our model is akin to the popular Friedkin-Johnsen model, with the added complexity of vertex-dependent media signals and confirmation bias, both of which help explain some of the most important factors leading to polarization. The analysis of the model is done on a directed random graph, capable of replicating highly inhomogeneous real-world networks with various degrees of assortativity and community structure. Our main results give the stationary distribution of opinions on the network, including explicitly computable formulas for the conditional means and variances for the various communities. Our results span the entire range of inhomogeneous random graphs, from sparse to dense.

3 A New Class of Bounds for Convergence of Markov Chains to Equilibrium

Yanlin Qu, Peter W. Glynn, Jose Blanchet, Stanford University, Stanford, CA

We introduce a unified framework to derive computable convergence bounds for Markov chains. Under this framework, bounds with various rates, ranging from polynomial to exponential, are derived from a single "contractive drift" (CD) condition. These bounds are computable, as all elements are explicitly defined in terms of one-step transition expectations. Various techniques are devised to verify CD for examples from queueing theory and stochastic optimization. For these examples, we obtain sharp bounds that scale correctly with respect to model parameters such as the traffic intensity in queueing models and the step size in optimization algorithms.

4 Distributed Rate Scaling in Large-Scale Service Systems

Debankur Mukherjee[1], Daan Rutten[1], Martin Zubeldia[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Minnesota, Minneapolis, MN

We consider a large-scale parallel-server system, where each server independently adjusts its processing speed in a decentralized manner. The objective is to minimize the overall cost, which comprises the average cost of maintaining the servers' processing speeds and a non-decreasing function of the tasks' sojourn times. This problem is compounded by the lack of knowledge about task arrival rate and the absence of centralized control or communication among the servers. Drawing on stochastic approximation, we present a novel rate-scaling algorithm that ensures the convergence of all server processing speeds to the globally asymptotically optimum value as the system size increases. En route, we also analyze the performance of a fully heterogeneous parallel-server system, where each server has a distinct processing speed, which might be of independent interest.

Frontiers in Adaptive Experimentation

Community Committee Choice Session

Session Chair: Hongseok Namkoong, Columbia University, New York, NY

Session Chair: Hannah Li, MIT, West Menlo Park, CA

1 Poisson Limits for Bernoulli Bandits

Wenjia Ba[1], Lin Fan[2], Peter W. Glynn[2], J. Michael Harrison[2], [1]Amazon, Menlo Park, CA, [2]Stanford University, Stanford, CA, Contact: linfan@stanford.edu

We introduce a new asymptotic regime for modeling bandit experiments with low success probability Bernoulli rewards. By considering success probabilities of $O(\gamma)$ in the limit of γ decreasing to zero, over time horizons of $O(1/\gamma)$, we show that the sample-path behavior of adaptive algorithms such as Thompson sampling can be approximated by solutions to stochastic ODE's driven by Poisson processes. Our results reveal insights about the regret behavior of such algorithms, as well as that of simple and tuning-free dynamic batch updating strategies.

2 Online RL For Digital Health Interventions: The Art Of Reward Design

Kelly W. Zhang, Columbia University, New York, NY, Contact: kelly.w.zhang@columbia.edu

Dental disease is one of the most prevalent chronic illnesses in the US. Advances in digital tech, like electric toothbrushes and smartphones, offer potential for promoting quality toothbrushing in real-time. We develop an online RL algorithm for learning when to send vs not send feedback/educational messages to patients via a mobile app to best promote quality toothbrushing. A key challenge is ensuring the RL algorithm is simple enough to learn in this data-sparse, real-world setting, while at the same time still manages to model delayed effects of sending messages (i.e., user burden). Via careful reward design we help the RL algorithm maximize high-quality brushing while accounting for user burden. Our RL algorithm is currently being pilot tested for a clinical trial that is planned to start in fall 2023.

3 Diffusion Models for Experimentation

Victor Araman, American University of Beirut, Beirut, Lebanon

We consider a decision maker who must choose an action in order to maximize a reward function that depends also on an unknown parameter. The decision maker can delay taking the action in order to experiment and gather additional information on the unknown parameter. We model the decision maker's problem using a Bayesian sequential experimentation framework and use dynamic programming and diffusion-asymptotic analysis to solve it. For that, we scale our problem in a way that both the average number of experiments that is conducted per unit of time is large and the informativeness of each individual experiment is low. Under such regime, we derive a diffusion approximation for the sequential experimentation problem, which provides a number of important insights about the nature of the problem and its solution.

Green Products, Services and Market Mechanisms

Community Committee Choice Session

Session Chair: Metin Cakanyildirim, The University of Texas at Dallas, Richardson, TX

Session Chair: Lingling Shi, The University of Texas-Dallas, Richardson, TX

1 The Economical and Environmental Impacts of Reselling Returns

Xin Wang[1], Yulan Amanda Wang[2], Kanglin CHEN[3], [1]The Hong Kong University of Science and Technology, Kowloon, Hong Kong; [2]The Hong Kong Polytechnic University, Hung Hom, Hong Kong; [3]Southern University

of Science and Technology, Shenzhen, China
Many retailers resell returns with no quality problems as new to save costs as well as reduce carbon emission and other negative environmental impacts. However, customers might express concerns and incur valuation reduction when they receive returns resold as new. In this study, we examine the impact of reselling returns on the market and the environment. We show that when consumers have valuation reduction towards receiving returns, reselling returns can benefit the retailer, consumers, and the environment simultaneously. Interestingly, educating consumers to be more tolerant of receiving returns might result in higher carbon emission.

2 On the Environmental Impact of Load Shifting in the Day-Ahead Market

Clarisse Dupont[1], Yashar Ghiassi-Farrokhfal[2], Derek W. Bunn[3], Olga Kuryatnikova[4], [1]Erasmus university, Rotterdam, Netherlands; [2]Erasmus University, Rotterdam School of Management, Rotterdam, NY, Netherlands; [3]London Business School, London, United Kingdom; [4]Erasmus University, Rotterdam, Netherlands. Contact: dupont@rsm.nl

Storage and Demand Response can enhance renewable energy sources integration by managing imbalances through load shifting. However, these flexible assets may inadvertently increase the CO2 emissions of electricity procurement because of their inefficiencies and the shape of the marginal emission curve. We develop a model to understand the market conditions under which this phenomenon occurs in the day-ahead market. We then formulate three solutions - a capacity cap, a CO2 tax, and a transaction tax - to integrate load-shifting agents without increasing CO2 emissions. We further evaluate and confirm the validity of our analytical findings in more practical and diverse settings and through numerical studies, using data from the Dutch day-ahead market.

3 Data-Driven Operations for a Grid-Vehicle Integration System

Ziliang Jin[1], Jianqiang Cheng[2], Kai Pan[1], Zuo-Jun Max Shen[3], Yulan Wang[1], [1]The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]University of Arizona, Tucson, AZ, [3]University of California, Berkeley, CA, Contact: ziliang-lms.jin@connect.polyu.hk

We examine a grid-vehicle integration system that uses vehicle-to-grid (V2G) technology to connect the grid and the electrical vehicle (EV) sharing system. Our focus is on the operation of this integration system under uncertainties. We formulate this problem as a two-stage robust mixed-integer program. To improve the solving process, we propose three approaches that incorporate alternating direction method of multipliers (ADMM), machine learning (ML), and strong valid inequalities, respectively. Our approaches significantly outperform a commercial solver in both computational time and solution quality based on real data. Our findings suggest that in addition to enhancing the operation efficiency of the grid, V2G also promotes sustainability by reducing carbon emissions. However, the extent of this contribution varies under different power load patterns.

4 Pricing and Producing Green Products Under Subsidy Termination and Evolving Coopetition

Lingling Shi[1], Metin Cakanyildirim[2], Suresh P. Sethi[2], [1]The University of Texas-Dallas, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX, Contact: metin@utdallas.edu

Governments offer subsidies to consumers to reach green product adoption targets. Subsidies will terminate. Accounting for subsidy termination and interplay among subsidy, learning-by-doing and competition, we develop a two-period Stackelberg-Nash game between the government and manufacturers. We find that the government spends less subsidy expenditure with qualified-sales rule compared to all-sales rule. Each manufacturer adopts zero-inventory and skimming price strategies. Two manufacturers may learn individually or as a group. Interestingly, under group learning, a manufacturer's total equilibrium production quantity in two periods decreases in his rival's initial cost when the cooperation through group learning outperforms the competition between the manufacturers. Besides, group learning benefits the three parties only in specified cases.

Intelligent Decision Making and its Applications

Community Committee Choice Session

Session Chair: Kuo-Ping Lin, 1</sup

1 Using Long Short-Term Memory for Waste Disposal Forecasting

Kuo-Ping Lin[1], Kuo-Chen Hung[2], [1]Tunghai University, Taichung City, Taiwan; [2]Hungkuang University, Taichung City, Taiwan. Contact: kplin@thu.edu.tw

This study attempts to apply Long Short-Term Memory (LSTM) to forecast the daily amount of recycling clinical and related waste generated. LSTM networks can capture dependencies in sequential data over long time lags. In this study, LSTM, support vector regression (SVR), generalized regression neural network (GRNN) and autoregressive integrated moving average (ARIMA) are examined to forecast the daily amount of recycling clinical and related waste generated. Empirical results indicate the LSTM model demonstrates better performance and robustness compared to the other approaches; The LSTM method can help experts in hospitals develop reasonable waste disposal projects, which can help the waste management system effectively achieve operational reliability and economy.

2 Community/Committee'S Choice Submission
I-Jan Wang, Taiwan

3 Application on Text Analytics for Supply Chain Resource Limits Assessment
Chih-Yuan Chu, Tunghai University, Taichung, Taiwan. Contact: cychu@thu.edu.tw
Designing resilient supply chains that can recover from the negative impacts of risk events is an important issue in product development. Accordingly, this study aims to utilize textual data from news articles and earnings call transcripts to assess the resource limits, one of the essential indicators of supply chain vulnerability. An integrated factor analysis (FA) and Analytical Network Process (ANP) method was proposed to model the company's supply chain resource limits index with potential importance weights. The results showed that the shortages of resources such as production capacity, energy, and manufacturing components are the most critical sub-factors. A company resource limits index (CRLI) and supply chain resource limits index (SCRLI) were developed to assist companies in evaluating the resource limits vulnerability.

4 Applying Robust Stochastic Optimization on Scheduling Problem in Electronic Manufacturing Services Industry
Kang-Ting Ma[1], Che-Wei Chou[2], Ren-Hong Luo[1], You-Qin Wang[1], [1]National Dong Hwa University, Hualien, Taiwan; [2]Feng Chia University, Taichung, Taiwan. Contact: cwchou@fcu.edu.tw
EMS excels in the manufacture and assembly of electronic products, handling a variety of components, including printed circuit board assembly (PCBa). PCBa comprises three main stages: Surface-Mount Technology (SMT), Dual in Package (DIP), and Assembly-Test-Packaging (ATP). While scheduling typically relies on due dates, the manual nature of SMT's post-process introduces uncertainty in process time. Therefore, this study aims to develop robust strategies for machine operation and overtime through a stochastic optimization mathematical model. To estimate the uncertainty of production time in post-process, we develop a simulation model to appraise the production time of varied products during the DIP and ATP process where full of variations in the manufacturing environment. This scheduler helps practitioners to meet the delivery schedule on time.

5 A Study on the Application of Data Envelopment Analysis to Evaluate the Innovation Performance of Taiwan's Fastener Industry
Sheng-Pin Wu, Tai-Yu Lin, National Cheng Kung University, Tainan, Taiwan
The fastener industry faces unprecedented challenges due to Covid-19 and competition from mainland China and Southeast Asian countries. This study evaluated the innovative performance of twelve listed companies. The R&D expense ratio, patent-grade distance, and net operating income were analyzed using data envelopment analysis. It has been found that R&D expenditures positively correlate with innovation performance and business turnover but not with patents. R&D expenditures in the fastener industry are driven by developing new products and processes. Adding new products and technologies will increase the company's overall benefits. The innovation energy accumulation and scale technical efficiency can also be improved in the fastener industry.

CC-North 125B
Job Market Candidates - Responsible Operations
Community Committee Choice Session
Session Chair: Alp Sungu, London Business School, London, United Kingdom

1 Incentives And Conditions For Protecting Tropical Forests And Improving Smallholder Welfare
Xavier Warnes[1], Dan Andrei Iancu[1], Erica Plambeck[1], Joann de Zegher[2], [1]Stanford University, Stanford, CA, [2]MIT Sloan, Cambridge, MA, Contact: xwarnes@stanford.edu
Environmental science documents that agricultural production is a dominant driver of deforestation in developing countries. Complex land tenure systems coupled with low enforcement of conservation laws enable farmers to illegally convert tropical forests into productive land in search of a better income. We propose group incentives

conditional on protecting a specific forest area to prevent this deforestation while increasing farmer welfare. We model the deforestation decisions using a cooperative game in partition function form and show how these area-conditional incentives can leverage the existing social capital in agricultural communities. Finally, we demonstrate these incentives' effectiveness by using data from the Indonesian context.

2 Centralized Versus Decentralized Pricing Controls For Dynamic Matching Platforms

Omer Saritac[1], Ali Aouad[1], Chiwei Yan[2], [1]London Business School, London, United Kingdom; [2]University of Washington Seattle, San Francisco, CA, Contact: osaritac@london.edu

Motivated by recent regulations and increased public scrutiny on platform control, we analyze how pricing centralization affects online service platforms using a fluid model of dynamic two-sided matching. We explore outcomes from a fully centralized pricing system, where the platform sets the price, to a fully decentralized one, where suppliers set prices. Our research uncovers the structure of stationary market equilibria and resulting social welfare under various degrees of centralization. We find that in 'impatient' markets, centralized platforms yield higher social welfare, while in more patient markets, decentralized pricing approaches first-best outcomes. Semi-centralized pricing rules, offering some flexibility to suppliers in setting their prices, recover near-optimal outcomes in most market conditions.

3 Keep Water Flowing: The Hidden Crisis of Rural Water Management

Chengcheng Zhai[1], Rodney P. Parker[2], Kurt M. Bretthauer[2], Jorge Mejia[2], Alfonso J. Pedraza-Martinez[2], [1]Kelley School of Business, Bloomington, IN, [2]Indiana University, Bloomington, IN, Contact: zhaic@iu.edu

In rural areas of sub-Saharan Africa (SSA), people rely on handpumps for clean drinking water. Unfortunately, handpumps break down frequently due to lack of maintenance and repair. We collected mechanic visit and water point functionality data from three SSA countries. We develop a Markov decision process (MDP) that captures the main features of a maintenance program. The MDP determines the optimal schedule for NGO mechanics to visit water points, with the aim of minimizing water point downtime and the logistics costs. Our research challenges the notion held by many NGOs that preventive maintenance is costly and that monitoring and collecting functionality information is the key to improving water point functionality. We recommend NGOs invest in increasing water points reliability before investing in collecting more functionality information.

Smart Bases

Community Committee Choice Session

Session Chair: Gregory S. Parnell, University of Arkansas, Fayetteville, AR

1 Smart Sensor Data Streams for Smart Bases

Natalie Myers, [1</sup]

The 2020 Army Installation Strategy establishes a vision for a future, modern Army that reduces costs and improves the environment, quality of life, security, and mission readiness by leveraging smart and connected technologies. Data-informed, smart installations will allow the Army to enable a data-rich, reconfigurable, and technology-enhanced information-age construct. To meet this end state, installations are looking for implementation guidance on how to leverage these technologies and generate the needed data. Researchers from the Army's Engineer Research and Development Center (ERDC) lead recent efforts to pilot smart city technologies to enable the identification and implementation strategies for Army installations. Join this session to learn about technologies being piloted at installations today and the data they are providing. These technologies include weather sensor to better inform everything from base closures to training schedules, as well as video surveillance to monitor remote fence lines or traffic congestion.

2 Leveraging Weather and Climate Intelligence Across Installation Platforms

Randy K. Buchanan, Engineer Research and Development Center, MS

Weather intelligence efforts support the modernization of installation decision-making processes by applying complex computational analytics and high-performance computing assets to inform decision makers for making real-time holistic weather-related decisions as well as supporting long-term climate resilience planning. Installations across the Department of Defense currently utilize weather and climate data but have a need for data at a rate and resolution not currently available. Multiple systems are trying to access and use much of the same data and information. Discovering, documenting, and leveraging these multiple systems is a formidable task, but can serve as a force multiplier to reduce duplication and increase impacts.

3 Weather Intelligence for Military Installation Decision Support - Lessons Learned

George E. Gallarno[1], Jaylen E. Hopson[1], Brendon Hoch[2], John P. Richards[1], Randy K. Buchanan[1], [1]US Army Corps of Engineers, Engineer Research and Development Center, Vicksburg, MS, [2]US Army Corps of Engineers, Engineer Research and Development Center, Vicksburg, MS, Contact: George.E.Gallarno@erdc.dren.mil

A plethora of authoritative weather observation and forecast-related data sources are readily available for analysis and modeling building. The sheer volume and variety of data sources complicates the task of acquiring and preparing relevant weather intelligence for military installation leadership in order to facilitate timely decisions in advance of extreme weather events. We overview lessons learned from data acquisition and implementation for two case study locations (Fort Carson, CO and Fort Moore, GA), illustrating a preliminary data pipeline (i.e., extraction, transformation, loading, and analysis) for extracting meaningful insights necessary for more consistent, transparent, and data-driven installation-level decisions.

4 Application of AI/ML on Local Climatological Data for Installation Forecasting Visibility

William A. Anderson[1], Brendon Hoch[2], Christina Rinaudo[1], John Richards[1], Randy Buchanan[1], George Gallarno[1], [1]Engineer Research and Development Center, Vicksburg, MS, [2]Engineer Research and Development Center, Hannover, NH, Contact: William.A.Anderson@erdc.dren.mil

Ground level visibility forecast data can be a valuable source of information for installation leaders who make decisions on airfield operations, unit training, and installation access that are impacted by visibility, which often is poorly forecast. This research examines the potential for machine learning algorithms to predict visibility using standard measured atmospheric data. Researchers applied a range of machine learning algorithms to collected historic local climatological data to examine the tenability of predicting forecast visibility. Considerations for over-fitting, multi-collinearity, and data sourcing were addressed to ensure the best model is selected. Case study results for Ft. Carson, CO and Ft. Moore, GA are discussed.

5 Preventing Heat Related Injuries in Military Trainings

Eric Specking[1], Gregory S. Parnell[2], Anthony Beger[1], William Anderson[3], Randy Buchanan[3], [1]University of Arkansas College of Engineering, Fayetteville, AR, [2]University of Arkansas, Fayetteville, AR, [3]Engineer Research and Development Center, Vicksburg, MS

Heat injuries cause major problems for the United States military with the Pentagon reporting a 68% increase in permanent damage or death caused by serious heat strokes. Fort Benning is home to one of the largest Army training posts and has the most heat related injuries in the military due to its climate. Training personnel currently use the WetBulb Globe Temperature Index and training details to assess risk. This presentation will 1) provide insights on how temperature impacts soldiers and current risk assessment methods, 2) describe our approach, which uses a data-driven weather-informed process, and 3) discuss future work of the project, which includes migrating our tool to the U.S. Army's Virtual Testbed for Installation Mission Effectiveness (VTIME) cloud environment.

Optimization for Experimentation and Personalization in Managerial Settings

Community Committee Choice Session

Session Chair: Spyros Zoumpoulis, INSEAD, Fontainebleau, France

1 Adaptive Experimental Design for Personalized Treatment Policies

Molly Offer-Westort, University of Chicago

The goal of an multi-arm trial may be to learn which of several interventions is most effective, where the metric of success is simple regret. When candidate intervention sets vary across individuals, or when there is heterogeneity in which intervention is best, the objective may be to learn a personalized treatment policy. Adaptive designs can be used to learn policies with lower regret faster. We discuss design considerations, with application to a Facebook Messenger chatbot study targeting sources of COVID-19 vaccine hesitancy among 22,000 social media users in Kenya and Nigeria. After optimizing messaging using an adaptive experimental design, we compare an interactive concern-addressing chatbot to a chatbot that delivers a non-interactive public service announcement (PSA), as well as to a control, no information, condition.

2 Stochastic Optimization Forests

Nathan Kallus[1], Xiaojie Mao[2], [1]Cornell University, Long Island City, NY, [2]Tsinghua University, Beijing, China. Contact: maoxj@sem.tsinghua.edu.cn

We study contextual stochastic optimization problems, where we leverage rich auxiliary observations (e.g., product characteristics) to improve decision making with uncertain variables (e.g., demand). We show how to train forest decision policies for this problem by growing trees that choose splits to directly optimize the downstream decision quality, rather than split to improve prediction accuracy as in the standard random forest algorithm. We prove that our splitting criteria consistently approximate the true risk and that our method achieves asymptotic optimality. We extensively validate our method empirically, demonstrating the value of optimization-aware construction of forests and the success of our efficient approximations.

3 Optimal Experimentation for Learning Personalized Policies Across Locations

Stefanos Poulidis, Georgina Hall, Spyros Zoumpoulis, INSEAD, Fontainebleau, France. Contact: stefanos.poulidis@insead.edu

Firms wish to learn personalized policies for customers in heterogeneous yet related locations to maximize their monetary gains. To do this, they conduct experiments at each location to estimate the parameters of a customer response function. A key decision is which action to assign to each participant in the experiment, especially when a participant can only be assigned one action, or there are budget constraints. The existing experimentation methodology considers locations and experiments individually. In this work, we leverage the relationship between locations in the experimentation problem to learn more profitable policies by proposing novel estimators and a semidefinite programming approach.

4 A Perturbation-Based Approach to Optimistic-Pessimistic Duality in Robust Optimization

Louis L. Chen, Johannes Royset, Naval Postgraduate School, Monterey, CA, Contact: louischenusa@gmail.com

We revisit the duality between "Primal-Worst" and "Dual-Best" robust optimization formulations through the lens of a perturbation-based approach. In doing so, we find a more general and arguably simpler framework to develop this duality, expand on its prior results, highlight its connection to traditional duality, and show how it can derive a number of modern duality results not typically viewed as part of an optimistic-pessimistic framework. We also show applications in a variety of Operations and Management contexts and discuss the implications of this duality that occasionally pairs convex and non-convex programs.

Data-driven Behavioral Service Operations

Community Committee Choice Session

Session Chair: Qiuping Yu, Georgetown University/Georgia Tech, Washington, DC

Session Chair: Masoud Kamalahmadi, University of Miami, Coral Gables, FL

1 Measuring Strategic Behavior by Gig Economy Workers: Multihoming and Repositioning

Gad Allon, Kenneth Moon, Daniel Chen, University of Pennsylvania, Philadelphia, PA, Contact: gadallon@wharton.upenn.edu

This study investigates the decision-making processes of gig economy workers, focusing on their choices regarding platform engagement and work locations. We analyze extensive worker activity data to explore how workers optimize their earnings and respond to incentives for platform switching and location changes. Our findings highlight the heterogeneity of worker preferences and reveal the costliness of multihoming compared to repositioning. Our findings suggest the significance of enabling free multihoming and efficient repositioning for improved earnings and service levels, providing valuable insights for platform operators and regulators.

2 Fairness in Policing and Crime Prevention with Causal Inference

Jonathan Zhou[1], Zheng Dong[1], Yao Xie[2], Qiuping Yu[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgetown University/Georgia Tech, Washington, DC, Contact: jyz@gatech.edu

We study how scheduling and dispatching policy impact police effectiveness and fairness using event-level police patrol and 911-call data from the Atlanta Police Department. Our findings suggest that two key factors—police availability and the design of patrolling divisions—contribute significantly to service quality disparities and differences in policing behavior across neighborhoods. Based on these results, we propose an optimization framework to mitigate disparities between zones and improve police service quality.

3 A Manager and an AI Walk into a Bar: Does ChatGPT Make Biased Decisions like We Do?

Yang Chen[1], Meena Andiappan[2], Tracy Jenkin[1], Anton Ovchinnikov[3], [1]Queen's University, Kingston, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Smith School of Business, Queen's University, Kingston, ON,

Canada. Contact: tracy.jenkin@queensu.ca

Large language models such as ChatGPT have garnered global attention, promising to disrupt and revolutionize business operations. With increasing reliance on artificial intelligence (AI), there is an urgent need to understand whether there are systematic biases in AI decision-making given they are trained with human data and feedback, which themselves may be highly biased. This paper tests a broad range of behavioral biases commonly found in humans that are especially relevant to operations management. We found that while ChatGPT can be much less biased and more accurate than humans in problems with an explicit mathematical nature, it also exhibits many biases humans possess. Our research characterizes ChatGPT's behaviors in decision-making and showcases the need to consider potential AI behavioral biases when developing and employing AI for business operations

4 Racial and Gender Biases in Customer Satisfaction Surveys: Evidence from a Restaurant Chain

Masoud Kamalahmadi[1], Qiuping Yu[2], Yong-pin Zhou[3], [1]University of Miami, Coral Gables, FL, [2]Georgetown University, Washington, DC, [3]University of Washington, Seattle, WA, Contact: yongpin@uw.edu

Racial and gender inequalities are ubiquitous in the workplace. Whereas previous studies have primarily focused on employer discrimination, we study the role of customers, using 1,444,044 transactions and 257,656 customer satisfaction surveys from a full-service casual-dining restaurant chain in the US. We find that customer ratings of servers are biased against racial minority, and, interestingly, also against females despite their majority in this occupation. We further show that racial biases diminish as the uncertainty about the servers' ability decreases, while gender biases may even increase. These results suggest that statistical discrimination is the primary driver for racial biases, while status-based discrimination is likely the main driver for gender biases. Given these underlying mechanisms, we propose tailored strategies to mitigate the biases.

5 Impact of Empirical Research on Operations Management

Nalin Shani, Maria Ibanez, Kellogg School of Management, Evanston, IL

Empirical research has contributed significantly to the academic field of operations management(OM). There has also been a steady increase in empirical research being generated. Given this trend, an important question arises regarding how does empirical research shapes and drives the OM literature. We plan to investigate the impact empirical research had on recent publications in OM.

Operations Research Approaches for Managing Chronic Diseases

Community Committee Choice Session

Session Chair: Karen T. Hicklin, University of Florida, Gainesville, FL

1 Improving Equity in Access Through Network Design: A Case Study of Specialist Cancer Care in Rwanda

Abel Sapirstein, Lauren N. Steimle, Georgia Tech ISyE, Atlanta, GA, Contact: asapirstein3@gatech.edu

Cancer is a growing cause of death in Rwanda and much of the developing world. Successful diagnosis and treatment of cancer requires orchestration of many specialists, often working together in a dedicated hospital. However, concentrating specialists in a small number of hospitals may further disadvantage populations currently without access to care. In this talk, we consider existing barriers to access and potential system improvements to increase access to specialist cancer care in Rwanda. We present a flexible modeling approach which is capable of weighing cost, demand for care, and provider availability while maximizing accessibility. We parameterize the model using publicly available data and propose solutions that align with the objectives of government and NGO partners.

2 Colorectal Cancer Tumor Proliferation Characteristics And Socioeconomic Status In The Southern Community Cohort Study

Zoe L. Walts[1,2], Thomas Lawler[2], Timothy Su[3], Qiuyin Cai[3], Mark Steinwandel[4], Wei Zheng[3], Shaneda Warren Andersen[1,2,3], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin Carbone Cancer Center, Madison, WI, [3]Vanderbilt University School of Medicine, Nashvillle, TN, [4]Vanderbilt Institute for Clinical and Translational Research, Rockville, MD, Contact: zwalts@wisc.edu

Black and low-income Americans experience increased colorectal cancer (CRC) mortality compared to White and high-income groups. Cox proportional hazards models were built to calculate hazard ratios (HR) and 95% confidence intervals (CI) of income, race, and factors related to socioeconomic status (CRC screening history, insurance status) with tumor expression of two proteins, ki-67 and p53, in incident CRCs. Ki-67 is a cell proliferation marker. P53 is a key cell cycle regulator. Income was positively associated with ki-67 (HR:1.48,CI:1.02-2.18). Lack of both insurance (HR:1.38,CI:0.88-2.16) and CRC screening (HR:1.43,CI:0.94-2.17) were marginally associated with ki-67. Lack of CRC screening was marginally associated with p53 (HR:1.56,CI:0.93-2.62). This evidence supports the hypothesis that socioeconomic resources may impact tumor development.

3 Maintaining Fairness in Chemotherapy Schedules Under Uncertainty

Batuhan Celik[1], Serhat Gul[2], Özlem Karsu[1], [1]Bilkent University, Ankara, Turkey; [2]TED University, Ankara, Turkey

Chemotherapy scheduling is hard to manage under uncertainty in infusion durations, and focusing on expected performance measure values may lead to undesired outcomes for some patients. This study aims to schedule daily patient appointments, considering a fair environment regarding patient waiting times. We maximize a fairness metric inspired by CVaR within a two-stage stochastic mixed-integer nonlinear programming model. We identify the optimal fairness level using a binary search algorithm. To solve stochastic feasibility problems at each iteration, we propose a novel reduce-and-augment algorithm. We use real data from an oncology hospital to compare our approach with multiple scenario reduction techniques from the literature.

Modeling and Controlling Epidemics

Community Committee Choice Session

Session Chair: Ujjal Kumar Mukherjee, University of Illinois, Urbana-Champaign, Champaign, IL

1 Hotspots for Emerging Epidemics: Multi-Task and Transfer Learning over Mobility Networks

Sebastian Souyris[1], Shuai Hao[2], Ujjal Kumar Mukherjee[3], Yuqian Xu[4], Sridhar Seshadri[5], Anton Ivanov[6], Mehmet Ahsen[6], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]University of Illinois Urbana-Champaign, Champaign, IL, [3]University of Illinois, Urbana-Champaign, Champaign, IL, [4]UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [5]University of Illinois, Champaign, IL, [6]University of Illinois at Urbana-Champaign, Champaign, IL, Contact: souyrs@rpi.edu

This paper introduces a data-driven framework to identify potential COVID-19 hotspots using advanced analytical methodologies, such as a long short-term memory (LSTM) model, multi-task learning, and transfer learning. The model considers mobility data and leverages historical influenza transmission data to improve predictions. We demonstrate that a hotspot-based lockdown policy can potentially reduce new infections by 21% compared to an infection-based policy and can perform similarly to a state-wide lockdown, but targeting fewer areas. In addition, including transfer learning from past data boosts hotspot prediction accuracy by 53.4%. This approach outperforms traditional epidemiological models and offers a practical tool for policymakers to make informed decisions on epidemic control.

2 When Machines Will Take Over? Algorithms for Human-Machine Collaborative Decision Making in Healthcare

Mehmet Ahsen[1], Mehmet U.S. Ayvaci[2], Radha Mookerjee[3], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas- Dallas, Richardson, TX

We study a hospital's optimal acquisition of single or multiple predictive AI algorithms for redesigning work to allocate tasks between humans and machines. We analytically characterize whether and when human-machine collaboration strategy is desirable against the machine-alone strategy or human-alone strategy. We use data from a recent crowdsourced deep-learning mammography challenge to demonstrate the value of the optimal use of AI in radiology. Our findings can inform efforts in reimagining work in the age of AI.

Health Care, Modeling and Optimization

Community Committee Choice Session

Session Chair: Min Kyung Lee, Purdue University, West Lafayette, IN

1 Admission and Patient Transfer Decisions in a Hospital Network via Reinforcement Learning

Jorge R. Vera, Matías De Geyter, Pontificia Universidad Católica de Chile, Santiago, Chile. Contact: jvera@ing.puc.cl

Decision making in healthcare is a complex problem due to uncertainty and dynamic. One very important problem is related to decisions on patient admissions. In a healthcare network composed of various hospitals, it should be convenient to consider the combined capacity of the whole system. Hence, besides admissions to a hospital, the transfer of patients to others is also a possibility. These decisions depend not only on patient medical condition but also on current capacity of the various areas of the hospitals. In this work, we have formulated the problem as a Markov Decision Process, and we address it using a Reinforcement Learning approach where the expected future cost is estimated using a Neural Network combined with simulation, based on the Double Deep Q Networks methodology. We show promising results in various test problems.

2 Using a Vaccine Scheduling Recommendation App to Make an Informed Immunization Schedule Decision in China

Dawei Wang[1], Rui Bian[2], Sujian Situ[2], Yongyu Su[2], Joel Sokol[3], Pinar Keskinocak[3], Paul Griffin[4], Yao-Hsuan Chen[5], [1]Merck & Co., Inc., Rahway, NJ, [2]MSD China Holding Co., Ltd., Shanghai, China; [3]ISyE Georgia Tech, Atlanta, GA, [4]The Pennsylvania State University, University Park, PA, [5]MSD (UK) Limited, London, United Kingdom. Contact: dawei.wang@merck.com

Fear of pediatric vaccines being co-administrated and the desire to catch up with delayed vaccines according to national immunization schedule due to ongoing COVID-19 pandemic are posing a real challenge to both healthcare providers and caregivers in China. In this study, we adapted a previously published vaccine scheduling model from the US to account for specific requirements and restrictions in the Chinese pediatric vaccination environment. The model has been further adapted as an online App tool to solve the aforementioned challenges in real time and in a user-friendly manner.

3 Modeling Multistate Health Transitions with Hawkes Processes

Jiwon Jung, Kiseop Lee, Mengyi Xu, Purdue University, West Lafayette, IN, Contact: jung320@purdue.edu

We present a multistate health transition model with a Hawkes process. Despite the popularity of Markovian assumptions, our observational findings suggest that the elderly who have experienced functional disability have a higher chance of functional disability and mortality. To account for the impact of past events and their duration, we incorporate a Hawkes process to estimate the intensity of age and gender-specific transitions: functional disability, recovery, and mortality. The estimation results suggest that functional disability and mortality intensities significantly increase on the onset of the disability and decay as the duration since the latest transition gets longer.

4 A Holistic Exploration of Transgender and Nonbinary Experiences Through a Causal Lens

Min Kyung Lee[1], Yuehwern Yih[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: lee1239@purdue.edu

Transgender and gender nonbinary (TNB) individuals experience significant health disparities, including limited healthcare access, delays in seeking care, and poorer psychological and general health outcomes. This study employs a causal lens to assess psychological health and healthcare utilization among TNB individuals using data from the Behavioral Risk Factor Surveillance System and the

U.S. Transgender Survey. Through the application of causal analysis techniques, such as propensity score matching and joint mixed-effects models with g-computation, we aim to uncover the underlying causal factors contributing to these disparities. This research seeks to inform targeted interventions and policies to address the unique healthcare needs of TNB individuals, ultimately promoting health equity and improving overall health outcomes in this population.

5 Controlling Covid-19 Positivity Rates in Schools

Zeynep Ertem[1], Anseh Danesharasteh[2], [1]State University of New York- Binghamton, Vestal, NY, [2]Binghamton University, Binghamton, NY

To make in-person learning easier, CDC recommended several mitigation strategies. Following these recommendations, the state of Massachusetts, implemented various COVID-19 prevention measures to ensure a safe re-opening and in-person environmentincluding Surveillance testing, test to stay testing, and on-site symptomatic testing. On the other hand, vaccination has been recommended as one of the most effective ways to reducetransmission for different age groups in schools. In this study, we conducted an interrupted time series (ITS) Regression to evaluate students' COVID-19 positivity rate using various preventive policies such as vaccines and masking policy, considering the testing programsas the treatment event.

Interpretability in Machine Learning for Healthcare

Community Committee Choice Session

Session Chair: Jeremy Watts, University of Tennessee, Knoxville, TN

Session Chair: Anahita Khojandi, University of Tennessee, Knoxville, TN

1 MRI Prediction of Breast Cancer-Related Lymphedema

Jeremy Watts, University of Tennessee, Knoxville, TN, Contact: gkm819@vols.utk.edu

Breast cancer-related lymphedema occurs in up to 20% of women treated for breast cancer. Lymphedema is a chronic condition with no known cure, which can dramatically reduce patients' quality of life. While risk factors associated with the development of lymphedema have been shown, predictive algorithms have had limited success in identifying these patients. In this study, we examine the role of pre-operative MRI alongside demographic and clinical data in the prediction of breast cancer-related lymphedema. To this end, we leverage machine learning algorithms to identify anatomical variations in patients' MRIs associated with risk. The clinical explainability of pre-operative MRI was considered to aid physicians in identifying patients with a greater risk.

2 Interpretable Policies and the Price of Interpretability in Hypertension Treatment Planning

Wesley J. Marrero[1], Gian Garcia[2], Lauren N. Steimle[3], Jeremy Sussman[4], [1]Thayer School of Engineering at Dartmouth, Hanover, NH, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgia Tech ISyE, Atlanta, GA, [4]University of Michigan, Ann Arbor, MI, Contact: wesley.marrero@dartmouth.edu

Markov Decision Process (MDP) models are commonly used tools for optimizing sequential decisions under uncertainty in medical decision making. If the parameters of an MDP satisfy certain assumptions, the optimal policy is guaranteed to be monotone. Unfortunately, these assumptions are not always satisfied. In this research, we define the price of interpretability (PI), which measures the gap between the optimal and an interpretable policy. We assess the PI for the best-performing monotone policy (BMP) and the novel class-ordered monotone policy (CMP), which preserves interpretability along user-defined state and action classes. Within the context of hypertension treatment, we demonstrate that the CMP can be computed faster and achieves greater total quality-adjusted life years across a population of 66.5 million people in the US, compared to the BMP.

3 An Optimization Approach For Effective And Equitable Allocation Of Substance Use Treatment Centers

Matthew Baucum[1], Matt Harris[2], Lawrence Kessler[2], Guanyi Lu[3], [1]Florida State University College of Business, Tallahassee, FL, [2]University of Tennessee, Knoxville, TN, [3]Florida State University, Tallahassee, FL

Substance use disorder (SUD) is a pressing health concern in the U.S., and connecting communities with accessible SUD treatment is a growing public health imperative. In this paper, we develop a predict-then-optimize framework for allocating limited SUD treatment resources within U.S. states. We first use instrumental variable regression to estimate the effect of SUD treatment centers on county-level substance-related death rates. We then formulate a quadratic optimization problem that allocates treatment centers while balancing effectiveness (i.e., reducing the greatest number of substance-related deaths), equity (allocating centers to counties with the highest death rates), and equality (allocating centers based on population). We analyze our recommended treatment center allocation strategies to provide actionable insights for policymakers.

4 Headache Classification and Automatic Biomarker Extraction from Structural MRIs Using Deep Learning

Md Mahfuzur Rahman Siddiquee[1], Jay Shah[1], Catherine Chong[2], Simona Nikolova[2], Gina Dumkrieger[2], Baoxin Li[1], Teresa Wu[1], Todd Schwedt[2], [1]Arizona State University, Tempe, AZ, [2]Mayo Clinic, Phoenix, AZ

We present a deep learning-based classification pipeline to distinguish brain MRIs of individuals with migraine, acute post-traumatic headache (APTH), and persistent post-traumatic headache (PPTH) from healthy controls (HC). It includes data preprocessing, binary classification of HC vs. headache type using a 3D ResNet-18, and biomarker extraction from the trained 3D ResNet-18. We got 75%, 75%, and 91.7% classification accuracies for migraine, APTH, and PPTH, respectively. The most significant biomarkers identified by the classifier for migraine were caudate, caudal anterior cingulate, superior frontal, thalamus, and ventral diencephalon; for APTH, lateral occipital, cuneus, lingual, pericalcarine, and superior parietal; finally, for PPTH, cerebellum, middle temporal, inferior temporal, inferior parietal, and superior parietal.

Analytics of OM

Community Committee Choice Session

Session Chair: Georgia Perakis, Massachusetts Institute of Technology, Cambridge, MA

1 Robust Methods For Hierarchical Time Series Forecasting In Operations

Pin-Yu Chen[1], Alkiviadis Mertzios[2], Georgia Perakis[3], Wei Sun[4], Asterios Tsiourvas[2], Yada Zhu[5], [1]IBM Thomas J. Watson Research Center, New York, NY, [2]MIT, Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, [4]IBM T. J. Watson Research Center, Yorktown Heights, NY, [5]IBM, Yorktown Heights, NY, Contact: mertzios@mit.edu

In this work, we develop novel methods for Hierarchical Time Series forecasting. A key goal is model robustness so that node failures in the hierarchy do not particularly affect the results. Our is general enough to be extended to most optimization based approaches so that it is robust to node failures. We develop an optimization based method where we derive a formulation which produces robust solutions that are reconciled in sample. We test our method against real-world datasets ranging from transportation to demand prediction. We demonstrate improvement over existing, non-robust approaches.

2 Document Classification with Reference Information: Model and Insights

Evan Yao[1], Josh Wilde[1], Retsef Levi[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: evanyao@mit.edu

We present a methodology for automatically classifying documents into pre-specified classes without the need for excessive manually labeling. An expert is called upon to curate reference information, external documents which describe the desired classes, after which a nearest-neighbor search is used to assign each document an initial label, and then that label is updated in an iterative fashion. Our methodology achieves nearly the same accuracy as training a supervised classifier after labeling all the documents manually. To explain our strong behavior, we create a model for how the documents and reference information are jointly drawn with one being a corrupted version of the other. The model is used to explain why our methodology works well, while theoretical and empirical studies help support our insights.

3 Counterfactual-Driven Prescriptive Tree

Wei Sun, Shivaram Subramanian, Youssef Drissi, Zhengliang Xue, Markus Ettl, IBM Research, Yorktown Heights, NY, Contact: sunw@us.ibm.com

In this talk, we present a framework to learn interpretable optimal policy from observational data. The proposed framework consists of a causal teacher model which produces counterfactual outcomes corresponding to different treatment actions, and a prescriptive student model which distills a set of optimized policies in the form of a tree. We show the resulting prescriptive tree can be learned greedily for swift deployment. As the greedy heuristic is unable to incorporate constraints that are often critical for enterprise applications, we introduce a scalable mixed-integer program that solves the constrained policy prescription problem via column generation. We will highlight the results from an online test that shows a 7% increase in revenue over the legacy pricing benchmark, where we applied this solution to a large US airline in premium seat upsell.

4 Towards Improving the Interpretability of Deep Learning

Dimitris Bertsimas, Zhen Lin, Rama Ramakrishnan, Massachusetts Institute of Technology, Cambridge, MA, Contact: zhen2019@mit.edu

We develop low depth (up to depth 8) classification trees with hyperplanes to closely approximate neural networks. In this way, we contribute in increasing the interpretability of neural networks. To facilitate the stronger performance of the trees, we develop an optimization-based adaptive learning method to generate additional data for training the trees. We also propose variants of our method based on randomization and the combination of optimization and randomization. This method improves the performance of the trees in approximating the neural networks, and in real-world classification tasks. We show this optimization method performs better than randomization. We report computational results on 59 real-world classification datasets, with different sizes of neural networks with accuracy 95% relative to the neural network.

5 Predictive Analytics for Auto Insurance Industry Under Market Shocks

William Zhang[1], Saurabh Amin[1], Georgia Perakis[2], Aron Brenner[1], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA

A key challenge faced by the insurance industry is the prediction of replacement cost of an asset under highly non-stationary conditions (e.g., market fluctuations and supply chain shocks). We develop a modeling approach for automobile replacement costs that accounts for a lack of historical data on replacement costs by leveraging historical data from key economic indicators. This approach involves nesting smaller models, each involving feature subsets with temporal dependencies to generate accurate and explainable predictions. Our main contribution is a new model selection procedure based on varying feature importance and confidence intervals. Our results show that this approach achieves better performance for various evaluation metrics in comparison to classical methods such as random forests and ensemble models.

Digital Supply Chains

Community Committee Choice Session

Session Chair: Behnam Malmir, Virginia Tech, Charlottesville, VA

1 Information or No Information Sharing in Closed-Loop Supply Chains

Maryam Esmaeili[1], Aram Bahrini[2,3], Robert Riggs[3], [1]Alzahra University, Tehran, Iran, Islamic Republic of; [2]University of Illinois Urbana-Champaign, Champaign, IL, [3]University of Virginia, Charlottesville, VA, Contact: bahrini@illinois.edu

In this paper, we investigate the impact of information sharing on the performance of a two-level closed-loop supply chain consisting of one manufacturer and one retailer, such that the manufacturer is a leader and the retailer is a follower. In the forward supply chain, the manufacturer sells products through the retailer, and in the reverse supply chain, the manufacturer collects the used products. Manufacturers and retailers have private information about demand despite uncertainty. We obtain the Stackelberg equilibrium for retail price, wholesale price, and the collecting rate of the used products. We compare their profits under information and no information-sharing scenarios. Results show that information sharing in the closed-loop supply chain under a leader-and-follower scenario only sometimes increases the profits of the manufacturer and the retailer.

2 Adopting Blockchain Technology for Real-Time Agri-Food Supply Chain Visibility Improvement

Ali Ala[1], Behnam Malmir[2], Hamed Baziyad[3], [1]Shanghai Jiao Tong University, Shanghai, China; [2]Virginia Tech, Charlottesville, VA, [3]Tarbiat Modares, Tehran, Iran, Islamic Republic of

The article explores the impact of blockchain technology on the agri-food supply chain. The study identifies eight fundamental indicators in the food industry based on blockchain technology and uses the fuzzy DEMATEL method to determine structural and cause-and-effect relationships between these indicators. The findings indicate that traceability and fraud prevention are the most effective indicators, while the intelligent contract index is the most effective. The study suggests that blockchain can be an effective solution for achieving transparency and reliable tracking in the food industry.

3 Pricing and Returns in the Era of Big Tech: Implications of Information Asymmetry Reversal

Kiarash M. Hassani, Murray Lei, Anton Ovchinnikov, Queen’s University, Kingston, ON, Canada. Contact: 18kmh4@queensu.ca

We present a model to optimize the sales and return policy of a monopolistic seller under three information scenarios and examine the resultant profit and consumer surplus. The results of the base model show that when returns are not allowed, the firm collects twice as much profit when it has equal information compared with the standard information asymmetry. When returns are allowed, full information is always better than equal information, and equal information is always better than no information for the firm. Likewise, when the firm is fully informed, it is always profitable to allow returns. When returns are not free for consumers, we end up with various pricing policies based on the magnitude of return hassle costs and other variables. These policies and their effects on the firm and consumers differ depending on the firm's information level.

4 Cost Based - AI Platform for Inventory Replenishment of Retail Pet Products

Shiyang Huang[1], Selen Onel[2], Erdem Eskigun[3], [1]Chewy Inc., Plantation, FL, [2]Chewy, Plantation, FL, [3]Chewy, Mill Creek, WA

The retail industry is constantly seeking ways to optimize its operations and reduce suboptimal buying decisions and associated costs. Several strategies for retail order cost minimization are proposed in the literature but these strategies need to be personalized based on the specific retail requirements. At Chewy, we studied shortcomings of multiple such systems and developed a superior cost optimization platform-based service for buying decisions that combines powerful mathematical concepts, linear programming, dynamic programming, and machine learning models.

Healthcare Operations Management: Theory and Practice

Community Committee Choice Session

Session Chair: Ozden Engin Cakici, American University, Washington

1 Expanding Healthcare Services in Underserved Rural Areas

Rodney P. Parker[1], Kurt M. Bretthauer[1], Jonathan Eugene Helm[1], Masoud Kamalahmadi[2], Gregory Katzman[3], [1]Indiana University, Bloomington, IN, [2]University of Miami, Coral Gables, FL, [3]Richard L. Roudebush VA Medical Center, Indianapolis, IN, Contact: rodp@indiana.edu

We explore the effect of expanding healthcare services in underserved rural areas of the U.S. on their residents' access to care and utilization of healthcare services. Using data from a large healthcare system, we show that opening healthcare clinics improves access to care and affects demand in the entire network.

2 Payment Models for Coordinating Care Between Hospitals and Post-Acute Care Providers

Kenan Arifoglu[1], Tolga Tezcan[2], Hang Ren[3], [1]UCL School of Management, University College London, London, United Kingdom; [2]Rice University, Houston, TX, [3]George Mason University, Fairfax, VA

The traditional payment models (e.g., diagnosis-related-group (DRG) or outcome-based) primarily designed for conditions whose episode of care only involves a single provider. However, several conditions require care by more than one provider (e.g., hip/knee replacement) and traditional payment models do not provide sufficient incentives to coordinate care for such conditions.. Motivated by the Comprehensive Care for Joint Replacement (CJR) payment model recently introduced by the Center for Medicare and Medicaid Services (CMS), we propose simple payment models that provide care coordination between different providers, and improve cost efficiency and care quality in a collaborative way.

3 Using Information Technology to Improve Access to Medical Care

Opher Baron[1], Fanying Chen[2], Abraham Seidmann[3], [1]University of Toronto, Toronto, ON, Canada; [2]Boston University, Boston, MA, [3]Boston University, NEWTON, MA, MA, Contact: fanying@bu.edu

Our research on patient care delivery is inspired by an extensive field project with a large HMO to address the labor shortage and capacity limit, thus improving access to care (i.e., reducing waiting times) and revenue. We study how the combination of AI and a novel waiting line control mechanism can potentially support the effective introduction of a secondary care channel. We analyze the new system performance in overall capacity, service quality, and the cost of care delivery. Our initial theoretical, numerical, and empirical results show that this combined mechanism improves care delivery at a relatively low cost.

4 Telehealth in Acute Care: Pay Parity and Patient Access

Ozden Engin Cakici[1], Alex Mills[2], [1]American University, Washington, DC, [2]Baruch College, City University of New

York, New York, NY

Telehealth pay-parity policy requires payers to reimburse healthcare providers equally for telehealth and office visits. Using a three-stage game, we study the impact of telehealth reimbursement on provider's operational decisions, where patients choose between telehealth and office. We find that pay parity can decrease patient access and discuss its implications.

Operations, Risk, and Commodities

Community Committee Choice Session

Session Chair: Danko Turcic, University of California, Riverside, 900 University Ave., CA

Session Chair: Panos Kouvelis, Washington University in St. Louis

1 All-Weather Hedging, Reshoring Decision Making, and Integrated Risk Management

Andrea Roncoroni[1], Gianna Figà-Talamanca[2], Paolo Guiotto[3], [1]ESSEC Business School, Cergy-Pontoise, France; [2]University of Perugia, Perugia, Italy; [3]University of Padova, Padova, Italy. Contact: roncoroni@essec.edu

Corporate exposure may change after severe market shocks, e.g., a pandemic, a geopolitical turmoil, or any extreme event. This change entails model risk, which in turn may undermine the effectiveness of IRM policies and drain liquidity to make suitable adjustments. We propose a novel hedge selection criterion: the hedge should be "All-Weather" in that it performs uniformly well across the selected dimension of model risk. We focus is on supply chain reliability as such a dimension. Concepts and heuristics are developed for a stylized newsvendor featuring an unreliable supplier. We show that the optimal combined forward hedge is All-Weather, while optimal single forward hedges are not. In a model of capacity reshoring, we show that All-Weather hedging yields a valuable time delay effect.

2 Revisiting Least Squares Monte Carlo for Option Exercise Using Meta Learning

Selvaprabu Nadarajah[1], Parshan Pakiman[2], Naushara Saldin[1], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois-Chicago, Chicago, IL, Contact: nsaldi2@uic.edu

Least squares Monte Carlo (LSM) is popular for exercising financial and real options. Recent sophisticated methods requiring heavy computation outperform LSM, also showing LSM's sensitivity to parameter choices. We present meta-learning LSM, which iteratively learns parameters by leveraging policy and bound information, while retaining LSM's simplicity.

3 Optimal Trading Policy for a Commodity in the Presence of Inventory Conversion Flexibility

Amar Sapra[1], Sridhar Seshadri[2], [1]Indian Instiitue of Management-Bangalore, Bangalore, India; [2]University of Illinois, Champaign, IL, Contact: sseshadr_98@yahoo.com

We examine the optimal blending and storage policy in the face of stochastic prices for a trading firm that seeks to take advantage of arbitrage opportunities through blending of commodities. Towards this end, we formulate a two-period model for a firm that trades in three grades of a commodity such that two of the grades can be blended to obtain the third grade. We find that the bid-ask spread plays a significant role in the structure of the optimal blending and storage policy: when the bid-ask spread is equal to zero, the optimal policy has a simple form; otherwise, the simple form breaks down. We also develop insights into the interplay between storage and blending capacities and the structure of the optimal policy.

4 Empirically Grounded Analytics For Commodity Markets

Ye Liu[1], Panos Kouvelis[2], Danko Turcic[3], [1]Olin Business School, Washington University in St. Louis, St. Louis, MO, [2]Olin Business School, Washington University in St. Louis, St. Louis, MO, [3]A. Gary Anderson Graduate School of Management, University of California, Riverside, Riverside, CA, Contact: ye.liu@wustl.edu

We study a data-driven model of a hog farm. Based on the prevailing market prices and inventory availability, a risk-averse farmer must periodically decide what hogs to sell and what hedges to implement while having to fulfill a contract with a meatpacker. Our optimal policy is derived through machine learning.

Behavioral Queueing

Community Committee Choice Session

Session Chair: Dongyuan Zhan, University College London, London, United Kingdom
Session Chair: Rouba Ibrahim, University College London, London, United Kingdom

1 On Customer (Dis)honesty in Unobservable Queues: The Role of Lying Aversion

Arturo Estrada Rodriguez, School of Management University College London, London, United Kingdom. Contact: arturo.rodriguez.18@ucl.ac.uk

We construct a queueing-game-theoretic model where customers make strategic claims to reduce their waiting time, and the Manager decides on the static scheduling policy based on those claims to minimize the expected delay cost. We develop a lying aversion model where customers incur both delay and lying costs. We run controlled experiments to validate our modelling assumptions regarding customer misreporting. We then study the equilibrium that arises in our game and find that under certain conditions, the optimal policy is to use an *honour system* where service priority is given according to customer claims. We also find that it may be optimal to *incentivize more honesty* by means of an *upgrading policy* where some customers who claim to not deserve priority are upgraded to the priority queue. We find that the upgrading policy deviates from the celebrated cμ rule.

2 Rationally Inattentive Queueing with Customer Retrials

Caner Canyakmaz[1], Tamer Boyaci[2], [1]Ozyegin University, Istanbul, Turkey; [2]ESMT Berlin GmbH, Berlin, Germany. Contact: caner.canyakmaz@ozyegin.edu.tr

We investigate a strategic queueing model where customers do not directly observe the queue size but are able to acquire costly information about it. Customers are rationally inattentive and optimally trade off the benefits of better information against the costs associated with it while also considering the joining behavior of other customers. We assume that customers either choose to join the queue, balk, or retry at a cost hoping for a shorter queue in the future. We set up a game-theoretic framework and show that a unique symmetric equilibrium exists. We also show the existence of a unique threshold for the retrial cost that determines whether customers balk or retry, and that this threshold decreases in customers' information cost.

3 Order Ahead for Pickup: Promise or Peril?

Ke Sun[1], Yunan Liu[2], Luyi Yang[3], [1]Beijing University of Chemical Technology, Beijing, China; [2]North Carolina State University, Raleigh, NC, [3]University of California, Berkeley, Berkeley, CA

We study the innovative mobile-order-ahead technology that has been increasingly adopted by quick-service restaurants (e.g., Starbucks). With mobile ordering, customers can order ahead remotely in a mobile application on their phones and pick up their orders at the restaurant. Our paper highlights the unintended consequences of ordering ahead and provides practical design guidance for improving its performance.

4 Dynamic Scheduling of a Multiclass Queue in the Halfin-Whitt Regime: A Computational Approach for High-Dimensional Problems

Ebru Kasikaralar[1], Baris Ata[2], Michael Harrison[3], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]Stanford University, Palo Alto, CA, Contact: ebrukasikaralar@chicagobooth.edu

We consider a finite-horizon Markovian queueing model of a telephone call center, where multiclass calls are served by a single pool of agents. Calls can end through service or abandonment. Each call class is characterized by its distinct arrival rate process, service rate, abandonment rate, and abandonment penalty. We focus on solving this MDP with high-dimensional state vectors, which poses challenges for conventional dynamic programming methods. To address this, we adopt the Halfin-Whitt heavy traffic regime and describe the approximating diffusion control problem. The resulting HJB equation from the limiting diffusion control problem characterizes the optimal policy. Inspired by Han et al. (2018), we introduce a novel computation approach using deep neural networks to solve the associated high-dimensional HJB equation and approximate the optimal policies.

5 The Impact of Procedural and Distributive Justice on Patient Flow in Hospitals

Galit Bracha Yom-Tov[1], Matias Kohn[1], Anat Rafaeli[2], [1]Technion - Israel Institute of Technology, Haifa, Israel; [2]Technion - Israel Institute of Technolog, Haifa, Israel. Contact: galit.yomtov@yahoo.com

We investigate the impact of procedural and distributive justice in routing patients between ED and inpatient wards on patient LOS. Using diff-in-diff analysis we show a large reduction in hospitalization LOS (14.7%) and in ED LOS (17%) when fair routing is used. We investigate the mechanisms that drive this reduction.

Innovative Supply Chain Operations

Community Committee Choice Session

Session Chair: Tunay Tunca, Robert H. Smith School of Business, College Park, MD

1 Cybersecurity Investment Spillover: Implications for the Supply Chain

Duy Duc Dao, Hooman Hidaji, University of Calgary, Calgary, AB, Canada

As cybersecurity threats become more prevalent and IT supply chains more intertwined, both providers and firms need to invest in cybersecurity to secure their supply chains. Moreover, the downstream demand externality that firms exert on one another (competition or complementarity) moderate the interaction of provider and firm investments. We find that provider investment incentivizes firm investment only if the provider investment has a large positive spillover on firm investment, and that downstream competition negatively moderates the impact of provider investment on firm investment. Interestingly, in the case of substitutable (complementary) provider-firm investment spillover, increased provider investment benefits firm profit only if downstream externality is positive (negative).

2 The Effectiveness of Supplier Buy Back Finance: Evidence from Chinese Automobile Industry

Tunay Tunca[1], Daehoon Noh[2], Bin Yang[3], Weiming Zhu[4], [1]Robert H. Smith School of Business, College Park, MD, [2]University of California, San Diego, San Diego, CA, [3]China Development Bank, Beijing, China; [4]HKU Business School, Hong Kong, China. Contact: ttunca@umd.edu

Facing budget-constrained buyers, a novel approach for large suppliers is adopting buy-back financing schemes to relieve their downstream partners and reduce channel costs. Using game theoretical analysis and structural estimation of data from Chinese automobile industry, we analyze the efficiency of such financing schemes, and explore their impact on operational decisions and contract design. We find that such contract agreements can improve channel efficiency significantly over traditional financing methods.

New Models and Algorithms for Resource Allocation Problems

Community Committee Choice Session

Session Chair: Murray Lei, Queen's University, Kingston, ON, Canada

1 Maximum Optimality Margin: A Unified Approach for Contextual Linear Programming and Inverse Linear Programming

Shang Liu[1], Chunlin Sun[2], Xiaocheng Li[1], [1]Imperial College Business School, London, United Kingdom; [2]Stanford University, Stanford, CA, Contact: s.liu21@imperial.ac.uk

In this paper, we study the predict-then-optimize problem where the output of a prediction task is used as the input of some downstream optimization problem, say, the objective coefficient vector of a linear program. The existing approaches largely suffer from either (i) optimization intractability and statistical inefficiency or (ii) requiring strong condition(s). We develop a new principle called maximum optimality margin which designs the loss function by the optimality condition of the downstream optimization. Our formulation enjoys both computational and statistical efficiency. More importantly, our new approach only needs the observations of the optimal solution rather than the objective function, which makes it a new and natural approach to the inverse linear programming. We also demonstrate its performance using numerical experiments.

2 Assortment and Inventory Planning Under Stockout-Based Substitution: The Many-Products Regime

Jingwei Zhang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: zhangjingwei@cuhk.edu.cn

We study the joint assortment and inventory planning problem with stockout-based substitution. In this problem, we pick the number of units to stock for the products at the beginning of the selling horizon. Each arriving customer makes a choice among the set of products with remaining on-hand inventories. Our goal is to pick the stocking quantities to maximize the total expected revenue from the sales net of the stocking cost. Using a fluid approximation for the problem, we give solutions with performance guarantees that significantly improve earlier results. The optimality gap that we give under the multinomial logit model is the first one that does not depend on the number of products. We can guarantee that the stocking quantities generated by our rounding scheme perform well when both the demand volume and number of products are large.

3 Asymptotic Optimality of Open-Loop Policies in Lost-Sales Inventory Models with Stochastic Lead Times

Xingyu Bai, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: xingyub3@illinois.edu

Inventory models with lost sales and large lead times are notoriously difficult to manage. Recently, it has been proven that in the lost-sales inventory model with divisible products, as the lead time grows large, a simple constant-order policy is asymptotically optimal. In this work, we consider the lost-sales inventory model in which the lead time is not only large but also random. Under the assumption that placed orders cannot cross in time, we establish the asymptotic optimality of constant-order policies as the lead time increases for the model with divisible products. For the model with indivisible products, we propose a bracket policy and prove that the bracket policy is asymptotically optimal. Our results on divisible products also hold for the models with order crossover and random supply functions. Finally, we provide a numerical study to derive further insights.

4 Incentivizing Resource Pooling

Chen Chen[1], Yilun Chen[2], Pengyu Qian[3], [1]New York University Shanghai, Shanghai, China; [2]CUHK Shenzhen, Shenzhen, China; [3]Purdue University, West Lafayette, IN, Contact: cc8029@nyu.edu

We study a decentralized multi-server system, where each server is associated with an M/M/1 queue and aims to minimize its time-average job holding and processing costs. Servers have limited information on the other servers. The objective is to design a mechanism that incentives resource pooling among servers. We design a simple token-based system to achieve this. A server can earn tokens by offering help and spend tokens to request help from other servers, in its self-interest. We analyze the system by employing an approximation methodology that combines the mean-field equilibrium with a fluid approximation. Leveraging this, we design key elements of the mechanism and present our main result: the proposed mechanism incentivizes *complete* resource pooling, and the resulting system performance achieves that under centralized control when the number of servers is large.

5 Costly Data Sampling in the Newsvendor Problem

Lennart Baardman, Hyun-Soo Ahn, Zijin Zhang, University of Michigan, Ann Arbor, MI, Contact: baardman@umich.edu

Deciding on production quantities of new products has to be done well before selling starts. When demand distributions are known, production quantities can be decided by solving a newsvendor problem. In practice, the demand distribution of a new product is unknown, and there is no historical data to estimate the distribution from. However, data can often be acquired at a cost, for example through surveys or test markets. We consider the problem of determining the optimal sample size such that our profit, accounting for data acquisition cost, is maximized. Theoretically, we show the optimal sample size is difficult to characterize, but can be bounded, and we provide policies that compute near-optimal sample sizes. Computationally, we show that our policies result in near-optimal profits for the newsvendor.

1 When To Trust Your Suppliers While Training Them For Sustainability Under Asymmetric Information?

Özge Tüncel[1], **Tarkan Tan[2], Tim Kraft[3], [1]Maastricht University, Eindhoven, Netherlands; [2]University of Zurich, Zurich, -, Switzerland; [3]NC State - Poole College of Management, Raleigh, NC, Contact: o.tuncel@maastrichtuniversity.nl**

More and more companies are training their suppliers to enhance the sustainability impact created in their value chains. In the paper, we model the buyer's training decisions for suppliers with different initial sustainability capabilities. The buyer's training effort, and the supplier's initial capability and sustainability effort together create the sustainability impact. While both parties benefit from the sustainability impact, the supplier gains additional utility from the training effort. However, the buyer does not know the initial capability of the supplier. He can choose to fully trust the supplier or offer an imperfect prediction tool to his supply chain sustainability managers. Our findings offer insights into the supplier's preference to over or under-report, and the impact of using the prediction tool on the buyer.

2 Delivery Terms for Voluntary Carbon Offsets

Vishal Agrawal[1], Gokce Esenduran[2], Safak Yucel[1], [1]Georgetown University, Washington, [2]Purdue University, West Lafayette, IN, Contact: gesendur@purdue.edu

A carbon offset represents one unit of reduction in greenhouse gas emissions that can be used to compensate for emissions that occur elsewhere. Companies purchase voluntary carbon offsets under two delivery terms. The first is prompt delivery, where a seller first undertakes the investment, then yield uncertainty realizes, based on which the seller determines the price for carbon offsets as a recourse action. The second is forward delivery, where a buyer orders a certain quantity of offsets before the seller invests. Therefore, there is quantity risk due to yield uncertainty as the seller may generate fewer offsets than the buyer's order. Motivated by the importance of choosing the right delivery term for buyers, in this paper, we ask a fundamentally important question: Which delivery term should a buyer prefer, and which one leads to a higher environmental benefit?

3 Supply Chain Disruptions and Labor Violations: An Empirical Investigation

Li Ding[1], Basak Kalkanci[2], [1]Georgia Tech, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: lding60@gatech.edu

In this study, we aim to determine if major supply chain disruptions contribute to increased labor violation incidents and examine how the impact (if any) varies across industries as well as over time. By leveraging the exogenous shocks on production demand and labor supply and performing a staggered difference-in-difference analysis, our study aims to provide valuable insights into the causal relationship between supply chain disruptions and labor incidents.

4 Is Fast Fashion Really Killing the Planet? a Comparison to Traditional Apparel Supply Chains

Aditya Balaram[1], Mark Ferguson[2], Olga Perdikaki[2], [1]Loyola Marymount University, Los Angeles, CA, [2]University of South Carolina, Columbia, SC, Contact: aditya.balaram@grad.moore.sc.edu

Apparel retailers have typically followed either the traditional (long lead times and more durable products) or the fast-fashion approach (shorter lead times and less durable products). We compare these two approaches in terms of environmental impact, focusing on the effects of leftover inventory, product durability, and markdown pricing. We also examine how policy makers can reduce the environmental impacts of the two approaches, and provide guidance on which life-cycle phases sustainability efforts should be focused on.

Financial Risk Analysis

Contributed Session

Session Chair: Yan WANG, University of Hong Kong, Hong Kong, China

1 Market Ambiguity Attitude and the Risk-Return Tradeoff

Mark Schneider[1], Soroush Ghazi[1], Jack Strauss[2], [1]University of Alabama, Tuscaloosa, AL, [2]University of Denver, Denver, CO, Contact: maschneider4@cba.ua.edu

The risk-return tradeoff for the aggregate stock market predicts that periods of high market volatility are followed by periods with higher average market excess returns. Despite being viewed as a fundamental law of finance, the risk-return tradeoff has been difficult to identify in the data, with some studies finding no relation or even a negative relation between market volatility and future excess returns. Motivated by a representative agent asset pricing model in the presence of Knightian uncertainty, we obtain the theoretical prediction that market ambiguity attitude moderates the risk-return tradeoff. We introduce a methodology for measuring market ambiguity attitude and test its relevance for explaining the risk-return tradeoff in in-sample and out-of-sample tests. We find support for the theoretical predictions.

2 The Impact of Macroeconomic Announcements on Risk, Preference, and Risk Premium

Takuya Kiriu[1], Norio Hibiki[2], [1]Osaka University, Toyonaka, Japan; [2]Keio University, Yokohama, Japan. Contact: kiriu@econ.osaka-u.ac.jp

This study examines the impact of macroeconomic announcements on the risk premium and its sources under time-varying preference. We propose a novel method to decompose risk premium changes into the risk and preference components, which are estimated from option prices immediately before and after the announcement using the Recovery Theorem. The results of the empirical analysis for the United States stock market indicate that (1) the negative (positive) macroeconomic announcement surprise increases (decreases) the risk premium; (2) the risk component mainly drives the increase (decrease) in the risk premium; and (3) the preference component has limited influence on the risk premium.

3 Investment Timing, Upper Reflecting Barrier, and Debt-Equity Financing

Takashi Shibata[1], Michi Nishihara[2], [1]Tokyo Metropolitan

University, Hachioji, Japan; [2]Osaka University, Toyonaka-Shi, Japan

This study considers how an upper reflecting barrier affects the interaction between financing and investment decisions. Here, a magnitude of upper reflecting barrier can be regarded as the degree of intense market competition. We show that fierce competition (a decrease in upper reflecting barrier) reduces the amount of debt issuance and delays investment, which decreases the credit spreads and leverage.

4 Estimating Var and Cvar Sensitivity when Sample Path is Discontinuous

Xianyu Kuang[1], Guangwu Liu[1], Dan Zhu[2], [1]City University of Hong Kong, Hong Kong, Hong Kong; [2]Monash University, Melbourne, Australia. Contact: dwyanekuang1996@gmail.com

Estimating the sensitivities of risk measures, such as the Value-at-Risk and the Conditional Value-at-Risk, is essential in many optimization applications, from hedging in financial markets to allocation of resources in large supply chains. As the underlying models become more complicated due to market innovations, the existing literature that often relies on a relatively simple structure breaks down. In this paper, we fill the gap by allowing the loss itself to exhibit discontinuities in the parameters of interest. Examples of this type include exotic options that possess look-back features and stochastic activity networks. We derive the closed-form expressions of the associated derivatives and present an estimation algorithm that is efficient and easy to implement. The numerical results show that our method is robust in performance across a range of examples.

5 Out-of-Sample Performance-Based Estimation of Expected Returns for Portfolio Selection

Yan Wang, Peng-Chu Chen, The University of Hong Kong, Hong Kong, China. Contact: yanw@connect.hku.hk

This paper provides a framework for obtaining estimates of expected asset returns for portfolio selection. The framework relies on a linear model based on the estimates of out-of-sample portfolio returns, where the expected asset returns are the coefficients to be estimated. The model is fitted by Bayesian regression to a synthetic data set generated from a set of historical asset returns over a limited time horizon. The estimator is computed using a Gibbs sampler; although the set of historical asset returns is finite, it is consistent and asymptotically efficient as the size of the synthetic data set grows to infinity. An empirical study shows that under appropriate conditions, with or without norm constraints, mean-variance portfolios constructed using this estimator produce better out-of-sample mean returns and Sharpe ratios than benchmark portfolios.

Machine Learning for Optimization

Community Committee Choice Session

Session Chair: Bo Lin, University of Toronto, ON, Canada

1 Neur2SP: Neural Two-Stage Stochastic Programming

Justin Dumouchelle, Rahul Patel, Elias B. Khalil, Merve Bodur, University of Toronto, Toronto, ON, Canada. Contact: justin.dumouchelle@mail.utoronto.ca

Stochastic programming (SP) is a powerful modeling framework for decision-making under uncertainty. This work tackles two-stage stochastic programs (2SPs), the most widely used class of SP models. Solving 2SPs requires optimizing over a computationally intractable expected value function. A mixed-integer linear or nonlinear program in the second stage further aggravates the intractability, even when specialized algorithms that exploit problem structure are employed. Finding high-quality (first-stage) solutions - without leveraging problem structure - can be crucial in such settings. We develop Neur2SP, a method that approximates the expected value function via a neural network to obtain a surrogate model. Our extensive experiments on four benchmark 2SP problem classes with different structures demonstrate the efficiency and solution quality of Neur2SP.

2 Fast Continuous and Integer L-Shaped Heuristics Through Supervised Learning

Eric Larsen[1], Emma Frejinger[1], Bernard Gendron[2], Andrea Lodi[3], [1]Université de Montreal, Montreal, QC, Canada; [2]Universite de Montreal (DIRO), Montreal, QC, Canada; [3]Cornell Tech, New York, NY

We propose a methodology to speed up the solution process of mixed-integer linear two-stage stochastic programs targeted towards problems where the second stage is highly demanding. Our core idea is to gain large reductions in online solution time while incurring small reductions in first-stage solution accuracy by substituting the exact second-stage solutions with fast, yet accurate supervised machine learning predictions. The proposed method can solve hard benchmark instances, on average, in 9-20% of the time it takes the state-of-the-art exact method. Average optimality gaps are in most cases less than 0.1%.

3 A Machine Learning Approach to Solving Large Bilevel and Stochastic Programs: Application to Cycling Network Design

Bo Lin, Timothy Chan, Shoshanna Saxe, University of Toronto, Toronto, ON, Canada. Contact: imbo.lin@mail.utoronto.ca

We present a machine learning-based approach to solving bilevel programs that involve a large number of followers. We propose an optimization model that considers a sampled set of followers and exploits a machine learning model to estimate the objective values of unsampled followers. We embed machine learning model training into the optimization problem, which allows us to use general follower features that can not be represented using leader decisions. We prove bounds on the optimality gap of the generated leader decision as measured by the original objective function. We demonstrate the performance of our approach using synthetic instances of a cycling network design problem. Finally, we perform a real-world case study on cycling infrastructure planning, where we apply our approach to solve a network design problem with over one million followers.

4 Predict-Then-Calibrate: A New Perspective of Robust Contextual LP

Chunlin Sun[1], Linyu Liu[2], Xiaocheng Li[3], [1]Stanford University, Stanford, CA, [2]Tsinghua University, Beijing, China; [3]Imperial College Business School, London, United Kingdom. Contact: ly-liu19@mails.tsinghua.edu.cn

Contextual optimization, also known as predict-then-optimize or prescriptive analytics, addresses optimization problems involving covariates or context. Here, we focus on a risk-sensitive variant and propose a generic algorithm design paradigm called predict-then-calibrate. Our approach involves initially developing a prediction model, independent of downstream risk or robustness considerations, and then employing calibration techniques to quantify prediction uncertainty. By disentangling the prediction model from calibration/uncertainty quantification, we unleash the full potential of off-the-shelf machine learning methods while providing risk and robustness guarantees. Additionally, this paradigm yields new generalization bounds for the contextual LP problem and sheds light on the existing results of DRO in the contextual LP setting.

Topics in Integer Programming and Combinatorial Optimization

Community Committee Choice Session

Session Chair: Joseph Paat, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada

1 On Generating Function Method to Parametric Mixed-Integer Optimization

Luze Xu, Matthias Koeppe, University of California, Davis, Davis, CA

We study the problem of maximizing polynomial functions of fixed degree over the mixed-integer points of a polytope of fixed dimension. Our approach is based on the generating function method inspired by Barvinok's algorithm and the fully polynomial-time approximation scheme (FPTAS) by De Loera, Hemmecke, K{"o}ppe, and Weismantel for optimization in fixed dimension. Building on previous research on intermediate sums on polyhedra, we establish a connection between two ways of computing the generating function over mixed-integer points via Gale transformation. Additionally, we implement the computation of these types of generating functions in SageMath. With the generating function, we develop an approximation algorithm for the parametric optimization problem, which arises in bilevel mixed-integer programming.

2 Towards a Characterization of Maximal Quadratic-Free Sets

Joseph Paat, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada

S-free sets are known to have a variety of applications, perhaps most notably in the generation of intersection cuts. When it comes to generating cuts using S-free sets, inclusion-wise maximal sets generate stronger cuts. In this talk we consider maximal S-free sets when S is defined by a quadratic inequality. We demonstrate that maximal quadratic-free sets can be generated using a map from an n-sphere to an m-sphere. Conversely, any such map that is also non-expansive defines a maximal S-free polyhedron. Underlying our work is a characterization of (not necessarily quadratic) maximal S-free sets, which allows us to also generate non-polyhedra maximal quadratic-free sets. This is joint work with Gonzalo Munoz and Felipe Serrano.

3 How Branch-and-Bound Compares to Sherali-Adams for 0-1 Integer Programs

Yatharth Dubey, Carnegie Mellon University

In this talk, we compare two systematic techniques to build strong extended formulations for 0-1 integer programs: specifically, the Sherali-Adams hierarchy, and Branch-and-

Bound. We exhibit simple instances for which Branch-and-Bound constructs a compact perfect formulation while Sherali-Adams requires an exponential number of variables and constraints, and vice versa. Finally, we discuss necessary and sufficient conditions for Branch-and-Bound to outperform Sherali-Adams in the context of polytopes described by no-good constraints. We hope that several parts of the proof are general enough to expand this analysis to more inclusive families of polytopes.

4 Unifying Strongly Polynomial Algorithms for Several Subclasses of Linear Programs

Bento Natura, Georgia Institute of Technology

The existence of a strongly polynomial algorithm for linear programs (LP) is one of the most important open problems in theoretical computer science and beyond. The last decades have seen tremendous progress for special subclasses of LP (e.g., minimum cost flow, multi-commodity flow, and discounted Markov decision processes) whose proofs of strong polynomiality rely on very different ideas, algorithms and techniques. Together with Allamigeon, Dadush, Loho, and Végh (FOCS 2022) we devised an interior point method that runs in strongly polynomial time whenever a certain notion called straight line complexity is polynomially bounded. Taking this algorithm as a blackbox, we show how strong polynomiality for many of the subclasses of LP can be recovered.

Roundoff-Error Free Linear Algebra

Community Committee Choice Session

Session Chair: Erick Moreno-Centeno, Texas A&M University

Session Chair: Christopher Lourenco, US Naval Academy, Annapolis, MD

1 Overview of Roundoff-Error-Free Methods for Solving Linear Systems

Christopher Lourenco[1], Erick Moreno-Centeno[2], [1]US Naval Academy, Annapolis, MD, [2]Texas A&M University, College Station, TX, Contact: lourenco@usna.edu

Exactly solving linear systems is a fundamental problem in mathematics, operations research, and computer science. In this talk, we present the roundoff-error-free framework for solving linear systems. Specifically, this framework comprises dense LU, Cholesky, and QR factorizations as well as sparse LU and Cholesky factorizations. Moreover, each of these algorithms utilize exclusively integer-arithmetic and, in the sparse case, solve the system Ax=b in time proportional to arithmetic work---to date the only exact algorithms with this property. We conclude by describing two associated software packages which were shown to outperform competitor exact rational and exact iterative approaches. This software can be accessed either in C or via easy to use MATLAB and Python interfaces.

2 Round-Off Error Free QR Factorization via Integer-Preserving Gram-Schmidt

Lorena Mejia Domenzain, Texas A&M University, College Station, TX

QR factorization (A=QR) is widely used in math, computer science, and engineering to solve least squares problems. A critical property in QR is that Q's columns are pair-wise orthonormal. However, in some problems, round-off errors incurred when factorizing A can lead to a loss in orthogonality and, thus, incorrect solutions. Round-off Error Free (REF) QR factorization (A=QDR) was developed to address this issue; therein, Q's columns are pair-wise orthogonal, R is a right-triangular matrix, and D is a diagonal matrix; importantly, Q and R are integral matrices. This talk presents an Integer-preserving Gram-Schmidt orthogonalization process (IPGS) and an efficient IPGS-REF QR algorithm; both guarantee the critical orthogonality property using integer arithmetic.

3 An Early Termination Criteria for Dixon's Method

Kelsey Kitzmiller, Texas A&M University, College Station, TX

Dixon's p-adic lifting algorithm uses modular arithmetic to find exact solutions to systems of linear equations. Although this method is state-of-the-art for solving dense systems exactly, it often performs significantly more iterations than necessary to compute the solution. In order to avoid some of these unnecessary computations, a new early termination criteria is presented which is based on Cabay's criteria for congruence technique algorithms. This stopping procedure is predicated on a new version of rational reconstruction which partially reconstructs the modular image found at each p-adic lifting iteration. The complete algorithm maintains the same worst-case complexity as Dixon's original method but is more efficient in practice, as it performs only a small number of iterations beyond those which are necessary to compute the solution.

4 Efficient Exact Linear Program Solving

Ram V. Krishnamoorthy[1], Christopher Lourenco[2], [1]US Naval Academy, Annapolis, MD, [2]US Naval Academy, Annapolis, MD, Contact: m243456@usna.edu

Top-commercial Linear Program solvers generally perform well for the vast majority of instances, but over 20 years of literature have shown that they suffer from inaccuracies in 3-5% of problems due to improper floating-point (fixed-precision) calculations. When exactness or higher precision is needed, exact LP solvers exist; the forefront of which is SoPlex, an open-source algorithm that validates the optimality of LPs by using exact rational factorizations to solve key linear systems. These rational factorizations are the bottleneck of SoPlex, in the worst case occupying over 90% of the run time, and significantly slowing the exact solver. This project aims to address these drawbacks thereby improving our ability to efficiently solve LPs exactly.

Efficient Algorithms for Large-scale Nonsmooth Optimization Problems in Data Science

Community Committee Choice Session

Session Chair: Guojun Zhang, The Hong Kong Polytechnic University, Hong Kong, China

2 A Feasible Method for Solving an SDP Relaxation of the Quadratic Knapsack Problem

Tianyun Tang, National University of Singapore, Singapore, Singapore

In this talk, we consider solving the low-rank SDP of the quadratic knapsack problem whose feasible region is an algebraic variety. We analyze the local geometric properties of singular points on this algebraic variety. With the geometric properties, we prove that under an appropriate rank condition, any second order stationary point of the non-convex problem is also a global optimal solution without any regularity assumption. This rank condition is much weaker than the classical rank condition if the coefficient matrix has certain special structures. We design a feasible method that can escape from non-optimal non-regular points. Numerical experiments are conducted to verify the high efficiency and robustness of our algorithm for solving large-scale quadratic knapsack problems with up to one million items. Joint work with Prof. Kim-Chuan Toh.

2 An Efficient HPR Algorithm for the Wasserstein Barycenter Problem with $0({\rm Dim(P)}/\varepsilon)$ Computational Complexity

Guojun Zhang, Yancheng Yuan, Defeng Sun, The Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: guojun.zhang@connect.polyu.hk

In this paper, we propose and analyze an efficient Halpern-Peaceman-Rachford (HPR) algorithm for solving the Wasserstein barycenter problem (WBP) with fixed supports. While the Peaceman-Rachford (PR) splitting method itself may not be convergent for solving the WBP, the HPR algorithm can achieve an $O(1/\varepsilon)$ non-ergodic iteration complexity with respect to the Karush-Kuhn-Tucker (KKT) residual. More interestingly, we propose an efficient procedure with linear time computational complexity to solve the linear systems involved in the subproblems of the HPR algorithm. As a consequence, the HPR algorithm enjoys an $O({\rm Dim(P)}/\varepsilon)$ non-ergodic computational complexity in terms of flops for obtaining an ε-optimal solution measured by the KKT residual for the WBP, where ${\rm Dim(P)}$ is the dimension of the variable of the WBP.

Computing and Optimization in Electric Grid Applications

Community Committee Choice Session

Session Chair: Xiangyu Zhang, National Renewable Energy Laboratory

Session Chair: Mengmeng Cai, 1</sup

1 Economic, Reliable and Secure Low-Carbon Electricity System Modeling

Xin Fang, Mississippi State University, MISSISSIPPI STATE, MS, Contact: xfang@ece.msstate.edu

In this seminar, an electricity market clearing model with renewable uncertainty and a cyber-physical dynamic simulation (CPDS) model capturing the uncertainty of the two-layer communication latency and power dynamics of DERs will be presented. The current LMP concept is extended to price renewable uncertainty explicitly. The benefits of variable resources providing AGC services are simulated comprehensively. The AGC model with communication delay is designed to validate DERs' frequency regulation services. The economics, reliability, and security regarding renewable and DER integration can be simulated in the proposed framework.

2 Delivery-Risk-Aware Flexibility Reserve Scheduling for Aggregated Distributed Energy Resources

Mengmeng Cai[1], Michael Blonsky[1], Elina Spyrou[2], [1]National Renewable Energy Laboratory, Golden, CO, [2]Imperial College London, Golden, CO, Contact: mengmeng.cai@nrel.gov

Distributed energy resources (DERs) offer valuable operational flexibility when aggregated. Innovative market products have emerged recently to harness and monetize the value of these flexible assets for variability management. However, DERs are subjected to delivery risk, i.e., the risk of not being able to deliver the flexibility in real-time at the amount committed in day-ahead, due to uncertainties in end-use behaviors and market operating conditions. This prevents DERs from effectively participating in the market. To address this issue, we propose a risk-aware flexibility reserve scheduling model leveraging two-stage stochastic optimization. This model assists DER aggregators in estimating a portfolio envelope within which the DERs can be freely dispatched to meet end-use needs and adapt to system operation realizations in real-time.

3 Grid-edge Modeling and Optimization to support Decarbonization and Resilience

Anamika Dubey, Washington State University, Pullman, WA

With rapid decarbonization goals and ambitious urban electrification targets, the electric power grid is undergoing unprecedented changes. The proliferation of distributed energy resources and flexible loads is pushing the control and operational requirements of the grid to the edge, thus significantly increasing the scale and complexity of grid operations. These grid-edge resources also hold the potential to support grid resilience in the aftermath of extreme weather events, which are impacting grid more often and with higher severity. Effective use of grid-edge resources to support decarbonization goals and resilience necessitates advances in modeling, analysis, and optimization of emerging electric power networks. In this talk, we will focus on the challenges and solutions to integrating grid-edge into grid operations. Along with traditional physics-based approaches, we will emphasize the need for scientific machine learning techniques to address the emerging computational challenges.

4 Differentiable Programming for Modeling and Control of Energy Systems

Jan Drgona, Pacific Northwest National Laboratory, Richland, WA, Contact: jan.drgona@pnnl.gov

This talk presents differentiable programming (DP) for domain-aware learning of differentiable models for dynamical systems. We introduce differentiable predictive control as a data-driven model-based policy optimization method that systematically integrates the principles of classical model predictive control with differentiable programming. We also show how to use recent developments in control barrier functions and neural Lyapunov functions to obtain online performance guarantees for neural control policies. We demonstrate the performance of these new DP-based methods in a range of simulation case studies, including modeling of networked dynamical systems, building control, and dynamic economic dispatch, including real-time deployment in an embedded device, serving as a proof of concept for control as a service setup.

Optimization under Uncertainty with Applications in Power Systems

Community Committee Choice Session

Session Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN

1 New Formulations and Pricing Mechanisms for Stochastic Electricity Market Clearing Problem

Harsha Gangammanavar, Saumya Sakitha Sashrika Ariyarathne, Southern Methodist University, Dallas, TX, Contact: harsha@smu.edu

In this talk, we present new formulations of the stochastic electricity market clearing problem based on the principles of stochastic programming, precisely the notion of nonanticipativity. We design new pricing mechanisms by developing suitable dual optimization problems for these models. Our analysis illustrates the ability of these new pricing mechanisms to provide long-run revenue adequacy for the system operators and cost recovery and price distortion under every scenario for all market participants. We demonstrate these benefits through numerical experiments conducted on well-known test systems.

2 Bilevel Optimization Model for Distribution Network with Uncertain Renewables and Flexible Loads Under Wasserstein Metrics

Can Yin[1], Yiling Zhang[2], Jin Dong[3], [1]University of Minnesota, Twin Cities, Minneapolis, MN, [2]University

of Minnesota, Twin Cities, Minneapolis, MN, [3]Oak Ridge National Laboratory, Oak Ridge, TN, Contact: yin00412@umn.edu

Abstract: This work considers a distribution network pricing with uncertain renewables and flexible loads. We formulate a stochastic bilevel program to procure minimum-cost energy and decide optimal pricing for prosumers in the upper-level problem given the uncertainty in renewable energy productions. The lower-level problem optimally schedules the prosumers' flexible load (i.e., HVACs) according to the pricing decisions of the upper-level problem. Assuming the distribution of uncertainty is not known perfectly, the problem is solved using distributionally robust optimization under Wasserstein metrics. The problem is reformulated as a mixed-integer linear program. We conduct preliminary computational experiments on the IEEE 33-bus systems.

3 A Robust Bilevel Uncertainty-Set Maximization Approach for Optimizing Power Grid Flexibility with Integer 2nd-Stage Decisions

William Yang, University of Washington, Seattle, WA, Contact: wtyang15@uw.edu

We have seen a worldwide increase in renewable energy penetration necessary for reducing the global carbon footprint. However, the integration of renewable energy in the electricity sector has introduced significant uncertainty, hindering the power grid's ability to reliably balance energy supply and demand and increasing the risk of costly renewable energy curtailment or blackouts. We present a robust 2-stage uncertainty-set optimization method that helps grid flexibility by maximizing the net load deviation the system can tolerate. To solve this problem, we use a novel Primal Generation Algorithm based on column-and-constraint-generation (CCG). We test it on a virtual power plant case study to demonstrate its ability to improve grid flexibility with greater renewable energy penetration and show that our algorithm is more efficient than standard CCG algorithms.

4 Power Grid Resilience Optimization Using Decision-Dependent Uncertainty

Samuel O. Affar[1], Hugh Medal[2], Yang Chen[3], Guodong Liu[3], [1]University of Tennessee, Knoxville, Knoxville, TN, [2]University of Tennessee, Knoxville, TN, [3]Oak Ridge National Laboratory, Oak Ridge, TN, Contact: saffar@vols.utk.edu

Extreme weather events can cause unplanned disruptions in power distribution systems, highlighting the need for resilience-oriented action. This ongoing study proposes a two-stage stochastic mixed-integer program with decision-based uncertainty to determine how to optimally protect power distribution systems against such disruptions. In the first stage, a set of lines are hardened. A random set of destroyed lines is then realized. The probability for each element is dependent on the hardening decisions made in the first stage, i.e., decision-dependent uncertainty. In the second stage, network reconfiguration and DERs (Distributed Energy Resources) utilization decisions are made. The model seeks to minimize the expected cost of load shedding. To find a computationally fast way to solve the model, the study explores a decision-independent reformulation.

2 Maximal Quadratic-free Sets

Gonzalo Muñoz, Universidad de O'Higgins, Rancagua, Chile

The intersection cut paradigm is a powerful framework that facilitates the generation of valid linear inequalities, or cutting planes, for a potentially complex set S. The key ingredients in this construction are a simplicial conic relaxation of S and an S-free set: a convex zone whose interior does not intersect S. Ideally, such S-free set would be maximal inclusion-wise, as it would generate a deeper cutting plane. However, maximality can be a challenging goal in general. In this work, we show how to construct maximal S-free sets when S is defined by a general quadratic inequality. Our maximal S-free sets are such that efficient separation of a vertex in LP-based approaches to quadratically constrained problems is guaranteed.

1 Labor Momentum Stock Selection Strategies Through Supply Chain Network

Rei Yamamoto[1], Akifumi Isogai[2], [1]Keio University, Yokohama, Japan; [2]Mitsubishi UFJ Trust Investment Technology Institute Co., Ltd., Tokyo, Japan. Contact: rei.yamamoto@ae.keio.ac.jp

This study focuses on the propagation of job postings through the supply chain structure between firms and proposes an investment strategy that uses this information. Specifically, we find that an increasing number of job openings in customer firms affects the performance and stock price of supplier firms. The empirical analysis in the U.S. stock market confirms that the proposed strategy has a high stock selection effect in the manufacturing industry, where inter-firm ties are strong.

2 Modern Pandemic Crises and Default Risk: A Worldwide Evidence

KungCheng Ho, Fuzhou University of International Studies and Trade, fuzhou, China. Contact: kcho731101@163.com

This paper examines the relationship between modern health pandemic crises and financial stability. Specifically, it collects data on 250,223 firms in 43 countries (or regions) during five modern pandemic crises, SARS (2003), H1N1 (2009), MERS (2012), Ebola (2014), and Zika (2016), and finds that pandemic crises significantly increase the default risk of enterprises. Further analysis shows that formal and informal institutions acted as a "cushion" against the pandemic crisis. This paper addresses the hitherto inadequacy of COVID-related data. In addition, this paper argues that governments should build sound state institutions to withstand macroeconomic shocks and highlights the heterogeneity of default risk for enterprises operating in countries with different institutions.

3 Statistical Validation of Centrality in Financial Networks

Agathe Sadeghi, Zachary Feinstein, Stevens Institute of Technology, Hoboken, NJ, Contact: asadeghi@stevens.edu

Network analysis often relies on estimated networks which may deviate from the true interlinkages, impacting the accuracy of centrality measure. We introduce a statistical validation method for the centrality measure, leveraging a regression model to construct the underlying network and a centrality measure reflecting contagion risk. Our proposed methodology enables researchers to derive the distribution of the centrality measure, construct confidence intervals and conduct statistical tests to assess the validity of centrality values. We employ simulations to compare theoretical and empirical distributions with the true centrality. Our results demonstrate that the estimated centralities consistently fall within the 95% confidence interval. We apply our methodology to financial data which results in identifying statistically significant central nodes.

The Impact of Uncertainty on Transportation Systems

Community Committee Choice Session

Session Chair: Handong Yao, 1</sup
Session Chair: Xiaopeng Li, 1</sup
Session Chair: Yiheng Feng, Purdue University, West Lafayette, IN
Session Chair: Qianwen Li, University of South Florida, Tampa

1 How to Understand, Accommodate, and Overcome Uncertainties in Traffic Control?

Brian Park, University of Virginia, Charlottesville, VA, Contact: bp6v@virginia.edu

In this talk, I will discuss challenges in traffic control due to uncertainties and what can be done to accommodate and possibly overcome such uncertainties. An example of traffic signal control is used to demonstrate the impact of uncertainties that negate some control variables and robust control to accommodate uncertainties. The challenges involved in a microscopic traffic simulation model calibration/validation due to uncertainties will also be discussed. I will also discuss challenges in connected automated vehicles again due to uncertainties and how to deal with them.

2 Learning Naturalistic Driving Environment with Statistical Realism

Xintao Yan, Zhengxia Zou, Shuo Feng, Haojie Zhu, Haowei Sun, Henry Liu, University of Michigan - Ann Arbor, Ann Arbor, MI, Contact: xintaoy@umich.edu

For simulation to be an effective tool for the training and testing of autonomous vehicles, the simulator must produce realistic safety-critical scenarios with distribution-level accuracy. However, due to the high dimensionality of real-world environments and the rarity of long-tail safety-critical events, how to achieve statistical realism in simulation is a longstanding problem. In this study, we develop NeuralNDE, a deep learning-based framework to model naturalistic driving environments. The results show that NeuralNDE can achieve both accurate safety-critical driving statistics (e.g., crash rate/type/severity and near-misses, etc.) and normal driving statistics. To the best of our knowledge, this is the first time that a simulator can reproduce the real-world driving environment with statistical realism, particularly for safety-critical events.

70 Years of Urban Network Modeling: Past, Present, and Future

Community Committee Choice Session

Session Chair: Yanfeng Ouyang, U of Illinois at Urbana-Champaign, Urbana, IL
Session Chair: Qi Luo, Clemson University, Clemson, SC
Session Chair: Lili Du, University of Florida, Gainesville, FL
Session Chair: Samitha Samaranayake, Cornell University, Ithaca, NY

1 A Brief History of Urban Travel Forecasting

Marco Nie, Northwestern University, Evanston, IL

In this talk I will briefly review the history of urban travel forecasting, from the founding of the field in the 1950s to the present day. I will begin with the development of the "traditional" methods and how they had shaped the practice of transportation planning. Then, I turn to the scholarly efforts and achievements that had made the field a thriving multidisciplinary scientific enterprise. I also address the shortcomings of the existing methodologies that have drawn sharp criticisms in the past. The talk ends with my speculations about the future of the field.

2 Perspectives on Future Urban Network Modeling - Opportunities and Research Needs

Elise Miller-Hooks, George Mason University, Fairfax, VA

This talk will discuss the future of urban transportation network modeling opportunities and research needs, recognizing recent and coming advances in computing technologies, capabilities and methodologies. It will further imagine changing societal transportation needs and expectations. A key aim will be to spark creation of ideas for in-depth discussion with audience participation.

3 Special Session Informs TSL Urban Transportation SIG and TRB AEP-40

Qi Luo, Clemson University, Clemson, SC

This special session is co-hosted by INFORMS TSL Urban Transportation SIG and TRB AEP-40 Transportation Network Modeling Committee. Our goal is to attract a broader audience at INFORMS to recognize the recent advances in network modeling and spark an in-depth discussion of vital research topics in the coming decade.

Methods for Process Operations
Contributed Session
Session Chair: Yulin An, State College, PA

1 Prediction of Spring Steel Wire Rod Hardness Based on Wire Rod Rolling Process Data: A Case Study
Sungjun Hur, SEOKKYU PYO, Sungkyunkwan university, gyeonggi-do, Korea, Republic of. Contact: sjhur22@g.skku.edu
This paper presents a study on predicting the hardness of wire rod produced in Hyundai, a major steel production company in Korea. We install a line scanner in Hyundai's wire rod rolling process to collect a large amount of operational data. We then derive critical factors by analyzing the collected data with XGboost and Shapley additive explanations. In addition, we conduct experiments for exploring the effects of the critical factors on the hardness under various rolling process conditions. The hardness prediction model is built by the experimental data and validated by consultant with Hyundai's rolling process engineers. Future research directions on predicting the hardness are discussed in conclusion.

2 Functional Response from a Mixture Experiment: Design Choice and Analysis
Mona Khoddam, Arizona State University, Tempe, AZ, Contact: mkhoddam@asu.edu
This presentation discusses the problem of designing and analyzing mixture experiments when the response is functional, i.e., a series of data points collected over a continuum. Single viscosity values at fixed shear rates may fail to capture the differences in rheological properties among different chemical formulations. The presentation compares space-filling designs and I-optimal designs with respect to measures of predictive performance, and demonstrates the advantages of using self-validated ensemble modeling for simultaneous estimation and validation of predictive models in small-sample experiments with mixtures.

3 Degradation Modeling and Prediction Based on Monotonic Multi-Output Gaussian Process
Jinwen Sun, Congfang Huang, Shiyu Zhou, Dharmaraj Veeramani, University of Wisconsin-Madison, Madison, WI, Contact: jsun279@wisc.edu
This work presents a novel approach for degradation modeling and prediction using monotonic multi-output Gaussian process (MOGP). The monotonicity information is imposed by adding virtual observations and an approximate Bayesian inference method is employed to fit the model. The proposed method accommodates the monotonicity constraint of degradation processes, ensuring realistic and reliable modeling and prediction. Experimental results on simulation studies and the real-world dataset demonstrate the superior performance of the proposed approach compared to existing techniques.

4 Demonstration of an Intrinsic Geometrical Approach for 3-D Statistical Process Control from Real Scanned Discrete Manufactured Parts
Yulin An[1], Enrique Del Castillo[2], [1]Penn State University---University Park, State College, PA, [2]Pennsylvania State University, University Park, PA, Contact: yba5115@psu.edu
Statistical process control (SPC) has witnessed increased sophistication in metrology accompanied by increased size and complexity in the datasets related to production and manufacturing processes. Recently, spectral statistical approaches for 3-D SPC have been proposed, based on the estimation of the Laplace-Beltrami (LB) operator and its spectrum which provides a unique part feature description that carries considerable geometrical and topological information. In this talk, we present a practical demonstration of the methods based on sequences of real laser scans that generate meshes to which our methods are then applied.

How the Integration of AI and Blockchain is Changing the World
Community Committee Choice Session
Session Chair: Jinwook Lee, Drexel University, Philadelphia, PA

1 Uber Freight Like-Wise: How the Intersection of 3PLs and Blockchain Can Help Disrupted Logistics Network

Lanqing Du[1], Jinwook Lee[2], [1]DREXEL UNIVERSITY, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, Contact: ld695@drexel.edu

Third-party logistics services (3PLs) have historically been crucial to the commercial transportation sector. Looking ahead, technology enablers (blockchain) and the gig economy all contribute to reinventing the industry. On-demand 3PL services, compared to long-term contracts, became paramount for both carriers and shippers. In this paper, we study related decision-making problems on a disrupted logistics network, where nodes represent different 3PLs with their own disruption levels, and edges denote a shipping volume between a pair of nodes. To assess the added benefit from the development of information, infrastructure, and resource resilience, we additionally take into account the effect of blockchain-enabled transparent information communication integrating 3PL services in the activity-based model.

2 Bias and Unfairness in Automated Recruitment Tools

Qiao Lu[1], Lanqing Du[2], Jinwook Lee[3], [1]University of Pennsylvania, Philadelphia, PA, [2]DREXEL UNIVERSITY, Philadelphia, PA, [3]Drexel University, Philadelphia, PA, Contact: qiaolu@upenn.edu

Automated recruitment tools were invented in the early 1990s. They were designed to automate the process of organizing job applications. These tools were advanced by AI technologies in the 2000s, which could analyze and select candidate profiles based on a wide range of criteria, including experiences, skills, and education. Many companies utilized them to accelerate the hiring process and save costs. However, in recent years, bias and unfairness were perceived in the use of AI-powered recruitment tools, such as prejudicial treatment of different groups of people on the basis of gender or race. In this research, our goal is to determine bias and unfairness related to automated recruitment tools, investigate potential solutions, and identify research gaps.

3 Artificial Intelligence to Reduce Radiation-Induced Cardiotoxicity in Lung Cancer Radiotherapy: A Novel Functional Radiomics Using Cardiac Fdg-Pet/Ct

Wookjin Choi, Adam Dicker, Yevgeniy Vinogradskiy, Thomas Jefferson University, Philadelphia, PA, Contact: wookjin.choi@jefferson.edu

Traditionally, radiation-induced cardiotoxicity has been studied using cardiac radiation doses rather than functional imaging. We developed artificial intelligence (AI) models based on novel cardiac delta radiomics using pre- and post-treatment FDG-PET/CT scans to predict overall survival in lung cancer patients undergoing radiotherapy. We identified four clinically relevant delta radiomics features with the AI prediction models. The best model achieved an AUC of 0.91 on the training set and 0.87 on the test set. We are a pioneering group in AI for functional cardiac imaging. If validated, this approach will enable to use standard PET/CT scans as functional cardiac imaging with good predictive AUC for OS, as well as provide automated methods to provide functional cardiac information for clinical outcome prediction AI in lung cancer patients.

4 Community/Committee'S Choice Submission

Sung-Cheol Kim, Psychogenics, NJ

Temporal data points of animal movements provide valuable insights into an agent's health status. We propose a machine-learning approach to classify applied drugs based on animal behavior data collected through sensors. Our model, Gated Transformer Networks (GTN), employs Transformer networks with Attention architectures to analyze both temporal and channel features. GTN captures channel data's relative weight and signal variations' importance within time windows, enhancing classification performance. Experimental results demonstrate GTN's superiority in drug classification tasks. Our findings highlight GTN's potential as an efficient and reliable tool for classifying drugs based on their effects on animal behavior. This research contributes to drug discovery by optimizing therapeutic interventions using animal behavior data.

5 Web 3.0 and Smart Contracts: A Paradigm Shift for Supply Chain Coordination

Jinwook Lee[1], Lanqing Du[2], [1]Drexel University, Philadelphia, PA, [2]DREXEL UNIVERSITY, Philadelphia, PA, Contact: jl3539@drexel.edu

Some practical limitations and constraints of the Web 2.0-based supply chain network are the following: diverse regulatory policies; poor intricate network; ERP and a single point failure (centralized system); robustness; a lag in data integration; no transparency; no direct communication system among related participants. In the Web 3.0 based-supply chain network, powered by blockchain and artificial intelligence, many of the above-mentioned problems can be solved using appropriate algorithms that can be embedded in the system through (1) smart contracts; and (2) decentralized network systems. Looking at the supply chain as a p2p network on a graph, we use nodes and edges to

represent peers and related transaction flows and values. Business applications of NFTs, smart contracts, supply chain monitoring, and outlier detection are presented.

Learning for Optimization: Performance and Robustness

Community Committee Choice Session

Session Chair: Bartolomeo Stellato, Princeton University, Princeton, NJ

1 Learning for Robust Optimization

Irina Wang[1], Cole Becker[1], Bart Paul Gerard Van Parys[2], Bartolomeo Stellato[1], [1]Princeton University, Princeton, NJ, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: iywang@princeton.edu

We propose a data-driven method to automatically learn the uncertainty sets in robust optimization. Our training procedure reshapes the uncertainty sets by minimizing the expected performance across a family of problems while guaranteeing constraint satisfaction. We develop a stochastic augmented Lagrangian method that relies on differentiating the solutions of the robust optimization problems with respect to the parameters of the uncertainty set. We show sublinear convergence to stationary points under mild assumptions, and finite-sample probabilistic guarantees of constraint satisfaction using empirical process theory. Our approach can learn a variety of uncertainty sets while preserving tractability. Numerical experiments show that our method outperforms traditional RO approaches. We implement our method in the open-source package LROPT.

2 End-to-End Learning to Warm-Start Fixed Point Optimizers

Rajiv Sambharya[1], Vinit Ranjan[1], Georgina Hall[2], Brandon Amos[3], Bartolomeo Stellato[1], [1]Princeton University, Princeton, NJ, [2]INSEAD, Fontainebleau, France; [3]Meta, NYC, NY, Contact: rajivs@princeton.edu

We introduce a machine learning framework to warm-start fixed-point algorithms for parametric convex optimization. Our architecture consists of a neural network mapping problem parameters to warm-starts, followed by a predefined number of fixed-point iterations, with the loss function defined as the final fixed-point residual. In this way, the neural network predicts warm-starts with the end-to-end goal of minimizing the downstream loss. We provide PAC-Bayes generalization bounds on unseen data for common classes of fixed-point operators, including contractive and averaged operators. We apply our framework to popular algorithms including ADMM and Douglas-Rachford splitting to solve problems in control, statistics, and energy. Our approach significantly reduces the number of iterations required to solve these problems through learned warm-starts.

3 Data-Driven Performance Certification of First Order Methods for Parametric Quadratic Optimization

Vinit Ranjan, Rajiv Sambharya, Bartolomeo Stellato, Princeton University, Princeton, NJ, Contact: vranjan@princeton.edu

We introduce a framework to certify finite step convergence of first-order methods for parametric convex quadratic optimization. We formulate the certification problem as a maximization problem with performance metrics in the objective and algorithm iterations in the constraints. Our modular framework encodes, through quadratic constraints, a wide range of proximal algorithms and sets for initial iterates and problem parameters. We derive tractable convex relaxations using semidefinite programming and solve them via a custom operator splitting technique that scales to high dimensions. We demonstrate finite-sample probabilistic guarantees of the computed worst-case behavior using Wasserstein distributionally robust optimization. Numerical examples show that our method significantly reduces the conservatism of classical worst-case convergence bounds.

4 A Differentiable Architecture for Mixed-Integer Optimization

Gabriele Dragotto, Bartolomeo Stellato, Princeton University, Princeton, NJ, Contact: bstellato@princeton.edu

We consider the problem of optimizing a sequence of mixed-integer linear optimization problems (MIPs) with varying parameters. By combining recent advances in cutting plane generation and differentiation through convex optimization problems, we construct a new differentiable architecture to predict the optimal cutting planes from the key parameters of each instance. During the offline phase, our method maximizes the cutting planes' efficiency by evaluating the derivative of the solution of the continuous relaxations with respect to the cut-generating parameters. We show on preliminary computational results that, once trained, our architecture computes solutions with low infeasibility and suboptimality with fast and predictable execution times.

Human Trafficking

Community Committee Choice Session

Session Chair: Baris Tezcan, Northeastern University, Brookline, MA

1 Breaking the Chains: An Innovative Network Interdiction Approach to Combat Labor Trafficking in Agricultural Supply Chains

Arezoo Jafari, Priscila de Azevedo Drummond, Shawn Bhimani, Amy Farrell, Kayse Lee Lee Maass, Northeastern University, Boston, MA, Contact: jafari.a@northeastern.edu

The agriculture industries in the United States significantly contribute to the nation's economy, providing support for over 40 million jobs. Farm workers, a critical workforce in these industries, are particularly vulnerable to labor trafficking and exploitation due to their immigration status and limited government resources for inspection. This study aims to develop a network interdiction model to aid law enforcement agencies in making well-informed decisions to combat labor trafficking networks more effectively. The proposed stochastic network interdiction model seeks to evaluate the potential benefits of inter-agency collaboration in enhancing their ability to dismantle trafficking operations. By doing so, the study aims to provide insights and strategies to protect farm workers better and maintain the integrity of the food and agriculture industries.

2 Using Analytics to Combat Sex Trafficking

Nickolas K. Freeman, Burcu B. Keskin, Greg Bott, University of Alabama, Tuscaloosa, AL, Contact: nkfreeman@cba.ua.edu

Sex trafficking refers to the use of force, fraud, or coercion for the purposes ofsexual exploitation. Several news and technical reports document links between commercial sex ads and sex trafficking. Our team leads an initiative named STANDD (Sex Trafficking Analytics for Network Detectionand Disruption) for The University of Alabama's Institute of Data and Analytics. Under this initiative, we manage an analytical pipeline that leverages techniques from the areas of network science and machine learning to transform ad data into products used by law enforcement and non-profit partners in counter-trafficking efforts. This presentation will focus on our ongoing efforts as well as emerging areas of research in this space.

3 Integration of Behavioral and Decision Science Methods to Design and Evaluate Interventions for Labor Trafficking and Exploitation

Matt Kammer-Kerwick, UT Austin, Austin, TX

This presentation describes a process we developed in a recent paper that integrates behavioral and decision science methods to design and evaluate interventions. We developed this process by extending a framework used to study partially observable systems with uncertain outcomes wherein there are multiple participating parties with competing goals. The extended framework that we proposed builds from artefactual data collection, thematic analysis, and descriptive analysis, toward predictive modeling and agent-based modeling. We apply our extended framework to an exploratory case study that examines the potential of worker centers as a venue for deploying interventions to address labor exploitation and human trafficking. We will also discuss ongoing research to integrate reinforcement learning to optimize model-based policy design.

4 Disrupting Human Trafficking Recruitment Using Community-Based Resource Allocation Models

Baris Tezcan[1], Kayse Lee Lee Maass[1], Thomas Sharkey[2], Yongjia Song[2], Lauren Martin[3], Kelle Barrick[4], Amy Farrell[1], [1]Northeastern University, Boston, MA, [2]Clemson University, Clemson, SC, [3]University of Minnesota, Minneapolis, MN, [4]RTI International, Research Triangle Park, NC, Contact: tezcan.b@northeastern.edu

A person's risk of being trafficked is greatly influenced by their (lack of) access to community support structures. We model a trafficker's process of recruiting sex trafficking victims using a network where states represent a potential victim's fluctuating likelihood of being trafficked, various trafficking recruitment strategies, and chances of being re-trafficked after leaving their trafficker. Potential victims transition from one state to another probabilistically. We aim to allocate resources throughout this network in a way that changes the state transition probabilities with the objective of minimizing the exploitation a victim experiences. We design and validate the states with a human trafficking survivor advisory board and generate data using inverse optimization that utilizes stakeholder interviews and relevant data from the literature.

Recent Advancements in Process Monitoring of Complex Data

Community Committee Choice Session

Session Chair: Xiulin Xie, University of Florida, Gainesville, FL

1 Optimizing Control Chart Parameters: A Simultaneous Perturbations Stochastic Approximation Approach

Daniele Zago[1], Giovanna Capizzi[1], Peihua Qiu[2], [1]University of Padua, Padova, Italy; [2]University of Florida - Department of Biostatistics, Gainesville, FL, Contact: dzago@ufl.edu

Selecting control chart design parameters is a critical aspect of statistical process control. The typical approach minimizes the average run length when detecting a specific out-of-control scenario, while maintaining the in-control average run length fixed to a specific value. However, the control charts that are typically employed admit no explicit solutions, thus requiring a costly optimization routine. Furthermore, optimizing a multidimensional set of parameters is often computationally challenging when using traditional approaches. To address this problem, we propose an efficient two-step algorithm based on stochastic approximations. Our approach is applicable to univariate and multivariate control chart parameters, and simulated results indicate that our method is computationally more efficient that traditional approaches.

2 An Adaptive Cusum Chart for Drift Detection

Fan Yi, University of Florida, Gainesville, FL

In practice, sequential processes often have gradual changes in their process distributions over time. This is related to the drift detection problem in statistical process control. Most existing methods for drift detection are designed based on the assumption that the related drift is linear or have another specific pattern. In reality, however, such specified patterns may not be valid. We suggest an adaptive CUSUM chart to handle the drift detection problem with a flexible drift pattern. The new method integrates the general framework to construct a CUSUM chart based on the generalized likelihood ratio statistic and estimation of a shift size by the exponentially weighted least square regression procedure. Simulation and real example studies show that the proposed method is effective in various cases considered.

3 Profile Monitoring via Eigenvector Perturbation

Takayuki Iguchi, Air Force Institute of Technology, OH

Control charts monitor quality characteristics of a process over time to quickly detect undesirable behavior. There is a growing need for more flexible control charts (e.g., profile monitoring) to handle increasingly complex processes. A practitioner can experience alarm fatigue if the sampling rate is high (say, once a millisecond) and the control chart is set to an average in-control run length (ARL_0) of 370 as is typical in the literature. As alarm fatigue may result in detrimental effects to product quality, we seek to reduce the false alarm rate. Unfortunately, doing so usually increases the average out-of-control run length (ARL_1). Motivated by recent work on eigenvector perturbation theory, we develop two computationally fast nonparametric control charts which outperform their competition by achieving both an ARL_1 close to or equal to 1 and an ARL_0 on the order of 10^6.

4 Profile Monitoring of Random Functions with Gaussian Process Basis Expansions

Jonathan R. Stewart[1], Eric Chicken[1], Andrés Felipe Barrientos[1], Takayuki Iguchi[2], [1]Florida State University, Tallahassee, FL, [2]Air Force Institute of Technology, Wright-Patterson Air Force Base, OH

We consider online profile monitoring of random functions that admit basis expansions with Gaussian coefficients for out-of-control state detection. Our problem features two sources of variation: additive error and random fluctuations through random coefficients in the basis representation of functions. We study two-phase monitoring problems where the first stage learns the in-control process and the second stage leverages the learned process for out-of-control state detection. We outline learning and monitoring methods that exploit the Gaussianity of the basis coefficients to develop scalable and effective monitoring methods that makes weak functional assumptions. We demonstrate the potential of our method through simulation studies that highlight some of the nuances that emerge in profile monitoring of random functions.

Recent Advances in Cyber-Physical Security - Part I

Community Committee Choice Session

Session Chair: Dan Li, Clemson University, Clemson, SC

Session Chair: Akash Tiwari, Texas A&M University, College Station, TX

1 An Integrated Cyber-physical Risk Assessment Framework for Worst-case Attacks in Industrial Control Systems

Navid Aftabi[1], Dan Li[2], Thomas Sharkey[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: naftabi@g.clemson.edu

Industrial Control Systems (ICSs) are critical infrastructures vulnerable to cyberattacks causing physical damage. This paper proposes an optimization-based cyber-risk assessment framework integrating cyber and physical systems in ICSs. The framework identifies high-risk cyberattacks by maximizing physical impact, quickly accessing cyber system components with limited vulnerabilities, evading physical system detection, and adhering to cyber and physical constraints. This framework provides a tool for generating the worst-case attack strategies to evaluate existing detection schemes. Numerical and case studies verify its effectiveness, showing that a worst-case strategic attacker can significantly accelerate physical system failure time while remaining undetected compared to a random attacker.

2 Advancing the Security of Cyber-Physical Manufacturing Systems: Challenges and Opportunities

Mohammed Shafae, Md Habibor Rahman, University of Arizona, Tucson, AZ, Contact: shafae1@arizona.edu

The threat of cyberattacks on smart manufacturing systems has been rapidly growing, with the potential for a multitude of different attack types, ranging from industrial espionage to system sabotage, causing physical equipment damage, operational downtime, and compromised product quality and reliability. Due to the cyber-physical nature of manufacturing systems, among several other unique aspects, traditional cyber-only security solutions are insufficient to defend manufacturing systems against the rampantly growing cyberattack threat. This talk discusses the importance of dedicated research and the development of additional cyber-physical defense measures designed for manufacturing. A critical review of current research efforts in this domain will also be presented, as will the opportunities for the future of this emerging research area.

3 Privacy-Preserving Data Sharing Strategy for Process-Defect Modeling in Metal-Based Additive Manufacturing

Wenmeng Tian[1], Mahathir Bappy[1], Durant Fullington[2], [1]Mississippi State University, Mississippi State, MS, [2]Mississippi State University, Starkville, MS, Contact: tian@ise.msstate.edu

Cyber-enabled manufacturing and cloud-enabled data sharing can equip small-to-medium manufacturers (SMMs) with the unique strengths of advanced metal-based additive manufacturing (AM) technologies. However, the AM process data often contains sensitive design information that is unfortunately vulnerable to design leakage when shared on the cloud platform. In this talk, we first discuss the design information disclosure in metal-based AM process data. Subsequently, a new adaptive AM printing path de-identification method is introduced. The proposed method generates synthetic melt pool images by removing the information of printing path trajectory while retaining the quality attributes for process-defect modeling. The synthetic melt pool images will be shared on the cloud to enable secured collaborative modeling among numerous AM users.

4 Spectral Dynamic Watermarking Cybersecurity Defense for Manufacturing Machine Tool Controllers

Akash Tiwari[1], Satish Bukkapatnam[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: akash.tiwari@tamu.edu

Sensing devices within manufacturing machine tool controllers are vulnerable against several cyberattacks. These attacks can be detected by the technique of dynamic watermarking (DWM) by introducing secret signals imposed onto the control signals. The DWM technique is known to cause unfavourable disturbance to precision manufacturing processes. The technique of Spectral DWM (S-DWM) is presented which introduces secret signals in the frequency domain to minimize design disturbance. We present experiment case studies to show that the S-DWM, in comparison to DWM detects attacks with ~5% deterioration in ARL and 95% improvement in path deviation.

Data Analytics and Quality Control with Industrial Big Data

Community Committee Choice Session

Session Chair: Kaibo Wang, Tsinghua University, Beijing, China

1 Change Point Detection Of Multimode Processes Considering Both Mode Transitions And Parameter Changes

Jun Xu[1], Jie Zhou[2], Xiaofang Huang[2], Kaibo Wang[1], [1]Tsinghua University, Beijing, China; [2]Goldwind Science&Technology Co.,Ltd., Beijing, China. Contact: xu-j19@mails.tsinghua.edu.cn

Multimode processes refer to processes that work in multiple operating modes. Motivated by the torque control process of a wind turbine, we determine that there exist two types of changes in multimode processes: (1) mode transitions and (2) parameter changes. We propose a novel modeling framework for the offline change point detection problem of multimode processes considering both types of changes. We characterize each mode with a parametric cost function and formulate the problem as an optimization model. With certain assumptions, the asymptotic property ensures the accuracy of the model solution. To solve the model, we propose an iterative algorithm and develop a multimode-pruned exact linear time (multi-PELT) method for initialization. The simulation study and the real case study demonstrate the effectiveness of our method against alternative methods.

2 Multi-Node System Modeling and Monitoring with Extended Directed Graphical Models

Dengyu Li, Kaibo Wang, Tsinghua University, Beijing, China. Contact: lidy20@mails.tsinghua.edu.cn

Complex manufacturing systems usually contain a large number of variables with complicated relationships that cannot be expressed by simple functional relationships, thus increasing the difficulty of modeling and monitoring these systems. The directed graphical model (DGM) has been used for describing the relationship among variables. However, the DGM fails to consider the structural information among them that usually exists. To address this problem, an extended directed graphical model (EDGM) is proposed. Taking prior engineering knowledge into consideration, the EDGM uses groups of variables as nodes in the graph model and can effectively represent the relationship within and between nodes and provide promising monitoring performance. Numerical experiments and a real world case study are performed to verify the effectiveness of the proposed methods.

3 Two Approaches to Monitoring Multivariate Poisson Counts: Simple and Accurate

Jian Li, Xi'an Jiaotong University, Xi'an, China. Contact: jianli@xjtu.edu.cn

We consider the monitoring of multivariate correlated count data and adopt the Multivariate Poisson (MP) distribution with a two-way covariance structure for modeling MP counts, which has marginal Poisson distributions in each dimension and allows for pairwise correlations. Based on this, we develop two control charts to simultaneously monitor the mean vector and covariance matrix of MP counts. The first chart enjoys a simple charting statistic and is computationally fast, whereas the second one is accurate and provides a gold standard for monitoring MP counts. We also give recommendations on choice between them. Numerical simulations have demonstrated the advantages of the proposed two charts, and in non-Poisson cases we also test their robustness against underdispersion and overdispersion that are encountered often in count data.

Solar Power

Community Committee Choice Session

Session Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO

1 Evaluating Different CSP Optimization Models

Kathleen Tomon, Colorado School of Mines, Golden, CO

The market for hybrid concentrating solar power (CSP) is increasing due to the growing demand of green energy. We explore four different hybrid CSP modeling approaches ranging from classical optimization to black-box heuristics. We use case studies with different energy markets to assess the advantages and disadvantages of these modeling approaches to provide recommendations for modeling hybrid systems.

2 Assessing The Cost, Environmental, And Equity Trade-offs Of Energy Transition Pathways In The U.S.

Teagan Goforth[1], Destenie S. Nock[1], Maxwell Brown[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]National Renewable Energy Laboratory / Colorado School of Mines, Golden, CO, Contact: tgoforth@andrew.cmu.edu

Many countries have committed to decarbonizing their energy system, but there is uncertainty with how to achieve a sustainable and just transition. This analysis investigates how the trade-offs of decarbonization outcomes are distributed across vulnerable groups. To assess this, we tie a US-wide capacity expansion planning model to a multi-criteria decision analysis to investigate the trade-offs of cost, environmental, and equity metrics across different electricity

futures. To evaluate equity, we investigate regional and community level distribution of health and economic impacts across different vulnerable groups and evaluate these across metrics like the Gini coefficient. We find that the Base case has short-term benefits in terms of cost and emissions, but by 2050, has solely cost benefits, with higher emissions than other scenarios.

3 Technoeconomic Comparison Between Concentrated Solar Power and Photovoltaic Power as Extended-Duration Peaking Resources
Xander Bard, The Ohio State University, Columbus, OH
We explore the ability of a concentrating solar power (CSP) plant with thermal energy storage (TES) to provide varying peaking capacity. The hourly operation of the CSP plant is simulated and optimized to determine its potential to provide energy during a variable peak-load window, ranging from 1 to 24 hours, for each day of the year. Then, we compare the ability of a photovoltaic (PV) system with lithium-ion battery energy storage to the behavior of the optimized CSP plant.

Policy-enabling models for Renewable Energy, CCS and Decarbonization technologies

Community Committee Choice Session

Session Chair: Olivier Massol, IFP School, Rueil-Malmaison, France
Session Chair: Emma Jagu Schippers, CentraleSupélec, France

1 Carbon Removal Beyond Borders: How to Share the Gains from Inter-Regional Cooperation
Solene Chiquier[1,2], Emma Jagu[3,4], Niall Mac Dowell[5], Olivier Massol[6,4], [1]MIT Joint Program on the Science and Policy of Global Change, Cambridge, MA, [2]MIT Energy Initiative, Cambridge, MA, [3]IFP Energies nouvelles, Rueil-Malmaison, France; [4]CentraleSupelec, Gif-sur-Yvette, France; [5]Imperial College London, London, United Kingdom; [6]IFP School, Ruel-Malmaison, France. Contact: chiquier@mit.edu
International cooperation could greatly reduce the cost of deploying carbon dioxide removal (CDR) to levels compatible with the Paris Agreement. We examine whether and how multilateral agreements can be successfully implemented for deploying inter-regionally CDR. After evaluating coalitional gains resulting from such international cooperation when deploying inter-regional CDR pathways, we apply cooperative game theory to assess how these gains can be shared in a fair and mutually accepted manner, *i.e.,* key criteria to ensure successful inter-regional cooperation. Bridging the gap between cost-optimization problem and cooperative game theory, we provide recommendations to policymakers on fair gain-sharing principles that ensure the successful materialization of multilateral agreements, and thus the deployment of CDR at the Paris Agreement's levels.

2 Building More and Regretting Less: Oversizing Co_2And H_2Pipeline Systems Under Uncertainty
Adrien Nicolle[1], Olivier Massol[2], [1]Climate Economics Chair, Paris, France; [2]IFP School, Rueil-Malmaison, France. Contact: olivier.massol@ifpen.fr
Both Carbon Capture and Storage (CCS) and hydrogen systems require the installation of costly pipeline infrastructures transporting CO_2 or H_2. We first develop analytical models of the technology of these pipeline systems . That analysis shows that these technologies can be represented using Cobb-Douglas production functions. We then examine the least-costly deployment of an infrastructure serving unknown future demand patterns to clarify the optimal degree of oversizing that must be installed. As these anticipations may fail to materialize, we compare several possible deployment scenarios using a minimax regret perspective. Our findings provide insights on the microeconomics of these new infrastructures and show that building them ahead of proven demand is always a regret-minimizing strategy.

3 On the Design of Carbon Capture and Storage Policy Under Different Market Structures
Joseph Edward Duggan, University of Dayton, Dayton, OH, Contact: jduggan1@udayton.edu
Carbon Capture and Storage (CCS) is increasingly being recognized as having a role in decarbonizing the power sector. We examine a stylized model of carbon capture and storage under different forms of imperfect competition to examine the effects of both subsidies to incentivize CCS as well as emissions taxes to examine how these policy instruments impact market performance and social welfare. We explore the implications of private information on firms' costs of undertaking CCS on designing subsidy policy and the potential and limits of CCS in mitigating a variety of market failures.

4 Carbon Removal Beyond Borders: How to Share the Gains from Inter-Regional Cooperation
Emma Jagu Schippers[1], Solène Chiquier[2], Olivier Massol[3],

[1]CentraleSupélec, Gif-sur-Yvette, France; [2]MIT, Cambridge, MA, [3]IFP School, Rueil-Malmaison, France. Contact: emma.jagu@centralesupelec.fr

International cooperation could greatly reduce the cost of deploying Carbon Dioxide Removal (CDR) to levels compatible with the Paris Agreement. This paper examines the conditions for a multilateral agreement on interregional CDR deployment between four regions - the United States, the European Union, Brazil, and China. Using the Modelling and Optimization of Negative Emissions Technologies (MONET) framework and cooperative game theory, we provide a unique perspective towards deploying CDR cost-effectively to levels compatible with the Paris Agreement objectives, showing that multilateral agreements in accordance with Article 6.2 could enable international cooperation. Our approach clarifies guiding principles on fair gain-sharing to ensure such agreements can materialize.

5 Designing Retirement Strategies for Coal-Fired Power Plants to Address Air Quality and Health Considerations

Carla Campos[1], Emily Pakhtigian[2], Wei Peng[1], Joel Landry[3], Hannah Wiseman[4], [1]The Pennsylvania State University, State College, PA, [2]The Pennsylvania State University, State College, PA, [3]The Pennsylvania State University, State College, PA, [4]The Pennsylvania State University, State College, PA, Contact: carlacampos.sm@gmail.com

By considering six coal plant retirement strategies for Pennsylvania that vary by targets and priorities, we find the spatial distribution of the air quality impacts depends on which units are shut down and where. In addition, Pennsylvania's coal retirement decisions also influence the power generation and associated air quality impacts in the rest of the PJM region.

GO Competition Construction

Community Committee Choice Session

Session Chair: Richard Paul O'Neill, ARPA-E, Silver Spring, MD

1 Go Competition Challenge 3 - Features and Impacts of Model Formulation

Jesse Holtzer, PNNL, WA

The Grid Optimization (GO) Competition Challenge 3 is a problem of AC security constrained unit commitment (SCUC). In this presentation we will describe some of the special features of the model formulation of this problem and touch on some of the impacts of these features on solutions and solver algorithms. For example, we will explore the impact of AC modeling on unit commitment. SCUC is widely used in the context of DA electric power system scheduling and markets, as well as in shorter term look ahead and longer term planning applications. In these applications, a DC power flow and balance model is typically used. For this competition, we used an AC model to enable voltage and reactive power to be influential in determining the optimal generation schedule. We will examine the impacts of this and other model features on solutions and solution techniques.

2 New Developments to Synthetic Grids

Farnaz Safdarian, Texas A&M University, College Station, TX, Contact: fsafdarian@tamu.edu

The synthetic grids are created to avoid disclosing any confidential information and facilitate research on realistic power grid data. These grids are consistently improved to be more realistic and more importantly more reliable and resilient. The improvements include updates to generator parameters, load offer curves, and grids to accommodate different loading and weather conditions. We also have been working on better ways to visualize the operation of electric grids.

3 The Grid Optimization Competition Challenge 3 Benchmark Algorithm

Robert Parker, Carleton Coffrin, Los Alamos National Laboratory, Los Alamos, NM

We have implemented a benchmark solver for the Grid Optimization Competition Challenge 3 optimization problem in order to test the solution platform and evaluation tools, to validate datasets, and to provide a known solution approach against which to compare competition submissions. This talk describes the decomposition approach taken by the benchmark algorithm and presents the performance of different configurations of the algorithm on datasets from the competition.

Solving Emerging Power System Optimization and Control Problems

Community Committee Choice Session

Session Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL

1 Optimal Public Safety Power Shutoff Program with N-1 Contingency Constraints

Feng Qiu, Argonne National Laboratory, Lemont, IL

To mitigate wildfire risk caused by power delivery facilities, utility companies have a standard practice, which is to shut off certain power delivery facilities in risky areas temporarily (called Public Safety Power Shutoff program or PSPS). Due to challenges of determining wildfire risks more precisely, PSPS is often carried out in more areas and for longer time than needed, resulting in excess power outages and significant interruptions to power supply. This work will explore a more optimized PSPS by reducing the load shedding and power outages. At the same time, we consider the fundamental N-1 security constraints in the PSPS model. We propose an optimization model and efficient solution algorithms to address the computational complexity.

2 Development of Optimal Offering Strategy of Virtual Power Plants: An SDDP Approach

Bai Cui, Iowa State University, Ames, IA, Contact: baicui@iastate.edu

Virtual power plants (VPPs) are becoming viable players in the wholesale electricity market. Due to various distributed energy resource components, VPP generation cost is affected by the real-time market price realization. To incentivize their market participation, VPPs should be able to make profit-maximizing power offerings based on price forecasts. This paper proposes a multistage stochastic optimization model to design VPPs' optimal power offering considering the price uncertainty in the day-ahead market. Our proposed model includes a virtual stage to determine the profit-maximization power offering and descendent stages to optimize DERs' cost-minimizing dispatch. We propose a zeroth-order gradient descent solution algorithm to solve the mutlistage stochastic optimization model. The algorithm internalizes a stochastic dual dynamic programming algorithm to optimize the DERs' dispatch and provide gradient information by numerical estimation. We iteratively update the power offering using the gradient estimation. Simulation results using test systems show good performance for large-scale multistage stochastic optimization problems.

3 Real-time Optimization for Wind-to-H_2 Driven Critical Infrastructures

Qifeng Li, University of Central Florida, Orlando, FL

This talk presents a real-time optimal operation model for the wind-to-hydrogen-driven low-carbon critical infrastructure (W2H-LCCI), where the energy consumption of CIs mainly comes from wind power, which can significantly reduce the carbon emission from CIs. The resulting optimization problem is a large-scale mixed-integer convex program (MICP). In order to solve the large-scale MICP problem in real-time, a fast solution method based on active constraint and integer variable prediction (ACIVP) is introduced. The ACIVP method predicts the binary variables and the active constraints based on the historical data of optimal solutions. As a result, only a small-scale continuous convex optimization problem needs to be solved online. To increase the accuracy of the ACIVP method, a method of feature space expansion is employed.

Optimization and Deep Learning

Community Committee Choice Session

Session Chair: Kimberly Villalobos Carballo, Massachusetts Institute of Technology, Cambridge, MA

1 Robust Upper Bounds for Adversarial Training

Kimberly Villalobos Carballo, Massachusetts Institute of Technology, Cambridge, MA, Contact: kimvc@mit.edu

Many adversarial training methods for deep learning leverage upper bounds of the adversarial loss to provide security guarantees against adversarial attacks. Yet, these methods rely on convex relaxations to propagate bounds for intermediate layers, which affect the tightness of the bound at the output layer. We introduce a new approach to adversarial training by minimizing an upper bound of the adversarial loss that is based on a holistic expansion of the network instead of separate bounds for each layer. This bound is facilitated by state-of-the-art tools from Robust Optimization; it has closed-form and can be effectively trained using backpropagation. Across a variety of data sets we demonstrate that our approach is substantially more robust than state-of-the-art methods for larger perturbations, and it matches their performance for small perturbations.

2 Prescriptive Neural Networks with an Interpretability Option

Lisa Everest, Vasiliki Stoumpou, Massachusetts Institute of Technology, Cambridge, MA, Contact: leverest@mit.edu

We present a novel method that trains neural networks for prescriptive problems. Given a dataset with covariate features, treatments prescribed for each observation, and the corresponding outcome, we aim to prescribe the treatment that optimizes the outcome for a given observation. Our method involves three steps: 1) performing a counterfactual estimation step, 2) training a prescriptive neural network (PNN) with an appropriate prescriptive objective, and 3) training a corresponding classification tree that ensures interpretability without compromising performance. We apply this methodology to both structured and unstructured data and demonstrate that PNNs are tractable, flexible, and strongly-performing prescriptive models that can handle complex data structures.

3 Interpretable NLP For Identifying Risk Factors Of Intimate Partner Violence In Clinical Notes

Matthew Peroni, Jiayi Gu, MIT, Cambridge, MA, Contact: jgu321@mit.edu

With the rise of language models, there is increasing interest in using natural language data in modeling tasks in healthcare. However, previous works use black-box encoder models to generate feature representations which cause any modeling to lose all interpretability. In this work, we develop new modeling approaches that use encoder language models in a way that preserves some interpretability and allows us to identify critical passages in text for a given prediction task. We apply this to our work of identifying victims of Intimate Partner Violence (IPV) in clinical settings that utilizes tabular EHR and clinical notes. This methodology allows us to identify segments of text that represent potentially risk factors of IPV.

Problems in Railway Operations

Contributed Session

Session Chair: Rahman Torba, SNCF & Mines Saint-Etienne, Paris, France

1 Optimization of Possession Times in Railway Networks: A Heuristic Approach

Yannick Burmeister, Dr. Arturo Crespo, Prof. Dr. Andreas Oetting, Technical University of Darmstadt, Darmstadt, Germany. Contact: burmeister@verkehr.tu-darmstadt.de

While possession times (due to railway construction and maintenance works) usually render portions of the railway infrastructure temporary unavailable, they are necessary to upkeep the its long-term serviceability. Therefore, possession times and the construction processes themselves must be planned and executed in such a way that railway operations are impaired as little as possible. Using graph theory and heuristic methods this contribution proposes a new approach for optimizing the planning of railway construction processes and possession times. The resulting approach enables a better capacity consumption in the railway network by allowing a smarter planning of possession times and a faster realization of railway construction works.

2 Improving Freight Train Throughput in the Indian Railway Network: A Structural Analysis

Himanshu Arha[1], Milind Sohoni[1], Kashish Arora[1], Raja Gopalakrishnan[2], [1]Indian School of Business, Hyderabad, India; [2]Indian Railways, New Delhi, India

In this paper, we study how to reduce congestion on the Indian Railway network. Specifically, we model a section controller's hold decision for a freight train at a railway station and estimate it using high-frequency train flow data. Using our estimates, we design policies to reduce congestion on the network.

3 Planning Services on Metro Rail Operations

Narayan Rangaraj, Indian Institute of Technology Bombay, Mumbai, India. Contact: narayan.rangaraj@iitb.ac.in

In countries like India, planning and operating metro rail services in urban areas is a challenging task, as it is often a supply constrained environment. Resources such as system headway (track capacity), rolling stock and crew could all be constraining factors, especially for handling peak period demands. We propose an integrated system for maximizing the benefit to commuters from the deployment of available resources using tools from optimization and simulation. A particularly useful framework is that of Periodic Event System Scheduling (PESP). We discuss application experience and possibilities, using the PESP framework and others. The decisions considered include line planning, vehicle scheduling and crew planning. The performance measures used are (i) waiting and travel time for customers, and (ii) vehicle and crew utilization.

4 Robust Scheduling in Sncf Railway Maintenance Centers

Rahman Torba[1,2], Stéphane Dauzère-Pérès[1], Claude Yugma[1], Cédric Gallais[2], Juliette Pouzet[2], [1]Ecole des Mines de Saint-Etienne, Gardanne, France; [2]SNCF, Saint-Denis, France. Contact: r.torba@emse.fr

This work addresses a multi-skill resource-constrained multi-project scheduling problem which originates from SNCF heavy maintenance factories. To solve large instances a new memetic algorithm combining a genetic algorithm with a simulated annealing procedure is implemented. Computational experiments conducted on real instances validate the efficiency of the algorithm. However, most of processing times are uncertain and additional tasks, with a known probability to be executed or not, can be encountered. Therefore, we will discuss on how to integrate these uncertainties in the decision process to generate robust schedules. The objective is to maximize the probability of meeting customer deadlines.

Computing Techniques in Defense Settings

Community Committee Choice Session

Session Chair: Rob Mark Curry, United States Naval Academy, Annapolis, MD

1 Optimizing Cooperative Interdependent Attack Graphs to Compromise Cyberinfrastructures

Robert Mark Curry, United States Naval Academy, Annapolis, MD

As infrastructures in our society become increasingly interdependent, the possibility of attacks utilizing these interdependencies also increases. In this work, we consider attacks from multiple attackers working cooperatively to reach their goals. We model this problem under the assumption that more than one exploit may have to be used by an attacker to reach their objective. We provide a mixed-integer program (MIP) for this attacker model, and we provide a bounding algorithm that iteratively improves a series of upper and lower bounds to determine an. optimal solution. Furthermore, we provide preliminary analysis showing the computational effectiveness of our algorithm.

2 Optimal Basing of Aircraft for the Operational Support Airlift Program

Anna Svirsko, Will Traves, Gary Lazzaro, United States Naval Academy, Annapolis, MD, Contact: svirsko@usna.edu

The Operational Support Airlift (OSA) Program maintains a set of commercial aircraft owned and operated by the federal government to augment combat aircraft during war by moving military personnel and cargo or conducting intelligence runs. We study the usage of OSA aircraft during peacetime when OSA aircraft are used to transport Department of Defense personnel and cargo. From FY16 - FY19, the OSA program was able to fulfill over 85% of all transport requests in the continental United States. However, some bases consistently experience a high percentage of unsupported requests. This study considers alternate basing locations of aircraft within the OSA program to improve peacetime mission support.

3 Analyzing Daily Sorties at Nas Kingsville Utilizing Alternative Refueling Methods

Joseph Carl Foraker, Aimpoint Digital, Atlanta, GA, Contact: jcforaker@gmail.com

Training Air Wing TWO (TRAWING 2) is responsible for intermediate and advanced phases of Undergraduate Jet Pilot Training, and provides the U.S. Navy and Marine Corps with newly winged aviators. Our objective is to improve operations at TRAWING 2 using sortie output and aircraft refuel waiting time as measures of performance. We create a discrete-event simulation to model daily jet flow and operations at TRAWING 2. We compare current operations with alternative refueling strategies that incorporate hot pit refueling to minimize the time jets spend on the ground between consecutive sorties. We consider different factors and run a variety of experiments to determine the impact of fueling strategies on resource utilization in an effort to generate more sorties. We analyze the results of these experiments and determine which strategies lead to the largest number of sorties.

4 Marine Corps Prior Service Recruiting Optimization

Gary Lazzaro, United States Naval Academy, Annapolis, MD, Contact: lazzaro@usna.edu

We optimize the recruiting of prior service Marines into the Selected Marine Corps Reserve. Marine Corps Recruiting Command (MCRC) divides the US into six districts with 88 prior service recruiters (PSR) split between 20 offices to solicit prior service Marines. We solve two distinct problems. First, should the district boundary lines be changed to reflect current prior service recruiting challenges? Second, should locations of PSRs be changed in order to better contact prior service Marines? K-Means Clustering enables us to redraw the Marine Corps recruiting district lines to equitably distribute the recruit population. Our linear program optimizes the relocation of the PSRs to reserve center locations nationwide to minimize total distance traveled by recruiters.

5 Maximizing Occupied Nodes in Dynamic Network Flow Problems Using Time Indexed Graphs

Tanner Nixon, Robert Mark Curry, United States Naval Academy, Annapolis, MD

In this work, we seek to determine a schedule of network flows to be sent over a sequence of discrete time periods in order to maximize the total value of all occupied nodes. A node is deemed *occupied* when some minimum level of flow exists at a node from one time period to the next. We solve this problem three ways implementing a time-indexed graph, a time-expanded graph, and a heuristic algorithm which separates the network flow schedule into a sequence of sub-schedules. Utilizing a randomly generated data set, we show how heuristic algorithm consistently solves the problem faster than the MIP while producing high-quality near-optimal solutions. The heuristic algorithm should be used in time-sensitive applications when the MIP takes a considerable amount of time.

Human-AI Interaction

Community Committee Choice Session

Session Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

1 Finding a Needle in a Haystack: Identifying Valuable Information to Improve Human-AI Collaboration

Kris Johnson Ferreira[1], Jordan D. Tong[2], Shirley Huang[1], [1]Harvard Business School, Boston, MA, [2]University of Wisconsin Madison, Madison, WI, Contact: kferreira@hbs.edu

A key reason for allowing decision-makers to override AI predictions is because they might have access to private information that is unobserved by the AI algorithm - yet valuable in making predictions - for which they can use to improve upon the AI. Unfortunately, though, identifying valuable private information is often easier said than done, in part because it can be quite difficult for decision-makers to distinguish whether private information is valuable; such a distinction is left to their intuition and experience, which may be shrouded by noise. We propose a new method to identify decision-makers who use valuable private information. Via a series of controlled online experiments, we evaluate the effectiveness of our method compared to two natural benchmarks and uncover insights as to why our method outperforms both.

2 Causal Inference with Unstructured Data as Control Variables

Xu Sikun[1], Zhenling Jiang[2], Dennis Zhang[3], [1]Washington University in St Louis, ST LOUIS, MO, [2]University of Pennsylvania, Philadelphia, PA, [3]Washington University in St Louis, ST LOUIS, MO, Contact: sikun@wustl.edu

As unstructured data (e.g., images or videos) become increasingly available, they have become important confounders in empirical causal inference models. To control for unstructured data, many studies follow an embed-then-estimate framework. Researchers train a representation learning model to generate lower-dimensional embeddings of the unstructured data as inputs to causal inference models. We argue that such a framework can lead to biased causal estimates due to the training objective of the embedding model. We propose a confounding embedding method that effectively extracts low-dimensional embeddings from unstructured data as confounders. We demonstrate the effectiveness of the proposed method in obtaining accurate causal effect estimates using several examples, including a lab experiment with Visual-ChatGPT-generated synthetic images as stimuli.

3 Does Digital Mental Healthcare Service Access Affect Care Outcomes? Evidence from a Natural Experiment

Jiayuan Tian[1], Liangfei Qiu[2], Guohou Shan[3], [1]University of Florida, Gainesville, FL, [2]University of Florida Warrington College of Business Administration, Gainesville, FL, [3]Temple University, Philadelphia, PA

Mental illnesses like depression and anxiety are prevalent. To address them, mental healthcare services provided by digital platforms have been adopted recently. However, it is unknown whether and how the mental healthcare service access over digital platforms may affect the care outcomes. Building on the theoretical mechanisms of accessibility, our study leverages a natural experiment of the launch of mental healthcare digital platforms to investigate the impact of the digital access of mental healthcare services in terms of the mentally unhealthy days and the number of smokers at U.S. county level. Furthermore, we explore how disadvantage groups and the internet penetration moderate the main impact to unpack mechanisms.

4 Identity Disclosure and Anthropomorphism in Voice Chatbot Design: A Field Experiment

Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC
Fueled by the widespread adoption of algorithms and artificial intelligence (AI), the use of chatbots has become increasingly popular in various business contexts. In this paper, we study how to effectively and appropriately use voice chatbots via leveraging two design features (i.e., identity disclosure and anthropomorphism) and evaluate their impact on the firm operational performance.

Sunday, October 15, 12:45 PM - 2:00 PM

CC-North 232C
Applications on Greenhouse Gas Emission Reduction
Contributed Session
Session Chair: Elif Haktanir Aktas, Bahcesehir University, Istanbul, Turkey

1 Impacts of Building Sector GHG-Limiting Ordinances on Long-Term Investment Decisions Considering Policy Uncertainty
Stephanie Wilcox[1], Ozge Kaplan[2], Ben Field Hobbs[1], [1]Johns Hopkins University, Baltimore, MD, [2]U.S. Environmental Protection Agency, Durham, NC
Several cities in the U.S. have enacted GHG-limiting ordinances to reduce on-site building sector emissions. However, analyses of the ordinances' long-term impacts on natural gas and power system infrastructure investment are missing from the literature. In this study, we extend the U.S. EPA's City-Based Optimization Model for Energy Technology to model long-term minimum cost energy and building sector investment decisions of NYC's GHG-limiting ordinance. Our results show that the cost-optimal investment decisions depend significantly on the inclusion of necessary system upgrades such as natural gas main replacements and future costs of "clean" natural gas substitutes.

2 Renewable Energy Pathways to Carbon Neutrality in China
Zhenhua Zhang[1], Ziheng Zhu[2], Jessica A. Gordon[3], Xi Lu[4], Da Zhang[2], Michael R. Davidson[5], [1]University of California, San Diego, La Jolla, CA, [2]Tsinghua University, Beijing, China; [3]University of California, Berkeley, Berkeley, CA, [4]Tsinghua University, Beijing, China; [5]University of California, San Diego, La Jolla, CA, Contact: zhenhua@ucsd.edu
China has announced ambitious climate policy goals of reaching peak carbon emissions by 2030 and carbon neutrality by 2060. This process requires a large increase in low-carbon renewable energy and complementary infrastructure. While these long-term objectives are clear, the deployment structure, pace, and distributional impacts are uncertain. To address this gap, we developed a power system planning and operation model with a high spatial and temporal resolution for deploying renewables, storage systems, and transmission lines. We adapted this model to evolving power system conditions and input assumptions by sequentially linking the outputs of each decade to simulate technology vintaging mechanisms. The combined model outputs across periods identify feasible and efficient pathways for renewable deployment from 2020 to 2060.

3 Pathways to Carbon Neutrality in California's Heavy-Duty Transportation Sector
Eleanor M. Hennessy, Madalsa Singh, Ines Azevedo, Stanford University, Stanford, CA, Contact: emh@stanford.edu
California has a goal of reaching net zero greenhouse gas (GHG) emissions by 2045. Nearly 8% of the state's GHG emissions come from the heavy-duty transportation sector. We assess decarbonization strategies using two policy options: zero-emission vehicle (ZEV) sales mandates and accelerated retirement programs. We build a detailed, bottom-up fleet turnover model paired with an emissions and air quality model to track the evolution of the vehicle fleet and associated cumulative health and climate impacts of each policy. We track health impacts by race and income. We use second-hand vehicle prices to estimate the cost of retirements and identify the most cost-effective policies. We find ZEV sales mandates are insufficient to reach California's climate targets, and accelerated retirement policies targeting heavy-heavy duty vehicles are most cost-effective.

4 Incentive-Based Travel Behavior Change Mechanism to Mitigate System Level Carbon Emissions
Viswa Sri Rupa Anne[1], Srinivas Peeta[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: vanne3@gatech.edu
In recent years, incentives are being proposed to change travel behavior to reduce system-level congestion. The transportation sector is one of the largest contributors of greenhouse gases in the United States, and behavior change strategies have the potential to reduce these emissions. This study proposes an incentive mechanism that nudges users

to carbon-efficient routes to reduce system-level carbon emissions. It uses a bi-level optimization framework to generate time-varying dynamic incentives.

5 Integration of Agricultural Fields with Hydrogen Valleys: A Decision Support Model for a Circular Economy
Elif Haktanir, Bahcesehir University, Istanbul, Turkey. Contact: elif.haktaniraktas@eng.bau.edu.tr
The decarbonization of the global economy is a pressing challenge in the 21st century, requiring substantial reductions in greenhouse gas emissions. The European Union (EU) has set an ambitious target to become the first climate-neutral economy by 2050, with Hydrogen Valleys playing a significant role in achieving this goal. Hydrogen Valleys contribute to the decarbonization of the EU's economy by promoting the production of green hydrogen and facilitating its utilization in various applications. Despite the significant potential for integrating agricultural fields with Hydrogen Valleys to foster a circular economy, this area remains largely unexplored in the existing literature. This paper aims to develop a decision support model that facilitates the integration of agricultural fields with Hydrogen Valleys.

1 Mental Health Awareness through Pedagogy
Sofía Pérez-Guzmán, Georgia Institute of Technology, Atlanta, GA
Deciding to start a Ph.D. is not an easy task. Yet, many of us decide to trust our abilities and knowledge to take that step and enroll in the program of interest. While everyone's path is unique, for the most part, life as a Ph.D. student is challenging and requires hard work, sacrifice, and perseverance. It makes one wonder why to pursue this path? How to overcome the challenges faced during these years? Is it worth the sacrifice? This panel is intended to cover all these questions about life as a Ph.D. student, hearing opinions from current and former Ph.D. students.

Empirical PSOR II

Community Committee Choice Session

Session Chair: Anqi Wu, Florida International University, Miami, FL
Session Chair: Chengyue Huang, University of Iowa, Iowa City, IA

1 Prioritizing Electric Utility Companies for Smart Meter Adoption: Empirical Evidence from the United States
Yue Gao, Jin Fang, Jing Zhang, Clark University, Worcester, MA, Contact: jinfang@clarku.edu
The reliability of a power distribution system is a critical indicator of its ability to supply uninterrupted electric power to customers. The installation of smart meters has been identified as a means of enhancing reliability by reducing power outages and restoration time. Smart meters are an essential component that aids in balancing energy supply and demand, promoting efficient energy use, raising awareness about energy savings among consumers, and improving the reliability of electricity supply. This study

employs a simultaneous equations model and network analysis to prioritize electric utility companies in the United States. Our research findings underscore the significance of smart meter adoption and provide valuable insights for policymakers and electric utility companies.

2 Politicizing Policy Response? Ramifications and Remedies

Chengyue Huang[1], Min Zhang[1], Natasha Foutz[2], Weiguo (Patrick) Fan[1], Rui Chen[3], [1]University of Iowa, Iowa City, IA, [2]University of Virginia, Charlottesville, VA, [3]Iowa State University, Ames, IA

Policy politicization is increasingly prevalent, undermining policy efficacy and public trust. This study proposes a computational framework to conceptualize, quantify, and uncover potential mechanisms of policy politicization. We evaluate the framework through two studies: one on general COVID-19 mask policy and another on firms requiring masks for entry. Our analyses of over 2.6 million tweets show that politicization decreases the reach of pro-policy tweets and increases the exposure of anti-policy tweets. The potential mechanisms may involve diverting audience attention and influencing their attitudes. Remedies include promoting messages from public health authorities to reduce politicized responses. Our research contributes insights into policy politicization, public opinion, and effective communication strategies in polarized environments.

3 Supply Network Complexity, Regulatory Risk and Firms' Engagement in Influencing Climate Change Policies

Zhenzhen Yan[1], Sriram Narayanan[2], Tobias Schoenherr[3], [1]Idaho State University, Pocatello, ID, [2]Michigan State University, East Lansing, MI, [3]Michigan State University, East Lansing, MI, Contact: zhenzhenyan@isu.edu

To enhance organizational legitimacy and competitive advantages, many firms have strived to go beyond policy compliance and engage in influencing climate change policies (EICCP). This research focuses on the antecedents of EICCP by examining the effects of risk and network factors on EICCP. Specifically, we examine whether firms' EICCP under regulatory risks is contingent upon the features of their supply network. This study contributes to the climate change and public policy literature. Our endeavor also responds to the call for more policy-related studies in our field from a supply chain perspective.

4 Consolidation Effect on Data Breaches in Hospitals

Nan Clement, University of Texas at Dallas, Richardson, TX, Contact: nclement@utdallas.edu

I study whether and how hospital mergers increase data breach probability. Using a stacked difference-in-differences estimation strategy, I show that in the two-year window after hospital consolidation, incidents of data breaches more than double as compared to the pre-treated groups. The effect is robust to changes in the two-year time window, sample size, or how standard errors are clustered. The signaling effect and the incompatibility effect of mergers cause more hacking activities such as phishing and ransomware attacks. Conversely, the complementary effect of organizational capital reduces such an increase. The truncated regression for the past five years shows that the situation is getting worse because of soaring cases of hacking activities, even though the efforts to address misconduct breaches were effective.

Sustainability and Equity

Community Committee Choice Session

Session Chair: Abhinav Shubham, Georgia Institute of Technology, Atlanta, GA

1 Sequential Bias And Initial Disparity In Online Grading Systems

Jiaxin Pei[1], Zhihan (Helen) Wang[2], Jun Li[2], [1]School of Information, University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: helwang@umich.edu

Surname initial-ordered grading is the default configuration in the four largest online learning management systems (Canvas, Blackboard, Moodle, Brightspace), which covers over 90% of the US and Canadian markets. Through analyzing over 30 million grading records from a large public university, we found a significant and sizable sequential grading bias where assignments graded later receive worse grading outcomes, as well as more negative and less polite comments. Moreover, the system design converts such behavioral bias into a surname initial bias - Students with alphabetically lower-ranked surname initials constantly receive worse grading outcomes due to lower ranking in the grading queue. Our study calls for operational and organizational improvements from system designers and education institutions to foster a more equal online grading environment.

2 Impact of Female Inspector Presence on FDA Inspection Outcomes

Shirin Shahsavand[1], George Ball[2], Kevin Mayo[1], Kaitlin Wowak[3], [1]Washington State University, Pullman, WA, [2]Operations and Decision Technologies, Kelley School of Business, Indiana University, Bloomington, IN, [3]University of Notre Dame, Notre Dame, IN

The impact of gender on decision-making and outcomes in operations is a growing area of concern in academic literature and practical settings. Prior research indicates that differences in gender are highly salient in regulatory environments. We examine this phenomenon among inspectors examining FDA-regulated drugs and medical devices. We examine 20 years of inspections, exploring the relationship between the inspector's gender and the inspection outcome. We find that the presence of a female inspector is associated with the most severe outcome. Our study provides insights to academics and regulators regarding how the presence of female inspectors may influence inspection outcomes that impact customer health and safety.

3 Playing Fair? Environmental Impacts and Practices of Facilities in Minority Communities

Abhinav Shubham, Ravi Subramanian, Georgia Institute of Technology, Atlanta, GA, Contact: ashubham3@gatech.edu

Drawing on comprehensive US EPA and Census data, we examine the association between presence of substantial racial minority populations in host communities and facility-level environmental impacts and impact-reduction strategies. Our findings offer evidence for firms and policy makers to consider fairness and equity in managing and regulating environmental risks.

Digital Economy and Digital Governance

Community Committee Choice Session

Session Chair: Cong Cao, Zhejiang University of Technology, Hangzhou, China

1 The Challenges and Opportunities Brought by Digital Economy Partnership Agreement Rules to Digital Governance

Cong Cao, Zhejiang University of Technology, Hangzhou, China. Contact: congcao@zjut.edu.cn

In recent years, scholars have discussed the promotion and impact of globalization of digital trade on the optimal allocation of digital resources, and further pointed out that China needs to adapt to the trend of globalization of digital governance, promote a high level of openness, enhance cross-border autonomy, especially actively join high-level digital trade agreements, and effectively expand international cooperation on digital governance in China. on the one hand, seek a balance between security and development, freedom and order, and gradually integrate the demands of all parties into the global digital economy development planning and digital governance framework. on the other hand, strengthen the exchange and cooperation of all parties in government, projects and talents, and contribute Chinese wisdom and Chinese solutions to global digital governance.

2 Community/Committee'S Choice Submission

3 Do You like Talking to an Omnipotent Human-Like Robot? the Effect of Highanthropomorphism in Intelligent Virtual Assistants on Consumer Confirmation

Sihan Cheng, Zhejiang University, Hang Zhou, China. Contact: 202005710302@zjut.edu.cn

This study presents an investigation of the perceptual and expectation transfer mechanisms of consumers when interacting with intelligent virtual assistants (IVAs). A mixed-method design is used to identify four perception variables and propose a theoretical model using the ECM model. The model explores the relationship between IVA design, perceptual factors, expectation confirmation, and consumer attitude toward IVAs to promote sustainable usage. Using a quantitative survey, the study collects valid data and analyzes the results using PLS-SEM. The findings indicate that IVAs can enhance consumer perception and increase perceived usefulness while promoting sustainable usage. This study offers insights that can contribute to expanding theory and driving the development of the IVA industry.

4 Living Together for the Future: Exploring the Willingness of Functional Restricted Groups to use New Public Infrastructure Under the Integration of Virtual and Real Worlds

Zhenyang Shen, Zhejiang University of Technology, Hangzhou, China. Contact: 202101260120@zjut.edu.cn

The development of the digital age has created a new field where physical space and virtual space intersect, but the adoption of new technologies in this field poses challenges to the lives of functionally restricted groups. To explore the factors that affect the willingness of functionally restricted groups to use new public infrastructure in this context, we constructed a research model based on UTAUT theory, and the research results effectively identified the impact of factors from three perspectives: individual, social, and technological. This study groundbreaking focuses on the issue of inclusivity in the field of virtual and real integration, which helps to guide building a society for the common development of all humanity.

5 Exploring the Changes in Audience Satisfaction when Watching Sports Events on Live Streaming Platforms

Jinyang Zhou, Zhejiang University of Technology, Hangzhou, China. Contact: 202105710327@zjut.edu.cn

Recently, with the development of live broadcast platforms such as self-media, sports event broadcasting has also shifted from traditional TV broadcasting to live broadcast platform, this paper believes that in the scene of watching games in the live broadcast room, some nature characteristics and behavioral characteristics of sports fans have certain typicality, and according to the theory of social service landscape, a research model with perceived value as an intermediate variable is established to study the impact of interactive behavior and similarity between audiences in this service landscape on the perceived value and satisfaction of other users.

Persuasion in Social Networks

Community Committee Choice Session

Session Chair: Tauhid Zaman, Yale University, New Haven, CT

1 Shaping Opinions In Social Networks With Shadow Banning

Yen-Shao Chen, Tauhid Zaman, Yale University, New Haven, CT, Contact: yen-shao.chen@yale.edu

Social networks are global platforms for shaping public opinions. Concerns about harmful content led to content moderation policies like shadow banning that restricts content visibility. Although shadow banning can be strategically utilized to mitigate the impact of harmful content, it also raises the risk of arbitrary opinion manipulation. In this talk, we formulate shadow banning as a linear program to find a scalable shadow banning policy for large-scale networks. Our findings demonstrate the significant potential of shadow banning as a powerful technique for precise opinion manipulation. However, we caution that its application should be exercised with care, especially when seeking to combat the effects of dangerous content. This research sheds light on the importance of responsible and transparent content moderation practices on social media platforms.

2 Measuring the Persuasive Power of ChatGPT

Weining Fang, Tauhid Zaman, Yale University, New Haven, CT, Contact: weining.fang@yale.edu

This study investigates the persuasive power of machine-generated content, specifically the ability of ChatGPT to influence human attitudes. 2,000 US adults aged 18 and above were recruited from Prolific and randomly assigned to an intervention group (n=1,000) and control group (n=1,000). Participants initially completed a survey on sports, education, or entertainment attitudes. They then read a paragraph, unaware it was generated by ChatGPT. The intervention group received a topic-relevant paragraph, while the control group read an unrelated paragraph on nature or history. The participants were then asked to answer the same survey questions to assess any change in attitudes. This before-and-after design measures the impact of AI-generated contents on perspectives, offering insights for marketing, education, and policy-making.

3 Pro-Russia Twitter Bots in the Ukrainian War

Tauhid Zaman, Yale University, New Haven, CT

This study investigates Twitter bots supporting pro-Russia narratives during the Ukrainian war. Analysis reveals sustained bot creation over a decade. Prior to the invasion, bots tweeted in Russian, but shifted to English later. Many bots exhibit multilingual capabilities, using over 40 languages. Notably, the bots amplify renowned Western anti-war voices. These findings offer essential insights into the strategies employed by pro-Russia bots, their influence on discourse, and implications for information warfare in future conflicts.

4 Detecting Twitter Bots using ChatGPT Embeddings

Michael Rossetti, Georgetown University, Washington, DC

Established methods for detecting automated social media accounts known as “bots” can be complex and computationally expensive. We simplify the process by leveraging text embeddings from commercially available large language models. We obtain embeddings from the OpenAI API representing tweets posted by a sample of 7,500 Twitter users discussing the first impeachment of US President Donald Trump. We are able to achieve high classification accuracy by training simple models (Logistic Regression, Random Forest, and XGBoost) directly on these embeddings to predict various labels including bot status, political sentiment, and language toxicity. Our work demonstrates a simple and cost effective way of detecting bots, and shows the breadth of applications for these embeddings in performing a variety of social network classification tasks.

Digital Platforms and Innovation

Community Committee Choice Session

Session Chair: Sidika Candogan, 1</sup

1 Data Sharing and Market Protection

Linsheng Zhuang[1], Jussi Keppo[2], Zhi Chen[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: linsheng.z@u.nus.edu

The success of many AI-powered applications (such as the automated driving systems) hinges on their access to big data. However, for privacy reasons, countries around the globe have been stepping up measures and even regulations to prevent data from being shared beyond their borders. As a result, multinational firms cannot tap into data collected in different markets to improve their applications. In this paper, we analyze the effect of market protection on AI innovation for multinational firms which compete in different markets.

2 Assortment Display, Price Competition and Fairness in Online Marketplaces

Hanwei Li, City University of Hong Kong, Hong Kong, Hong Kong

Online platforms have been expanding the seller base to widentheir product assortment to match the heterogeneous preferences ofconsumers. Nevertheless, the increasing number of sellers has intensifiedcompetition and resulted in sellers setting lower product prices. Thus, it is unclear whether displaying all sellers tothe entire customer base maximizes platform revenue. Motivated byplatforms such as Airbnb and eBay, we consider a game-theoretical setup inwhich each seller on the platform provides a single-unit product to aheterogeneous customer base and competes with other sellers on price. Weinvestigate sellers' optimal pricing decisions and the platform's optimalassortment display policy, characterized by the number of partitions andthe sellers and traffic assigned to each partition. We find that the platformshould display the entire assortment to all customers when demand issufficiently high. Moreover, we propose a tabulation algorithm and amixed-integer programming formulation to solve for the optimal decisionsof sellers and the platform. Moreover, we incorporate fairness constraints tobalance platform revenue and the fairness of both parties on the platform.We also present a case study to gauge the impact of the partitioneddisplay policy in the context of Airbnb. Finally, we extend the case inwhich each seller supplies a distinct product with an inventory size of one byconsidering scenarios in which each product has more than one unit.

3 Practical Lessons from Innovation with Digital Platforms

Joel Wooten, University of South Carolina, Columbia, SC

Digital platforms have served as an engine for innovation and disruption. To appreciate both the impact of these applications and the unanswered questions that are relevant for researchers, we will look at some lessons and insight from papers, recent startups, and the changing world of online tools.

4 External Innovation Mechanisms: A Modeling-Based Comparative Analysis

Sangjic Lee, Kohei Nishiyama, Nariaki Nishino, The University of Tokyo, Bunkyo-ku, Tokyo, Japan. Contact: sangjiclee@tmi.u-tokyo.ac.jp

As various mechanisms for implementing external innovation emerge and become available for companies, it is necessary to explore the problem of selecting the optimal combination of activities in according to the business environment. To this end, we (1) develop a framework for comparing the mechanisms, (2) formulate the decision-making structure of stakeholders for each mechanism using game theory, and (3) analyze the compatibility of the mechanisms with various levels of environmental factors through theoretical and experimental analysis. Implications for the selection of external innovation method are derived by comparatively interpreting the results with the business cases.

Mechanisms Impacting Collaboration, Product Development, and Entrepreneurship

Community Committee Choice Session

Session Chair: Cheryl Gaimon, Georgia Institute of Technology, Atlanta, GA

1 Hierarchical Influence Structures and Collaborative Success in Online Communities: Explaining Peer Production Performance in the R/Place Event

Shizhen Chen, Tian Chan, Anandhi S. Bharadwaj, Emory University, Atlanta, GA, Contact: shizhen.chen@emory.edu

Online communities (OCs), e.g. Reddit or Wikipedia, are open collectives of individuals whose members are often anonymous and communicate in an environment constrained by technological mediation. In this paper, we empirically investigate the collaborative mechanisms of OCs in Reddit's r/place 2022 event. The event requires individuals to collaborate to produce an image pixel by pixel for an OC, it also put OCs in competition with each other. We show that hierarchical influence structure in an OC outperforms only when competition intensity is low. However, flat influence structure outperforms when competition intensity is high. We theorize and find empirical evidence that flat influence structures are better at engaging lurkers under high competition intensity.

2 Consumer Privacy and Personalized Recommendation on Online Platforms

Farzad Fathi, Yi Xu, Bo Zhou, University of Maryland, College Park, MD

This study explores the trade-off between consumer privacy and personalized recommendations on online platforms. A model is developed, characterizing consumers' willingness to pay and product tastes, with privacy levels impacting platform decisions. Results indicate that as privacy increases, platform profits decrease, but consumer utility follows a non-monotonic pattern. The research suggests that preserving privacy may not be the optimal policy.

3 How Entrepreneur Incentives Impact Product Development at Lean Startups

K. Sudhir[1], Steve Yoo[2], [1]Yale School of Management, New Haven, CT, [2]UCL School of Management, London, United Kingdom. Contact: o.yoo@ucl.ac.uk

The lean startup method (LSM) has gained wide acceptance among entrepreneurs and investors as an experimentation based, data-driven approach to product development and learning about product-market fit. But in practice, an entrepreneur's product development choices are motivated not only by learning about product-market fit, but also by the incentive to obtain downstream investor funding and favorable funding terms. We introduce a game theoretic model of product development using LSM that accounts for the entrepreneur's incentives to gain insight on how the incentives endogenously distort the lean startup product experimentation process. Our analysis clarifies that in practice, LSM's efficacy in launching successful innovations is nuanced, and not unambiguous for entrepreneurs, investors and the overall innovation economy.

4 Hybrid Entrepreneurship: An Operational Analysis

Zeya Wang[1], Morvarid Rahmani[2], Karthik Ramachandran[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: zeya.wang@scheller.gatech.edu

We investigate the debate between fully committed entrepreneurship and a hybrid approach in which the entrepreneur retains a stable "day job". A model-based investigation of the trade-offs reveals conditions under which the hybrid approach is optimal, and when it is optimal to make a full commitment. We also study how the entrepreneur's abilities and location may affect their strategy.

Deep Learning Based Data Mining on Unstructured Electronic Health Records

Community Committee Choice Session

Session Chair: Zhuqi Miao, [1]</sup

1 Automated Identification of Atrial Fibrillation from Single-Lead Ecgs Using Multi-Branching Resnet

Jianxin Xie[1], Bing Yao[2], [1]University of Tennessee, Knoxville, TN, [2]The University of Tennessee Knoxville, Knoxville, TN, Contact: jxinxie@gmail.com

Atrial fibrillation (AF) is the most common cardiac arrhythmia, which is clinically identified with irregular and rapid heartbeat rhythm. AF puts a patient at risk of forming blood clots, which can eventually lead to heart failure, stroke, or even sudden death. An advanced analytical model is crucial for interpreting ECG signals and aiding AF diagnostics. We propose a deep-learning method for automated AF identification from single-lead ECGs. We use the continuous wavelet transform to extract time-frequency features, develop a CNN structure incorporating ResNet for effective training, and multi-branching architectures to address imbalanced data. We evaluate the methodology using two real-world ECG databases, and results show superior performance compared to traditional models.

2 Leveraging Active-Supervised Learning and In-Context Learning to Identify Mobility Functioning Information in Clinical Text

Thanh Thieu, Tuan-Dung Le, Moffitt Cancer Center and Research Institute, Tampa, FL, Contact: thanh.thieu@moffitt.org

Limitation in physical function, or frailty, is an important component of geriatric assessment. It disqualifies elderly cancer patient from clinical trials or systemic therapies such as chemotherapy. It contributes to eligibility of U.S. social security programs and benefits. Mobility function is a self-contained, observable domain of physical function that has shared roles in both clinical and socioeconomic applications. Using the National NLP Clinical Challenges (n2c2) research dataset, we implement pool-based query-by-committee active supervised learning BERT models for mobility-related entity recognition. We additionally compare against few-shot learning on large-language models including T5 family, UL2, and ChatGPT. We present models accuracies and empirical lessons.

3 Natural Language Processing Models for Identifying Review of Systems Information from Clinical Notes

Hieu T. Nghiem[1], Zhuqi Miao[2], Thanh Thieu[3], Zheng Han[1], Johnson Thomas[1], [1]Oklahoma State University, Stillwater, OK, [2]SUNY-New Paltz, New Paltz, NY, [3]Moffitt Cancer Center, Tampa, FL, Contact: hieu.nghiem@okstate.edu

A Review of Systems (ROS) is a standard checklist in a clinical note that includes questions regarding all the major organ systems. It is an important tool for doctors to gather information about patient symptoms and overall health. However, extracting and analyzing ROS information from free-text clinical notes is a time-consuming task that can add to the documentation burden for doctors. To tackle the challenge, we developed a transformer-based NLP model. The model utilizes Clinical-Assertion-Negation BERT to recognize ROS-related symptoms and identify their associated negations, enabling the model to determine the presence or absence of symptoms. Once the symptoms are identified, the model maps them to the appropriate organ systems. By utilizing the model, the ROS information extraction process can be automated, resulting in improved efficiency and accuracy.

4 Recognizing Patient History from Clinical Notes Using Natural Language Processing

Tuan-Dung Le[1], Suhao Chen[2], Thieu Thanh[3], Zhuqi Miao[4], [1]University of South Florida, Tempa, FL, [2]South Dakota School of Mines and Technology, Rapid City, SD, [3]Moffitt Cancer Center and Research Institute, Tampa, FL, [4]SUNY-New Paltz, New Paltz, NY, Contact: miaoz@newpaltz.edu

History of Present Illness (HPI) and Past, Family and Social History (PFSH) are two crucial sections of a clinical note, providing valuable information that assists physicians in diagnosing and developing treatment plans. Moreover, they enable effective communication and continuity of care among healthcare professionals involved in the patient's care. However, extracting and analyzing patient history data documented in free-text clinical notes constitute a significant burden to healthcare professionals. To address this challenge, this study developed a transformer-based named entity recognition model, which can identify detailed HPI and PFSH elements from clinical notes. We evaluated the model's performance by comparing its accuracy with that of other methods. Additionally, we conducted error analyses to reveal the factors impacting the model's accuracy.

Economic Models for Market Interactions and Decisions

Community Committee Choice Session

Session Chair: Peter Zhang, Carnegie Mellon University,

Pittsburgh, PA

1 Distributionally Robust Principal-Agent Problems and Optimality of Contract Menus

Peter Zhang, Carnegie Mellon University, Pittsburgh, PA

We propose a distributionally robust principal-agent formulation and a theoretical framework to quantify a contract menu's optimality gap. By our framework, the optimality gap of a contract menu is broken down into an adjustability gap and an information rent. Our results shed light on the existence of more positive results in the literature in terms of a simple menu's optimality in a worst-case setting rather than in a Bayesian setting. We show that this high-level observation relates to two basic technical facts: the sum of quasi-concave functions is not quasi-concave in general; the maximization operator and the expectation operator do not commute in general.

2 Evidence, Access, and Progress: A Mechanism Design Approach to Accelerated Drug Approval

Giuseppe Lopomo, David Ridley, Peng Sun, Chenxi Xu, Duke University, Durham, NC, Contact: chenxi.xu@duke.edu

Under the controversial accelerated approval program, the US Food and Drug Administration (FDA) gives conditional approval to drugs with a lower standard of evidence. After approval, the drug maker must conduct an additional trial to stay on the market. FDA advisors have resigned over approvals of drugs with insufficient evidence of effectiveness under the accelerated program. The rationale for the program is that it gives patients earlier access to drugs. We show another benefit of using mechanism design tools. The accelerated program promotes investment in drug trials for diseases that manufacturers might otherwise have neglected. Furthermore, we show that the relationship between evidence and the scope of the drug label should be nonlinear.

3 On the Convergence of No-Regret Learners to the Approximate Bayes-Nash Equilibrium in Single-Object Auctions

Mete Ş. Ahunbay[1], Martin Bichler[2], [1]Technical University of Munich, Garching, Germany; [2]Technical University of Munich, Garching B. München, Germany

Recent advances in equilibrium learning find approximate Bayes-Nash equilibrium in discretized versions of a wide variety of auction games. This is surprising, because equilibrium learning often cycles and can exhibit formally chaotic behavior in general finite games. However, it is known that no-regret learners converge to a coarse correlated equilibrium (CCE). Thus, to study convergence to Bayes-Nash equilibrium in single-item auctions, we analyze the Bayesian CCE polytope of first-price, second-price, and all-pay auctions, as well as Tullock contests. We show that the set of Bayesian CCE is close to the unique BNE of these games if the c.d.f. of the prior is concave. In particular, for refinements of discretizations parametrized by n, the maximum Wasserstein distance of any Bayesian CCE to the BNE is O(1/n). This suggests that an important class of games is learnable.

4 Comparing Centralized and Decentralized Matching in Labor Markets

Srinivasa Kartikeya Puranam[1], Michael Katehkais[2], [1]Rutgers University, Camden, NJ, [2]Rutgers University, Newark, NJ, Contact: karti@camden.rutgers.edu

Two mechanisms for matching which are dubbed centralized and decentralized mechanisms are compared. The payoff to the Labor Market Intermediary (LMI) which facilitates the matching in both mechanisms is studied. A discussion of when each of the two mechanisms are optimal is provided. Numerical simulations and their results are also presented.

Infectious Disease Management and Control Policy

Community Committee Choice Session

Session Chair: Eyyub Yunus Kibis, Montclair State University, Montclair, NJ
Session Chair: Ozlem Cosgun, Montclair State University, Wayne, NJ

1 Hospital Utilizations During Covid 19 Pandemic: An Efficiency Problem

Eyyub Yunus Kibis[1], Musa Caglar[2], Ali Dag[3], Serhat Simsek[4], [1]Montclair State University, Montclair, NJ, [2]Tulane University, New Orleans, LA, [3]Creighton University, Gretna, NE, [4]Montclair State University, Wayne, NJ, Contact: kibise@montclair.edu

In this study, we develop a compartmental dynamic MIP model to investigate the transmission of the COVID-19 pandemic within a community. We propose policies that will help state governments to control the pandemic and reduce patient density at overcrowded hospitals. Our model predictions closely fit the real outbreak data and suggest

that the deployment of makeshift hospitals as post-treatment facilities will result in the most efficient use of resources to control the pandemic.

2 Modelling Hospital Bed and Ventilator Capacity Under Non-Pharmaceutical Interventions During Covid-19

Ozlem Cosgun[1], Eyyub Yunus Kibis[2], [1]Montclair State University, Wayne, NJ, [2]Montclair State University, Montclair, NJ

During the COVID-19 outbreak, all countries faced a critical shortage of beds and ventilators that caused a dramatic increase in mortality rates. In this study, we propose a capacity planning model that includes the optimal hospital bed and ventilator capacity expansion decisions under non-pharmaceutical interventions to minimize the number of deaths in New York City during COVID-19. An epidemic disease compartmental model (S4IRD) is proposed to project COVID-19 infections over time, and a MIP optimization model is developed to decide on the optimal bed and ventilator expansion amounts that minimize the number of deaths over time.

3 At What Prevalence of Resistance Should Empiric Antibiotic Treatment for Gonorrhea Change? a Cost-Effectiveness Analysis

Xuecheng Yin[1], Reza Yaesoubi[2], [1]Yale University, New Haven, CT, [2]Yale School of Public Health, New Haven, CT

Common diagnostic tests for gonorrhea do not provide information about the susceptibility of infection to antibiotics. Guidelines recommend changing antibiotics used for empiric therapy once resistance prevalence exceeds 5%. However, the basis for this threshold is not clear. We developed a model of gonorrhea transmission to project gonorrhea-associated costs and loss in quality-adjust life-years (QALYs) under different switch thresholds among men who have sex with men in the US. Using cost-effectiveness analysis, we identify hypothetical switch thresholds for varying values of willingness-to-pay per QALY and showed the health and economic burden of gonorrhea and the effective lifespan of antibiotics depends on the selected threshold

Computation Research in Social Study

Community Committee Choice Session

Session Chair: Yicheng Song, University of Minnesota, Minneapolis, MN

Session Chair: Teng Ye, 1</sup

1 Understanding How Competing Products of Different Quality Tiers Affect Consumer Purchase and Return Decisions and the Implications to E-Commerce Platform Growth

Jisu Cao[1], Sha Yang[2], Chunmian Ge[3], [1]Arizona State University, Tempe, AZ, [2]University of Southern California, Los Angeles, CA, [3]South China University of Technology, Guangzhou, China. Contact: caojisu0319@gmail.com

We study the spillover effects of competing products of different quality tiers on consumer purchases and returns. Although third-party sellers bring revenue to e-commerce platforms, low-tier products may create a negative spillover on purchases and returns for existing ones, thus hurting overall profits. To understand this tradeoff, we developed and estimated a general-equilibrium model of consumers' purchase and return choice and sellers' entry decisions on their products using data from a leading e-commerce platform. We find that one unit increase in low-tier products is related to a .20% increase in return rate. Using counterfactual simulations, we derived important policy implications on consumer purchase and return rate, competition, and profits for platforms under two growth strategies: promoting high-tier entries vs. deterring low-tier entries.

2 Does "meaningful Use Attestation" Improve The Efficiency Of Emergency Department Care

Jingyan Dai, Liangfei Qiu, University of Florida Warrington College of Business Administration, Gainesville, FL, Contact: Jingyan.Dai@warrington.ufl.edu

The Centers for Medicare and Medicaid Services introduced the "Meaningful Use" program in 2009, which offers financial incentives to eligible healthcare providers who use Electronic Health Records (EHRs) in a meaningful way to enhance patient care. In our research, we investigated the effects of EHR utilization, as indicated by the "Meaningful Use Attestation" status of hospitals, on the efficiency of their emergency department care. To conduct our empirical analysis, we employed a staggered difference-in-differences approach using a hospital-level dataset spanning from 2011 to 2017. Additionally, we examined the moderating effects of the "Meaningful Use Attestation" on emergency department efficiency.

3 30 Million Canvas Records Reveal Widespread Sequential Bias and System-induced Surname Initial Disparity in Grading

Jiaxin Pei[1], Zhihan (Helen) Wang[2], Jun Li[2], [1]School of

Information, University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, MI
Through analyzing 30 million Canvas grading records from a large public university, we found a robust and sizable sequential grading bias that assignments graded later tend to 1)receive lower scores 2)be ranked lower in the class and 3)receive comments that are more negative and less polite. Such a bias directly leads to negative outcomes that students graded later 1)are more likely to submit regrade requests and 2) receive lower final course grades. We further show that the grading system design converts the individual-level grading bias into a systematic bias against students with alphabetically lower-ranked surname initials, who constantly receive worse grading outcomes due to lower ranking in the grading queue. Such disparity is significant in a wide range of subjects and is more evident for complex grading tasks with higher workloads and longer average grading time.

4 Cleansing Public Discourse: Are Subreddit Bans Effective?

Xiaoxuan Xu, Feng Mai, Jingyi Sun, Stevens Institute of Technology, Hoboken, NJ, Contact: xxu62@stevens.edu

Shutting down online communities for content policy breaches is a draconian and controversial moderation strategy. This research examines the impact of subreddit bans on the toxicity and bias present in related communities' discussions. Our study shows that these bans can effectively lower explicit toxicity in other subreddits, underscoring the deterrent effect of these stern measures in shaping public discourse. However, we observe that levels of implicit bias appear to rise over time following such bans. This highlights the intricate challenges of mitigating subtler forms of bias in online settings.

Advanced Deep Learning and Modeling Approaches for Time Series and Complex Network Analysis

Community Committee Choice Session

Session Chair: Shouyi Wang, University of Texas at Arlington, Arlington, TX

1 Learning from the Interactions within Complex Networks

Shuo Wang, University of Texas at Arlington, Arlington, TX

Complex networks are prevalent in our society - from nature to engineering infrastructures. Hence, revealing the underlying interactions, especially their dynamic structure, is the key to understanding the nature of targeted complex networks. Here, we adopt dynamic modeling to infer the dynamic interactions of a complex network from massive time-variant data. Several applications will be shown to demonstrate the applicability of this work.

2 A Multi-Modal Deep Fusion Framework of EEG and MEG for Brain Source Imaging

Meng Jiao, Feng Liu, Stevens Institute of Technology, Hoboken, NJ

This paper introduces a Multi-Modal Deep Fusion (MMDF) framework for solving the Electrophysiological Source Imaging (ESI) inverse problem, termed as MMDF-ESI. The framework combines Electroencephalography (EEG) and Magnetoencephalography (MEG) measurements using a specialized deep learning approach. The experiments show that MMDF-ESI provides superior localization accuracy and stability over single modality methods, particularly for larger activation areas and under low signal-to-noise ratio conditions, while enabling more concentrated reconstruction of the brain sources.

3 Prediction of Cannabis Addictive Patients with Graph Neural Networks

Shihao Yang, Feng Liu, Stevens Institute of Technology, Hoboken, NJ

This study explores the use of Graph Neural Networks (GNN) and its variants to enhance brain imaging classification in diverse populations, with data drawn from public neuroimaging databases. Focusing on the functional Magnetic Resonance Imaging (fMRI) data of cannabis addicts versus a healthy control group, we achieved an approximate accuracy rate of 80% in distinguishing the groups, with addicts showing significant functional connectivity alterations. These results underscore AI's potential in brain imaging and public health strategies.

4 An U-Net Based Deep Learning Approach to Predict Voxel Level Treatment Response for Lung Cancer Using 3D PET/CT Imaging Data

Shouyi Wang, Jie Han, University of Texas at Arlington, Arlington, TX

This study proposes a novel approach for predicting voxel-level treatment response in lung cancer patients using 3D PET/CT imaging data. The method is based on the U-Net deep learning architecture, which effectively leverages the spatial information present in the images. By analyzing the PET/CT scans, the model predicts the response of individual voxels to treatment. This approach holds promise for personalized treatment planning and assessment, potentially improving outcomes for lung cancer patients through more targeted therapies.

Community Committee Choice Session

Session Chair: Ruixun Zhang, Peking University, Beijing, China

1 Personalized Pricing, Network Effects, and Corporate Social Responsibility

Yan Xiong[1], Liyan Yang[2], [1]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]University of Toronto, Toronto, ON, Canada. Contact: liyan.yang@rotman.utoronto.ca

We propose a theory of corporate social responsibility by linking it to the firm's product markets. The firm's product exhibits network effects in the sense that the product's value to each consumer increases with the number of consumers. Moreover, with the technology development, the firm can adopt personalized pricing for each consumer. We show that such a firm could use social responsibility as a commitment device for low product prices, which helps overcome the coordination problem among consumers. In this way, the firm's profit function increases, supporting the notion of ``doing well by doing good.''

2 Principal Trading Arrangements: Optimality Under Temporary and Permanent Price Impact

Markus Baldauf[1], Christoph Frei[2], Joshua Mollner[3], [1]University of British Columbia, Sauder School of Business, Vancouver, BC, Canada; [2]University of Alberta, Edmonton, AB, Canada; [3]Northwestern University, Kellogg MEDS, Evanston, IL, Contact: cfrei@ualberta.ca

We study the optimal execution problem in a principal-agent setting. A client (for example, a pension fund, endowment, or other institution) contracts to purchase a large position from a dealer at a future point in time. In the interim, the dealer acquires the position from the market, choosing how to divide his trading across time. Price impact may have temporary and permanent components. There is hidden action in that the client cannot directly dictate the dealer's trades. Rather, she chooses a contract with the goal of minimizing her expected payment, given the price process and an understanding of the dealer's incentives. Many contracts used in practice prescribe a payment equal to some weighted average of the market prices within the execution window. We explicitly characterize the optimal such weights: they are symmetric and generally U-shaped over time.

3 A Spectral Analysis of High-Frequency Information Content

Agostino Capponi[1], Lintong Wu[2], Ruixun Zhang[2], [1]Columbia University, New York, NY, [2]Peking University, Beijing, China. Contact: wltsms@pku.edu.cn

We develop a framework to decompose information content into frequency-specific components and estimate its periodicity using the vector autoregressive model of Hasbrouck (1991) and the spectral framework of Wu, Zhang, and Dai (2022). We find that high-frequency periodicities in information content widely exist, particularly at 10-minute and 5-minute frequencies. We observed a strong correlation between information content periodicity and volumes as well as liquidity measures such as the spread. This supports the informational explanation for the spectral patterns in volumes (Wu, Zhang, and Dai, 2022), and the informational perspective of bid-ask spreads which is charged by market makers to mitigate adverse selection costs (Glosten and Milgrom, 1985).Long-short portfolios constructed based on a periodicity factor yield monthly Fama-French alphas of up to 1%.

4 Who Benefits from Securities Exchange Innovation?

Konstantin Sokolov[1], Andriy Shkilko[2], Eduard Yelagin[1], [1]University of Memphis, Memphis, TN, [2]Wilfrid Laurier University, Waterloo, ON, Canada

Securities markets continuously innovate to keep pace with technology. It isoften debated if such innovation is beneficial, and which market participants capture the benefits. We contribute to this debate by examining liquidity effects of a wide range of proprietary products and services introduced by trading venues in the United States. Exchange innovation is generally associated with liquidity improvements for those investors, who trade in small quantities. The effect is opposite for institutional investors; their trading costs increase, and their market participation declines. Democratizing access to innovation helps mitigate the above-mentioned adverse effects.

1 Multi-Item Order Fulfillment Revisited: LP Formulation and Prophet Inequality

Ayoub Amil[1], Ali Makhdoumi[2], Yehua Wei[3], [1]Duke University - Fuqua School of Business, Durham, NC, [2]Duke University, [3]Duke University, Durham, NC

In this work, we revisit the multi-item order fulfillment model introduced by Jasin and Sinha (2015). Specifically, we study a dynamic setting in which an e-commerce platform (or online retailer) with multiple warehouses and finite inventory is faced with the problem of fulfilling orders that may contain multiple items. The platform's goal is to minimize the expected cost incurred from the fulfillment process, subject to warehouses' inventory constraints. Unlike the classical literature on multi-item fulfillment, we propose an alternative offline formulation of the problem. In particular, in our model, the platform sequentially selects methods to fulfill the arriving orders. A method consists of a set of facilities that will determine which warehouses the items will ship from and, more importantly, whether multi-item orders will be split. Under this formulation, we design a class of dynamic policies that combine ideas from randomized fulfillment, prophet inequalities and subgradient methods for the general multi-item fulfillment model. Specifically, by establishing connections between the fulfillment and prophet inequality literature, we prove that our algorithm is both asymptotically optimal and has strong approximation guarantees in non-asymptotic settings. Our result shows that there is a simple and near-optimal procedure for solving multi-item fulfillment problems once the online retailer has enough inventory, independently of other problem parameters. To the best of our knowledge, this is the first result of this type in the context of multi-item order fulfillment. In addition, and of independent interest, our analysis also leads to new asymptotically optimal bounds for network revenue management problems.

2 Order-Optimal Correlated Rounding for Fulfilling Multi-Item E-Commerce Orders

Will Ma, Columbia University, New York, NY

We study the dynamic fulfillment problem in e-commerce, in which incoming (multi-item) customer orders must be immediately dispatched to (a combination of) fulfillment centers that have the required inventory.A prevailing approach to this problem, pioneered by Jasin and Sinha in 2015, has been to write a "deterministic" linear program that dictates, for each item in an incoming multi-item order from a particular region, how frequently it should be dispatched to each fulfillment center (FC). However, dispatching items in a way that satisfies these frequency constraints, without splitting the order across too many FCs, is challenging. Jasin and Sinha in 2015 identified this as a correlated rounding problem and proposed an intricate rounding scheme that they proved was suboptimal by a factor of at most ≈q/4 on a q-item order. This paper provides, to our knowledge, the first substantially improved scheme for this correlated rounding problem, which is suboptimal by a factor of at most 1+ln(q). We provide another scheme for sparse networks, which is suboptimal by a factor of at most d if each item is stored in at most d FCs. We show both of these guarantees to be tight in terms of the dependence on q or d. Our schemes are simple and fast, based on an intuitive idea; items wait for FCs to "open" at random times but observe them on "dilated" time scales. This also implies a new randomized rounding method for the classical Set Cover problem, which could be of general interest.We numerically test our new rounding schemes under the same realistic setups as Jasin and Sinha and find that they improve runtimes, shorten code, and robustly improve performance. Our code is made publicly available online.

3 Regret Minimization with Noisy Observations

Mohammad Mahdian[1], Jieming Mao[1], Kangning Wang[2], [1]Google Research, New York, NY, [2]Stanford University, Stanford, CA

In a typical optimization problem, the task is to pick one of a number of options with the lowest cost or the highest value. In practice, these cost/value quantities often come through processes such as measurement or machine learning, which are noisy, with quantifiable noise distributions. We study such scenarios using a regret minimization model.

In our model, the task is to pick the highest one out of n values. The values are unknown and chosen by an adversary, but can be observed through noisy channels, where additive noises are stochastically drawn from known distributions. The goal is to minimize the regret of our selection, defined as the expected difference between the highest and the selected value on the worst-case choices of values. We propose an algorithm that gives a constant-approximation to the optimal regret for any n.

4 Inference on the Optimal Assortment in the Multinomial Logit Model

Shuting Shen[1], Xi Chen[2], Ethan Xingyuan Fang[3], Junwei Lu[4], [1]Cambridge, MA, [2]New York University, [3]Duke University, Durham, NC, [4]</sup

Assortment optimization has received active explorations in the past few decades due to its practical importance. Despite the extensive literature dealing with optimization algorithms and latent score estimation, uncertainty quantification for the optimal assortment still needs to be explored and is of great practical significance. Instead of estimating and recovering the complete optimal offer set, decision-makers may be interested in testing whether a given property holds for the optimal assortment, such as whether they should include several products of interest in the optimal set, or how many categories of products the optimal set should include. This paper proposes a novel inferential framework for testing such properties. We consider the widely adopted multinomial logit (MNL) model, where we assume that each customer will purchase an item within the offered products with a probability proportional to the underlying preference score associated with the product. We reduce inferring a general optimal assortment property to quantifying the uncertainty associated with the sign change point detection of the marginal revenue gaps. We show the asymptotic normality of the marginal revenue gap estimator, and construct a maximum statistic via the gap estimators to detect the sign change point. By approximating the distribution of the maximum statistic with multiplier bootstrap techniques, we propose a valid testing procedure. We also conduct numerical experiments to assess the performance of our method.

5 Information Design of a Delegated Search

Yangge Xiao[1], Zhenyu Hu[1], Shouqiang Wang[2], [1]National University of Singapore, Singapore, Singapore; [2]The University of Texas at Dallas, DALLAS, TX

A principal delegates a sequential search to an agent, who bears the search cost and controls when to terminate searching. Upon termination, the search payoff is split between the principal and agent. However, only the principal can evaluate each search outcome. The principal designs an information policy to strategically disclose private outcomes over time to the agent. We show the optimal policy is fully prescribed by a sequence of deterministic *acceptance standards.* The agent is recommended and voluntarily willing to continue the search if and only if the current termination payoff fails to meet that period's standard. When the search results are not recallable, the acceptance standards are informative and determined *recursively* across different periods as the optimal stopping thresholds that the principal would employ should she conduct each search by herself at a *shadow cost*. When the search results are recallable, the optimal policy provides no information and the agent keeps searching up to a *cutoff period*, after which the acceptance standard in each subsequent period is determined *independently* of other periods by equating the agent's search cost with his marginal return from an additional search in that period.

Session Chair: Bahar Viniche, York University, Toronto, ON, Canada

1 Unmanned Aerial Vehicle Routing and Search Planning in a Disaster Area Considering Uncertainty and Equity

Nastaran Oladzadabbasabady[1], Rajan Batta[2], Miguel Lejeune[3], [1]University at Buffalo (SUNY), Buffalo, NY, [2]University at Buffalo (SUNY), Buffalo, NY, [3]George Washington University, Washington, D.C., DC

This work presents an approach to improve routing and searching decisions for a fleet of Unmanned Aerial Vehicles (UAVs) that are in charge of finding victims in a post-incident area. The proposed approach involves two mathematical optimization models: a deterministic model, and a stochastic programming model to address uncertain characteristics of practical humanitarian operations that affect the route and search planning. Due to limited search resources, search operations have great potential for inequities to occur, meaning in some areas, search is conducted with considerably less resources than other areas. In order to ensure equitable assignment of UAVs, innovative equity metrics are integrated into both models. The resulting models enable efficient and equitable decision-making for UAV route and search planning.

2 A Simulation-Heuristic Method for Drone Delivery in Rural Areas

xudong wang[1], Xueping Li[2], [1]The University of Tennessee, Knoxville, knoxville, TN, [2]University of Tennessee, Knoxville, Knoxville, TN, Contact: xwang97@vols.utk.edu

Under the current Covid-19 pandemic, drones greatly improve logistics, especially in rural areas, where inefficient road networks and long distances between customers reduce the delivery capacity of conventional ground vehicles. Besides, charging stations can improve the service range by drones' limited flight range. In this study, we utilize simulation to optimize the drone delivery system design to minimize the cost of the delivery system. As facility siting is usually difficult to optimize, we propose a novel simulation-heuristic framework to find near-optimal solutions. In addition, we conduct a case study using real-world data collected from Knox County, Tennessee, which showed our approach saves 15% on total costs over the benchmark.

3 Tactical Fleet Planning in Drone-Enabled Deliveries

Bahar D Viniche[1], Opher Baron[2], Oded Berman[2], Mehdi Nourinejad[1], [1]York University, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: bahardv@yorku.ca

Last-mile delivery is a time-sensitive and costly leg of the supply chain, requiring innovative delivery methods to recipients. Drones bring substantial value to this sector by avoiding congested road networks and travelling aerial trajectories at higher speeds. We present models of drone-assisted routing strategies in last-mile delivery using parametric design. At the strategic level, adding drones to the fleet requires characterizing the benefits of reducing delivery times. The study bridges the gap of incorporating routing-based operational level constraints, including drone flight range, multi-launching, and coordinating drone trajectories with truck paths. The analysis shows three outcomes, in which the performance of the delivery operations is limited by the capacity of the trucks, the range of drones, or the timing coordination of the trucks and drones.

Optimization for Freight Transportation

Contributed Session

Session Chair: Christian Truden, University of Klagenfurt - Department of Operations, Energy, and Environmental Management, Klagenfurt, Austria

1 Dynamic Berth Allocation Policies in the Deep-Sea Terminals

Behman Orkun Tunay, Erasmus University, Rotterdam, Netherlands. Contact: tunay@rsm.nl

The Port of Rotterdam is a critical gateway for Western European industries in global trade. However, its substantial emissions contribution requires active decarbonization efforts to meet EU targets. Inland waterways play an important role for the modal shift towards a sustainable European transport network but the competition between the deep-sea vessels and the barges for the limited capacity challenges the terminals for their berth allocation policies. This research focuses on evaluating prioritization policies the deep-sea vessels and barges for berth allocation in deep-sea terminals, considering long-term performance and key performance indicators (KPIs) such as berth utilization, vessel throughput, waiting times, barge congestion, and modal split, using queuing networks.

2 An Exact Optimization Approach for Ship Schedule Recovery in Liner Shipping Networks Under Conflicting Objectives

Zeinab Elmi, Bokang Li, Maxim A. Dulebenets, Florida A&M University-Florida State University, Tallahassee, FL, Contact: elmi.zeinab@gmail.com

A variety of unexpected events can disrupt liner shipping schedules. Different ship schedule recovery options can be adopted in response to disruptive events. This study proposes a novel multi-objective model for ship schedule recovery that aims not only to minimize the total late ship arrivals at ports but also to minimize the total profit loss due to disruptive events that may occur at sea and/or at ports. An exact optimization algorithm is presented to obtain optimal Pareto Fronts. The computational experiments conducted for a real-life transit route demonstrate that the proposed exact optimization algorithm is able to generate Pareto Fronts in a timely manner and provide interesting insights.

3 The Relevance of an Enhanced Assessment of Follow-Up Conflicts in the Heuristic-Based Adjustment of Railway Schedules in Real-Time

Arturo Crespo Materna, Cedric Steinbach, Shanqing Chai, Hendrik Speh, Andreas Oetting, Technische Universität Darmstadt, Darmstadt, Germany. Contact: crespo@verkehr.tu-darmstadt.de

The execution of the planned railway operations requires schedule adjustments due to stochastic events. Due to their flexibility and efficiency, heuristic Conflict Detection Conflict Resolution (CDCR) approaches are arguably the most relevant methods to constitute decision-support tools for conducting the schedule adjustment. In CDCR approaches, conflicts are synchronously solved by generating a set of conflict resolution alternatives (CRAs). Only the most optimal CRA is later implemented to resolve the conflict. Therefore, each of the generated CRAs needs to be assessed not only based on their direct impact on the operations but also taking into account the conflicts they may induce on other trains (i.e.

follow-up conflicts). Thus, an assessment function with "look-ahead" capabilities becomes central for ensuring the quality of the adjustment process.

4 The Service Network Design Problem with Fleet and Emissions Management

Christian Truden, University of Klagenfurt - Department of Operations, Energy, and Environmental Management, Klagenfurt, Austria

While hydrogen fuel cell and battery-electric vehicles present opportunities to reduce emissions, effectively integrating their use into operations given range limitations, recharging (refueling) times, and sparse infrastructure requires careful planning. A recognition that the emissions associated with energy production can vary from one region to another is critical. This is also true with respect to the price of both energy and diesel fuel. In this work, we consider fleet management decisions regarding how many vehicles of each type (diesel, battery-electric, hydrogen) a carrier should acquire as well as in what regions they should operate. The impact of these fleet-level decisions on customer service is captured by explicitly modeling the routing of shipments and vehicles while recognizing the consumption of limited onboard resources.

Theory and Application in Queueing Systems

Contributed Session

Session Chair: Akhil Singla, Northwestern University, Evanston, IL

1 On the Output Dynamics of the Discrete-Time M/G/1-Queue

Christoph Jacobi, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany. Contact: jacobi@kit.edu

The departure process of the M/G/1-queue is a point process. However, decomposition methods often assume departure streams to be renewal, which causes approximation errors when analyzing downstream queues. We investigate the auto-correlation of the departure process to find situations where the renewal assumption is not justified. We model the M/G/1-queue as a discrete-time Markov chain and compute the joint probability distribution of two departure instances that are ￼ > 0 instances apart. Numerical results show the effect of auto-correlation on the renewal assumption in decomposition methods.

2 Conic Integer Reformulations for Bandwidth Packing Problem with Queuing Delays

Masoud Amel Monirian[1], ONUR KUZGUNKAYA[2], Navneet Vidyarthi[2], [1]Concordia University, Montreal, QC, Canada; [2]Concordia University, Montreal, QC, Canada

We study the Bandwidth Packing Problem with Queuing Delay Cost (BPP-QDC) that arises in telecommunication networks. The decision in BPP-QDC is to choose the calls to accept and assign them on a single path to maximize the revenue on a network with limited link bandwidth. The resulting nonlinear problem has been solved in literature by exact methods of finite linearization and cutting plane algorithm up to a network size of 50 nodes. We present several equivalent reformulations of BPP-QDC as a mixed-integer second-order cone programming model. We further strengthen the proposed reformulations with McCormick and polymatroid cuts. Our results show that the best-proposed reformulation is capable of solving 191 out of 243 instances to optimality for networks with 80 nodes. The proposed polymatroid and McCormick cuts reduce the computation time by 11% and 22%, respectively.

3 A Markovian Continuous Approximation Modeling Forperformance Evaluation Ofbatch Processing on a Single Machine

Mohsen Nikfar, Alexander Vinel, Auburn University, Auburn, AL

This work proposes a modeling approach for performance evaluation of batch processing with sequence-dependent setup times on a single machine. We consider Poisson arrivals of jobs and a maximum for batch size and queue length. A typical existing approach is to assume a known distribution for the processing time of the batch. In contrast, we employ a continuous approximation, which allows us to characterize the full distribution for batch processing time (which is a solution to an instance of random TSP). The resulting model is a semi-Markov process, and we are able to derive expression for its limiting distribution and corresponding performance measures. The model is validated against a Monte-Carlo. We will also present some illustrative case studies.

4 Assessment of Performance of the Production Floor Based on the Impact of the Raw Materials Queue

Shahriar Tanvir Alam[1], Fahima Akter Azrin[2], Abu Saleh Md. Nakib Uddin[2], Moddassir Khan Nayeem[3], [1]University of Southern California, Los Angeles, CA, [2]Military

Institute of Science and Technology, Mirpur, Bangladesh; [3]University of Texas at San Antonio, Texas, TX, Contact: alams@usc.edu
This paper formulates the single server queuing models and provides a performance evaluation. The performance for "*Single Server Finite Queue Length Infinite Queue Population Model*" is most desirable where the raw materials have to wait for less time in the queue (approximately 55.65%) and reduces the queue length by approximately 57.68%. Based on the findings of the queue performance, an ARENA-based simulation has been illustrated to visualize the productivity of the production floor considering the impact of the raw materials queue. The simulation result shows that the implementation of the finding from the assessment of the queue performance increases the output by 2.4 times compared to the present condition.

5 Optimal Control Of Join Decision In Fork-Join Queues

Akhil Singla, Seyed Iravani, Northwestern University, Evanston, IL, Contact: akhilsingla@u.northwestern.edu
In fork-join (FJ) queues, each incoming job is copied to all its parallel servers. The join decision to predict and remove the job from the system is decided by a join server using all or some of the parallel server evaluations. FJ can capture the trade-off of speed and accuracy commonly arises in knowledge-based service systems like fact-checking for social media platforms, hospital diagnosis operations, legal systems. We study the optimal control of join decision in FJ queues. We show that the optimal dynamic join decision policy follows a double score threshold structure and a step-wise threshold structure in system queue sizes. We also propose an intuitive Line Heuristic (LH) that uses a simpler queueing model and performs within 2% optimality gap. To control the complex dynamics of FJ queues, we simply suggest decision makers to control the number of jobs in the system.

1 Valuation of a Sequential Compound Option Considering Generation and Transmission Expansions

Gazi Nazia Nur, K Jo Min, Iowa State University, Ames, IA
This study addresses an electric power decision-maker who has to decide on generation expansion in the short run and transmission expansion in the long run. To aid the decision-maker, we model an electrical expansion problem using a sequential compound option which includes a generation addition option followed by a transmission line addition option. Electricity demand is uncertain, and we assume it follows geometric Brownian motion. When demand increases, it creates a necessity for additional generation capacity. The network often needs a new transmission line to circulate this additional electricity. Thus, the demand and existing elements in the network influence later expansion decisions. We calculate the option value based on the benefit of the added components, and the benefit is determined from the reduction in locational marginal price after the supplements.

2 Using Real Option to Evaluate a Cap and Floor Compensation Model for a DC Connection Between ERCOT and the Western Grid

LUIZ BRANDAO[1,2], James S. Dyer[3], [1]PUC-Rio, Rio de Janeiro, Brazil; [2]University of Texas at Austin, Austin, TX, TX, [3]University of Texas-Austin, Austin, TX, Contact: brandao@iag.puc-rio.br
We will describe the use of real option pricing concepts to value a proposed transmission line linking the electric power grids in ERCOT (Texas) and the Western Interconnection (California and the West Coast). This study will examine novel pathways for the financing of transmission assets, including a cap and floor cost recovery system such as those used for inter-grid facilities in Europe and for major infrastructure projects in other countries. These cap and floor compensation models have characteristics similar to call options and put options on uncertain stock prices, and their value can be estimated in much the same way.

3 Abnormal Detection Using Two-Stage Method in Combined Power Plant

Yunhee Kim[1], Suk Joo Bae[2], [1]Hanyang University, Seoul, Korea, Republic of; [2]Hanyang University, Seoul, Korea, Republic of. Contact: yuuun@psm.hanyang.ac.kr
The paper presents a two-stage model for detecting abnormal events in complex systems using time series clustering and the Mahalanobis distance. Stage one involves clustering sensors with similar patterns using a DTW-based time-series clustering algorithm. A health indicator is then computed for each cluster using PCA and the Mahalanobis

distance. In stage two, the Mahalanobis distance calculates an abnormal score for each data point, and points exceeding a predefined threshold are flagged as abnormal. The method was evaluated using real-world power plant data, showing superior accuracy and efficiency compared to existing techniques. This approach has the potential to reduce computational resources needed for abnormal event detection, making it promising for real-world applications.

4 An Efficient Learning-Based Solver for Two-Stage DC Optimal Power Flow with Feasibility Guarantees

Ling Zhang, Daniel Tabas, Baosen Zhang, University of Washington, Seattle, WA, Contact: lzhang18@uw.edu

Two-stage stochastic DC optimal power flow (OPF) problems are computationally challenging to solve due to the large number of scenarios needed to accurately represent the uncertainties. We propose a learning method to solve two-stage problems efficiently and optimally. A technique called the gauge map is incorporated into the learning architecture design to guarantee the learned solutions' feasibility to the network constraints. That is said, the second-stage decisions are approximated by feed-forward functions that only output feasible solutions. Simulation results on standard IEEE systems show that, compared to iterative solvers and the widely used affine policy, our proposed method not only learns good-quality solutions but also accelerates the computation by orders of magnitude.

1 Distributionally Robust Linear Quadratic Control

Bahar Taskesen, EPFL, Lausanne, Switzerland

We consider a generalization of the classic Linear-Quadratic-Gaussian (LQG) control problem, where the noise distributions are unknown and belong to Wasserstein ambiguity sets. The objective is to minimize a worst-case cost across all distributions in the ambiguity set. We prove that a control policy that is linear in the observations is optimal for this problem. We also propose an efficient Frank-Wolfe algorithm that efficiently identifies the least-favorable distributions within the Wasserstein ambiguity sets and then computes the controller's optimal policy using Kalman filter estimation.

2 Large Deviations and Metastability Analysis for Heavy-Tailed Dynamical Systems

Xingyu Wang, Northwestern University, Evanston, IL

We propose a framework integrating large deviations and metastability analysis of heavy-tailed dynamical systems. Applying it to heavy-tailed stochastic difference/differential equations, we provide sample path large deviations and first exit time analysis, offering the heavy-tailed counterparts of the classical Freidlin-Wentzell and Eyring-Kramers theories. Moreover, our results systematically characterize the intricate phase transitions in first exit times and an intriguing global behavior under truncated heavy-tailed dynamics that sheds light on the generalization mystery in deep learning.

3 Dynamic Resource Allocation: Spectrum of Achievable Performances and Algorithmic Design Principles

Akshit Kumar, Columbia Business School, New York, NY

This work explores the impact of distributional assumptions on algorithmic performance in dynamic resource allocation problems. We identify a novel fundamental driver of regret character showing that polynomial regret is unavoidable. We introduce the Conservativeness with respect to Gaps (CwG) principle and propose the Repeatedly Act using Multiple Simulations (RAMS) algorithm, achieving near-optimal performance. Our findings are in sharp contrast to existing guarantees and provide insights into the fundamental drivers of algorithmic performance in resource allocation.

1 Getting Away with More Network Pruning: From Sparsity to Geometry and Linear Regions

Junyang Cai, Bucknell University, Lewisburg, PA

In this work, we explore how sparsity also affects the geometry of the linear regions defined by a neural network, and consequently reduces the expected maximum number of linear regions based on the architecture. We observe that pruning affects accuracy similarly to how sparsity affects the number of linear regions and our proposed bound for the maximum number. Conversely, we find out that selecting the sparsity across layers to maximize our bound very often improves accuracy in comparison to pruning as much with the same sparsity in all layers, thereby providing us guidance on where to prune.

2 Retail on Autonomous Wheels: A Time-Sensitive Traveling Salesman Problem

Zhuolun Dong, University of Texas at Austin, Austin, TX

Wheeled vending stores are emerging in cities. We study a retail paradigm where a wheeled store transverses across an urban district, seeks suitable locations to perch at, and serves local demand. We propose a "time-sensitive TSP", which generalizes the TSP by incorporating three time-sensitive factors: service busyness, demand tardiness, and product freshness decay. We build the upper and lower bounds of the optimal reward in the asymptotic regime using the continuous approximation approach. Our findings suggest that mobile retail has the potential to become a more profitable paradigm.

3 Cornell University Uses Integer Programming to Optimize Final Exam Scheduling

Tinghan Ye, Georgia Institute of Technology, Atlanta, GA

This paper presents an integer programming framework for final exam scheduling at Cornell University. Assisting the University Registrar over three consecutive semesters, the flexible framework accommodates diverse constraints, including front-loading large courses and excluding specific time slots within the exam period. The flexibility to generate multiple schedules with different model variants facilitates trade-offs in varying levels of exam conflicts. Results showcase significant time and effort savings for the university administration while enhancing student and faculty satisfaction.

The Importance of Mentorship in OR/ Analytics Fields

Community Committee Choice Session

Session Chair: Gabriela Gongora-Svartzman, Carnegie Mellon University, Pittsburgh, PA

1 Accompaniment: Experiences in Mentoring People Into and Through a PhD

Chris Ryan, Sauder Business School

I will discuss my experiences in accompanying undergraduate students in their decision to apply for a PhD, go through a PhD program, and ultimately graduate and find academic positions.

2 The Impact Of Mentorship Advice In Coding Project Courses

Gabriela Gongora-Svartzman[1], Larry Heimann[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: ggongora@cmu.edu

Engagement and mentorship with students is a topic of great interest to universities, and with proper structure, software project courses provide a good avenue to make these connections between mentors and students. Knowing that mentors have different styles and provide advice in a broad spectrum of areas, the question arises as to what type of mentoring has the most significant impact. This study analyzed the communication patterns between mentors and teams using data collected from bi-weekly mentoring meetings and final project evaluations. Findings suggest that mentoring advice can positively impact project outcomes. Sentiment analysis shows that mentors who provided neutral advice had a lower impact on project outcomes than mentors who gave a mix of positive and negative advice. These findings suggest future steps to improve mentorship in analytics fields.

3 Mentoring New Faculty Members in a Liberal Arts Setting

Richard Forrester, Dickinson College, Carlisle, PA

In this talk, we discuss the nuanced and distinct aspects of mentoring new tenure-track faculty members in a liberal arts setting. The liberal arts environment requires a unique approach compared to research-focused institutions, and we will examine best practices for guiding new faculty towards achieving tenure, including excellence in teaching, scholarship, and service. Additionally, we will examine how new faculty can fully embrace the academic lifestyle, while providing guidance on advising students and integrating within the campus community.

4 Purposeful Pathways: Mentoring Undergraduates

Kevin Hutson, Furman University, Greenville, SC, Contact: kevin.hutson@furman.edu

At Furman University, we have embarked on an intentional plan of mentoring called Pathways to help undergraduates find their purpose. The first two years are designed to help students adjust to college and explore its opportunities. The final two years are designed to help students specialize in their chosen fields and transition to what is next. This talk focuses on mentoring in the final two years by helping students explore their desired interests through undergraduate research and internships. We discuss how to find the right project for each student and how to develop the foundational skills needed to help them succeed for their chosen pathway. We also talk about developing relationships with industry partners to provide real-world experiences for students to further develop their skills.

Healthcare Operations

Contributed Session

Session Chair: Taranga Datta, ndian Institute of Management, Kolkata, India

1 Dynamic Incentive Design in the Medicare Shared Savings Program

Xinyue Fei[1], Frank Y. Chen[2], WEI ZHANG[3], [1]City University of Hong Kong, Hong Kong, Hong Kong; [2]City University of Hong Kong, Tat Chee Avenue, Hong Kong; [3]Zhejiang University, Hang Zhou, China. Contact: xinyuefei2-c@my.cityu.edu.hk

The Medicare Shared Savings Program (MSSP) has shown modest progress and an incentive-participation dilemma since its inception. This work redesigns the MSSP contract from a long-term perspective, considering providers' heterogeneity, private information, random savings generation, and uncontactable efforts. We construct optimal and approximated contracts, justifying the current contract form with differential tracks while refining the sharing rates and benchmarks to resolve the incentive-participation dilemma. It also suggests how to set appropriate targets in the healthcare pay-for-performance reform to prevent the ratchet effect. We show how the ratchet effect erodes healthcare performance and sustainability in the long run, suggesting the curse of public extracting provider efficiency developed from experience.

2 Personalized Disease Screening Decisions

Ali Hajjar[1], Oguzhan Alagoz[2], [1]MBSC of Business and Entrepreneurship, KAEC, Saudi Arabia; [2]University of Wisconsin-Madison, Madison, WI, Contact: hjaar@wisc.edu

The needs of patients with multiple chronic conditions (MCC) are poorly addressed by the clinical practice guidelines. We develop a stochastic modeling framework to personalize the disease screening decisions for patients with or at risk of developing a chronic condition. We present our framework by personalizing breast cancer screening for women with diabetes using our modeling framework. We uncover some crucial policy insights that the prior medical community did not acknowledge. We find some important policy insights that were not recognized before by the medical community.

3 Navigating Pharmacy Access: An Agent-Based Simulation of Consumer Preferences

Md Morshedul Alam, Lihui Bai, University of Louisville, Louisville, KY

Through a novel approach of combining Agent-Based Simulation and a Mixed Multinomial Logit (MMNL) model, this research studies consumer preference and decision making in choosing community pharmacies, considering both individual-specific and pharmacy-specific characteristics. The results, by analyzing choice probabilities and health-seeking behaviors, will provide insights to design efficient community pharmacy networks that promote improved accessibility and utilization of community pharmacies, therefore optimizing public health outcomes.

4 Understanding Factors Influencing Patient Resistance to Teleconsultation

Taranga Datta[1], Narain Gupta[2], Sumanta Basu[1], [1]Indian Institute of Management Calcutta, Kolkata, India; [2]MDI Gurgaon, Gurugram, India. Contact: tarangad18@iimcal.ac.in

In our research, we analyze the resistance behavior exhibited by both potential adopters and current users of teleconsultation. This resistance poses a significant barrier to the widespread acceptance of technology-driven innovations in healthcare, including teleconsultation services. We draw on a mixed-methods approach to study the factors leading to resistance. Our analysis combines quantitative surveys and qualitative interviews, offering a comprehensive view of patient resistance. We operationalize a conceptual model comprising barriers to the use of tele-consultation by the individual patients. The findings are significant for both healthcare providers as well as policymakers, with an aim to enhancing teleconsultation adoption and ultimately improving healthcare accessibility and delivery.

Pandemic Management Applications

Contributed Session

1 Epidemic Dynamics of Network in Determining Optimal Human Mobility

ADEOLA C. ADEGBEMIJO[1], Oyekanmi Olatunde[2], Ademola Adedoyin[3], [1]State University of New York at Binghamton, Binghamton, NY, [2]State University of New York at Binghamton, Binghamton, NY, [3]State University of New York at Binghamton, Johnson City, NY, Contact: aadegbe1@binghamton.edu

Epidemics are a severe public health concern due to their ability to cause widespread illness, death, and economic disruption. The emergence of new infectious agents, such as the COVID-19 pandemic, has highlighted the need for effective intervention strategies to control the contagion dynamics. This research presents a network agent-based model to simulate the spread of infectious diseases in two spatial regions under different lockdowns. It uses data science techniques to predict the dynamics of the SIRS-RE model and explore the optimal frequency of interactions between individuals to reduce the effect of infectious diseases.

Session Chair: Weimar Ardila, University of Kansas, Lawrence, KS

2 Optimal Social Distancing Policy Under Partial Social Compliance

Hyelim Shin[1], Taesik Lee[2], [1]KAIST, Daejeon, Korea, Republic of; [2]KAIST, Daejeon, Korea, Republic of

Epidemics pose a significant global threat, and controlling their spread requires effective policies such as social distancing. As it can result in substantial social and economic costs, it is important to design a social distancing policy that balances its benefits and costs. Another factor to consider is the social feedback from community members, as pandemic fatigue can decrease compliance with the policy, negatively impacting its effectiveness. This study proposes a single-leader multiple-followers Stackelberg game that captures the relationship between policymaker, who sets the policy, and community members, who adjust their behavior accordingly. Observations on the optimal social distancing policies demonstrate the importance of considering the community members' compliance and offer practical insights into effective social distancing policy design.

3 Strengthening Community Resilience in Pandemic Mitigation: A Continuous-Time Markov Decision Model Approach

Weimar Ardila Rueda[1], Alex Savachkin[2], Daniel Hernando Romero Rodriguez[3], [1]University of Kansas, Lawrence, KS, [2]University of South Florida, Tampa, FL, [3]Universidad del Norte, Barranquilla, Colombia. Contact: weimar@ku.edu

In the face of a pandemic outbreak, effective mitigation strategies are crucial to minimizing human losses and maintaining essential services. However, depending only on a well-matched pandemic strain vaccine may not always be feasible. In such cases, non-pharmaceutical interventions (NPIs) are vital in reducing contact between infected and uninfected individuals. Nonetheless, implementing aggressive NPI measures can have significant economic implications for communities. To address this challenge, we propose a stochastic dynamic optimization model based on an infinite horizon Continuous-Time Markov Decision Process. This approach balances intervention investment and community resilience improvement. Specifically, we aim to reduce the initial performance drop during the post-disruption response.

Session.Location:CC-West 213B

Topics in Healthcare

Contributed Session

Session Chair: Joseph Mollick, Texas A&M University - Corpus Christi, Corpus Christi, TX

1 A Precise Nursing Training System Integrating Conversational Artificial Intelligence and Mixed Reality

Kamelia Sepanloo[1], Yijie Chen[2], Young-Jun Son[1], [1]Purdue University, West Lafayette, IN, [2]University of Arizona, Tucson, AZ, Contact: ksepanlo@purdue.edu

Using mixed reality technology, we have developed a nursing training system that creates scenarios with different digital patients and symptoms, allowing nurses to practice interactions with digital patients in a safe, controlled, and realistic environment. In addition, the system is augmented with a conversational artificial intelligence (AI) model that allows the nurse to have regular conversations with a digital patient to practice communication and empathic skills, as well as to learn how to provide appropriate care and treatment. In this work, we delve deeper into our conversational AI model and the natural language processing methods to improve language comprehension, including text classification using feed forward and convolutional networks, part-of-speech tagging using maximum entropy Markov models, and local and global models for dependency parsing.

2 Managing Patient Safety Culture for Healthcare Organizations: An Exploratory Study with Correspondence Analysis at Cheng Ching General Hospital

Seung-Hwan Km[1], Shao-Jen Weng[2], Hsin-Hung Wu[3], Chih-Hsuan Huang[4], Wan-Lin Hsieh[5], Pao-Sheng Shen[5], Yii-Ching Lee[6], [1]Embry-Riddle Aeronautical University, Prescott, AZ, [2]Tunghai University, Taichung City, Taiwan; [3]National Changhua University of Education, Changhua City, Taiwan; [4]Hubei University of Economics, Wuhan City, China; [5]Tunghai University, Taichung, Taiwan; [6]Cheng Ching General Hospital, Taichung City, Taiwan

We investigate the relationships that the various safety characteristics have with gender, age, and workplace of medical staff in relation to patient safety culture. An exploratory study was performed by using the correspondence analysis with nine patient safety characteristics from the Chinese version of SAQ (Safety Attitude Questionnaire). The results showed Hospital Management Support for Patient Safety, Teamwork across Hospital Units, and Hospital Handoffs and Transitions showed significant relationships with the gender and age of employees, while Safety Climate, Stress Recognition, Hospital Management Support for Patient Safety, and Teamwork across Hospital Units resulted in significant relationships with the workplace and age of employees. We provide some implications to improve the patient safety culture of an organization.

3 Social Media Addiction, Its Effects on Addicts, and Its Relevance to Businesses: A Literature Review

Joseph Mollick, Texas A&M University - Corpus Christi, Corpus Christi, TX

We try to understand how individuals' social media addiction relates to business strategies. We analyze scholarly journal articles to classify the victims of this addiction based on dimensions such as demographics, sexual orientation, technostress, and social capital. We identify the effects of this addiction on one's contentment, job performance, achievements, community engagement, sense of belonging, habits, fatigue, anxiety, depression, emotions, and wellbeing. We identify businesses that are beneficiaries of individuals' addictive use of social media and generate relevant hypotheses.

1 Improving Adversarial Robustness Through The Contrastive-guided Diffusion Process

Yidong Ouyang[1], Liyan Xie[1], Guang Cheng[2]; [1]The Chinese University of Hong Kong, Shenzhen, China, [2]University of California, Los Angeles, USA

Robust learning requires a significantly larger amount of training samples compared with standard classification. Therefore, how to improve the sample efficiency of synthetic data for the downstream task is of great importance. In this paper, we first analyze the optimality condition of synthetic distribution for achieving improved robust accuracy. We show that enhancing the distinguishability among the generated data is critical for improving adversarial robustness. Thus, we propose the Contrastive-Guided Diffusion Process (Contrastive-DP) to guide the diffusion model. We validate our theoretical results using simulations and image datasets.

2 Calibrating A Car-following Model To Capture Impacts Of Connected And Automated Vehicles On Human-driven Vehicles

Zhitong Huang, John Hourdos; Leidos, USA

The impacts of vehicle automation systems (VAS) on transportation operations must be accurately assessed to support different transportation agencies in preparing for the deployment and adoption of VAS technology. To this end, we calibrate the Intelligent Driver Model (IDM) using field data from a data collection project, which involved SAE level 1 and 2 VAS-equipped vehicles. Statistical testing confirms significant behavioral differences between human drivers interacting with VAS and those driving conventional vehicles.

We also employ a machine learning-based methodology to refine the IDM model calibration to investigate changes in human driver behavior when interacting with VAS

3 Improving Urban Sustainability Through Solar Panel Identification On Building Rooftops

Maryam Ahmadi; Clark University, USA

Climate change urgency requires reducing greenhouse gas emissions. Solar power integration is effective, needing detailed information on solar system locations and capacity. High-resolution imagery helps, but manual identification of solar panels is tedious and error-prone. The project develops a CNN model using satellite image processing to identify solar roofs and segment panels accurately. The model aids researchers, governments, and the public in uncovering rooftop patterns, monitoring usage, evaluating incentives, and supporting sustainable city development.

4 Understanding Social Perception, Interactions, And Safety Aspects Of Sidewalk Delivery Robots Using Sentiment Analysis

Yuchen Du, Tho V. Le; Purdue University, USA

This paper conducts an in-depth sentiment analysis of comments on YouTube videos concerning sidewalk delivery robots (SDRs). Through meticulous examination of these comments, we aim to decipher public attitudes, perceptions, and concerns regarding SDRs to effectively guide the progression of SDR-related industries. Utilizing both machine learning and neural network models, we classify manually annotated comments based on their sentiment. Additionally, this research investigates the temporal variation in public viewpoints on technology adoption. By synthesizing and analyzing these findings, we aspire to provide invaluable insights to stakeholders in the SDR sector.

5 Estimating Population Through Remote Sensing: A Novel Multi-Scale Building Classification Approach

Minseok Kim, Yao Zhao; Rutgers University, USA

Even in a data-driven era, reliable, affordable data collection remains a hurdle. Our study uses machine learning in remote sensing, providing a cost-effective census alternative. We offer a novel approach to building detection requiring needs only a binary mask for building footprints, eliminating costly labelling. The process then classifies building types by aggregating results from multi-scale classifiers, trained separately at various zoom levels of satellite images, thereby mimicking human-like thought in image interpretation. Post obtaining building data, our model predicts residential and work population based on building use and volume, derived from shadow-simulated height.

6 Real-time Decision Support For Human-machine Interaction In Digital Railway Control Rooms

Léon Sobrie[1], Marijn Verschelde[2]; [1]Ghent University, Belgium, [2]IÉSEG School of Management, France

In digital railway control rooms, traffic operators can on-the-spot choose to use automation. As these choices are frequently suboptimal, we propose a real-time decision support tool to improve human-machine interaction (HMI) at Infrabel, Belgium's railway infrastructure company. The tool provides predictive and prescriptive analytics on both expected and desirable HMI at the 15-minute level for each workstation. We perform an extensive benchmark for machine and deep learning approaches, with a focus on both accuracy and explainability. To obtain prescriptions, we compare the predictions of HMI with their desirable counterparts.

7 Federated Cooperative Multimodal Data Fusion

Mohammad Amini; University of Florida, USA

Multimodal data fusion is a technique that combines data from multiple sources to gain a comprehensive understanding of complex systems. However, multi-modal data is often decentralized, and sharing sensitive data can compromise individual privacy. To address this issue, we propose a cooperative federated multimodal data fusion approach that preserves the privacy of data sources. With a federated approach, computations are performed locally on each dataset without requiring direct access to data. The approach has potential applications in healthcare, finance, and transportation, where sensitive data is involved, to enable more effective and secure collaboration among organizations.

8 A Transformer Network For Longitudinal Modeling Of Low Birthweight Prediction Using A Large-scale Dataset In The U.S.

Yang Ren, Dezhi Wu, Yan Tong, Ana López-De Fede, Sarah Gareau; UNIVERSITY OF SOUTH CAROLINA, USA

Low birthweight (LBW) is a significant health issue causing infant mortality, chronic health problems, and higher healthcare costs. Previous studies proposed machine learning (ML) based LBW prediction models with limitations without incorporating important features derived from pregnant persons' previous delivery history, and thus bringing biases to the ML prediction models with a lower accuracy. We proposed a novel transformer-based model with the capability to model sequential relationships and capture contextual information across delivery history events to improve LBW prediction. Our model is also expected to further expand to other disease prediction applications.

9 Comparative Study Of Distillation-enabled Multi-stage And Other Incremental Learning Methods For Online Process Monitoring In Advanced Manufacturing

Boris Oskolkov, Zhangyue Shi; Oklahoma State University, USA

Incremental Machine Learning (IML) methods are a class of machine learning methods that can be used to train models on streaming data. In this work, we compare the performance of distillation-enabled multi-stage incremental learning (KDeMIL) with other IML for online process monitoring. We evaluate the methods on a real manufacturing process and show that KDeMIL outperforms the other methods in terms of F-score and robustness. Also, we discussed learning capabilities and potential advantages of observed models and considered computational cost.

10 Robust Self-Supervised Deep Tensor Decomposition For Corrupted Time Series Data

Zihan Zhang[1], Ziyue Li[2], Jianjun Shi[1]; [1]ISyE Georgia Tech, USA, [2]University of Cologne, Germany

Classification of time series data in machine learning faces challenges like multivariate properties, spatiotemporal dependencies, and high labeling costs, which reduce precision. Industrial scenarios intensify these with data noise and anomalies. We present Robust Self-Supervised Deep Tensor (RSDT) Decomposition to tackle these. RSDT augments data, then decomposes it into low-rank structures and anomalies, highlighting true data insights. Using contrastive self-supervised learning, RSDT captures class-aware features, tapping into generative networks for latent patterns. RSDT proves robust for time series classification.

11 Survival Of Heart Failure Disease Propensity Model Using Machine Learning

Grace T. Babalola[1], Ademola Adedoyin[1], Adeola C. Adegbemijo[1], Damilola Amire[2], Deborah Aransiola[3], Akintomiwa Akintunde, MD[4], Oluwatunmise D. Halim, RN[2]; [1]State University of New York at Binghamton, USA, [2]East Tennessee State University, USA, [3]Accenture, Canada, [4]Meharry Medical College, USA

Heart failure (HF) is the leading cause of death in the world, but if detected early, are easy to treat. With ML algorithms, EMR data could be analyzed to help detect patterns/associations otherwise undetectable by physicians. This study utilized multiple feature selection techniques with five ML algorithms to classify and predict HF patients' survival. The model precision, recall, and the AUC_ROC was used to evaluate the performance of the various classifiers implemented. Gradient boosting, followed by linear discriminant analysis showed better accuracy in classifying HF patient survival over SVM algorithm. The most important indicators of HF survival are age, cholesterol level, and gender.

12 Business Foot Traffic Prediction Using Graph Neural Networks

Mohsen Bahrami[1], Hasan Alp Boz[1], Selim Balcisoy[2], Alex Pentland[1]; [1]Massachusetts Institute of Technology, USA, [2]Sabanci University, Turkey

Accurately estimating the potential foot traffic for a new business is crucial for location decisions. Leveraging visit patterns and places (POI) datasets, we use a GNN architecture that relies on GraphSAGE neighborhood and POI embeddings. We use 2 stacked GraphSAGE layers to extract the node embeddings in a heterogeneous graph setting. The resulting neighborhood and POI embeddings are concatenated to be fed to 3 linear layers with leakyReLU activation functions to obtain the final logit values. We evaluate the model performance in 2 different urban settings: Monroe County, NY, & Boston MSA. The model yields significant scores of 0.66 and 0.64 AUROC outperforming all baseline models.

13 Analysis Of Factors Contributing To Diabetes-related In-patient Stays In The United States

Ruchi D. Kukde, Aindrila Chakraborty, Jaymeen Shah; Texas State University, USA

This research aims to identify the factors that could reduce the preventable hospitalizations of diabetic patients by examining the 2018 National Inpatient Sample (NIS) dataset. Utilizing this nationwide dataset, this research found that age, demographics, income, insurance policies, severity of illness, and comorbidities are critical and warrant further investigation. The findings suggest diabetes education, awareness, timely screening, and lifestyle changes can reduce diabetes-related complications and lower hospitalizations. The overall goal is to guide healthcare administrators and policy makers to develop initiatives to lower preventable hospitalizations.

14 Implementing Big Data Framework To Evaluate Transportation Infrastructure In Near Real Time And Improve Disaster Response Logistics

Adetola Odebode, Ashlea Bennett Milburn, Haitao Liao, Serhan Dagtas, Xiao Huang, Jose Azucena, Sharafat Hossain; University of Arkansas, USA

Emergency responders are driven by logistical issues like what resources are needed, when and where, and how those resources should be delivered during disaster events. For a disaster response to be successful and effective, situational awareness of the state of the transportation infrastructure along which key movements, such as supply distribution must occur, is crucial. To do this, we develop a framework that uses cutting-edge data analytics tools and techniques to route important resources while taking advantage of social media and other data sources for essential and timely information. We present the work in progress toward implementing this framework using Hurricane Harvey as a testbed.

15 Improving Fairness In Machine Learning With Subgroup Threshold Optimization

Cecilia Ying[1], Stephen Thomas[2]; [1]Queen's University, Canada, [2]Queen's University, Canada

In an effort to improve the accuracy of credit lending decisions, many financial intuitions are now using predictions from machine learning models. However, recent research has shown that the predictions have the potential to be biased and unfair towards certain subgroups of the population. We introduce a new fairness technique, called Subgroup Threshold Optimizer (STO) as a post-hoc adjustment technique to address this. STO works by optimizing the classification thresholds for individual subgroups in order to minimize the overall discrimination score between them. Our experiments on a real-world credit lending dataset show that STO can reduce gender discrimination by over 90%.

16 Integrating Developmental Flight Testing And Crew Served Weapons Using Image Classification

James B. Mackey; US Air Force, USA

The MH-139A, replacement for the UH-1N, is undergoing developmental testing to include integrating crew served weapons. Calculating safe trajectories and limitations on weapons use is time consuming not practical for the compressed testing timeline. Integrating high-speed camera photography with calibration measures and image classification techniques the analysis team developed a methodology to map rotor blade position during handling quality testing to determine blade location during typical engagement profiles. This approach enabled the team to rapidly model the safe employment envelope for the MH-139A crew served weapons and compress the test schedule to meet delivery timelines.

17 Forecasting With Moving Averages Time Series Methods: On The Importance Of The Time Lag

ILIAS NIKOLOPOULOS[1], Konstantinos NIKOLOPOULOS[2]; [1]Royal Lancaster Grammar School, United Kingdom, [2]Durham University, United Kingdom

Time Series Methods have been popular in industry and academia due to their simplicity, computational cost, replicability and yet surprisingly accuracy too; evidenced in many empirical forecasting competitions. Of special interest the Moving Average family of methods with focus on the moving window, and also the (understudied) importance of the calculation 'lag', the t axis difference between the moving average centroid t value and the point in time that the forecast refers to. This is the focus of this research with intuitively appealing results in the M3-competition annual dataset (645 time series) and clear implications for the theory and practice of OR/MS, and respective IS applications.

18 Financial Distress Prediction Using Machine Learning

Minh Nguyen; University of Hawaii, USA

This study explores financial distress prediction for public firms in Vietnam as a transition economy by combining variables from the Altman and Merton model. We employ four machine learning methods, including linear discriminant analysis, logistic regression, support vector machines, and neural networks. Our results show that the models combining the Altman's and Merton's variables outperform those that only use either of these lists of variables in terms of both balanced accuracy and Matthew coefficient correlation (MCC). Moreover, the predictive performances for the case of non-delisted firms are generally better than those for the case of delisted firms.

19 Dynamic Ensemble Weighting

Mohammad Fili, Parvin Mohammadiarvejeh, Guiping Hu; Iowa State University, USA

Complex data structures often require a blend of algorithms to accurately capture the intricate relationship between the response variable and the features. Numerous approaches exist for aggregating a collection of predictive models and harnessing the capabilities of strong learners. Ensemble techniques are one such set of algorithms that merge the predictions from individual learners using weights. However, assigning weights to models without considering the areas of expertise for each learner can result in suboptimal performance. To address this issue, we propose an algorithm that dynamically assigns weights to the learners in a pool, considering the spatial information of data points.

20 A Hybrid Model Approach For New Product Launch Forecast

Yujia Ke, Elenna Dugundji; Massachusetts Institute of Technology, USA

This research initializes a hybrid model to forecast new product launch, which consists of a linear base model and an add-on model. This model can be used for business scenario planning and gives guidance to material, inventory, and financial planning.

21 Multi-agent Reinforcement Learning For Optimal Integrated Operation Of Power Distribution Systems

Jiachen Xi[1], Alfredo Garcia[1], Roohallah Khatami[2], Christine Chen[3]; [1]Texas A&M University, USA, [2]Southern Illinois University, USA, [3]University of British Columbia, Canada

We propose a multi-agent decentralized reinforcement learning approach to efficiently adjust electricity demand, generation, and line power flow in a timely fashion to ensure the reliable operation of the electric power system with uncertainty. By formulating the optimal integrated operation of an interconnected but independently operated distribution system as a bi-level optimization problem, we leverage RL algorithm with a twin-actor-critic structure to determine the optimal policies for flow control between areas (upper level) and demand/generation adjustment inside each area (lower level).

22 Oversampling Multigenerational Families And Immigrant Groups In The New Jersey Population Health Cohort Study

Steven B. Cohen; RTI International, USA

The New Jersey Population Health Cohort Study is the largest study to explore factors that influence health and well-being in the state. More specifically, the study seeks to improve our understanding of how life events and stress affect health and resilience, and identify health disparities encountered by historically disadvantaged groups, multigenerational families, and immigrant groups. To help ensure precision targets for planned analytical investigations are achieved for the overall study and specifically for multigenerational families and immigrant groups, model-based oversampling strategies are employed. This presentation describes the modeling approach and its performance.

23 Causal Graph Discovery From Self And Mutually Exciting Time Series

Song Wei[1], Yao Xie[1], Christopher Josef[2], Rishikesan Kamaleswaran[2]; [1]Georgia Institute of Technology, USA, [2]Emory University School of Medicine, USA

We present a generalized linear structural causal model, coupled with a novel data-adaptive linear regularization, to recover causal directed acyclic graphs (DAGs) from time series. By leveraging a recent Variational Inequality (VI) formulation, we cast the causal discovery problem as a general convex optimization, and develop a non-asymptotic recovery guarantee. We demonstrate the effectiveness of our approach in recovering highly interpretable causal DAGs over Sepsis Associated Derangements (SADs) while achieving comparable prediction accuracy to powerful ``black-box'' models such as XGBoost.

24 Thermodynasmt: A Thermo-dynamic Surface Mount Technology Framework For Predictive Modeling And Component Localization In Reflow Soldering Processes

Abdelrahman Farrag, Jaewoo Kim, Daehan Won, Sangwon Yoon, Yu Jin; Binghamton University, the State University of New York, USA

Addressing thermal control complexities during reflow soldering in SMT, which affect solder joint quality and component self-alignment, ThermoDynaSMT emerges as a pioneering multi-physics framework. By integrating a Physics-Informed Neural Network (PINN) and a hybrid model, ThermoDynaSMT accurately predicts PCB thermal profiles and component displacement vector during reflow. This innovative approach overcomes limitations of previous models, including computational costs, sensitivity to measurement errors, data intensity, and adaptability. Ultimately, ThermoDynaSMT enhances solder joint quality and optimizes assembly, contributing to the advancement of SMT processes.

25 The Daily Question: Engage Students In Your Intro Or Non-majors Course

Matthew A. Hawks, PhD; US Naval Academy, USA

Introducing data science to non-major students is challenging. The daily question offers an unobtrusive way to build student trust, naturally creating an intimate classroom atmosphere. Integrating daily questions with the course content and using ice-breakers increases attentiveness, community, and engagement. Anonymous end-of-term student opinion forms demonstrate initial success.

26 Identifying Key Topics In EV Charging Technology Through Patent Analysis

HeeSeok Moon, Hyunhong Choi; KYUNG HEE UNIVERSITY, Korea, Republic of

In this study, we examine electric vehicle (EV) charging patents to identify key technology trends, maturity levels, and correlations among different topics. Specifically, we employ the Structured Topic Model (STM) which identify latent topics in patent data, enabling us to gain insights about the technological landscape and development trend in the EV charging sector. Our findings showcase major focus areas by country and investigate technology maturity level of identified topics to identify key technological topics. Results of our study can offer valuable insights for policymakers or industry players to develop targeted strategies and investments for the EV charging infrastructure sector.

27 Enabling Privacy-preserving Prediction For Length Of Stay In ICU-A Multimodal Federated-learning-based Approach

Tongnian Wang, Yuanxiong Guo, Kim-Kwang Raymond Choo; The University of Texas at San Antonio, USA

Medical data often sits in data silos due to various regulatory, privacy, and ethical considerations, which complicates efforts to fully utilize machine learning, and may eventually exacerbate health disparities. We propose a Multimodal Federated Learning approach to predict patients' accurate remaining length of stay (LOS) in the ICU using multimodal data in a privacy-preserving manner. By applying our approach to a real-world medical dataset, we demonstrate the predictive power of our approach in the presence of privacy and data governance challenges and the necessity of involving different modalities.

28 Learning To Allocate And Price In Multi-Sided Markets

Landon Butler[1], Yigit Efe Erginbas[1], Kannan Ramchandran[1], Soham Phade[2]; [1]University of California, Berkeley, USA, [2]Salesforce, USA

Many large-scale online platforms, such as on-demand food and grocery delivery services, manage the allocation and pricing of a limited number of goods in a multi-sided marketplace. Participants in the market possess private valuations or reserve prices for all possible transactions, which can be queried through observing whether the participant would accept or reject a potential transaction at a particular price. Combining results from adversarial bandits and dynamic pricing, we propose a revenue-maximizing framework achieving sub-linear regret. Empirical studies based on synthetic and real-world data are presented that corroborate the effectiveness of our framework.

29 Diffusion Models For Mri Images Generation In Alzheimer's Disease

CHENXI YUAN; University of Pennsylvania, USA

Missing data is a significant challenge in medical research and clinical practice. To address the problem of missing MRI data in AD applications, we propose a Diffusion model-based longitudinal structural MRI Imputation framework (DLMI) that relies on conditional generation of a missing image at a single designated visit. Specifically, the DMRI model imputes the missing 3D MRI image by taking the past visit or both past and future visits as conditions during the image generation. We evaluate our method on the ADNI dataset. Experimental results show that our method can generate high-quality individual 3D structural MRI with high similarity to the missing visit's ground truth image.

30 Unpacking The Impact Of Imputation On Fairness

Parian Haghighat[1], Hadis Anahideh[2], Nazanin Nezami[3]; [1]University of Illinois at Chicago, USA, [2]University of Illinois Chicago, USA, [3]University Of Illinois- Chicago, USA

The education sector recognizes the power of predictive analytics to enhance student success rates. However, there are challenges to widespread adoption, including perpetuation of inequalities. Large-scale education data often have missing values, impacting representativeness and accuracy. This study assesses disparities in college-student success prediction, investigating the impact of imputation techniques on fairness. We conduct a prospective evaluation for less biased success estimation. Our analysis reveals that imputation introduces bias if testing follows historical distribution. Addressing societal injustice equalizes observations, and reduces bias.

31 An Empirical Analysis Of Polarization Game Over Social Networks

Xilin Zhang, Emrah Akyol, Zeynep Ertem; Binghamton University, USA

This paper quantitatively analyzes a game over a social network of agents, some of which are controlled by two players who maximize and minimize polarization over this network. Agents' opinions evolve according to the Friedkin-Johnsen model, and players can change only the innate opinion of an agent. The practically motivated constraint on the set of players' choice of agents to be disjoint transforms this simple zero-sum game into a compelling nonzero-sum game. We first analyze the functional properties of this game, and next we analyze the properties of the Nash equilibrium. The modified fictitious play algorithm obtained equilibria in synthetic and real networks.

32 Explanatory Data Analysis: Kpis, Data Visualization And Storytelling

Alan Ferrandiz; Core Analitica Inc., USA

Data analytics is the scientific process of discovering and communicating the meaningful patterns by turning raw data into insights for making better decisions. Most of the time, we focus on the discovery part, also called exploratory data analysis, but we usually forget the importance of effectively communicating these findings to an audience to help them make better decisions. This "last mile" of the data analytics connects data with business needs and is referred to as Explanatory Data Analysis and combines three skills: data, to turn raw data into KPIs, visualization, to visually represent data using dashboards and reports, and storytelling, to create an impact in the audience through stories.

33 Variable Selection For Kernel Two-sample Tests
Jie Wang[1], Santanu Dey[2], Yao Xie[1]; [1]Georgia Institute of Technology, USA, [2]ISyE Georgia Tech, USA
We consider the variable selection problem for two-sample tests, aiming to select the most informative features to best distinguish samples from two groups. We propose a kernel maximum mean discrepancy (MMD) framework to solve this problem and further derive its equivalent mixed-integer programming formulations for linear, quadratic, and Gaussian types of kernel functions. Our proposed framework admits advantages of both computational efficiency and nice statistical properties. Experimental results demonstrate good performance of our framework.

34 Dynamic Treatment Regime By Reinforcement Learning For Precision Public Health In Sequential Decision Environment
Jimi Kim; University of Texas at Dallas, USA
Precision public health initiatives can benefit from personalized intervention strategies based on individual characteristics. Dynamic Treatment Regimes (DTRs) are decision rules that adapt interventions over time based on an individual's response to the action. One of the challenges encountered in this setting is incomplete, observational data. To address this, we utilize Causal Identification inside of a Reinforcement Learning algorithm to estimate the DTR. We explore the potential of using DTRs by RL for precision public health initiatives at the state level in a sequential decision setting and demonstrate the effectiveness of our approach in improving healthcare policies.

35 Flat Minima Generalize For Low-rank Matrix Recovery
Lijun Ding[1], Dmitriy Drusvyatskiy[2], Maryam Fazel[2], Zaid Harchaoui[2]; [1]University of Washington and University of Wisconsin - Madison, USA, [2]University of Washington, USA
Empirical evidence suggests that for a variety of overparameterized nonlinear models, most notably in neural network training, the growth of the loss around a minimizer strongly impacts its performance. Flat minima -- those around which the loss grows slowly -- appear to generalize well. This work takes a step towards understanding this phenomenon by focusing on the simplest class of overparameterized nonlinear models: those arising in low-rank matrix recovery. In almost all cases, we show that flat minima, measured by the trace of the Hessian, exactly recover the ground truth under standard statistical assumptions.

36 Harnessing The Power Of Reinforcement Learning To Optimise Timetable Rescheduling
Xuewu Dai[1], Qi Zhang[2], Zhiming Yuan[3], Yisheng Lv[4]; [1]Northumbria University, United Kingdom, [2]CHINA ACADEMY OF RAILWAY SCIENCES, China, [3]China Academy of Railway Sciences, China, [4]Institute of Automation Chinese Academy of Science, China
Train Timetable Rescheduling (TTR) is a crucial task in the daily operation of high-speed railways (HSR) to maintain punctuality and efficiency in the presence of unexpected disturbances. However, it is challenging to promptly create a rescheduled timetable in real-time. This talk presents a reinforcement-learning method for real-time HSR rescheduling. The TTR problem is transformed into a multi-stage decision process,and a transferable generalised dispatching policy is learnt from a large amount of samples. Extensive experimental results demonstrate the effectiveness of the proposed method.

37 Toward Integrating Operation Research And Machine Learning- A Closed-loop Predict-and-optimize Framework And Its Application In Power Systems
Xianbang Chen; Stevens Institute of Technology, USA
In the widely-used open-loop predict-then-optimize process, machine learnings predict uncertainties, and then the operation research optimizes decisions. However, the prediction generally ignores its impact on the optimization. As a result, we present a closed-loop predict-and-optimize method that can improve the optimization performance by feeding the optimization back to the prediction.

38 **Poster**
Saiara Samira Sajid, Guiping Hu; Iowa State University, USA
Accurate yield prediction is essential in precision agriculture. Soil, weather, and management data can provide valuable information on crop yield. Technological advancement has paved the way to look beyond weather, soil, and management data and obtain genotype information of crop breeds. Including genotype information to predict phenotype has promising outcomes. However, genotype data had many features compared to the number of observations. Our research proposed a CNN-GRU structure to include genotype, weather, management, and soil data for higher yield prediction. The proposed model architecture uses GRU to extract the weather features, and 1D-CNN combines other features into DNN.

39 Efficient Frontier: Introducing A Novel Metric And An Active Learning Bayesian Framework For Cost-effective Multi-objective Manufacturing Optimization
Hamed Khosravi[1], Taofeeq Olajire[1], Ahmed Shoyeb

Raihan[2], Imtiaz Ahmed[2]; [1]WEST VIRGINIA UNIVERSITY, USA, [2]West Virginia University, USA
Optimizing the selection of data collection points is crucial in manufacturing experiments to minimize costs and time while obtaining a comprehensive understanding of the process. This paper introduces a novel data-driven Bayesian optimization framework for efficiently optimizing complex systems with multiple conflicting objectives. The method is evaluated on a real-world manufacturing dataset, showing its superiority in achieving similar manufacturing decisions with reduced costs and time.

40 Fairpilot: An Explorative System For Hyperparameter Tuning Through The Lens Of Fairness

Nazanin Nezami[1], Francesco Di Carlo[1], Hadis Anahideh[2], Abolfazl Asudeh[3]; [1]University Of Illinois Chicago, USA, [2]University of Illinois Chicago, USA, [3]University Of Illinois-Chicago, USA
Despite the potential benefits of machine learning (ML) in high-risk decision-making domains, the nondiscriminatory deployment of ML is not accessible to practitioners. To establish trust and acceptance, democratizing ML tools and fairness consideration are crucial. We introduce FairPilot, an interactive system designed to promote the responsible development of ML models by exploring a combination of various models, hyperparameters, and fairness definitions. FairPilot aims to address the challenge of selecting the "best" ML model by allowing users to select a set of evaluation criteria and then displays the Pareto frontier of models and hyperparameters as an interactive map.

41 Meta-learning In Games

Keegan Harris[1], Ioannis Anagnostides[1], Gabriele Farina[2], Mikhail Khodak[1], Steven Wu[1], Tuomas Sandholm[1]; [1]Carnegie Mellon University, USA, [2]Massachusetts Institute of Technology, USA
In classic game theory focus is on solving a single game in isolation, but strategic interactions often evolve dynamically, leading to many similar games to be solved. To address this, we introduce meta-learning for equilibrium finding, and establish meta-learning guarantees for a variety of games. We obtain convergence rates to equilibria that depend on natural notions of similarity between games encountered, while still recovering the single-game guarantees if the game sequence is arbitrary. We evaluate our algorithms on endgames faced by the poker AI Libratus against human professionals, and find that games with varying stack sizes can be solved significantly faster using our techniques.

42 Learning Predictions For Algorithms With Predictions

Mikhail Khodak[1], Maria-Florina Balcan[1], Ameet Talwalkar[1], Sergei Vassilvitskii[2]; [1]Carnegie Mellon University, USA, [2]Google, USA
A burgeoning paradigm in algorithm design is the field of algorithms with predictions, in which algorithms can take advantage of a possibly-imperfect prediction of some aspect of the problem. We introduce a general design approach for algorithms that learn predictors: (1) identify a functional dependence of the performance measure on the prediction quality and (2) apply techniques from online learning to learn predictors, tune robustness-consistency trade-offs, and bound the sample complexity. We demonstrate the effectiveness of our approach by improving or providing the first learning-theoretic guarantees for bipartite matching, ski-rental, page migration, and job scheduling.

43 An Adaptive Language Model For Chatbots With Reinforcement Learning

Jeremy Curuksu; Amazon, USA
Large language models used in ChatGPT and Alexa are limited by their ability to assess the validity of their own answers i.e., to fall back on a clarification prompt or an "*I don't know*" statement when appropriate. I applied reinforcement learning to optimize fallback selection and adapt to semantic pitfalls of a given LLM in a given interaction environment. In the current example, the agent fulfills intents in < 2 interactions on average in 99% of dialogues, by optimizing when best to ask for clarifications. In multi-agent simulations where the user cooperates, the agent fulfills intents in 1.3 interactions on average in 100% of dialogues.

44 A Multi-stage Feature Selection Model To Recognize Super-agers Using The Structural Brain Magnetic Imaging Resonance - A Uk Biobank Classification Study

Parvin Mohammadiarvejeh, Mohammad Fili, Guiping Hu, Auriel Willette; Iowa State University, USA
Cognitive aging is defined as the longitudinal decline in multiple cognitive processes. Although the decline in cognitive function is considered as a natural process as people get older, adults with preserving and improving cognitive abilities have been observed. In this study on the UK Biobank, we developed a multi-stage feature selection model to discriminate adults with improving versus declining cognitive function using longitudinal structural brain magnetic imaging resonance (sMRI) features. This study

found the most relevant and resilient brain areas in successful cognitive aging. These findings help adults to enhance cognition in their lifetime and mitigate Alzheimer's disease.

45 Online Pricing For Multi-user Multi-item Markets

Yigit Efe Erginbas, Thomas Courtade, Kannan Ramchandran; UC Berkeley, USA

Online pricing has been the focus of extensive research in recent years, particularly in the context of selling an item to sequentially arriving users. However, what if a provider wants to maximize revenue by selling multiple items to multiple users in each round? In this study, we tackle this challenge by designing online algorithms that can efficiently offer and price items while learning user valuations from accept/reject feedback. We focus on three user valuation models (fixed valuations, random experiences, and random valuations) and provide algorithms with nearly-optimal revenue regret guarantees.

46 Improving Classification Performance With Conjecturing System.

Fatemeh Valizadeh Gamchi, Paul Brooks; Virginia Commonwealth University, USA

This study explores a conjecturing system's effectiveness for classification tasks, generating conditions for desired properties. It generates new binary features based on discovered bounds among continuous features by incorporating bounds for each class. To test the approach, a microbiome dataset was used to identify body fluid type. Conjectures were included as predictors in a random forest model, resulting in improved prediction accuracy. Moreover, this system improves interpretability, making it a valuable tool in the classification field.

47 BAYESIAN RISK-AVERSE Q-LEARNING WITH STREAMING OBSERVATIONS

Yuhao Wang; georgia institute of technology, USA

We consider a robust reinforcement learning problem, where a learning agent learns from a simulated training environment. We adopt a formulation of Bayesian risk MDP (BRMDP) with infinite horizon, which uses Bayesian posterior to estimate the transition model and impose a risk functional to account for the model uncertainty. Observations from the real environment arrives periodically and are utilized by the agent to update the Bayesian posterior to reduce model uncertainty. We theoretically demonstrate that BRMDP balances the trade-off between robustness and conservativeness, and develop a multi-stage Bayesian risk-averse Q-learning algorithm with provable performance guarantees.

48 Transformer-based Reinforcement Learning Framework For Job Shop Scheduling Problem

Jaejin Lee[1], Seho Kee[2], Mani Janakiram[2], Mark A Wilkinson[2], George Runger[1]; [1]Arizona State University, USA, [2]Intel, USA

The job shop scheduling problem has a long history and continues to be actively studied due to its wide applicability in the manufacturing and production industry. In this context, we introduce a transformer-based reinforcement learning framework to solve job shop scheduling problems. Our proposed framework is designed to be problem size agnostic, enabling the trained model in less complex environment to solve instances of any complexity efficiently. Through our experiments, we demonstrate that the proposed model significantly outperforms existing dispatching rules on both synthetic instances and public benchmark instances, across a range of complexities.

49 Learning Ensembles Of Interpretable Simple Structure

Gaurav Arwade, Sigurdur Olafsson; Iowa State University, USA

Non-linear machine learning models achieve high performance but lack interpretability, while simple models for complex data may provide poor performance. However, many complex datasets have simple structures where a subset of data is more predictable; and using an ensemble of simple models can improve interpretability and accuracy. Healthcare datasets often have such structures, and interpretability is vital. This presentation defines simple structures and proposes a bottom-up algorithm for identifying them given certain assumptions. Using synthetic data, we demonstrate the algorithm's robustness and its ability to identify natural decision boundaries.

50 Neural Network Based Topic Modeling

Jeongjoon Hwang, Dohyun (Norman) Kim; Myongji University, Korea, Republic of

Topic modeling is a technique used to uncover latent thematic structures within a collection of documents, aiming to identify and extract underlying topics or themes present in the text data. Existing topic modeling methods have been successful in extracting the topics that exist within documents. However, they have the limitation of not being able to extract embedding vectors for the topics. To address this drawback, we propose a novel approach that utilizes neural networks to discover topics within documents and simultaneously extract embedding vectors for these topics. This advancement enables various additional analyses and in-depth exploration of document topics.

51 Clustering Autoregressive Weather Parameters For Validating A Winter Storm Planning System

Tianyu Xu, Jingyu Wang, Tianyuan Liu; Boston University, USA

This poster describes the validation process of a winter storm planning system developed for the MBTA in Boston. It predicts severities associated with ice formation, snow weight, road slickness, and other issues that need resources to address. The system is validated using an hour-by-hour simulation that requires inputs (i.e., historical weather parameters) that are interrelated within each day and autoregressive across hours. Two analytical steps are conducted. First, the statistical features within the historical daily weather data are explored to gain insights into the relationships. Second, a k-means clustering is employed to categorize each weather parameter across hours of a day.

52 How Consecutive ICT Policy Influences Economy In ICT Industry? : Empirical Study With Did Approach In K-unicorn Policy And Its Follow-up Projects

SeYeon Seo, JaeHong Park; Kyung Hee University, Korea, Republic of

The relationship between ICT policy and the ICT economy is a dynamic and on-going process. ICT policy influences economic growth continuously, not just once. Many policies have often sub-projects to support the original policy. However, previous studies have primarily examined the policy effect once and showed how such policy effect has lasted. So, we examine the effect of sub-projects implemented year after year to support an original policy, and how is the ICT economy changing as sub-projects have implemented with difference-in-difference methodology. So, this study contributes to the related literature by examining how the consecutive follow-up policy influences on economy continuously.

53 Adjustment Of Tourist Expenditure: The Role Of On-site Attribute-by-attribute Satisfaction On Tourists' Spending Behavior

GaHyun Jo[1], HoJung Yoon[2], JaeHong Park[1]; [1]Kyung Hee University, Korea, Republic of, [2]Sejong University, Korea, Republic of

Every country has its unique touristic activities (e.g., K-POP in Korea). Depending on tourists' level of satisfaction with activities, they tend to adjust expenditure for each activity. We examine the influence of attribute satisfaction at the destination level on tourist activity expenditure. Using the multiple discrete-continuous extreme value model, we investigate the own- and cross-satisfaction effects on the adjustment of tourist expenditure. We find the positive own-satisfaction effects on expenditure while an asymmetry cross-satisfaction effects on expenditure. This study is distinct from the literature by examining the relations among touristic activities with the MDCEV model.

54 Evaluation Of Rehabilitation Exercise Of Disabled People Based On Machine Learning With Joint Angle Data

Chaeyun Yeo[1], Yongwon Jo[2], Jinhyeok Park[2], Sihu Ahn[2], Sangmin Kim[2], Jungin Kim[2], Sangmin Lee[3], Min-Goo Lee[4], Younghoon Kim[5]; [1]Department of Artificial Intelligence, Kyung Hee University, Korea, Republic of, [2]Department of Industrial and Management Engineering, Korea University, Korea, Republic of, [3]College of Software and Convergence, Kangwoon University, Korea, Republic of, [4]School of Physiology, College of Medicine, Korea University, Korea, Republic of, [5]Department of Industrial and Management Systems Engineering, Kyung Hee University, Korea, Republic of

This study evaluates the physical abilities of individuals with disabilities by analyzing joint angle data obtained from upper limb exercise through a skeleton-based human pose estimation method. Seven machine learning models, including SVM, Random Forest, XGBoost, LGBM, and Catboost, were trained to assess movement performance. The performance of the models was interpreted using SHAP, and the results indicated that LGBM achieved the highest performance. The joint angle data analysis conducted in this study will provide indicators of rehabilitation exercise performance for individuals with disabilities, aiding in the development of effective rehabilitation exercise programs.

55 Multi-branching Temporal Convolutional Network With Tensor Data Completion For Diabetic Retinopathy Prediction

Zekai Wang[1], Suhao Chen[2], Tieming Liu[3], Bing Yao[4]; [1]The University of Tennessee. Knoxville, USA, [2]South Dakota School of Mines and Technology, USA, [3]Oklahoma State University, USA, [4]The University of Tennessee Knoxville, USA

Diabetic retinopathy (DR) is the leading cause of vision loss among working-aged adults. Due to the low compliance rate of DR screening and expensive medical devices for ophthalmic exams, many DR patients fail to seek medical attention until DR develops to irreversible stages. The systematically collected electronic health record (EHR) data provide a great opportunity to develop inexpensive tools for DR detection. This paper proposes a Multi-branching Temporal Convolutional Network with Tensor

Data Completion (MB-TCN-TC) to model the multivariate longitudinal EHRs for DR prediction. Experimental results show that MB-TCN-TC outperforms existing methods.

56 Anomaly Detection In Rotating Machinery:Enhancing The Performance Of The Anomaly Transformer And Robustness To Noise.

Gyucheol Lee[1], Younghoon Kim[2]; [1]Department of Artificial Intelligence, Kyung Hee University, Korea, Republic of, [2]Department Industrial and Management System Engineering, Kyung Hee University, Korea, Republic of

In this study, we conducted an analysis of anomaly detection using rotating machine data. We compared four models, including the Anomaly Transformer for time-series anomaly detection. Our results demonstrate that the Anomaly Transformer exhibited the best performance among the tested models. Furthermore, we proposed a noise-robustness enhancing method for real-world industrial scenarios, addressing challenges in noisy environments commonly encountered in the industry. These findings have significant implications, particularly for the accurate detection and diagnosis of rotating machinery abnormalities in industrial settings.

57 Risk Aversion In A Data-driven Multi-period Inventory Control Problem

Xianghua Jiang; National University of Singapore, Singapore

We study the multi-period risk-averse inventory control problem in a data-driven setting. We adopt the popular nested formulation for risk-averse programs to formulate this multi-period problem and its data-driven counterpart under a coherent risk measure. Our objective is to study the sample complexity bound such that with high probability the data-driven policy is near-optimal, i.e., the relative error of the risk under the data-driven policy compared to the optimal risk is arbitrarily small.

. In this study, we develop a zero-order framework for establishing the complexity bound on the sample sizes to guarantee near-optimality of the data-driven policy with given accuracy levels.

58 Language Models For Parsing Clinical Text In Traumatic Brain Injury

Hayley Falk; University of Michigan, USA

In TBI, brain CT radiology reports contain detailed information regarding injury acuity and severity, which is critically important for clinical decision-making and prognostication. However, most of this information is inaccessible because it is not captured in structured data fields in the electronic health record, thereby necessitating manual extraction through chart review. Chart review requires domain expertise, extensive resources, is error-prone, and difficult to scale. Therefore, we leverage domain-adaptive pretraining to develop a specialized clinical language model to detect the presence of acute traumatic intracranial injury from free-text radiology reports.

59 Higher-order Gradient Play Vs. Nash Equilibrium

Sarah Toonsi, Jeff Shamma; University of Illinois Urbana-Champaign, USA

Learning in games explores how Nash equilibrium (NE) sometimes can be attained through an interactive learning process where players adapt their strategies in response to the evolving strategies of other players. We study higher-order uncoupled learning dynamics in games through higher-order gradient play dynamics. We show that for any game with an isolated mixed-strategy NE, there exist higher-order gradient play dynamics that lead (locally) to that NE. Conversely, we show that for any higher-order gradient play dynamics, there exists a game for which the dynamics do not lead to NE. Finally, we show that some certain mixed-strategy NE necessitate using inherently unstable learning dynamics.

60 Consistent Exploration-exploitation Trade-off In Active Learning Regression With Dirichlet Process Prior

Upala Junaida Islam; Arizona State University, USA

Approaches of active learning usually focus on either exploration or exploitation or use ad-hoc measures to control their trade-off in the design space that may not be optimal. We develop a Bayesian hierarchical approach with Dirichlet process prior to dynamically balance the trade-off as more data are queried. We subsequently formulate an approximate Bayesian computation approach based on the linear dependence of data samples in the feature space to sample from the posterior distribution of the trade-off parameter obtained from the model. Our approach performs better or at least as well as either pure exploration or pure exploitation, and achieves posterior consistency as well.

61 Roadway Safety Models: Before, During And After Covid-19

Ennis Marshall, Ali Shirazi; University of Maine, USA

We conducted an extensive critical review of traffic safety research and the models proposed following the COVID-19 pandemic. We used probe data from freeways in Maine to develop models on the change in roadway speeding following the stay-at-home orders of the pandemic. We then go on to investigate how the odds of crashes were affected in the state of Maine using random effect logistic regression models. The odds of speeding increased in Maine following the onset of the pandemic and continued after that. Data also shows shifts in distribution of speed (especially the average speed). In Maine, we found a strong relationship between the coefficient of variation of speed and crash occurrence.

62 Evaluating The Negative Binomial- Lindley Model For Crash Hotspot Identification

Jhan Gil-Marin, Ali Shirazi; University of Maine, USA

The Negative Binomial (NB) model is the most common model used in safety analyses and evaluations - including hotspot identification. Recently, the Negative Binomial-Lindley (NB-L) model has been proposed as an alternative to the NB. The NB-L model overcomes several limitations of the NB, such as addressing excess zero observations. However, it is not clear how the NB-L model compares with the NB regarding the hotspot identification. This research designs a Monte Carlo simulation protocol to generate a wide range of simulated data characterized by different mean, dispersion, and percentage of zeros. Then, the Full-Bayes NB, and NB-L models were compared for hotspot identification.

63 Evaluating The Performance Of Rumble Strip Installations Using An Empirical Bayes Approach

Jhan Gil-Marin, Ali Shirazi; University of Maine, USA

This research analyzes the effectiveness of rumble strip installations in prevention of roadway lane departure crashes in Maine, U.S. using the Empirical Bayes (EB) approach. The predicted number of lane departure crashes, in the short term, is computed using the regression analysis of count data (with a negative binomial model). Then, the estimated long-term mean of crash is computed using the EB approach, considering the information from the predicted and observed crash data. The results show the effectiveness of rumble strip installations in prevention of crashes.

64 Precipitation Prediction Based On Historical Data Using The K- Nearest Neighbor Method

Sean Guidry Stanteen; University of Texas Arlington, USA

Weather, particularly precipitation, is an environmental condition on which agriculture is wholly dependent. As such, prediction on precipitation and other weather factors is essential to proper management of farming. A non-parametric machine learning method, k-Nearest Neighbor (kNN), is utilized to match historical patterns for short term prediction, and preliminary data testing shows the validity of the methodology. This work is in collaboration with Dr. Xunchang John Zhang, USDA-ARS Grazinglands Research Laboratory, El Reno, Oklahoma.

65 Using Machine Learning To Identify The Initial Planting Date Of Crops

Angela Avila; University of Texas at Arlington, USA

This study focuses on training a neural network to accurately predict the planting date of any given field by leveraging time series leaf area index (LAI) data. Specifically, we utilize LAI data collected in Bushland, TX over a span of 35 years as the basis for our model. Through a third-degree polynomial regression, the LAI time series growth of different crops is fitted, and the resulting coefficients are utilized to train a neural network, enabling estimation of the field's initial planting date. To enhance the effectiveness of the neural network training, our dataset is augmented by creating various third-degree polynomials that mimic the LAI growth patterns of crops.

66 Early Detection Of Healthcare Misinformation: A Novel Transfer Learning Method

Minjia Mao[1], Xiao Fang[1], Xiaohang Zhao[2]; [1]University of Delaware, USA, [2]Shanghai University of Finance and Economics, China

The growth of the internet greatly fuels the spread of misinformation, particularly healthcare misinformation. During the COVID-19 infodemic, the wide dissemination of misinformation about COVID-19 has caused social panic and undermined pandemic response efforts. Existing machine learning-based methods for detecting misinformation require labelled instances. However, there is a scarcity of labeled healthcare information in the early stages of its dissemination due to limited manpower and expertise. In response to this challenge, we propose a novel transfer learning method for early detection of healthcare misinformation by leveraging labelled information from other domains.

67 Bankruptcy Prediction During COVID-19 Outbreak Based On M5P Model Tree

Aqsa Bilal Hussain, Jingchun Sun; Xian Jiaotong University, China, China

The COVID-19 outbreak incapacitated the world and divulged the critical concern of financial risk management. Although there exist numerous research contributions in the financial risk forecasting domain, bankruptcy prediction, in particular, is a remarkable problem to explore for its importance in modern economics. Many works have proposed various methods for predicting financial distress; however, the implementation complexity for the bankruptcy predictions with conventional classification techniques is a major drawback. This paper uses the M5P tree algorithm and decision tree classifier to create a stable model for bankruptcy prediction, transforming it into simple if-then instructions. Tested on firms during the pandemic, the framework achieves over 99% accuracy in forecasting bankruptcies.

68 Machine Learning Enabled Model To Predict Parental Depression Symptoms At Neonatal Intensive Care Units

Fatima Sadjadpour; Virginia Tech, USA

Ten percent of babies born in the United States are admitted to the Neonatal Intensive Care Unit (NICU), which is a stressful experience for parents and makes them twice more at risk of depression. Our objective is to develop a machine learning model to identify parents who are more likely to have depression. Data is from parents of infants admitted to the NICU at Children's National Hospital from 2016 to 2017. Our study uses eight machine learning algorithms to identify the main risk factors of parental depressive symptoms. Risk factors highly associated with parental depression could be targeted for personalized interventions for a more productive screening system in healthcare.

69 A Framework For Selecting Technology For Operational Efficiencies In Crop Cultivation

University Washington, Masha Shunko; University of Washington, USA

We study precision agriculture technologies and their use cases in farm settings. We present a value stream map of crop cultivation cycle to identify the operational decisions that a farmer makes.

70 Spatio-temporal Point Processes With Deep Non-stationary Kernels

Zheng Dong; Georgia Institute of Technology, USA

Point process data has become ubiquitous in modern applications. Recurrent neural networks, while expressive, struggle to capture complex non-stationary dependencies among data. Another type of deep point process adopts neural networks to represent influence kernels. In this study, we take the latter approach and introduce a novel deep non-stationary influence kernel for spatio-temporal point processes. Efficient representation is achieved through low-rank decomposition, while a log-barrier penalty maintains the non-negativity constraint of the conditional intensity. The superior performance of our method is demonstrated on simulated and real data.

71 Machine Learning In Practice: Applications Of The Yolo Model

Dennis Cui[1], Ian Zhang[2], Carol Song[3], Wen Xie[4]; [1]Wayzata High School, USA, [2]Duke University, USA, [3]The Harker School, USA, [4]University of Texas Houston, USA

The recent developments in machine learning and AI have brought significant impacts and challenges for academia and practitioners. The research focuses on how an object detection model You-Only-Look-Once (YOLO) can be utilized to extract the locations of objects for applications in various fields, such as in marketing and security.

72 Gaussian Process Regression For Ragged Data Structure With Application In Mental Health

Youssef Hebaish, Sohom Chatterjee, Lewis Ntaimo, Hrayer Aprahamian; Texas A&M University, USA

We propose an approach for handling ragged data structures by partitioning the original dataset into subsets based on the inconsistent feature. This allows us to construct individual models for each subset. Performance evaluation is carried out using k-fold validation. We consider a mental health application, where Gaussian Process Regression is leveraged to enhance treatment outcome prediction. This framework empowers counselors to determine optimal treatment plans, facilitating evidence-based decision-making and personalized interventions.

73 Is All Well With Your Models?: Strategies To Deal With Concept Drifts

SeongHyun Seo, Dong-Joon Lim; Sungkyunkwan University, Korea, Republic of

This poster presents a concept drift detection method that can give an insight into the situation when the performance of the model deteriorates due to concept drift, auto-modeling may not be carried out effectively. We adopt feature selection and various model update strategies into the baseline algorithm, which is a conventional AL Framework, to detect the concept drift effectively and efficiently. These advanced strategies could successfully detect concept drift in real-world scenarios, and ensure consistent performance, and reliable predictions in dynamic environments.

74 FORECASTING VESSEL TRAFFIC AT THE PORT OF AMSTERDAM

Amina Benhassine, Rohan Alexander, Shobhit K. Yadav, Adriele Pradi, Elenna Dugundji, Thomas Koch; Massachusetts Institute of Technology, USA

Accurate vessel traffic forecasting is a critical factor in achieving smooth towage operations, and thus improving service delivery in ports. This study focuses on forecasting vessel traffic in the Port of Amsterdam on a daily basis. Our results were obtained using an XGBoost model with time series features and exogenous variables, resulting in a 87% accuracy.

75 Enhancing 7 Hospitals' Operations: Ai Decision Support Tool In Action

Kimberly Villalobos Carballo[1], Liangyuan Na[2], Dimitris Bertsimas[1]; [1]Massachusetts Institute of Technology, USA, [2]Massachusetts Institute of Technolgy-Operations Research Ctr, USA

In collaboration with Hartford HealthCare, we develop machine learning models predicting inpatient outcomes, i.e., 24hr/48hr discharge, ICU transfers, mortality and discharge dispositions (AUC 76%-93%). These predictions enable more discharges (10%-29%) and fewer 7/30-day readmissions (p-value <1e-3). We implement an automated pipeline displaying daily predictions with user-friendly software. Over 200 medical staff currently use our tool, resulting in a significant reduction in patient-average length of stay (0.67 days) and projected annual benefits of $55-$72 million for the system.

76 Calibrating Physics-based Process-structure-property Models In Metal Additive Manufacturing

Jiahui Ye[1], John S. Coleman[2], Gerald L. Knapp[2], Matthew R. Rolchigo[2], Alex J. Plotkowski[2], Alaa Elwany[1]; [1]Texas A&M University, USA, [2]Oak Ridge National Laboratory, USA

Uncertainty Quantification (UQ) of physics-based process-structure-properties (P-S-P) linkages can aid the qualification and certification (Q&C) of parts made via metal additive manufacturing (AM). The state-of-the-art facilities at Oak Ridge National Laboratory (ORNL) are leveraged to create a digital twin of powder-based metal AM builds. In this study, we aim to reduce the influence of various input uncertainties on outputs using a Bayesian network to calibrate multi-level surrogates against experimental data. This research was sponsored by the U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Advanced Materials and Manufacturing Technology Office.

77 Consumer Behavior In Boosted Stream Of Livestream

Jingyun Hu; Clemson University, USA

High visibility in livestream is crucial and influencers and brands can enhance their visibility by purchasing increased stream exposure through the platform, this tactic may not always guarantee higher sales. On the one hand, high visibility is associated with increased exposure, as platforms like Douyin actively promote the livestream to a more extensive audience. On the other hand, several factors may prevent high stream visibility from translating to high sales, including poor performance by influencers or suboptimal timing for promotion. Or consumer may become annoyed with the platform for frequently pushing the same livestream. This paper is to investigate this problem.

78 Learning From Unfolding Dynamics: Forecast-driven Adaptive Scheduling In Multi-service Non-stationary Queues

Sohom Chatterjee, Youssef Hebaish, Hrayer Aprahamian, Lewis Ntaimo; Texas A&M University, USA

We consider the problem of scheduling scarce resources in multi-service queues with time-varying demand. As arrivals unfold, future estimates may shift, necessitating a schedule update. By combining optimization techniques with a novel forecasting method that learns from evolving dynamics, we construct adaptive policies. The auto-regressive model can handle limited data, and features period-wise trends and lags, calibrated via a sub-optimization problem. This is complemented by a tractable reformulation scheme to reduce wait times. The case study, conducted on Texas A&M's counseling center, shows the benefits of our approach in enhancing access to vital mental health services.

79 When Foot Prohibition, Do Investors Listen? The Role Of Pandemics Shock In Stock Market Reactions To Capital Efficiency Market

kungCheng ho; Guangdong university of finance and economics, China

This study examines the impact of crises caused by modern health pandemics on price efficiency, proxied by measures of stock price delay. We analyze 381,688 firm-year observations across 39 countries during six recent pandemic crises: SARS (2003), H1N1 (2009), MERS (2012), Ebola (2014), Zika (2016), and COVID-19 (2020). We find that pandemics have a significant positive effect on price efficiency. The results are robust for different analyses. In addition, these findings support regulator confidence, confirming that sound regulations and maintaining national stability effectively enhance the impact of price efficiency on the capital market.

80 Machine Learning Modeling For All-types Hospital-acquired Conditions For Elderly Adults With Multiple Chronic Conditions In Texas

Ajit Appari[1,2]; [1]Boston University, USA, [2]Northeastern University, USA

Prior research often focused on building machine learning models for specific Hospital-acquired condition (HAC) among elderly population with specific anchor chronic disease. My study develops composite risk prediction model for all-type HACs among working age adults with multiple chronic conditions (MCC) using all payer administrative data on 1,108,349 hospitalizations (age: 65-90+yrs) during 2015Q4-2016Q4 across 627 hospitals in Texas. I developed Poisson regression model (with random effects) for HACs count with predictors including MCC patterns {extracted using Bernoulli Mixture model clustering}, patient, hospital, & physician factors adjusting for admission type & time factors

81 Sustainable Traffic Signal Control Model Based On Reinforcement Learning Considering The Ratio Of EVs On The Road

Woong Kang, Gwang-jong Ko, Taesu Cheong; Korea University, Korea, Republic of

With the deepening of climate change, sustainability has become a major topic, leading to an increase in the promotion of Electric Vehicles (EVs) along with policy incentives. We propose a new reinforcement learning-based sustainable traffic signal control model for the Intelligent Transportation System (ITS) considering EVs. Through a comparison with existing traffic signal control models, our model demonstrates superior performance in terms of CO_2 emissions and total waiting time. Furthermore, by comparing the results of signal control with varying EV ratios, we evaluate the influence of EV integration on the reduction of CO_2 emissions and total waiting time in an automated signaling system.

82 Machine Learning-based Metamaterial Structure Generation For Shoe Sole

Ziyang Zhang, Chenang Liu; Oklahoma State University, USA

This research innovatively combines machine learning and metamaterials to design shoe soles based on foot pressure distribution. Customizable metamaterials are integrated with algorithms to tailor better suppport on foot. Prototypes demonstrate improved pressure distribution and comfort compared to conventional soles. The study paves the way for advanced, adaptive footwear.

83 In-app Ads Or Cross-brand Marketing? The Marketing Strategy Of On-demand Platform With Media Service Platform

Xinyue Tan[1], Mingyang Chen[2], Daozhi Zhao[1]; [1]Tianjin Univiersity, China, [2]Henan Univiersity, China

This paper studies the cross-brand cooperation between on-demand platforms and media service platform. We consider the characteristics of the network effect existing at both the on-demand platform's supply and demand and the self-scheduling behavior of on-demand service providers. We examine a game-theoretic structure including the on-demand market (service provider, on-demand platform, and consumer) and the media service market (media platform, and consumer) and construct two models (in-app advertising and cross-brand cooperation) to study the decision-making optimization of platforms and the model-selecting optimization of the on-demand platform.

84 Market Design For The Berth Allocation Problem With Just-in-time Arrivals And Transshipments

Roger Lloret-Batlle; NISCI, China

Berths are a scarce and expensive resource. In case of schedule disruptions, common berth priority rules which do not account vessels' preferences are used. This is economically inefficient and makes the operation of ports less competitive. We present the first mechanism for a secondary market for the Berth Allocation Problem in case of schedule disruptions. Vessels are charged the externality they create to other vessels and the terminal. The mechanism is incentive compatible, individually rational and financially self-sufficient under certain conditions.

85 Diffusion-based Generative Models in Augmenting Additive Manufacturing Layer-wise Images

Emmanuel Yangue; Oklahoma State University, USA

Despite the rapid adoption of deep learning models to additive manufacturing, quality assurance issues continue to be addressed for this technology, with the limited availability of sampling objects for advanced studies. Thus, this study leverages the powerful diffusion generative model, notably the denoising diffusion implicit models (DDIM), for layer-wise generation in FFF AM. The proposed model demonstrates great potential for similarity image synthesis generation addressing sampling issues while maintaining diversity to explore possible new pattern variations. The generated images are improved and evaluated using a two customized kernel inception distance metrics: mKID and KIDIS.

86 System-level Electricity Sector Impacts Of Direct Air Capture Deployment

Aniruddh Mohan, Fangwei Cheng, Chris Greig, Eric Larson, Jesse D. Jenkins; Princeton University, USA

Direct Air Capture (DAC) of CO_2 is energy intensive given the low concentration of CO_2 in ambient air, but offers relatively strong verification of removals and limited land constraints to scale. Here, we use the GenX capacity expansion model to study how deployment of DAC impacts achieving a least cost net-zero CO_2 emissions electricity system. We model a suite of DAC approaches, covering geothermal and natural gas heat based DAC to a fully electric process. We find that even at levelized costs of capture as high as \$1000/tCO_2, DAC at million ton CO_2 removal scale lowers costs compared to a scenario without DAC where grid decarbonization must rely fully on a large buildout of renewables and nuclear energy.

87 A Simulation Based Study For Assessing The Performance Of Production Floor

Shahriar Tanvir Alam[1], Moddassir Khan Nayeem[2], Omar Abbaas[2]; [1]University of Southern California, USA, [2]University of Texas at San Antonio, USA

The performance for "*Single Server Finite Queue Length Infinite Queue Population Model*" is most desirable where the raw materials have to wait for less time in the queue (approximately 55.65%) and reduces the queue length by approximately 57.68%. Based on the findings of the queue performance, an ARENA-based simulation has been illustrated to visualize the productivity of the production floor considering the impact of the raw materials queue. The simulation result shows that the implementation of the finding from the assessment of the queue performance increases the output by 2.4 times compared to the present condition.

88 Impact Of Lane Changing Prediction On Connected Vehicle's Energy Efficiency: A Study On Speed Control

Maziar Zamanpour[1], Michael Levin[2], Zongxuan Sun[2]; [1]University of Minnesota, College of Science and Engineering, USA, [2]University of Minnesota, USA

Optimal speed control in connected autonomous vehicles (CAVs) can provide energy benefits. However, it is likely to increase the gap in front of the controlled CAV, which induces lane changing. This study proposes a modified traffic flow model that predicts lane changing occurrence to enhance the control. The model is derived considering the additional flow during lane changing. An optimal control strategy is then developed, subject to the predicted trajectory. Lane change prediction estimates future speed and gap of vehicles, based on predicted traffic states. The proposed model outperforms standard traffic models, resulting in up to 20% energy savings for prediction 3-5 seconds in advance.

89 Efficiently Charging Fleets of E-bikes and E-scooters

Alyf Janmohamed, Shane Henderson, David B. Shmoys; Cornell University, USA

Shared e-bike and e-scooter systems have grown rapidly raising new challenges around charging. We quantify the efficiency of different charging mechanisms used in real-world systems (e.g. employees swapping batteries, charging stations, crowd-sourced).We model a dockless e-bike sharing system as a closed queueing network. A city is divided into non-overlapping regions, each having 2 queues: charged and uncharged bikes. We formulate and solve a pricing problem to set static prices for trips between regions and provide performance guarantees. We also show the queueing network can be reduced to a 1D open queue. A case study on Minneapolis illustrates the tradeoffs between charging mechanisms.

90 Addressing The Patenting Process Bottlenecks With Blockchain Technology

Afrooz Moatari-Kazerouni; Widener University, USA

The pace of global innovation is ever increasing, with over one million patents granted worldwide every year. Yet the ability to capture a true measurable competitive advantage from the significant investment in patents remains elusive. The purpose of this research is to demonstrate how blockchain technology may help with patent authentication and management. To explore the process of the existing system and its shortcomings, a comprehensive literature review is conducted, and the patenting process is mapped. To overcome the highlighted barriers and limitations, a novel architecture design of the blockchain-enable patenting system is proposed.

91 Credit Based Congestion Pricing: Equilibrium Properties And Optimal Scheme Design

Devansh Jalota; Stanford University, USA

Credit-based congestion pricing (CBCP) has emerged as a mechanism to alleviate the inequity concerns of road congestion pricing - a promising strategy for congestion mitigation - by providing low-income users with credits to offset some of their toll payments. While CBCP offers potential for addressing inequity issues that hamper the viability of congestion pricing, the deployment of CBCP in practice is nascent, and the potential efficacy and optimal design of CBCP schemes have yet to be formalized. To this end, we study the design of CBCP schemes to achieve certain societal objectives and investigate their influence on traffic patterns when routing users in a multi-lane highway with an express lane.

92 Long-distance Electric Vehicle Paths: Online And Offline Path Planning

Ridvan Aksu, Mesut Yavuz; University of Alabama, USA

Electric Vehicle (EV) popularity and market share are rising thanks to their sustainable nature and increase in their efficiency. Yet, long charging times, limited infrastructure, and limited driving autonomy remains as obstacles for a commercial widespread adaptation of EVs. We investigate several heuristic, and math-heuristic methods to generate offline path planning methods and an online recourse procedure to decrease the associated costs, given the non-linear discrete multi-stage stochastic nature of the problem. We achieve significant cost savings when we perform a proactive path planning that anticipates online recourse due to the stochastic nature of the problem.

93 Food Brought By A Robot: How Serving Robot Affects Perceived Naturalness Of Food

Kengo Hayamizu, Yuki Haga, Rina Saito, Naoto Onzo; Waseda university, Japan
Extant research has revealed that serving robots at a restaurant have an impact on service and food quality evaluations by consumers. However, none of the studies have considered the impact of serving robots on perceived naturalness of food. Thus, we conducted online experiments of consumers by showing a picture of an actual serving robot. Two studies demonstrated that the serving robot (vs. human staff) decreases consumers' perceived naturalness of food, which results in the decreased food evaluation. This finding gives practical insights about the way to introduce serving robots in the restaurant business.

95 Rider Scheduling In Last-mile Delivery: Incorporating The Fluctuating Demand And Show-up Rate Dynamics
Moon Yuin, Dong Gu Choi; Pohang University of Science and Technology (POSTECH), Korea, Republic of
Last-mile delivery businesses face challenges in managing rider scheduling due to the fluctuating demand patterns and uncertainties in surrounding rider show-up rates, which differ from traditional employee scheduling problems. This study considers the rider scheduling problem through a two-stage mixed-integer stochastic programming, incorporating the above challenges and demand fluctuations.

96 Efficient Cloud Server Deployment Under Demand Uncertainty
Konstantina Mellou[1], Xiao-Yue Gong[2], Rui Peng Liu[3], Beibin Li[1], Thomas Coffee[3], Jeevan Pathuri[4], David Simchi-Levi[2], Ishai Menache[1]; [1]Microsoft Research, USA, [2]Massachusetts Institute of Technology, USA, [3]Amazon, USA, [4]Microsoft, USA
A main challenge faced by cloud providers is to ensure that they can accommodate the growing demand for compute resources. Towards that goal, providers need to deploy cloud servers agilely for uncertain future demand under many practical business constraints, without incurring unnecessarily large operational costs. In this work, we introduce the cloud server deployment problem, formulate it as a two-stage stochastic program and develop exact algorithms to efficiently obtain an optimal solution. We test our algorithms with real production traces from Microsoft Azure and demonstrate their effectiveness in cost reductions.

97 Dual Dynamic Programming For Stochastic Programs Over An Infinite Horizon
Caleb Ju[1], Guanghui Lan[2]; [1]Georgia Insitute of Technology, USA, [2]Georgia Institute of Technology, USA
We consider a dual dynamic programming algorithm for solving stochastic programs over an infinite horizon. We show non-asymptotic convergence results when using an explorative strategy, and we then enhance this result by reducing the dependence of the effective planning horizon from quadratic to linear. We then apply our algorithms to a class of problems called hierarchical stationary stochastic programs, which can model problems with a hierarchy of decision-making. We show that when the subproblems are solved inexactly via a dynamic stochastic approximation-type method, the resulting hierarchical dual dynamic programming can find approximately optimal solutions in finite time.

1 Ventilation Considerations in Medium- and Short-Term Underground Mine Planning
John Ayaburi; Colorado School of Mines, USA
Underground mines may face schedule disruptions due to the accumulation of heat. Ventilation systems serve as the primary source of fresh air. We develop an integer program to determine the airspeed within a ventilation system that maximizes mine productivity in the medium term, accounting for equipment heat output. We correspondingly provide a mixed-integer quadratically constrained program that

minimizes schedule deviation between medium- and short-term plans and determines the distribution of air across operating mine levels.

2 Fast Mulitilevel Neural Networks to Overcome Bias in Healthcare Applications

Rachel Bennett[1], Talayeh Razzaghi[2]; [1]University of Oklahoma, USA, [2]University of Oklahoma, School of Industrial and Systems Eng, USA

Healthcare datasets often suffer from both class and racial imbalance, which leads to underperforming machine learning models for the underrepresented groups. To overcome the bias, we perform graph coarsening to reduce the size of the data, train a neural network on the resulting balanced dataset, and gradually refine the model using "flip points" that estimate and modify the decision boundary of the trained network.

3 Analysis of Search Time for Target Search Applications Under Different Behavior Policies

Carlos Hurtado; University of Pittsburgh, USA

In search theory, we want to find an object considering: kinematics, detection devices, and optimization of the search. Our goal is to minimize the time to find a hidden object with a static but unknown location. Using sequential decision-making, the agent has to make a trade-off between exhaustive searches(exploration) and efficient searches (exploitation). We provide upper bounds in the expected time for pure exploration, pure exploitation, and multi-armed bandit.

4 Deploying a Robust Active Preference Elicitation Algorithm: Experiment Design, Interface, and Evaluation for Covid-19 Patient Prioritization

Caroline Johnston[1], Patrick Vossler[2], Simon Blessenohl[1], Phebe Vayanos[1]; [1]University of Southern California, USA, [2]Stanford University, USA

Preference elicitation uses AI or optimization to learn stakeholder preferences. The online robust preference elicitation method of Vayanos et al. (2020) outperforms other methods in simulation in terms of learning individuals' true utility. However, it makes multiple assumptions that are hard to verify in reality. We validate the method's performance in deployment using policies for prioritizing COVID-19 patients for scarce resources. We build a platform for preference elicitation and recruit MTurk workers (n = 193) to give preferences via a small number of pairwise comparisons. We show that the robust method recommends a policy with higher utility for 21% more users compared to random queries.

5 The Blockchain Newsvendor: Value of Freshness Transparency and Smart Contracts

N. Bora Keskin, Chenghuai Li, Jing-Sheng (Jeannette) Song; Duke University, USA

Motivated by blockchain applications in the fresh produce industry, we consider a problem in which a retailer faces stochastic and freshness-dependent consumer demand. The retailer can adopt blockchain technology to have more transparency on the freshness of supply. We quantify the value of blockchain-enabled freshness transparency by analyzing the retailer's expected profit growth and food waste reduction brought by adoption. Despite this substantial value for the retailer, blockchain adoption can decrease the supplier's expected profit. Hence, we design a family of smart contracts contingent on a blockchain-based freshness consensus and examine the contracts' win-win propositions.

6 Nonprogressive Diffusion on Social Networks: Approximation and Applications

yunduan Lin[1], Heng Zhang[2], Renyu Zhang[3], Zuo-Jun Max Shen[4]; [1]University of California, Berkeley, USA, [2]Arizona State University, USA, [3]The Chinese University of Hong Kong, China, [4]University of California Berkeley, USA

Our paper proposes a model and a fixed-point approximation (FPA) scheme for characterizing adoption limits in nonprogressive diffusion on social networks. The scheme offers both theoretical guarantee and computational efficiency, with maximal deviation decreasing asnetwork size and density increase, making it suitable for dense networks. It can be applied to applications such as influence maximization and pricing problems. Numerical studiesdemonstrate 1,000 times faster computation time and small approximation error.

7 Quasi-Experimental Designs for Learning Health Systems

Valerie Odeh-Couvertier, Gabriel Zayas-Caban, Amy Cochran, Brian Patterson, Kenneth Nieser; University of Wisconsin-Madison, USA

Learning systems use data to improve operations, with risk prediction algorithms playing a key role in deriving knowledge from data. While these algorithms identify individuals or processes that may benefit from interventions, measuring their impact remains a challenge. We develop a causal inference framework, with specific application to learning health systems, for estimating the average causal effect of intervening according to these continually assessed and updating risk prediction algorithms.

8 Modeling Heavy Machinery in an Underground Mine to Optimize Ventilation

Aaron Swift; Colorado School of Mines, USA

An underground mine ventilation system provides fresh ambient air, and dilutes dust and gases produced by equipment and blasting activity. It is also is one of the largest ongoing costs of an underground mining operation. We investigate impacts from the operation of an electric equipment fleet in order to determine optimal airflow.

9 Predicting Roll Force at a Continuous Casting Steel Mill

Edikan Udofia; Colorado School of MInes, USA

We develop regression model to improve prediction of roll forces in a large, hot-roll steel mill at industrial scale. Based on real-world plant data, we derive information from a constitutive physical model and include variable transformations, variable selection and model comparisons. We show how our model can help inform mill best practice in their scheduling operations.

10 Pharmaceutical Supply Chain Design Under Geopolitical Strain: A Stochastic Programming Approach

Martha L. Sabogal De La Pava, Emily L. Tucker; Clemson University, USA

Pharmaceutical supply chains are global. Suppliers, manufacturing plants, and markets are worldwide, exposing the supply chain operation to geopolitical risks. We propose a two-stage stochastic program to locate manufacturing plants and decide material flows in the presence of geopolitical strains and operational uncertainties, i.e., demand and capacity. We study how geopolitical strains affect location decisions, global shortages, and shortages by income level classification of countries.

11 Deep Learning Classification in Presence of Uncertain Predictors for Medical Decision Making

Maryam Kheirandish, Shengfan Zhang; University of Arkansas, USA

Deep learning classification models are becoming increasingly applicable in healthcare but are also significantly challenging due to the inherent uncertainties in clinical and laboratory test data. These errors are usually presented as sensitivity and specificity measures and do not follow a normal but some discrete distribution. We demonstrate the impact of these uncertainties on predictions and develop a framework to handle and quantify these uncertainties in medical decision-making problems.

12 Clustered Multi-Task Learning for Prediction of Adverse Pregnancy Outcomes

Sun Ju Lee, Gian-Gabriel Garcia; Georgia Institute of Technology, USA

In clinical prediction models, combining individual indicators into a composite outcome can help overcome issues associated with single outcomes such as low predictability and low prevalence. However, this may obscure relationships between predictors and single outcomes. We aim to resolve this trade-off by developing an optimization model to simultaneously cluster related outcomes and learn model parameters for each cluster. We apply our formulation to indicators comprising maternal and neonatal morbidity and demonstrate that our approach can aid interpretability by finding underlying groups of related tasks and deriving an interpretable set of predictors.

Mixed-Integer Programming Approaches to Generalized Submodular Optimization and its Applications

Tutorial Session

Session Chair: Douglas R. Shier, Clemson University, Pittsboro, NC

1 Mixed-Integer Programming Approaches to Generalized Submodular Optimization and Its Applications

Simge Kucukyavuz, Qimeng Yu, Northwestern University, Evanston, IL

Submodularity is an important concept in integer and combinatorial optimization. A classical submodular set function models the utility of selecting homogenous items from a single ground set, and such selections can be represented by binary variables. In practice, many problem contexts involve choosing heterogenous items from more than one ground set or selecting multiple copies of homogenous items, which call for extensions of submodularity. We refer to the optimization problems associated with such generalized notions of submodularity, Generalized Submodular Optimization (GSO). GSO is found in wide-ranging applications, including infrastructure design, healthcare, online marketing, and machine learning. Due to the often highly nonlinear (even non-convex and non-concave) objective function and the mixed-integer decision space, GSO is a broad subclass of challenging mixed-integer nonlinear programming problems. In this tutorial, we first provide an overview of classical submodularity. Then we introduce two subclasses of GSO, for which we propose polyhedral theory for the mixed-integer set structures that arise from these problem classes. Our theoretical results lead to efficient and versatile exact solution methods that demonstrate their effectiveness in practical problems using real-world datasets.

GAMS
Technology Tutorial

1 The Best of Both Worlds - Integrating Python and Gams
Atharv Bhosekar, GAMS Development Corp, Fairfax, VA, Contact: abhosekar@gams.com
Optimization applications combine technology and expertise from many different areas, including model-building, algorithms, and data-handling. Often, the gathering, pre/post-processing, and visualization of the data is done by a diverse organization-spanning group that shares a common bond: their skill in and appreciation for Python and the vast array of available packages it provides. For this reason, GAMS offers multiple ways to integrate with Python on the data-handling side, as well as offering some packages of our own (e.g. GAMS Transfer, GAMS Connect). In this talk, we will explore the benefits of this integration and demonstrate them using a real-world example complete with results on performance.

Fair and Socially Aware Practices in Operations Management
Community Committee Choice Session
Session Chair: Negin Golrezaei, Massachusetts Institute of Technology, Lexington, MA
Session Chair: Qinyi Chen, MIT, Cambridge, MA

1 Group Fairness in Dynamic Refugee Assignment
Daniel Freund[1], Thodoris Lykouris[2], Elisabeth Paulson[3], Bradley Sturt[4], Wentao Weng[1], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Harvard Business School, Cambridge, MA, [4]University of Illinois at Chicago, Chicago, IL
Ensuring that refugees and asylum seekers thrive (e.g., find employment) in their host countries is a profound humanitarian goal, and a primary driver of employment is the geographic location within a host country to which the refugee or asylum seeker is assigned. While recent research shows substantial positive impact by designing algorithms that maximize the average employment across all arriving refugees, we show that the impact of these algorithms can vary widely across key subgroups based on country of origin, age, or educational background. Thus motivated, we develop a simple and interpretable framework for incorporating group fairness into the dynamic refugee assignment problem and design algorithms with substantial improvements in group fairness compared to state-of-the-art algorithms with only small relative decreases (≈ 1%-2%) in global performance

2 Fair Markovian Search
Mohammad Reza Aminian[1], Vahideh Manshadi[2], Rad Niazadeh[1], [1]The University of Chicago, Booth School of Business, Chicago, IL, [2]Yale University, New Haven, CT
We start with the classic Pandora's box model under demographic parity constraints. Due to biases in prior data, group-unaware policies may lead to unfair treatment of groups. Candidates belong to two demographic groups and we constrain the policy to equalize the expected number of selection or opportunities across these groups. We show that optimal fair policy retains the index-based structure of the optimal unfair policy, but potentially randomizes between two policies that are dual-based adjustments of the unfair problem. Next, we consider richer search processes, such as search with rejection and multi-stage search, that can be modeled by joint Markov scheduling (JMS). Imposing general affine and convex ex-ante fairness constraints across an arbitrary number of groups or even individuals, we give a primal-dual algorithm to find the almost fair and optimal policy.

3 From AI Fairness to Justice: The Need for a Governance Ecosystem
Hoda Heidari, Carnegie Mellon University, Pittsburgh, PA
In this talk, I will provide an overview of the field that has come to be known as Fair AI. I will highlight the evolution of the field from narrowly-defined outcome-focused notions of fairness to broader conceptions of equity, procedural fairness, and societal justice and argue that the just use of AI in socially high-stakes domains will require strengthening the governance ecosystem around these technologies. I will unpack what that could look like and how researchers and educators can contribute to this effort positively.

4 Interpolating Item and User Fairness in Recommendation Systems

Jason Cheuk Nam Liang[1], Qinyi Chen[2], Negin Golrezaei[3], Djallel Bouneffouf[4], [1]MIT Operations Research Center, Cambridge, MA, [2]MIT, Cambridge, MA, [3]Massachusetts Institute of Technology, Lexington, MA, [4]IBM, Poughkeepsie, NY

In a multi-sided recommendation system where the platform interacts with diverse stakeholders such as sellers (items) and customers (users), each with their own desired outcomes, finding an appropriate middle ground becomes a complex operational challenge. In this work, we investigate the ``price of fairness'', which captures the platform's potential compromises when balancing the interests of different stakeholders. Motivated by this, we propose a fair recommendation framework where the platform maximizes its revenue while interpolating between item and user fairness constraints.We further examine the fair recommendation problem in a more realistic yet challenging online setting, and design a low-regret online optimization algorithm that preserves the platform's revenue while achieving fairness for both items and users.

5 Socially Fair Clustering and Its Generalizations

Ali Vakilian, Toyota Technological Institute at Chicago (TTIC), Chicago, IL

In center-based clustering (e.g., *k*-means), the clustering cost represents the quality of output and the lower the cost, the better the solution. This has motivated the ***socially fair clustering*** problem: the goal is to select *k* centers that minimizes the maximum clustering cost incurred by any of the *L* pre-specified groups of points in the input. This can be used to select a set of vaccination or polling sites to serve different communities in the population fairly.
In this talk, I present our tight O(log *L*/ log log *L*)-approximation for the problem which exponentially improves over the known O(*L*)-approximation. Moreover, I introduce a generalization of the problem called (*p*, *q*)-fair clustering which is a "relaxed" way of enforcing the fairness requirement and its objective interpolates between the objective of the classic *k*-clustering and that of socially fair clustering.

New Applications and Theory in Revenue Management

Community Committee Choice Session

Session Chair: Meichun Lin, University of British Columbia, Vancouver, BC, Canada

1 Context-Based Dynamic Pricing with Separable Demand Models

Jinzhi Bu[1], David Simchi-Levi[2], Chonghuan Wang[2], [1]The Hong Kong Polytechnic University, Hong Kong, Hong Kong; [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: jinzhi.bu@polyu.edu.hk

Motivated by the empirical evidence from the real-world dataset, we consider context-based dynamic pricing with separable demand models. The demand function is endowed with a separable structure in the form of f(p)+g(x), where p and x denote the price and feature vector respectively. Under different structures of f(p) and g(x), we systematically characterize the statistical complexity of the online learning problem. Specifically, we consider three models: (i) f(p) is linear and g(x) is non-parametric; (ii) f(p) is non-parametric and g(x) is linear; and (iii) f(p) and g(x) are both non-parametric. For each model, we design an efficient learning algorithm with a provable regret upper bound and establish an almost matching regret lower bound.

2 Learning to Rank Under Strategic Manipulation in Small and Large Markets

Qinzhen Li[1], Yifan Feng[2], Hongfan Chen[3], [1]National University of Singapore, Singapore, Singapore; [2]NUS Business School, Singapore, Singapore; [3]The Chinese University of Hong Kong, Shatin, China. Contact: qinzhen@u.nus.edu

We consider a dynamic learning and ranking problem for a digital platform that must account for potential manipulation by sellers through "brushing" activities such as fake sales. We formulate an N-seller-T-period dynamic "brushing war" game and provide a (static) budget-competition equilibrium characterization. Further, an approximate mixed-strategy equilibrium is identified for small markets with two sellers. In a large market with a continuum of sellers, we formulate a novel non-atomic game and characterize two extremes of pure-strategy equilibria: no-brushing equilibrium for high brushing cost, and self-reinforcing equilibrium for low brushing cost, both achieving complete learning. We also establish the conditions for demand functions that achieve complete learning for all brushing costs.

3 Algorithms for Loot Box Design

Jiangze Han[1], Christopher Thomas Ryan[1], Xin T. Tong[2], [1]University of British Columbia, Vancouver, BC, Canada; [2]National university of Singapore, Singapore, Singapore. Contact: jiangze.han@sauder.ubc.ca

Loot boxes are a primary source of revenue in the video game industry. Loot boxes randomly “drop” items of differing value. To design a loot box, sellers much choose the purchase price and drop rate (or drop probability) of each item. We show that, in general, the loot box design problem is NP-hard. By restricting the form of player utilities, we can solve the problem exactly in polynomial time when the number of items is fixed. Under different restrictions, we solve the problem approximately in polynomial time with fixed precision. Both restrictions are satisfied by a class of exponential utility functions. Some of our results follow by relating loot box design with selecting prices for each item and selling them directly. Here, we leverage a natural connection between prices and drop rates.

4 Score Approximation, Optimization And Generalization Of Diffusion Models

Yinbin Han[1], Renyuan Xu[2], Meisam Razaviyayn[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: yinbinha@usc.edu

The score-based generative models or diffusion models have achieved huge success in various generation tasks. However, the theoretical foundation of the diffusion models, especially learning the score function through denoising score matching, falls far behind. In this work, we proved the convergence of the optimization and generalization of the denoising score matching with neural network parameterization.

Design and Analysis of Marketplaces

Community Committee Choice Session

Session Chair: Chen Chen, New York University Shanghai

Session Chair: Pengyu Qian, Purdue University, West Lafayette, IN

1 Constant Regret Primal-Dual Policy for Multi-Way Dynamic Matching

Yehua Wei, Jiaming Xu, Sophie Yu, Duke University, Durham, NC

We study a discrete-time dynamic multi-way matching model with finitely many agent types that arrive stochastically and wait to be matched. State-of-the-art dynamic matching policies in the literature require the knowledge of all system parameters to determine an optimal basis of the fluid relaxation, and focus on controlling the number of waiting agents using only matches in the optimal basis (Kerimov et al., 2022a,b; Gupta, 2022). In this paper, we propose a primal-dual policy that schedule matches for future arrivals based on an estimator for the dual solution. Our policy does not require the knowledge of optimal bases, and is the first to achieve constant regret at all times under *unknown* arrival rates. In addition, we show that when the arrival rates are known, the primal-dual policy achieves the optimal scaling as the lower-bound described in (Kerimov et al., 2022a,b).

2 When a Platform Competes with Third-Party Sellers in Networked Markets: A Revenue Management Perspective

Hongfan(Kevin) Chen[1], Hai Wang[2], [1]The Chinese University of Hong Kong, Shatin, Hong Kong, China; [2]Singapore Management University, Singapore, Singapore. Contact: kevinchen@cuhk.edu.hk

We examine a platform marketplace that features both first-party and third-party sellers, with the platform charging commissions to third-party sellers and buyers for transactions. Meanwhile, the platform directly sets prices for first-party sellers in their dealings with buyers. We investigate how the platform’s profit-optimal price-commission decision is influenced by the network structure, which is characterized by complement and substitution of agents’ trading relationships in the marketplace. Furthermore, we develop an efficient $(1-\epsilon)$-approximation algorithm that ensures a fair distribution of surplus between the platform and its market participants in the equilibrium trades, taking into account fairness considerations.

3 Incentivizing Resource Pooling

Pengyu Qian[1], Chen Chen[2], Yilun Chen[3], [1]Purdue University, West Lafayette, IN, [2]New York University Shanghai, New York, NY, [3]CUHK Shenzhen, Shenzhen, China. Contact: qianp@purdue.edu

It is well known that resource pooling can significantly reduce congestion in multi-server queues. However, previous work has focused on centralized systems, and it is unclear whether similar results can be achieved in decentralized systems. We study a decentralized system where servers dynamically and strategically choose when to pool their processing capacity. Our results provide guidance for settings where servers belong to different entities, such as in the promising example of peer-to-peer cloud computing. We propose a simple protocol that uses artificial currency, and study an infinite-horizon stochastic game with multiple servers. We consider the mean-field equilibrium and explicitly characterize each server's optimal decision. We show that (surprisingly) our protocol can achieve performance similar to that of a fully centralized system (M/M/N queue).

RMP Applications for Social Good

Community Committee Choice Session

Session Chair: Scott Rodilitz, UCLA Anderson School of Management, Los Angeles, CA

Session Chair: Francisco Castro, UCLA Anderson School of Management, Los Angeles, CA

1 Limiting The Manipulability Of Citizens' Assembly Selection

Bailey Flanigan, Carnegie Mellon University, Madison, WI

Citizens' assemblies - in which randomly-chosen citizens convene to deliberate on a policy issue - are growing in influence globally. We study the manipulability of the algorithms used to choose assembly participants: because these algorithms must satisfy representation constraints according to volunteers' self-reported features, an individual could misreport these features to increase their chance of being selected, decrease someone else's, and/or gain panel seats for their group.

We study whether one can limit these types of manipulability by recruiting more volunteers. Strikingly, we show empirically and theoretically that the two SOTA selection algorithms - one of which is widely used - are highly manipulable, no matter the number of volunteers. We then propose a new algorithm and show that its manipulability declines at an optimal rate as the pool grows.

2 the Awkward Art of Asking: Optimal Fundraising for Non-Profit Organizations

Zhengchao Wang, Heikki Peura, Wolfram Wiesemann, Imperial College Business School, London, United Kingdom. Contact: z.wang19@imperial.ac.uk

Non-profit organizations often rely on costly fundraising campaigns to existing and potential donors for their financial viability. We collaborate with a large global charity to develop and test a data-driven approach to improve the targeting of their campaigns to boost net revenue. In a static single-campaign setting, we propose a decision-tree based donor classifications system to capture heterogeneous donor preferences. Next, accounting for the charity's regular diverse campaign offers, we develop a Markov Decision Processes model to account for temporal effects in donations. Using real data from the partner organization, our method demonstrates the potential for data-driven approaches to improve the success of non-profit fundraising campaigns.

3 Does the Right to Repair Promote Competition?

Luyi Yang[1], Cungen Zhu[2], Chen Jin[3], [1]University of California, Berkeley, Berkeley, CA, [2]National University of Singapore, Singapore, Singapore; [3]National University of Singapore, Singapore, Singapore

The "right to repair" (RTR) movement calls for government legislation that requires manufacturers to provide repair information, tools, and parts so that consumers can independently repair their own products with more ease. The initiative has garnered attention globally. The advocates for the initiative believe that the RTR can break manufacturers' monopoly on the repair market, benefit consumers, and further help reduce the environmental impact. This study aims to examine those arguments in a competitive setting in which two manufacturers compete in the product market. Further, we also investigate how the RTR shapes manufacturers' competition in the product. To this end, by employing an analytical model, we find that the RTR can generally trigger non-monotone changes in manufacturer competition, manufacturer profit, consumer benefit, and environmental impact.

4 A Data-Driven Approach to Improve Artisans' Productivity in Distributed Supply Chains

Divya Singhvi[1], Somya Singhvi[2], Xinyu Zhang[1], [1]New York University, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA

Despite their vital role in rural economy, artisanal supply chains continue to be plagued by low productivity and the highly fragmented nature of their upstream. This study presents research conducted in close collaboration with a leading exporter of handmade rugs in India, aimed at improving artisans' productivity in distributed supply chains. We provide robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity. To capitalize on the insight, we propose a novel predict-then-optimize framework for optimizing supervisor visits in the supply chain. By relating our problem to the celebrated prize-collecting TSP problem, we show the existence of a polynomial-time algorithm with provable performance guarantee. We see significant productivity improvement from extensive numerical analysis.

5 Design Variations in Digital Recommendations: An Experimental Study for Curating Visitor Experiences in Cultural Institutions

Ali Aouad[1], Abhishek Deshmane[2], Victor Martinez de Albeniz[2], [1]London Business School, London, United Kingdom; [2]IESE Business School, Barcelona, Spain. Contact: adeshmane@iese.edu
Cultural institutions use digital interfaces to enhance visitors' experience and guide them through art collections. This study examines the impact of design variations in digital recommendations on visitor engagement, satisfaction, and learning at the Van Gogh Museum. We use A/B testing and a switchback approach to evaluate the effect of differentiation across the "Highlights" and "Leisure" configurations of tours, along with better spacing. The outcomes measured include hit rates, time spent, selection rate, completion rate, and self-reported satisfaction levels. The results aim to identify factors that influence visitor experience and guide the design of recommended tours.

APS Special Session: Transfer/Meta-Learning

Award Session

Session Chair: Christina Lee Yu, Cornell University, Ithaca, NY

Session Chair: Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

1 Tutorial on Transfer/Meta-Learning

Hamsa Sridhar Bastani, Wharton School, Philadelphia, PA
In practice, we often encounter "small data" problems. This may be because data points are costly, the problem is high-dimensional, the environment is shifting, or the outcomes are rare/slow. In these cases, learning from problem-specific data is not sufficient, and we must additionally leverage data from related problems. Transfer/meta-learning estimators achieve this goal; we will survey several methods and their theoretical guarantees in different statistical regimes.

Learning and Decision-Making in Platforms

Community Committee Choice Session

Session Chair: Yichun Hu, Cornell University, New York, NY

1 Optimal Multitask Linear Regression and Contextual Bandits Under Sparse Heterogeneity

Xinmeng Huang, University of Pennsylvania, Philadelphia, PA, Contact: xinmengh@sas.upenn.edu
Multitask learning methods improve efficiency by leveraging commonalities across tasks/datasets while accounting for possible differences. We study multitask linear regression and contextual bandits under *sparse heterogeneity*, where the task-wise parameters differ from a global parameter sparsely. We propose the MOLAR estimate that shrinks task-wise OLS estimates towards their covariate-wise median. MOLAR improves the dependence of the estimation error on the data dimension compared to naive OLS estimates. We then apply MOLAR to develop methods for sparsely heterogeneous contextual bandits, obtaining improved regret guarantees over single-task bandit methods. We further show that our methods are minimax optimal by providing a number of lower bounds. We support the efficiency of our methods with experiments on both synthetic data and the PISA dataset.

2 Robust Fitted-Q-Evaluation and Iteration Under Sequentially Exogenous Unobserved Confounders

David Bruns-Smith[1], Angela Zhou[2], [1]University of California, Berkeley, Berkeley, CA, [2]USC Marshall School of Business Data Sciences and Operations, Los Angeles, CA, Contact: bruns-smith@berkeley.edu
Offline reinforcement learning is important in domains where online experimentation is costly, dangerous or unethical, and where the true model is unknown. However, most methods assume all covariates used in the behavior policy's action decisions are observed. This untestable assumption may be incorrect. We study robust policy evaluation/optimization in the presence of sequentially exogenous unobserved confounders. We assume the extent of possible unobserved confounding can be bounded by a sensitivity model and propose and analyze an (orthogonalized) robust fitted-Q-iteration that uses closed-form solutions of the robust Bellman operator. Our algorithm enjoys the computational ease of fitted-Q-iteration and statistical improvements from orthogonalization. We provide sample complexity bounds, insights, and show effectiveness in simulations.

3 Strategyproof Decision-Making in Panel Data Settings and Beyond

Keegan Harris[1], Anish Agarwal[2], Chara Podimata[3], Steven Wu[4], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Amazon, Newton, MA, [3]UC Berkeley, Allston, MA, [4]Microsoft Research, New York, NY, Contact: keeganh@cs.cmu.edu

We propose a framework for decision-making in the presence of strategic agents with panel data, a standard setting in econometrics where one gets noisy, repeated measurements of multiple units. We consider a setup where there is a pre-intervention period, when the principal observes the outcomes of each unit, after which the principal uses these observations to assign treatments. Our model can be thought of as a generalization of the synthetic controls framework, where units may strategically manipulate their pre-intervention outcomes. We identify necessary and sufficient conditions for a strategyproof mechanism that assigns interventions in the post-intervention period to exist. Under a latent factor model, we show that whenever a strategyproof mechanism exists, there is one with a simple closed form. Finally, we provide an algorithm for learning such a mechanism.

4 Uniformly Bounded Regret in Dynamic Fair Allocation

Santiago Balseiro[1], Shangzhou Xia[2], [1]Columbia University, Armonk, NY, [2]Columbia University, New York, NY, Contact: sx2182@columbia.edu

We study a dynamic allocation problem where sequentially arriving resources need to be allocated to fixed agents with linear utilities. Most prior works maximize the utilitarian welfare and may result in unfair concentration of resources on certain high-utility agents while leaving others' demands under-fulfilled. In this paper, aiming at balancing efficiency and fairness, we instead consider the broad collection of Holder-mean welfare metrics, including the Nash social welfare. We show the simple fluid policy derived from a deterministic problem attains uniformly bounded regret under all but the egalitarian welfare. Finally, we propose a new policy consisting of infrequently re-solving the fluid problem and thresholding the solution, which attains uniformly bounded regret against the hindsight optimum under the egalitarian welfare.

Information Theory, Statistics and Online Learning

Community Committee Choice Session

Session Chair: Alankrita Bhatt, CalTech

1 Universal Probability Assignment and Its Applications

Alankrita Bhatt, Caltech, Pasadena, CA

In modern statistical and data science applications, the probability distribution generating the data in question is unknown (or even absent) and decisions must be taken in a purely data-driven manner. In this talk, the information-theoretic approach of universal probability is revisited and expanded upon. This approach gives us general principles and guidelines for assigning sequential probabilities to data (based on which a decision can then be made), and has been used successfully over the years to problems in compression, prediction and estimation among others. The utility of this approach is then demonstrated through the example of universal portfolio selection with side information.

2 Statistical Complexity and Optimal Algorithms for Non-Linear Ridge Bandits

Han Yanjun, New York University, New York, NY

We consider the sequential decision-making problem where the mean outcome is a non-linear function of the chosen action. Compared with the linear model, two curious phenomena arise in non-linear models: first, there is an "burn-in period" with a fixed cost determined by the non-linear function; second, achieving the smallest burn-in cost requires new exploration algorithms. For a special family of non-linear functions named ridge bandits, we derive upper and lower bounds on the optimal burn-in cost, as well as on the entire learning trajectory during the burn-in period via differential equations. In particular, a two-stage algorithm that first finds a good initial action and then treats the problem as locally linear is statistically optimal. In contrast, several classical algorithms, such as UCB and algorithms relying on regression oracles, are provably suboptimal.

3 Adaptive Oracle-Efficient Online Learning

Guanghui Wang, Georgia Tech, GA

Classical online algorithms offer optimal performance guarantees but face scalability limitations. Oracle-efficient methods address this by leveraging offline optimization oracles to search through an exponentially-large decision space. However, they encounter challenges in adapting to friendly environments. In this talk, we explore two friendly scenarios: (a) "small-loss" problems and (b) IID data. We provide a new framework for designing online algorithms that are oracle-efficient and adapt well to the small-loss environment, under a particular condition which we call approximability (which is spiritually related to sufficient conditions provided by Dudik et al., (2020)). We identify a series of real-world applications for which approximability holds. We also extend the algorithm to an IID data setting and establish a "best-of-both-worlds" bound.

4 Oracle-Efficient Online Learning for Beyond Worst-Case Adversaries

Nika Haghtalab[1], Yanjun Han[2], Abhishek Shetty[1], Kunhe Yang[1], [1]UC Berkeley, Berkeley, CA, [2]MIT, Cambridge, MA

We study oracle-efficient algorithms for beyond worst-case analysis of online learning. We focus on two settings. First, the smoothed analysis setting where an adversary is constrained to generating samples from distributions whose density is upper bounded by 1/□ times the uniform density. Second, the setting of K-hint transductive learning, where the learner is given access to K hints per time step that are guaranteed to include the true instance. We give the first known oracle-efficient algorithms for both settings that depend only on the offline complexity of the class and parameters □ and K that capture the power of the adversary. This contrasts the computational separation between online learning with worst-case adversaries and offline learning.

Machine Learning Aided Causal Inference

Community Committee Choice Session

Session Chair: Harsh Parikh, Duke University, Durham, NC

1 Using Embeddings for Causal Estimation of Peer Influence in Social Networks

Irina Cristali[1], Victor Veitch[2], [1]University of Chicago, Chicago, IL, [2]Google / University of Chicago, Chicago, IL

We address the problem of using observational data to estimate peer contagion effects, the influence of treatments applied to individuals in a network on the outcomes of their neighbors. A main challenge to such estimation is that *homophily*—the tendency of connected units to share similar latent traits—acts as an unobserved confounder for contagion effects. We describe an approach to perform the required adjustment using node embeddings learned from the network itself. The main aim is to perform this adjustment nonparametrically, without functional form assumptions on either the process that generated the network or the treatment assignment and outcome processes. The key contributions are to nonparametrically formalize the causal effect in a way that accounts for homophily, and to show how embedding methods can be used to identify and estimate this effect.

2 Interpretable Causal Inference for Distributional Data Analysis

Srikar Katta, Duke University, Durham, NC, Contact: srikar.katta@duke.edu

Causal inference often focuses on estimating treatment effects when outcomes are Euclidean. However, distributions often better represent complex data like images, graphs, and high-frequency time series. By taking advantage of the geometry of the optimal transport-based Wasserstein space, we *learn a distance metric* that creates *almost exact matches* for high quality, heterogeneous treatment effect estimation with these distributional data. Because matching methods are naturally interpretable, we demonstrate how auditing matched groups can ensure trustworthy and robust decision making. We analytically guarantee the consistency of our estimation strategy and demonstrate via simulation that our approach outperforms state-of-the-art methods for distributional data analysis.

3 Graph Neural Network Based Double Machine Learning Estimator of Network Causal Effects

Baharan Khatami, UCSD, San Diego, CA

In this paper, we look into the problem of causal effect estimation in graph data in the presence of interference. We propose a novel framework that combines graph representation learning along with double machine learning to achieve a doubly robust estimator, robust to misspecification of one of the propensity or outcome models. We show that extending double machine learning framework to non-iid setting makes the estimator more robust compared to other types of estimators like prognostic modeling. We also show how expressive power of the graph representation technique contributes to the robustness of the estimation. Extensive experimental studies on multiple graph data, data generative processes using different embedding techniques show the effectiveness of our approach. We compare our method with existing baselines and outperform them in most of the cases.

4 Variable Importance Matching for Causal Inference

Quinn Lanners, Duke University, Durham, NC

Our goal is to produce methods for observational causal inference that are auditable, easy to troubleshoot, accurate for treatment effect estimation, and scalable to high-dimensional data. We describe a general framework called Model-to-Match that achieves these goals by (i) learning a distance metric via outcome modeling, (ii) creating matched groups using the distance metric, and (iii) using the matched groups to estimate treatment effects. Model-to-Match uses variable importance measurements to construct a distance metric, making it a flexible framework that can be adapted to various applications. Concentrating on the scalability of the problem in the number of potential confounders, we operationalize the Model-to-Match framework with LASSO. We derive performance guarantees for settings where LASSO outcome modeling consistently identifies all confounders (importantly without requiring the linear model to be correctly specified). We also provide experimental results demonstrating the method's auditability, accuracy, and scalability as well as extensions to more general nonparametric outcome modeling.

5 A Double Machine Learning Approach to Combining Experimental and Observational Studies

Harsh Parikh, Duke University, Durham, NC

In this work, we consider a setting where we have access to both an experiment and an observational study. The goal is to use both to improve our estimation of causal effects, knowing that either might be plagued by violations of the assumptions described above. To this end, we propose: (i) a test for either violation of conditional ignorability in the observational data or external validity of the experimental data and (ii) an estimator for the average treatment effect (ATE). Both (i) and (ii) draw strength from both experimental and observational datasets. Via double machine learning approaches, we prove that if external validity and conditional ignorability hold, the ATE estimator and the estimator underpinning our test are asymptotically normal, unbiased, and efficient. Furthermore, even if conditional ignorability fails, our ATE estimator is still consistent.

Decision Making for Robotic Systems

Community Committee Choice Session

Session Chair: Michael Caldara, Amazon.com, North Reading, MA

1 Amazon Robotics: Allocation for Tote-Based Fulfillment Centers

Yashoda Dadkar[1], Michael Caldara[2], [1]Amazon Robotics, North Reading, MA, [2]Amazon.com, North Reading, MA

Amazon Robotic Fulfillment Centers utilize hundreds of robotic drive units to bring portable shelves to and from processing stations so that items can be added and removed to fulfill customer orders. This talk gives an overview of Robotic Fulfillment Centers and how we use optimization algorithms to efficiently assign tasks to robots. Additionally, we discuss how changes to the storage shelf design to help present items to employees in an ergonomically friendly position and the introduction of a new workflow has required us to rethink our historical optimization strategy to meet system level objectives.

2 Amazon Robotics: Sort Centers Drive Allocation Modeling

Suzan Iloglu, Benjamin McClosky, Michael Caldara, Daniel Sabin, Amazon Robotics, Boston, MA

Amazon's Robotic Sortation Centers utilize hundreds of robotic drive units to sort packages by postal code for delivery to the end customer. The drives accomplish this task by transporting packages from induct stations to destination specific eject chutes, creating granular bundles of packages for downstream processing. This talk gives an overview of Robotic Sortation Centers and how we use optimization algorithms to efficiently plan drive missions from induct stations to eject chutes and back to power this robotic system.

3 Queue Management for Robotic Fulfillment Systems

Victor Amelkin, Amazon.com, North Reading, MA, Contact: amelkin@amazon.com

Amazon's automated fulfillment centers (FCs) use robotic drives for inventory transport from storage to stations under minute-to-hour-scale deadlines. To hedge against delivery time uncertainty, stations use drive queues, and an important problem is to maintain these queues sufficiently full yet not overflowing. State-of-the-art planners often achieve one of the two. We propose a scalable heuristic for joint work allocation and delivery scheduling to queues, relying on geometric packing of jobs' anticipated presence times in the queue occupancy schedules, proven to be effective at eliminating station underutilization and queue overflow in simulation. It is applicable to FCs, and any other environment with plannable transportation to queues.

Sunday, October 15, 2:15 PM - 3:30 PM

Applied Analytics

Community Committee Choice Session

Session Chair: Nancy Albers, 1</sup

1 Impact Analytics: A Multi-Measure Approach for Assessing and Classifying Business Journals

Nancy D. Albers[1], Caitlyn S. Albers[2], Tami L. Knotts[3], [1]University of South Carolina Aiken, Aiken, SC, [2]University of South Florida, Tampa, FL, [3]Louisiana State University Shreveport, Shreveport, LA, Contact: albersc@usf.edu

Universities need an effective method for distinguishing exceptional publications from average ones. Determining an appropriate process for assigning impact measures to journals for the purpose of determining faculty qualifications has remained a challenge. The process is complicated when the measure must span various disciplines, topics, methods, and purposes. There are many sources of measures of journal quality with a variety of methods for scoring/ranking. Conceivably, not every source is equally rigorous and may not apply equally to all disciplines. This research proposes a multi-measure approach for journal impact in business disciplines. The results have implications across disciplines where journal impact measures are used.

2 Examining the Impact of the Covid-19 Pandemic on Consumer Search Patterns in the European E-Retail Environment

Ravi Narayanaswamy[1], Richard Heiens[2], [1]University of South Carolina Aiken, Aiken, SC, [2]University of South Carolina Beaufort, Beaufort, SC, Contact: ravin@usca.edu

The study examines the relative importance of seven distinct channels as drivers of website traffic in the European e-retail market between the years 2019 and 2021 - direct, display ads, email, organic search, paid search, referrals and social media. Using both a log-log model and Two-step cluster analysis, the results reveal a significant shift in consumer search patterns over the time frame studied, with consumers exhibiting a greater response to paid search and email marketing in the post-COVID period.

3 AI Versus AI: A Study on the Effectiveness of Machine Learning-Based Detection Techniques

Ellis Reeves[1], Monica Martin[2], [1]University of South Carolina Aiken, Aiken, SC, [2]University of South Carolina Aiken, Aiken, SC

Plagiarism has been a growing concern for educational institutions since the advent of the Internet. The magnitude of this problem has become exponential with the emergence of artificial intelligence technologies (AI) like ChatGPT. However, the advanced capabilities of AI can be leveraged in a positive manner. This study examines the efficacy of an AI grading assistant (Packback) to combat plagiarism and validate content. The findings will provide implications for educators on possible avenues to use AI for content authentication and design grading mechanisms.

4 Examining Cybersecurity Awareness Among Students in U.S. Southeast Region

Travis D. Albers, University of Central Florida, Orlando, FL

The recent Covid-19 pandemic has coerced higher learning institutions in the United States to transition to online learning to deliver course content to their students. The increased enrollment in online courses has augmented student exposure to cyberspace. This study aims to analyze the level of cybersecurity awareness among students enrolled in universities in the U.S. Southeast region.

5 The ESG Firm Value Model

Aaron Kim[1], Sung Ik KIm[2], Davide Lauria[3], Svetlozar Rachev[3], [1]Stony Brook University, Stony Brook, NY, [2]Louisiana State University Shreveport, Shreveport, LA, [3]Texas Tech University, Lubbock, TX

This study aims to investigate the impact of incorporating environmental, social, and governance (ESG) factors on firm value models. The growing recognition of the significance of a company's ESG performance on its long-term financial performance has led to increased demand for ESG data and analysis by investors and firms. The study creates an ESG-inclusive firm value model, selects appropriate ESG metrics, assesses the model's accuracy, and compares it to a traditional model. The results will provide insights into the significance of ESG factors on firm value and the effectiveness of ESG-inclusive models in predicting firm value.

Sunday, October 15, 2:15 PM - 3:30 PM

Food Waste Reduction in Retail and Foodservice

Community Committee Choice Session

Session Chair: Ekaterina Astashkina, Ross School of Business, University of Michigan, Ann Arbor

Session Chair: Fan Zhou, University of Michigan, Ann Arbor, MI

1 Artificial Intelligence Based Systems for Reducing Food Waste

Yu Nu[1], Elena Belavina[2], Karan Girotra[3], [1]Cornell University/Cornell Tech, New York City, NY, [2]Cornell University, New York, NY, [3]Cornell Tech/Johnson Cornell University, New York, NY, Contact: yn292@cornell.edu

In this study we evaluate the effectiveness of two kinds of AI-based systems for reducing food waste in commercial kitchens- a computer-vision based waste monitoring system, and a machine-learning based system for managerial-bias detection. In a quasi-experimental setting where 800+ commercial kitchens adopted Winnow in a staggered manner, we first estimate food waste reductions due to the use of a waste monitoring system and the upgrade to AI-powered waste capture via synthetic difference-in-differences method. We also explore methods that utilize the high-resolution waste data to identify the root causes behind the higher-than-necessary waste levels, such as systematic biases in managing inventories. The deep-learning based time-series classifier (LSTM-FCN) we developed, is able to identify managerial biases with 95%+ accuracy from the real-world test data.

2 Reducing Waste in Foodservice

Yuwen Hu[1], Ekaterina Astashkina[2], Izak Duenyas[3], Feng Tian[4], [1]University of Michgan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, [3]University of Michigan-Ann Arbor, Ann Arbor, MI, [4]HKU, Hong Kong, China. Contact: yuwenhu@umich.edu

Food waste is a global environmental problem that spans multiple industries, including foodservice. We build a stylized model of a food provider that faces a consumer with uncertain demand. We identify the most effective strategies that reduce post-consumer food waste.

3 Food Waste in Grocery Retail: The Impact of Store Characteristics

Fabian Schäfer, Konstantin Wink, Alexander Hübner, Technical University of Munich, Straubing, Germany. Contact: fab.schaefer@tum.de

Our research investigates how store characteristics impact in-store food waste for a European retailer. We analyze the proprietary transaction and geo data from 174 retail stores using Double Machine Learning models to test our hypotheses. Our findings indicate that grocery store density, city size, and nearby household numbers significantly affect food waste levels relative to revenue. Our study provides novel insights for practitioners to consider when strategically planning store locations and reducing food waste, a crucial sustainability issue for retailers. Retailers can decrease costs and carbon emissions by identifying which store attributes lead to increased food waste.

4 On The Management of Premade Foods

Jae-Hyuck Park[1], Dan Andrei Iancu[2], Erica Plambeck[2], [1]New Jersey Institute of Technology, Newark, NJ, [2]Stanford University, Stanford, CA, Contact: jaehyuck.park@njit.edu

We examine a grocer's management of a premade food product. The retailer's goal is to maximize a weighted sum of direct profit and customer welfare. The retailer chooses shelf life, whether to issue items in FIFO or LIFO order, and whether to indicate the time when each item is prepared (i.e., timestamp). We find that LIFO universally outperforms FIFO when shelf life and issuance are jointly optimized. We also show that the retailer should timestamp items only if customers have heterogeneous preferences, and a positive decision hinges on the disposal cost being sufficiently low or the retailer caring substantially about customer welfare. Lastly, we show how a mandate to donate unsold food items can incentivize a retailer to increase the shelf life or cease disclosing the time at which a food item was made, which harms shoppers and reduces the quantity and quality of donated items.

Military Readiness

Community Committee Choice Session

Session Chair: Gregg J. Schell, CNA, Arlington, VA

1 Organic Repair Transfers to Increase Readiness

Gregg Schell, CNA, Arlington, VA

Managing the flow of spare parts through the supply chain is critical to ensuring high and sustained material readiness. Using a simulation model, we explored how alternative policies for repairing parts can affect costs and the probability of stock-outs at warfighter supply locations. We generated a decision-support framework for determining when the alternative policy should be implemented and estimated potential second-order effects on repair capacity and throughput.

2 Expanding Logistics Network Optimization Model for Novel Solutions

Lauren Claus, CNA, Arlington, VA

Future logistics distribution networks to support a distributed maritime operations (DMO) environment will require new sustainment strategies to supply the fleet. Novel logistics solutions, such as unmanned systems and shipboard additive manufacturing, are currently being explored as sustainment strategy options to meet these changing requirements. To evaluate the costs and operational benefits of these sustainment options, the scenario-based Constrained Optimization for Assessing Sustainment in Theater (COAST) model has been expanded to include these novel solutions alongside traditional logistics assets. The approach to incorporate these novel logistics solutions into the COAST model optimization framework will be presented.

3 Enhancing Military Medical Evacuation Dispatching with Armed Escort Management: Comparing Model-Based Reinforcement Learning Approaches

Andrew Gelbard, United States Air Force, Washington, DC

The military medical evacuation (MEDEVAC) dispatching problem involves determining optimal policies for evacuating combat casualties to maximize patient survivability during military operations. This study explores a variation of the MEDEVAC dispatching problem, focusing on controlling armed escorts using a Markov decision process (MDP) model and model-based reinforcement learning (RL) approaches. A discounted, continuous-time MDP model over an infinite horizon is developed to maximize the expected total discounted reward of the system. Two model-based RL solution approaches are proposed: one utilizing semi-gradient descent Q-learning, and another employing semigradient descent SARSA. A computational example, set in western and central Africa during contingency operations, serves to assess the performance of the RL-generated policies against the myopic policy, which is currently employed by military medical planners. The research also delves into sensitivity analysis and excursion scenarios to further evaluate the RL-generated policies. By explicitly controlling armed escort assets, dispatching authorities can better manage the location and allocation of these resources throughout combat operations. The findings of this study have the potential to inform military medical planning, operations, and tactics, ultimately leading to improved MEDEVAC system performance and higher patient survivability rates.

4 Allocation of Surveillance and Search Assets in Undersea Warfare

Sebastian Martin[1], Anna Svirsko[2], Daphne Skipper[2], Esra Toy[3], [1]United States Naval Academy, Annapolis, MD, [2]United States Naval Academy, Annapolis, MD, [3]Virginia Tech, Blacksburg, VA, Contact: m243966@usna.edu

The location of moving underwater targets requires initial detection by a sensor and follow-on tracking by an active search platform. We formulate a linear program that determines the placement of sensors and tactical search assets in a theoretical search area to maximize the number of tracked targets. Our model takes into account the different requirements of sensor types, sensor detection probabilities, and the effective placement of search assets in relation to sensors to enable timely response to detection. We test our model on theoretical scenarios of target movement in the open-ocean.

Modeling and Analysis of Biopharmaceutical Manufacturing Systems

Community Committee Choice Session

Session Chair: Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

Session Chair: Wei Xie, Northeastern University, Boston, MA

1 Biological System-of-Systems Framework for iPSC Culture in Aggregates

Wei Xie[1], Hua Zheng[1], Sarah Harcum[2], Keqi Wang[1], Paul Pei[1], [1]Northeastern University, Boston, MA, [2]Clemson University, Clemson, SC, Contact: w.xie@northeastern.edu

Large-scale production of induced pluripotent stem cells (iPSCs) is essential for cell therapies and regenerative medicines. Yet, due to strong cell-to-cell interactions, iPSCs self-aggregation can lead to insufficient nutrient supply and metabolic waste build-up for the cells located at core. We introduce a Biological System-of-Systems (Bio-SoS) framework characterizing causal interdependencies at individual cell, aggregate, and cell population levels. It quantifies spatial-temporal variations and predicts cell response to micro-environmental perturbation. This study can offer valuable insights to optimize the cell culture process and ensure that it follows the expected trajectory for successful cell growth and expansion.

2 Optimal Bleed-Feed Policies for Biomanufacturing

Coen Dirckx, 1</sup

We consider the bleed-feed method, which is a novel semi-continuous production strategy in biomanufacturing. The main trade-off concerning this strategy is the timing of the bleed-feed action. We show that a second trade-off regarding the bleeding amount exists. Optimizing this dual trade-off under uncertainty results in incremental productivity gains. We provide extensive numerical analysis and show that our model outperforms the current practice and the original bleed-feed model. A case study conducted at Merck Animal Health shows the practical application and value of our work.

3 Increasing the Productivity of a Multi-Stage Biomanufacturing Process Using MDP Modelling

Mirko Schoemig[1], Martin Grunow[2], [1]Technical University of Munich, Munich, Germany; [2]Technical University of Munich, Munich, Germany. Contact: mirko.schoemig@tum.de

Biopharmaceuticals are drugs produced in a multi-stage biomanufacturing process. The use of living cells introduces multiple operational uncertainties into the system. Today, the manufacturing stages are often treated as independent entities operated with fixed process control strategies, neglecting the trade-off these decisions create across stages. Further, process monitoring data routinely collected to prove regulatory compliance of the process, are not used for operational decision-making. We formulate the multi-stage biomanufacturing process as an MDP and determine an integrated policy. We show the applicability of the policy for a typical biomanufacturing process, focussing on the implementation of the operations policy in practice.

4 Applications of OR/MS Methodologies in Biomanufacturing: Our Vision and Future Research Directions

Tugce Martagan, Eindhoven University of Technology, Eindhoven, Netherlands

The applications of Operations Research and Management Science (OR/MS) methodologies created a significant impact on industries such as automotive and semiconductor manufacturing. However, there are only a limited number of papers and a few written accounts of success on OR/MS applications in biomanufacturing. Through our work presented in the 2022 Franz Edelman competition, we have proven that linking OR/MS with biomanufacturing drives sustainable and scalable productivity improvements. In this presentation, we will discuss our vision and future research directions to inspire and stimulate new research at the intersection of OR/MS and biomanufacturing.

Humans and Machines with Applications in Operations

Community Committee Choice Session

Session Chair: Mirko Kremer, Frankfurt School of Finance and Management gGmbh, Frankfurt Am Main, Germany

1 The Omnichannel Service Desk: Live Agents, Chatbots or Both?

Brett Hathaway[1], Maqbool Dada[2], Evgeny Kagan[3], [1]Brigham Young University, Provo, UT, [2]Johns Hopkins University, Baltimore, MD, [3]Johns Hopkins Carey Business School, Baltimore, MD, Contact: brett_hathaway@byu.edu

We examine the problem of designing an omnichannel service desk that integrates chatbots and live agents to respond to inbound service requests from customers. At the heart of this problem are two decisions: (1) Which channels should be offered: the chatbot channel, the live-agent channel, or both? (2) For the offered channels, how should the customer experience be designed? If the live-agent channel is offered, should it use a more personalized "concierge service" approach or a more efficiency-driven "gatekeeper" approach, in which the work is split between a gatekeeper and an expert? If the chatbot channel is offered, what is the optimal level of chatbot sophistication?

2 When Systems Fail: Training Data Accuracy and Operational Transparency

Chris Parker[1], Jorge Mejia[2], [1]American University, Washington, DC, [2]Indiana University, Bloomington, IN, Contact: chris.parker@american.edu

AI systems rely on accurate training data created by workers interacting with a remote system that can be unreliable. We investigate 1) to what extent can system failures impact worker performance after a system fails and is restored, and 2) what remedies exist that can reduce the impact of these failures on worker performance. To answer these questions, we conducted eight lab experiments and one field experiment in which subjects were asked to perform tasks commonly used to train data used for an AI model. Our results show that a system failure leads to a decrease in task accuracy after the system recovers from failure and comes back online. Providing employees with operational transparency about the failure restoration status brings accuracy back to pre-failure levels.

3 Improving Human-Algorithm Collaboration: Causes and Mitigation of Over- and Under-Adherence

Maya Balakrishnan[1], Kris Johnson Ferreira[1], Jordan D. Tong[2], [1]Harvard Business School, Boston, MA, [2]University of Wisconsin Madison, Madison, WI, Contact: mbalakrishnan@hbs.edu

Even if algorithms make better predictions than humans on average, humans may sometimes have additional private information that can improve their performance. How can we then help humans effectively use recommendations made by algorithms? We hypothesize people are biased towards a naïve advice weighting heuristic where they take a weighted average between their own prediction and the algorithm's, with a constant weight across prediction instances regardless of whether they have valuable private information. This leads to humans over-adhering to the algorithm's predictions when their private information is valuable and under-adhering when it is not. We validate our results in two lab experiments and also find that feature transparency, even when the underlying algorithm is a black box helps users more effectively discriminate when and how to deviate from algorithms.

4 Learning From Mistakes: Algorithmic Recommendations Complimenting Humans

Bryce Mclaughlin, Jann Spiess, Stanford Graduate School of Business, Palo Alto, CA, Contact: brycem@stanford.edu

Research in prescriptive analytics seeks to develop predictions which can map to loss-minimizing decisions. However, some problems which could benefit the most from prescriptive analytics face an additional challenge: a human takes the final decision after receiving information about a prediction, often as a risk score or recommendation. In response we consider a simple prescriptive design question: how can we optimally deploy this recommendation? We introduce a model capturing the endogenous response of the human to the recommendation's deployment. Under monotonicity-like assumptions, we are able to show that a minimax optimal deployment of the recommendation (over the feasible set of human response to the recommendation) is implemented using a threshold rule on the propensity of the human to make mistakes given the recommendations inputs.

5 Delegating Decisions and Blame to Humans and Machines

Mirko Kremer[1], Hossein Nikpayam[2], Francis de Vericourt[3], [1]Frankfurt School of Finance and Management gGmbh, Frankfurt Am Main, Germany; [2]ESMT Berlin, Mannheim, Germany; [3]ESMT Berlin, Berlin, Germany. Contact: m.kremer@fs.de

We study human-machine interaction in an environment where a principal delegates to an agent a risky diagnostic decision and pays the agent a discretionary bonus after observing the outcome that results from a combination of decision and luck. To make better decisions in expectation, the agent can rely on two sources of information - their own privately observed information and a recommendation from a statistical model ("machine"). We predict that bonus payments depend on outcomes and on whether the agent's decision aligned with the machine recommendation, with the result that agents are prone to aligning decisions with machine recommendations even when they should not, effectively over-relying on the machine. We design experiments to test these predictions under controlled laboratory conditions.

Pierskalla Best Paper Competition

Award Session

Session Chair: Hrayer Aprahamian, Texas A&M University, College Station, TX

1 Strategic Cross Subsidization in Healthcare Capitation Programs: Evidence from Medicare Advantage

Zhaowei She[1], Turgay Ayer[2], Bilal Gokpinar[3], Danny Hughes[2], [1]Singapore Management University, Singapore, Singapore; [2]Georgia Institute of Technology, Atlanta, GA, [3]UCL School of Managemen, London, United Kingdom

Healthcare Payers have increasingly adopted capitation payment models during the past decade. Utilizing a large commercial insurance database, we empirically characterize the allocation of capitation payments in Medicare Advantage (MA), the largest capitation program in the U.S.. The findings reveal that MA inadvertently encourages health plans to reallocate portions of the capitation payments intended for one group of patients to another, a practice known as strategic cross subsidization. By exploiting a policy-induced shock on MA capitation payments, we identify this cross subsidization practice through a difference-in-difference (DID) design.

2 Got (Optimal) Milk? Pooling Donations in Human Milk Banks with Machine Learning and Optimization

Timothy Chan[1], Rafid Mahmood[2], Rachel Wong[1], Ian Zhu[1], Sharon Unger[3], Debbie Stone[3], Deborah O'Connor[1], [1]University of Toronto, Toronto, ON, Canada; [2]Telfer School of Management, Ottawa, ON, Canada; [3]Sinai Health System, Toronto, ON, Canada

Human donor milk provides critical nutrition for the millions of infants that are born preterm each year. While the macronutrients in donor milk are critical to infant development, they vary by donation. In collaboration with Rogers Hixon Ontario Human Milk Bank, we developed a data-driven framework to pool multiple donations using machine learning and optimization. Over a one-year trial, our implementation yielded significantly higher macronutrient content than current pooling practices, with the proportion of pools meeting clinical fat and protein targets increasing by approximately 31%, with a 60% decrease in recipe creation time.

3 Can Predictive Technology Help Improve Acute Care Services? Investigating the Impact of Virtual Triage Adoption

Michael Freeman, Jiatao Ding, Sameer Hasija, INSEAD, Singapore, Singapore

This paper investigates the operational implications of virtual triage adoption within acute care services. A central problem in this context is patients' (in)ability to self-triage accurately, a notable contributor to ED overcrowding and treatment delays. Recent developments in predictive analytics have led to development of virtual triage tools, which offer immediate and cost-effective triage recommendations. This paper develops a queueing game model to examine how virtual triage influences patient behavior and system performance, and policy actions that maximize its operational advantages.

4 Reshaping National Organ Allocation Policy

Theodore Papalexopoulos[1], James Alcorn[2], Dimitris Bertsimas[1], Rebecca Goff[2], Darrin Stewart[3], Nikolaos Trichakis[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]United Network for Organ Sharing, Richmond, VA, [3]New York University Langone, New York, NY

The Organ Procurement & Transplantation Network (OPTN) initiated a major overhaul of its allocation policies, aiming to create a more efficient, equitable, and inclusive system. We introduce an analytical framework that illuminates tradeoffs and enables dynamic exploration of the efficient frontier. Jointly with OPTN, we applied our framework to design a new national allocation policy for lungs. Since March 9, 2023, all lungs in the U.S. are allocated according to this policy that we helped design. We extended our joint work to the redesign of kidney, pancreas, hearts, and liver allocation.

Drones for Healthcare Delivery

Community Committee Choice Session

Session Chair: Shakiba Enayati, University of Missouri - Saint Louis, St Louis, MO

1 A Simulation-Heuristic Method for Drone Delivery in Rural Areas

Xueping Li, [1</sup]

2 Cost-Effectiveness of Drone Delivered Aeds

Muhammad Maaz[1], K.H. Benjamin Leung[2], Justin J. Boutilier[3], Sze-chuan Suen[4], Timothy Chan[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University of Wisconsin - Madison, Madison, WI, [4]University of Southern California, Los Angeles, CA, Contact: m.maaz@mail.utoronto.ca

Early application of a defibrillator is one of the most important determinants of mortality and morbidity in cardiac arrests. Drones are increasingly studied as a way to quickly get defibrillators to cardiac arrest patients. However, the cost-effectiveness of such programs has not been studied. We use a Markov model to study the cost-effectiveness of drone-delivered defibrillators, taking into account the costs of the drones themselves and costs to the healthcare system. Our results show that they are cost-effective.

3 Coordinated Truck-Drone Pickup and Delivery with Time Windows for Pharmacies

Nawin Yanpirat, Daniel F. Silva, Alice E. Smith, Auburn University, Auburn, AL

This work aims to reduce the total service time in last-mile logistics in distributing prescription medications and other items from pharmacies to customers. Prescription medications require preparation by a certified pharmacist and should be delivered promptly within time windows. Other items can be picked up and delivered at any time. Customers can receive multiple items from different pharmacies, due to differences in availability, which is common for medications. We propose a mixed-integer linear programming model with pickup and delivery services using a single truck and multiple drones with multi-payload capacity. We solve realistically sized instances by using a novel variant of Simulated Annealing and reduce the total service time significantly relative to traditional truck-only approaches.

Medical Decision Making

Community Committee Choice Session

Session Chair: Narges Mohammadi, [1</sup]

1 More than Predictions: Machine Learning Interpretability for Clinically Actionable Bone Marrow Transplant Decisions

Yiyang Qu[1], Hamed Shourabizadeh[1], Dionne Aleman[1], Louis-Martin Rousseau[2], Fotios V. Michelis[3], [1]University of Toronto, Toronto, ON, Canada; [2]Polythechnique Montreal, Montreal, QC, Canada; [3]Princess Margaret Cancer Centre, Toronto, ON, Canada. Contact: aleman@mie.utoronto.ca

Allogeneic hematopoietic cell transplant (HCT) is a common treatment for leukemia and other hematological disorders, however, mortality remains high. We develop machine learning methods to better predict HCT outcomes for individual patient-donor pairs, using single-center data to best capture hidden but important factors. Our framework stratifies patients into risk-based Kaplan-Meier survival curves, facilitating more individualized treatment decisions compared to the standard survival analysis used in clinical research, which may not reflect specific patient characteristics. We then use explainable AI methods to discover new and impactful correlations between variables and outcomes that can be communicated to clinicians, specifically finding and verifying that the CD34+ stem cell dose should be tailored by patient age for acute leukemia patients.

2 Cost-Effectiveness of a Network of Lethal Ovitraps for the Prevention and Control of Dengue Fever

Yvonne Huijun Zhu[1], Joel Aik[2], Shuzhen Sim[2], Joel Goh[3], [1]National University of Singapore, Singapore, Singapore; [2]National Environment Agency, Singapore, Singapore; [3]NUS Business School, Singapore, Singapore. Contact: huijun96@u.nus.edu

We analyze the system-level cost-effectiveness of a network of lethal ovitraps for Dengue control. Benefits are modeled using an age-stratified multiple-infection epidemiological model and measured as reductions in disability-adjusted-life-years (DALYs). We estimate labor costs by modeling the workload needed for periodic maintenance of the traps via Traveling Salesmen Problems (TSPs).

3 Efficient Discovery of Cost-Effective Policies in Sequential, Medical Decision Making Problems

Narges Mohammadi[1], Reza Skandari[1], Anand Shah[2], [1]Imperial College Business School, London, United Kingdom; [2]Imperial College London, London, United Kingdom. Contact: n.mohammadi19@imperial.ac.uk

Policymakers use cost-effectiveness analysis to prioritize healthcare interventions. We develop an efficient algorithm that discovers the cost-effectiveness frontier and policies for sequential stochastic optimization problems and use it to devise easy-to-implement hearing loss screening strategies for patients with cystic fibrosis. We prove the theoretical properties of the solution methods.

4 Balancing Speed with Safety: An Analytical Approach to Improve FDA's Premarket Approval Pathway

Mohammad Zhalechian[1], Soroush Saghafian[2], Omar Robles[2], Anders Olsen[2], [1]Indiana University, Bloomington, IN, [2]Harvard University, Cambridge, MA

For a medical device to be approved under the FDA's Premarket Notification 510(K) pathway, the manufacturer can submit a claim indicating that it is as safe and effective as another legally marketed device. This vague regulatory process has led to a high recall rate for devices approved under this pathway, raising important concerns over the approach used by FDA. To find ways to improve this process, we have assembled a unique large-scale dataset that includes information on devices approved under this pathway from 2008 to 2020. We develop machine learning models capable of predicting the chance of recall for each applicant device, and make use of them to provide a data-driven policy for the FDA to improve its acceptance/rejection decisions.

Statistical Learning Problems in Healthcare

Community Committee Choice Session

Session Chair: Ozge Yapar, Indiana University, Kelley School of Business, Bloomington, IN

1 Experimentation Levels and Social Welfare Under FDA's Flexible Approval Policy

Amin Khademi[1], Hamed Rahimian[1], Saeid Delshad[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Central, SC, Contact: khademi@clemson.edu

The goal of this work is to study the impact of flexible approval standards on the experimentation levels and social welfare when pharmaceutical companies (firms) are strategic. Specially, one research question is under what conditions flexible approval standards can incentivize research for developing new drugs for rare diseases. We consider a Stackelberg game with the FDA and two firms in two distinct markets (diseases). The FDA sets the approval standards to maximize the social welfare consisting of benefit/cost of approving an effective/ineffective drug, and each firm seeks to maximize its payoff, consisting of the experimentation cost and potential benefit of taking the drug to the market upon approval, which is modeled by an optimal stopping of a diffusion process.

2 Combining Pre-Approval Clinical Trials and Post-Approval Spontaneous Adverse Event Reporting for Improved Safety Signaling

John M. Silberholz[1], Fernanda Bravo[2], Yunliang Chen[3], [1]University of Michigan Ross School of Business, Ann Arbor, MI, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]University of California, Berkeley, Berkeley, CA

A classical question in pharmacovigilance is how to combine pre-approval RCTs and post-approval surveillance data to increase the power for side effect detection. A key step is to learn the degree to which the observational data is biased before one can combine it with unbiased clinical trial data. In this work, we propose a model that uses information about common toxicities to help de-bias the observational data on rare toxicities through the correlation of bias among different toxicities (e.g., correlation due to co-reported drugs, indications, and patient health). Using Bayesian statistics, we analyze the benefit of "cross"-debiasing and identify the situation where such benefit is largest. Numerical experiments using real data from the FDA Adverse Event Reporting System (FAERS) suggest significant values of using cross-debiasing to improve drug safety signaling.

3 Personalized Incentives for Weight Loss

Qiaomei Li[1], Yonatan Mintz[1], Corrine Voils[2], Kara Gavin[2], [1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin Madison, Madison, WI

Financial weight loss incentives administered by a mobile app have been found to help patients lose weight. However, the efficacy of these interventions is dependent on patient adherence. Thus clinicians must find the appropriate incentives to administer to patients to ensure they adhere to the intervention and influence long term behavioral change. In this talk, we develop a personalized model for the patients' decision-making process in these interventions and use it to construct personalized incentives. To validate our model we perform a computational study using data from a randomized control trial. We find our method outperforms existing machine learning methods in terms of weight loss prediction at the end of the intervention using a short time-span of data and that our approach helps improve the efficacy of the intervention program with limited resources.

4 Learning From Observational Data In Healthcare

John R. Birge, University of Chicago, Chicago, IL

Many healthcare settings offer only observational data about treatments and their outcomes. Inferring causal relationships becomes complicated by the presence of hidden or partially observed confounding variables which can influence both treatments and their outcomes. Patterns of observations within and across individuals can be used to identify these factors. This talk will describe some approaches to this identification and implications for the design of optimal treatment protocols.

Healthcare Analytics in Emerging Data Settings

Community Committee Choice Session

Session Chair: Gian-Gabriel P. Garcia, Georgia Institute of Technology, Atlanta, GA

Session Chair: Che-Yi Liao, Georgia Institute of Technology, Atlanta, GA

1 Data-Driven Counterfactual Optimization for Personalized Clinical Decision-Making

Che-Yi Liao[1], Gian-Gabriel P. Garcia[2], Esmaeil Keyvanshokooh[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Mays Business School, Texas A&M University, College Station, TX

Machine learning-based health tools are becoming popular for informing treatment targets for high-risk patients with chronic diseases. However, using these tools alone, it is challenging to identify personalized treatment targets that lower the risks of adverse outcomes to a clinically acceptable range and are realistic, actionable, and robust to changes in these tools. To this end, we propose a data-driven approach called Distributionally Robust Selection of Clinical Role Models via Counterfactual Optimization (DISC^{2}O). With a case study on 5-year cardiovascular disease, we show that our model can recommend treatment targets with much lower risks of adverse health outcomes and slightly higher costs, compared to clinical practice recorded in that dataset and other benchmarks including the clinical practice that does not consider uncertainty in these health tools.

2 A POMDP Approach to Develop Anal Cancer Screening Recommendations

Jingyu Li, Lauren N. Steimle, Georgia Tech ISyE, Atlanta, GA, Contact: jli928@gatech.edu

Although anal cancer (AC) is rare in the general population, certain groups are known to be at significantly elevated risk of developing AC. Routine AC screening is considered as a potential strategy to identify high-risk individuals early and to ultimately mitigate AC burdens in high-risk groups. However, standardized AC screening has not been established. Trade-offs between higher costs of high-quality tests and lower sensitivity of more economic tests need to be assessed. In this work, we develop a POMDP model to optimize anal cancer screening strategies for HIV-positive populations in North America. Our model considers the natural history of anal carcinogenesis and HIV status jointly. We also account for the imperfect screening tests and find the optimal policy under such uncertainty.

3 Assessment for Disparities in Access to High-Quality Trauma Care Among Sociodemographic Groups

Xiaonan Sun, Shan Liu, Rebecca Maine, University of Washington, Seattle, WA, Contact: xnsun@uw.edu

Although trauma systems have been effective in reducing mortality rates among severely injured patients, access to high-quality trauma care is not equally distributed across all populations in the US. To identify these disparities, we developed a set of geospatial and non-geospatial metrics derived from routinely collected state data and linked to improved trauma care outcomes. We conducted statistical analyses to compare care quality within sociodemographic factors, including race, ethnicity, sex, age, insurance type, urban or rural residence, and Social Deprivation Index level, which have historically experienced uneven access to trauma care. Based on our findings, we propose the development of an optimization model that allocates medical resources and adjusts hospital functions to improve trauma care quality while addressing equity concerns.

4 Novel Pooling Strategies for Genetic Testing, with Application to Newborn Screening

Hussein El Hajj[1], Douglas R. Bish[2], Ebru Korular Bish[3], [1]Santa Clara University, Santa Clara, CA, [2]University of Alabama, Tuscaloosa, [3]University of Alabama, Tuscaloosa, AL, Contact: helhajj@scu.edu

Cystic fibrosis is among the most prevalent life-threatening genetic disorders, and can be caused by a large number of mutational variants. For cost-effectiveness, most U.S. newborn screening processes for cystic fibrosis start with a biomarker test, followed by a more expensive and accurate genetic test (DNA), which uses a limited variant panel, for those newborns with elevated biomarker levels.To overcome the cost barriers of expanded genetic testing, we explore a pooled DNA testing approach. This leads to a novel decision problem, to determine the variants to screen for and their assignment into multiple panels, and a pool size for each panel. We establish key structural properties of optimal designs; develop an exact algorithm that generates the Pareto optimal set of pooled DNA designs at different budgets; and derive key insights for practitioners.

5 Prescriptive 0-1 Neural Networks for Personalized Medicine

Yonatan Mintz[1], Vrishabh Patil[2], [1]University of Wisconsin Madison, Madison, WI, [2]Carnegie Mellon University, Pittsburgh, PA

A key challenge in medical decision making is learning treatment policies for patients with limited data.This challenge is particularly evident in personalized healthcare decision making, where models need to take into account the intricate relationships between patient characteristics, treatment options, and health outcomes. To address this, we introduce prescriptive networks, shallow 0-1 neural networks trained with mixed integer programming that can be used with counterfactual estimation to optimize policies in medium data settings. These models offer greater interpretability then deep neural networks and can encode more complex policies than common models such as decision trees. We show our models can outperform existing methods in both synthetic data experiments and in a case study of assigning treatments for postpartum hypertension.

SOLA Best Student Paper Award

Community Committee Choice Session

Session Chair: Ismail Capar, Texas A&M University, College Station, TX

1 Designing Layouts for Sequential Experiences: Application to Cultural Institutions

Abhishek Deshmane, Georgia Institute of Technology, Atlanta, GA

Experience providers - ranging from retail platforms to cultural institutions - need to decide on how to display an assortment of items for physical and digital interactions. In this paper, we develop a data-driven analytics framework to optimize these layout-related decisions for maximum user engagement. We develop a new dynamic choice model, called Pathway MNL, that represents visitor activity as a sequence of conditional logit experiments. Through an ongoing collaboration with the Van Gogh Museum, we validate the model on large-scale logs of visitor activity recorded through audio guides. We uncover significant relationships between visitors' choices and layout-related factors, among others. Finally, we analyze the resulting mathematical program for layout optimization and identify simple layout interventions that can significantly lift visitor engagement.

2 Robust Data-Driven Design of A Smart Cardiac Arrest Response System

Weiliang Liu, National University of Singapore, Singapore, Singapore

This paper studies the data-driven design of a smart emergency response system for out-of-hospital cardiac arrest that involves drones for automatic external defibrillator delivery and community responders alerted via a mobile application, in addition to ambulances. Based on a dataset with community responders' records from Singapore, we develop a robust joint deployment model of drone and ambulance to maximize the survivability of the response system while accounting for data uncertainty in OHCA occurrence and responders' behavior. We find that (i) hedging against uncertainty leads to a higher survival rate of the response system; (ii) a few drones are sufficient to increase the survival rate dramatically; and (iii) the impact of the behavior of responders on survival outcomes is more significant than that of simply adding drones/ambulances.

3 Charging Station Location and Sizing for Electric Vehicles Under Congestion

Omer Burak Kinay, Amazon, Toronto, ON, Canada

4 Planning Bike Lanes with Data: Ridership, Congestion, and Path Selection

Jingwei Zhang, Cornell University, Ithaca, NY

We study the bike lane planning problem considering its conflicting effects in reducing and increasing traffic congestion. In an extensive case study in Chicago, we estimate adding 25 miles of prescribed bike lanes can lift cycling mode share from 3.6% to 6.1%, with at most an 9.4% increase in driving times.

Social Network and Platform Operations

Community Committee Choice Session

Session Chair: yunduan Lin, University of California, Berkeley, Berkeley, CA

Session Chair: Zuo-Jun Max Shen, University of California Berkeley, Berkeley, CA

1 Optimal Subscription Pricing for Ridesharing Platforms

Shreyas Sekar[1], Hongyao Ma[2], Ben Berger[3], David C. Parkes[4], [1]University of Toronto, Toronto, ON, Canada; [2]Columbia University, New York, NY, [3]Tel Aviv University, Tel-Aviv, -, Israel; [4]Harvard University, Boston, MA

Ridesharing platforms have experimented extensively with subscription programs. Despite the large number of offers that users have been subject to, there seems to be little consensus on what a good subscription looks like. In this work, we study the design of subscription mechanisms in ridesharing with the goal of maximizing social welfare. Contrary to folk wisdom, any market equilibrium using *per-trip pricing only* is inefficient due to the presence of network effects.

We establish that when riders are homogeneous, a simple subscription (for example, pay a $10 fee to get $2 off every ride for a month) can in fact achieve the first-best social welfare. With a view towards operationalizing such a mechanism, we consider two extensions and show how to implement good subscriptions when a) many riders do not subscribe, and b) riders are heterogeneous in their trip frequency.

2 Contextual Stochastic Bilevel Optimization And End-to-end Learning

Yifan Hu[1], Jie Wang[2], Yao Xie[2], Andreas Krause[3], Daniel Kuhn[4], [1]EPFL, Lausanne, Switzerland; [2]Georgia Institute of Technology, Atlanta, GA, [3]ETH Zurich, Zürich, Switzerland; [4]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland. Contact: yifan.hu@epfl.ch

We introduce contextual stochastic bilevel optimization, a stochastic bilevel optimization template with the lower-level problem minimizing an expectation conditioned on some contextual information and the upper-level decision variable. This framework captures important applications such as meta-learning, causal optimal transport, and end-to-end learning. Due to the presence of contextual information, existing single-loop methods for classical stochastic bilevel optimization all fail. To overcome this challenge, we introduce an efficient double-loop gradient method based on the Multilevel Monte-Carlo technique and establish its sample and computational complexities. When specialized to stochastic nonconvex optimization, our method matches existing lower bounds. Extensive numerical experiments validate our theoretical results.

3 Dynamic Matching of Users and Creators on Social Media Platforms

Daniel Huttenlocher, Hannah Li, Liang Lyu, Asuman Ozdaglar, James Siderius, Massachusetts Institute of Technology, Cambridge, MA, Contact: lianglyu@mit.edu

Social media platforms are two-sided markets bridging content creators and users together. Existing literature on content recommendation algorithms used by platforms often focuses on user preferences, neglecting creator incentives to produce content. Creators may be dissatisfied with a small audience and leave the platform, which can deter their followers from engaging and induce more creators to leave. We propose a model of content recommendation where the platform matches users and creators sequentially, and players strategically decide to stay or leave at each time step. We show that only maximizing immediate engagement can perform poorly in the long run, but even approximating the first-best long-term engagement is NP-hard. We present heuristic-based algorithms with good long-term performance in a number of practical instances, with provable guarantees.

4 Nonprogressive Diffusion on Social Networks: Approximation and Applications

yunduan Lin[1], Heng Zhang[2], Renyu Zhang[3], Zuo-Jun Max Shen[4], [1]University of California, Berkeley, Berkeley, CA, [2]Arizona State University, Tempe, AZ, [3]The Chinese University of Hong Kong, Hong Kong, China; [4]University of California Berkeley, Berkeley, CA, Contact: yunduan_lin@berkeley.edu

Our paper proposes a model and a fixed-point approximation (FPA) scheme for characterizing adoption limits in nonprogressive diffusion on social networks. The scheme offers both theoretical guarantee and computational efficiency, with maximal deviation decreasing as network size and density increase, making it suitable for dense networks. Taking the widely studied influence maximization and pricing problems on a social network as examples, we further illustrate the broad applications of our FPA scheme. Finally, we conduct comprehensive numerical studies with synthetic and real-world networks. The FPA scheme shows 1,000 times more speed up in computation time than simulation. It achieves small approximation error, and outperforms conventional algorithms even when the social network is small and/or sparse.

5 Incentivizing High-Quality Content in Online Recommender Systems

Xinyan Hu, Meena Jagadeesan, Michael Jordan, Jacob Steinhardt, UC Berkeley, Berkeley, CA, Contact: xinyanhu@berkeley.edu

For content recommender systems, the platform's decision algorithm shapes the incentives of content producers. Many platforms employ online learning, which creates intertemporal incentives, since content produced today affects recommendations of future content. In this paper, we study the incentives produced by online learning, analyzing the quality of content produced at Nash equilibrium. We show that classical online learning algorithms, such as Hedge and EXP3, incentivize producers to create low-quality content. Motivated by this negative result, we design a different learning algorithm that correctly incentivizes producers to create high-quality content.

Empirical Studies in Healthcare Operations

Community Committee Choice Session

Session Chair: Fanyin Zheng, Columbia University, New York, NY

Session Chair: Yiwen Shen, HKUST, New York, NY

1 The Impact of Surgeon Daily Workload and Its Implications for Operating Room Scheduling

Yiwen Shen[1], Carri Chan[2], Fanyin Zheng[3], Michael Argenziano[4], Paul Kurlansky[4], [1]HKUST, Hong Kong, China; [2]Columbia Business School, New York, NY, [3]Columbia University, New York, NY, [4]Department of Surgery, New York Presbyterian/Columbia University Irving Medical Center, New York, NY, Contact: yiwenshen@ust.hk

In healthcare service systems, the workload level can substantially impact service time and quality. We investigate this relationship in the context of cardiac surgery. Using 5,600 cardiac surgeries in a large hospital, we quantify how individual surgeon's daily workload (number of cases performed in a day) affects surgery duration and patient outcomes. To handle the endogeneity issue, we construct novel instrument variables using hospital operational factors. We find surgeon's high daily workload leads to longer OR times and post-surgery length-of-stay. We develop a scheduling model that incorporates the estimated effects and show that it can lead to substantial improvement.

2 Adaptive Server Behavior to Schedule Deviations and Its Consequences: Evidence from Operating Rooms

Yiwen Jin[1], Yichuan Ding[2], Steven Shechter[1], Jugpal Arneja[3], [1]Sauder School of Business, UBC, Vancouver, BC,

Canada; [2]McGill University, Montreal, QC, Canada; [3]UBC, Vancouver, BC, Canada

We study how clinical teams adaptively adjust their service speed in response to real-time deviations from the planned operating room schedules and the further impacts on post-surgical risks. Using a unique surgery data set with actual and scheduled surgery time stamps, we find clinical teams speed up when they fall behind and slow down when they get ahead of schedule, with the slowdown exhibiting a stronger effect. We leverage the deviations from the schedule as an instrument variable and present a causal study that a faster-than-scheduled procedure duration erodes quality by increasing readmissions and reoperations. In a counterfactual analysis, we obtain a convex relationship between readmissions/reoperations and end-of-shift (EOS). Our findings help managers in scheduling surgeries to achieve desired efficiency-quality trade-offs and predict EOS time better.

3 Learning from Quality Signal to Improve Fairness and Accuracy: Evidence from the Hospital Readmissions Reduction Program

Mohamad Soltani[1], Robert Batt[2], Hessam Bavafa[2], [1]Alberta School of Business, University of Alberta, Edmonton, AB, Canada; [2]Wisconsin School of Business, UW-Madison, Madison, WI, Contact: soltani@ualberta.ca

Policymakers often employ quality indicators to evaluate the performance of an organization and to provide incentives for quality improvements. A potential concern, however, is that a specific quality indicator may not truly reflect the quality that is attributed to the performance of the organization. We explore the effects of the Hospital Readmissions Reduction Program on 30-day readmissions in over 2,000 hospitals in the U.S. Whereas the policy is indifferent between readmission reduction during the 30-day time window, we find that the level of improvement depends on the timing of readmission. We attribute this difference to the control that hospitals have over readmissions. This finding shows that 30-day readmission rate does not provide an accurate quality signal, and thus HRRP is not fair toward hospitals that treat low-income patients with limited access to care.

Crypto and Blockchain Economics

Community Committee Choice Session

Session Chair: Fasheng Xu, Syracuse University, Long Island City, NY

1 Equilibrium in a Defi Lending Market

Thomas Rivera[1], Fahad Saleh[2], Quentin Vandeweyer[3], [1]McGill University, Montreal, QC, Canada; [2]Wake Forest University, Winston-Salem, NC, [3]University of Chicago, Chicago, IL

We provide an economic model of lending on a blockchain. Such lending suffers a disadvantage when compared to traditional lending due to an inability to incorporate external information into setting interest rates (i.e., the Oracle Problem). For this reason, a blockchain lending equilibrium produces lower welfare than a competitive lending market equilibrium. We nonetheless show that an improvement in design is feasible to generate equilibrium interest rates, and therefore welfare, that is arbitrarily close to a competitive lending market equilibrium.

2 On The Security Of Optimistic Blockchain Mechanisms

Jiasun Li, George Mason University, Fairfax, VA

Many new blockchain applications (e.g., layer-2 scaling solutions, proof-of-stake layer-1 chains, and cross-chain bridges, etc.) adopt an "optimistic" design, that is, the system proceeds as if all participants are well-behaving, presumably sustained by some "stake-and-slash" mechanisms. We formulate the logic of such optimistic systems within a simple game and characterize all equilibria. We point out that such protocols cannot be secure if all participants are rational. Therefore, to ensure security, protocol designers have to either impose a trust assumption regarding the presence of altruistic participants or look for alternative designs (e.g., zero-knowledge proof-based designs).

3 Toward Understanding the Bitcoin Mining and Exchange Markets

Bowen Lou, University of Connecticut

We formulate a systematic framework that encompasses key dimensions of the Bitcoin exchange market, exchange rate and liquidity, and jointly model the entry and exit of the Bitcoin mining market, characterized by the supply and demand of mining rigs. By leveraging a unique dataset of the purchase and listing of mining rigs from a leading e-commerce platform, we find that the effects of key dimensions are pronounced for investors, as potential entrants to the Bitcoin mining market. They have a significant impact on the demand for mining rigs. Furthermore, our results indicate that the electricity consumption of mining Bitcoin moderates the effect of the Bitcoin exchange rate and liquidity on the demand for mining rigs.

4 Unobservable Investment Amount, Inventory Salvage Value, and Trade Credit

Jie Ning[1], Peter Ritchken[2], [1]Case Western Reserve University, Cleveland, OH, [2]Case Western Reserve, Cleveland, OH, Contact: jie.ning@case.edu

Input inventory fuels production and innovation. A cash-strapped firm with limited input inventory needs to borrow money to purchase more. In this case, the lender is an outside funder who does not observe the amount of inventory invested. We study such investment amount unobservability, accounting for inventory depreciation. Surprisingly, this financial friction has no effect on firms with risk-free production and random demand. In contrast, this friction may lead to high financing cost and under-investment for firms with risky innovation and fixed demand. We propose that the buyer-supplier interaction in trade credit (TC) mitigates this unobservability, and show that this mitigation creates value only if it goes all the way, i.e., when the firm offers full transparency to the supplier.

Parity, Priority, and Platforms

Community Committee Choice Session

Session Chair: Luyi Yang, University of California, Berkeley, Berkeley, CA

Session Chair: Shiliang Cui, Georgetown University, McDonough School of Business, McLean, VA

1 Advance Selling and Upgrading in Priority Queues

Yaolei Wang[1], Ping Cao[2], Jingui Xie[3], Dongyuan Zhan[4], [1]USTC, Hefei, China; [2]U of Science and Technology of China, Hefei, China; [3]Technical University of Munich, Heilbronn, Germany; [4]University College London, London, United Kingdom. Contact: d.zhan@ucl.ac.uk

We study advance selling and upgrading in a priority queue setting that emerges in the amusement park industry. Customers choose to buy the fastrack or regular tickets depending on their heterogeneous waiting costs. Advance tickets are cheaper, but buyers suffer from congestion uncertainty. Upgrading options allow customers to purchase regular tickets in advance and upgrade onsite. The seller aims to find the optimal pricing scheme to maximize revenue. We find that advance selling always improves revenue but upgrading may not, and identify conditions when allowing upgrading generates more revenue. Specifically, it may be more profitable to focus advance and upgrading prices on online customers and focus spot prices on offline customers. The upgrading option, though providing greater flexibility and customized experience, hurts consumer surplus.

2 Potty Parity: Process Flexibility via Unisex Restroom

Setareh Farajollahzadeh[1], Ming Hu[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Minneapolis, MN, Contact: ming.hu@rotman.utoronto.ca

Our paper analytically studies the issue of unequal access to restrooms for women and LGBTQ+ individuals and designs a plan to improve efficiency and fairness measured by totalitarian, Rawlsian fairness, and strict equality principles. While an all-unisex restroom design may seem like a viable solution, with everyone standing in the same line and pooling flexible servers, our analysis shows that it can lead to a decline in both efficiency and fairness measures. Instead, we suggest converting a men's restroom unit to a unisex restroom with some flexibility, improving both efficiency and fairness measures and reducing wait time disparities between gender-segregated restrooms. Therefore, a little-flexible system outperforms a fully flexible one.

3 Surge Pricing and Dynamic Matching for Hotspot Demand Shock in Ridehailing Networks

Philipp Afèche[1], Costis Maglaras[2], Zhe Liu[3], [1]University of Toronto, Rotman School of Management, Toronto, ON, Canada; [2]Columbia Business School, New York, NY, [3]Imperial College Business School, London, -, United Kingdom. Contact: afeche@rotman.utoronto.ca

We study a ride-hailing platform that matches price- and-delay sensitive riders with strategic drivers in the presence of an unpredictable demand shock at a hotspot. Our model captures the interplay of nonstationary demand, spatially distributed strategic supply, and delayed and risky supply response and incentives. We consider dynamic policies that jointly determine surge prices for riders, surge wages for drivers, and the spatial matching of riders to drivers. We characterize the structure and compare the performance of various policies that differ in terms of three attributes, temporal differentiation, spatial differentiation and risk sharing. Our results identify how system performance depends on the key timescales of rider patience and demand shock duration.

4 The Impact of Information Granularity and Priority in Managing Strategic Customers' Service Choices

Yue Hu[1], Ricky Roet-Green[2], Lin Zang[2], [1]Stanford University, Stanford, CA, [2]Simon Business School, University of Rochester, Rochester, NY, Contact: lzang@simon.rochester.edu

We study service systems with two types of service providers: the specialist and the generalist. The specialist can fulfill the service requirement of all customers, whereas the generalist can successfully serve customers with a probability that decreases with the customer's service complexity level. Upon an unfulfilled visit at the generalist, the customer needs a follow-up visit at the specialist. We model customers' strategic choices between the two service providers as a queueing game, and characterize the equilibrium of the queueing game and the socially optimal customer choices. We investigate the impact of information granularity, and find that improving customers' perception of their service complexity levels is not always optimal. This limitation can be overcome by simultaneously deploying a priority rule that can induce the social optimum.

Socially Responsible and Sustainable Supply Chain Management

Community Committee Choice Session

Session Chair: Han Zhang, Michigan State University, East Lansing, MI

1 Buyer Engagement in a Supplier's Social Responsibility Risk Management: Prevention, Detection, and Remediation

Junhao Vincent Yu[1], Tim Kraft[2], [1]Miami University, Oxford, OH, [2]NC State - Poole College of Management, Raleigh, NC, Contact: vincentyu@miamioh.edu

We study how buyers can proactively manage their suppliers' responsibility risk. We focus on a retailer's risk management strategy and consider three tactics the retailer can deploy—prevention, detection, and remediation—and study how combining the three can help the retailer achieve optimal results.

2 Financing and Farm-Gate Pricing Strategies for Agricultural Cooperatives with Cash-Constrained Farmers

Tava Olsen[1], Xiaoyan Qian[2,3], Spring Zhou[4], [1]Melbourne Business School, Melbourne, Australia; [2]University of Auckland?, Auckland, New Zealand; [3]Dongbei University of Finance and Economics, Dongbei, China; [4]University of Wollongong, Wollongong, Australia

Capital investment in agricultural cooperatives (co-ops) is typically limited to farmer-members; yet farmers are usually cash-constrained. In addition to common stock that is required from farmer-members, many coops are changing their financial structures by raising capital from external funds. This helps co-ops to collect enough capital, but also imposes several regulatory constraints due to the unique features of co-ops. In this talk, we present a modeling framework to examine a co-op's farm-gate pricing and financing strategies, considering two types of external equity: preferred stock that bears a fixed dividend rate and outside stock that carries the same economic rights as common stock. We leverage our analysis to offer tangible insights that can help an agricultural co-op to relieve financial constraints.

3 Fairness Regulation of Prices in Competitive Markets

Xingyu Fu, Hong Kong University of Science and Technology, Hong Kong, Hong Kong. Contact: xingyu.fu@connect.ust.hk

The loyalty penalty is a pricing strategy where firms charge higher prices to loyal customers while offering lower prices to non-loyal customers. In this study, we study the implications of fairness regulation to curb this unfair practice. We examine duopoly competition in two markets, where consumers are loyal to different firms in each market. The regulation mandates that the price gap between the two markets must not exceed a threshold. Our analysis reveals an intriguing interplay between competition and fairness regulation. When competition is intense, fairness regulation can mitigate competition between firms, resulting in Pareto improvements. On the other hand, when competition is weak, fairness regulation can enhance firms' existing monopoly power, potentially leading to collusive high prices that are detrimental to consumers.

4 Data-Driven Design of Index-Based Yield Protection Policy

Kehan Lu, Jing-Sheng Jeannette Song, Can Zhang, Duke University, Durham, NC

We study the design of a novel index-based yield protection policy offered by the government to subsidize smallholder farmers from crop yield loss. This policy uses an index-projected yield based on accessible yield-related features to determine government subsidy payments, avoiding costly actual yield assessments. However, existing policy designs emphasize accurate yield prediction, which may not lead to maximized the net benefit (farmers' utility minus government expenditure), especially with risk-averse farmers. We propose a one-step learning and optimizing framework that directly aims to maximize the net benefit. We prove the superiority of our framework over popular methods and establish performance guarantees for the learning algorithm. We also quantify the value of our framework by applying it to real livestock mortality data in Kenya.

5 Shipment Monitoring, Allocation and the Impact on Food Waste

Tao Lu, University of Connecticut, Storrs, CT

Sensor technologies enable supply chain firms to monitor the condition of each product unit and allocate them to destination markets of different transportation distances based on their conditions. A firm purchases a fresh produce for sale in two markets with uncertain demands. Post-harvest processes render a (possibly random) proportion of the product likely to spoil in transit. The longer the transportation distance, the higher the spoilage risk. The firm solves a two-stage optimization: It first determines a purchase quantity, and then decide how to allocate each unit (in either good or risky condition) between markets. We characterize the structure of optimal allocation policies and then use it to solve the first-stage problem. We find that shipment monitoring, despite being advocated for the potential to reduce food waste, may increase the total waste.

Value Chain Innovation: Pricing, Market Expansion, and Demand Learning

Community Committee Choice Session

Session Chair: Shi Chen, University of Washington, Foster School of Business, Seattle, WA

1 Dynamic Two-Part Pricing and Bidding for Display Ad Campaigns

Sami Najafi Asadolahi, Naren Agrawal, Stephen A. Smith, Santa Clara University, Santa Clara, CA, Contact: snajafi@scu.edu

Display advertising's growth has transformed business engagement with target audiences. Despite its benefits, managing campaigns is challenging due to uncertainties in arrival rates, user visits, and real-time auction outcomes. We aim to devise an optimization method for agencies to profitably price and bid for campaigns while maintaining clients expectations. We formulate real-time bidding strategies for impressions and pricing strategies for new campaigns, through a Markov decision process to maximize profits. Through analysis, we offer valuable insights, demonstrating the efficacy of strategies based on campaign arrival intensity. We present a practical, easily implementable heuristic that efficiently consolidates requested impressions into larger blocks, significantly reducing computation time while maintaining minimal impact on expected profit.

2 Supply Chain Contracting Under Nonparametric Demands

Shi Chen[1], Haipeng Luo[2], Yingfei Wang[3], Mengxiao Zhang[4], [1]University of Washington, Foster School of Business, Seattle, WA, [2]University of Southern California, Los Angeles, CA, [3]University of Washington, Seattle, WA, [4]University of Southern California, Los Angeles, CA, Contact: shichen@uw.edu

In this work, we re-consider the classic supply chain coordination and contracting problem but with unknown, nonparametric demands. We aim at developing online learning algorithms for the revenue-sharing and buy-back contracts such that both parties - the manufacturer and the retailer - achieve favorable regret bounds. For the retailer, our algorithm is essentially a stochastic online convex optimization problem with a high-probability regret guarantee. For the manufacturer, our algorithm is based on but different from the classic binary search, as the observation at each time period is not i.i.d but adaptively changing, noting that the retailer is also using an online algorithm to learn the optimal order quantity given the changing contract parameter values.

3 A Non-Parametric Learning Algorithm for a Stochastic Multi-Echelon Inventory Problem

Cong Yang[1,2], Tim Huh[3], [1]University of British Columbia, Vancouver, BC, Canada; [2]University of British Columbia, Vancouver, BC, Canada; [3]University of British Columbia, Vancovuer, BC, Canada

We consider a periodic-review single-product multi-echelon inventory problem with instantaneous replenishment. In each period, the decision-maker makes ordering decisions for all echelons. Any unsatisfied demand is backordered, and any excess inventory is carried to the next period. In contrast to the classic inventory literature, we assume that the information of the demand distribution is not known a priori, and the decision-maker observes demand realizations over the planning horizon. We propose a non-parametric algorithm that generates a sequence of adaptive ordering decisions based on the stochastic gradient descent method. We compare the T-period cost of our algorithm to the clairvoyant, who knows the underlying demand distribution in advance, and we prove that the expected T-period regret is at most O(√ T), matching a lower bound for this problem.

4 Startup Blitzscaling and the Venture Capital Method

Yishen Cai[1], Lingxiu Dong[2], Fasheng Xu[3], [1]University of Miami Herbert Business School, Miami, FL, [2]Washington University in St. Louis, Saint Louis, MO, [3]Syracuse University, Long Island City, NY, Contact: c.yishen@wustl.edu

Blitzscaling is a business strategy that prioritizes growth over efficiency in profit and it is typically found among expansion-stage startups. It attempts to expand both the market and the size of the operation with significant costs financed by serious investors such as Venture Capitalists (VCs). In practice today, the standard equity finance mechanism between a VC and a startup is derivative of Venture Capital Method. Contrary to other equity finance schemes, VC finance features an investor whose entire profit model pivoted on exit rather than profit sharing. The investee is a long-term (3-7 years) high-risk (90% failure) startup venture. We try to close the gap between practice and literature by modeling an expansion stage VC-backed startup with operational decisions that allocate a limited budget on marketing and capacity under different types of VC contracts.

Business Model Innovation: Models and Empirical Analysis

Community Committee Choice Session

Session Chair: Guangwen (Crystal) Kong, Temple University, Philadelphia, PA

Session Chair: Jingxuan Geng, Temple University, Philadelphia, PA

1 Inducing Effort and Adoption of Agriculture Innovation from Risk-Averse Farmers

Ruiping Ke[1], Lingxiu Dong[1], Jie Ning[2], [1]Washington University in St. Louis, Saint Louis, MO, [2]Case Western Reserve University, Cleveland, OH, Contact: k.ruiping@wustl.edu

It is challenging to induce risk-averse farmers to adopt agriculture innovations that are inherently risky and require set-up effort. We propose a novel debt-like contract to address this challenge. We investigate how this contract incentivizes a farmer to exert effort and provide conditions under which it yields a win-win outcome.

2 When Less is More: An Analytical Analysis and Empirical Evidence of a Telemedicine Platform

Jingxuan Geng, Guangwen (Crystal) Kong, Marco Qin, Temple University, Philadelphia, PA, Contact: jingxuan.geng@temple.edu

We consider a telemedicine platform that allows patients to seek multiple medical diagnoses from doctors online. We find that the pricing mechanism alone may yield a downward distortion on price to prevent doctors' over-participation compared to a centralized benchmark. With a control limit on the diagnosis number per inquiry, the platform can charge higher while maintaining an appropriate number of doctors' responses. When patients are delay sensitive, a platform may benefit from their increased delay sensitivity, and the profit improvement from the control limit may decrease with delay sensitivity. When doctors are heterogeneous in their service quality, the low-quality doctors may drive out all high-quality doctors. A control limit could increase high-quality doctors' participation. We empirically test the predictions and they support the analytical results.

3 Project Selection in Strategic Alliances

Pascale Crama[1], Guiyun Feng[2], Wenqi Lian[3], [1]Singapore Management University, Singapore, Singapore; [2]Singapore Management University, singapore, Singapore; [3]Lingnan University, Hong Kong, Hong Kong. Contact: pcrama@smu.edu.sg

Firms join in strategic R&D alliances to collaborate on multiple projects by combining R&D and marketing capabilities. The formation and structure of such an alliance must consider incentive and project selection issues in the presence of technical and market uncertainty, resource and market interactions, and varying levels of capabilities. Upfront contracts allow to reduce resource constraints, but reduce the ability to react to market uncertainty. We show how high levels of market uncertainty increase the impact of the innovator's marketing capabilities, where intermediate levels of marketing capabilities may be preferred.

AI / OR Applications in Sustainability and Climate Change

Community Committee Choice Session

Session Chair: Dr. Kedar Kulkarni, Jio AI Center of Excellence, Bangalore, India

1 AI Driven Predictive Maintenance of Photovoltaic (PV) Panel Junction Boxes

Anand Thirwani, Kedar Kulkarni, Rahul Nair, Jio AI Center of Excellence, Bengaluru, India

PV (photo-voltaic) panel manufacturing is a complex process and requires a high degree of precision to produce high-quality PV cells. A junction box is a crucial component in PV panels that shields the electrical connections between PV panels and the power generation system. Faults in junction boxes could adversely impact the system's performance, safety, and lifespan. Soldering issues in the junction box may result in high resistance and heating, which may lead to a fire. Identifying defective junction boxes is difficult and requires expert intervention. We propose an automated approach using machine learning and computer vision to detect defects using images of junction box inter-connect bends. This could significantly enhance the durability and performance of solar power generation systems.

2 From Disclosure to Action: Data-Driven Decarbonization for Enterprises

Vinamra Baghel[1], Ayush Jain[2], Jagabondhu Hazra[1], Manikandan Padmanaban[3], Ranjini Guruprasad[4], [1]IBM Research India, Bangalore, India; [2]IBM Research India, Lucknow, India; [3]IBM Research Labs, Bangalore, India; [4]IBM Research India, Bengaluru, India. Contact: jahazra1@in.ibm.com

Enterprises face immense pressure to address climate change by disclosing and reducing their GHG emissions across activities. While many companies have committed to long-term net-zero targets, there is a need for a systematic approach that can help enterprises to identify opportunities that can help them reduce their emissions. We address this gap by leveraging enterprise environmental data available in open domain and using data-driven approaches to create a sustainability knowledge base. We further perform clustering of enterprises based on parameters such as sector, geography, size, etc. We use the knowledge base and clusters to learn from similar enterprises and supply chains in to identify enterprise decarbonization projects.

Conic Optimization: Theory and Methods

Community Committee Choice Session

Session Chair: Mohammadhossein Mohammadisiahroudi, Lehigh University, PA

Session Chair: Pouya Sampourmahani, Lehigh University, PA

1 Spectral Bundle Methods for Primal and Dual Semidefinite Programs

Feng-Yi Liao[1], Lijun Ding[2], Yang Zheng[1], [1]University of California San Diego, San Diego, CA, [2]Wisconsin Institute for Discovery, Madison, WI, Contact: fliao@ucsd.edu

In this work, we present an overview and comparison of spectral bundle methods for solving both *primal* and *dual* semidefinite programs (SDPs). In particular, we introduce a new family of spectral bundle methods for solving SDPs in the *primal* form. The algorithm developments are parallel to those by Helmberg and Rendl, mirroring the elegant duality between primal and dual SDPs. The new family of spectral bundle methods achieves linear convergence rates for primal feasibility, dual feasibility, and duality gap when the algorithm captures the *rank of the dual solutions*. The original spectral bundle method by Helmberg and Rendl is well-suited for SDPs with low-rank primal solutions, while on the other hand, our new spectral bundle method works well for SDPs with low-rank dual solutions. These theoretical findings are supported by a range of large-scale numerical experiments.

2 On the Longest Chain of Faces of Completely Positive and Copositive Cones

Mitsuhiro Nishijima[1,2], [1]Tokyo Institute of Technology, Tokyo, Japan; [2]The Institute of Statistical Mathematics, Tokyo, Japan. Contact: nishijima.m.ae@m.titech.ac.jp

We study the *length of the longest chain of faces* and the *distance to polyhedrality* of closed convex cones. These lengths are related to various quantities in linear algebra and optimization, such as the Carathéodory number and the singularity degree. We establish that for any closed convex cone K sandwiched between a completely positive cone and a doubly nonnegative cone of order n, the length of the longest chain of faces of K is $n(n+1)/2 + 1$, and if $n \geq 2$, the distance to polyhedrality of K is $n(n+1)/2 - 2$, which are the worst cases possible for these lengths. The same results also hold for the dual cone, where K lies between the dual of a doubly nonnegative cone and a copositive cone.

3 A Higher-Order Interior Point Method for Semidefinite Optimization Problems Failing Strict Complementarity Condition

Pouya Sampourmahani[1], Ali Mohammad Nezhad[2], Tamás Terlaky[1], [1]Lehigh University, Bethlehem, PA, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Semidefinite optimization (SDO) problems are known to be solved efficiently using interior point methods (IPMs), however superlinear convergence is achieved only under the strict complementarity condition. Failing strict complementarity leads to losing analyticity of the central path at optimality. Based on a semi-algebraic description of the central path, we reparametrize the central path and then propose an IPM that exploits higher-order derivatives of the parametrized central path. We discuss the local convergence of our higher-order IPM and then present the numerical results.

4 Interior-Point Algorithms for Solving Sufficient Linear Complementarity Problems Based on a New Class of AET Functions

Tibor Illés, Corvinus University of Budapest, Budapest, Hungary

We propose new interior-point algorithms to solve sufficient linear complementarity problems. To define the search directions, we apply the algebraic equivalent transformation (AET) technique. We introduce a new class of AET functions, which differs from the classes used in the literature to determine search directions. We provide example AET function from our new class, which does not belong to the class of concave functions proposed by Haddou et al. Furthermore, the kernel function belonging to this AET function is neither eligible, nor self-regular kernel function. We prove that the interior-point algorithms using any member of this new class of AET functions have polynomial iteration complexity in the size of the problem, bit length of the data and in a special parameter, called handicap.

5 Solving Choice-Based Linear Programs in Huge Scale

Donghao Zhu[1], Hanzhang Qin[2], Kenji Fukumizu[3], [1]Techinical University of Munich, Munich, Germany; [2]Amazon, Jersey City, NJ, [3]The Institute of Statistical Mathematics, Tokyo, Japan. Contact: donghao.zhu@in.tum.de

Addressing huge-scale (extremely large) modeling challenges, like optimizing product assortments for online shopping platforms during promotional campaigns, can be daunting. To tackle such scenarios, we propose a choice-based linear programming approach. By developing a decentralized algorithm, we convert the original problem into a series of smaller sub-problems. This method has demonstrated its effectiveness in producing approximate solutions, with robust outcomes in both practical applications and theoretical contexts.

CC-North 221C

Recent Advances in Cutting Planes

Community Committee Choice Session

Session Chair: Aleksandr M. Kazachkov, University of Florida, Gainesville, FL

1 Learning Cutting Planes for Power Systems Optimization

Álinson Xavier, 1</sup

Tight formulations and cutting plane methods have been proposed for various optimization problems in power systems. However, because cuts can be computationally expensive to generate, and can make the linear programming relaxation of the problem significantly harder to solve, such approaches often fail to provide meaningful improvements in running time. This talk explores the usage of AI/ML to accelerate and improve the generation and selection of cutting planes. Computational experiments are conducted on the Security-Constrained Unit Commitment problem.

2 Solid Angle Measure for the Importance of Facets of Cyclic Group Polyhedra

Yuan Zhou, University of Kentucky, Lexington, KY, Contact: yuan.zhou@uky.edu

Solid angles of polyhedral cones, which indicate the proportion of space occupied by the cones, are of significant interest in integer programming. For example, researchers have used shooting experiments to predict the importance of facets of the cyclic group polyhedra introduced by Gomory, which are useful for generating cutting planes. However, the obtained facet sizes were not always consistent due to randomness. We propose utilizing the solid angle measure and comparing it with results from shooting experiments. The solid angle of a simplicial cone can be computed using a multivariable hypergeometric series, provided that the cone satisfies a certain condition related to positive-definiteness. We provide decomposition methods to ensure that the positive-definite criterion is met. We examine the asymptotic error of the series. Joint work with Allison Fitisone.

3 Curated Data Generation for Machine Learning-Based Cut Selection

Oscar Guaje[1], Aleksandr M. Kazachkov[2], Elias Khalil[1], [1]University of Toronto, Toronto, ON, Canada; [2]University of Florida, Gainesville, FL, Contact: o.guaje@mail.utoronto.ca

Cutting planes are a critical component of Mixed Integer Programming (MIP) solvers. In practice, decisions about which and how many cuts to add are usually made heuristically based on empirical evidence. A recent stream of research has explored the use of machine learning (ML) to inform cut selection decisions in MIP solvers. However, the performance of any cut selection strategy is tied to the strength of the generated cuts, and the possible impact of ML in cut generation remains unexplored. In this work, we present a framework to generate cuts for general MIP instances. The aim of our work is to build a curated dataset for learning to cut. Our framework addresses the following challenges that often arise in cut generation: the heuristic nature of separators, the discrepancy between traditional cut quality measures and bound improvement, and numerical issues.

4 Thinning the Herd of Open and Hard MIPLIB Models

Ed Klotz, Gurobi Optimization, Incline Village, NV, Contact: klotz@gurobi.com

The MIPLIB Mixed Integer Programming Library (https://miplib.zib.de/) classifies its models as easy (green), hard (yellow), or open (red).

This talk will consider one or two MIPs that are open or take days to solve and show how to solve them to optimality. Tactics used include visualization of the underlying process being modeled to discover useful reformulations, customized cuts to tighten the formulation, and solver parameter tuning.

Extended Formulations for Network Optimization: Modeling, Decomposition and Applications

Community Committee Choice Session

Session Chair: Alexandre Jacquillat, MIT Sloan School of Management, Cambridge, MA

1 A New Exact Algorithm For Electric Vehicle Routing With Subpath-Based Pricing Problem Decomposition

Sean Lo[1], Alexandre Jacquillat[2], [1]MIT Operations Research Center, Cambridge, MA, [2]MIT Sloan School of Management, Cambridge, MA, Contact: seanlo@mit.edu

A critical challenge in transportation decarbonization lies in the electrification of long-haul operations along highways. To support this transition, this paper tackles the electric vehicle routing problem, and proposes a modeling and algorithmic approach to solve it without time or charge discretization. Starting with column generation for the path-based set-partitioning formulation, we develop a novel algorithm for the pricing subproblem which generates and stitches together non-dominated subpaths. We also use *ng*-route relaxations iteratively, expanding neighborhoods until one obtains elementary paths. Numerical results show that our approach outperforms state-of-the-art algorithms and scales to realistic problem sizes.

2 Design and Operation of Demand-Responsive Microtransit Systems

Bernardo Martin-Iradi[1], Kayla Spring Cummings[2], Alexandre Jacquillat[3], [1]Technical University of Denmark, Copenhagen, Denmark; [2]Massachusetts Institute of Technology, Somerville, MA, [3]MIT Sloan School of Management, Cambridge, MA, Contact: bmair@dtu.dk

Demand-responsive microtransit defines a middle ground between public transit (reference route) and on-demand mobility (real-time routing adjustments). We formulate a two-stage stochastic program to optimize network design (in the first stage) and system operations (in the second stage). We propose an effective model representation based on time-space-load networks with subpath variables. We solve it via a tailored algorithm combining Benders decomposition and column generation. Results on real-world data indicate that the proposed algorithm outperforms baseline modeling and computational approaches, and that microtransit systems can provide win-win benefits compared to transit and ride-sharing systems —higher level of service, lower operating costs, and smaller environmental footprint.

3 Fragment Based Solution Methods for Vehicle Routing Problems

Lucas Sippel, Michael Forbes, The University of Queensland, Brisbane, Australia. Contact: lucas.sippel@uq.net.au

An emerging framework for solving vehicle routing problems uses a formulation with variables for sub-paths of routes, sometimes called fragments. Previously arc-flow and route based formulations have been used. Route based formulations often have stronger linear relaxations than arc-flow formulations, at the cost of having an exponential number of variables. Fragment based formulations usually have fewer variables than their route based counterparts, and so commercial solvers can be used following variable enumeration. We will outline the fragment based formulation and describe recent advancements for solving it, particularly incorporating Dynamic Discretization Discovery and leveraging the tight lower bound of the route based formulation.

4 Multiple-Vehicle Subadditive Dispatching: Formulations, Bounds and Column Generation

Ignacio Erazo[1], Alejandro Toriello[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Tech ISyE, Atlanta, GA, Contact: iien3@gatech.edu

Motivated by applications in production scheduling, e-commerce distribution and warehousing with a trade-off between batching economies and idleness while waiting for orders, we consider a multiple-vehicle subadditive dispatching problem. The problem is strongly NP-Hard, and we propose four different MILP formulations. We devise column generation procedures to solve the linear relaxations, and then derive theoretical results on the relaxation bounds. We test the empirical performance of our methods with machine scheduling instances, and perform a case study for tactical design of a same-day-delivery system.

On Hierarchical and Federated Optimization

Community Committee Choice Session

Session Chair: Farzad Yousefian, Rutgers University, Piscataway, NJ

1 Randomized Zeroth-Order Federated Methods for Nonsmooth Nonconvex and Hierarchical Optimization

Yuyang Qiu[1], Uday Shanbhag[2], Farzad Yousefian[1], [1]Rutgers University, Piscataway, NJ, [2]Pennsylvania State University, University Park, PA, Contact: yq117@scarletmail.rutgers.edu

Federated learning (FL) has recently emerged as an enabling framework for communication-efficient decentralized training. In this talk, we consider the development of zeroth-order FL methods for nonsmooth nonconvex and hierarchical stochastic optimization problems. We first develop a new randomized zeroth-order FL method where we leverage convolution-based smoothing and Clarke's subdifferential calculus. Secondly, we devise a unifying randomized implicit zeroth-order FL method. Importantly, this method enjoys employing single-timescale local steps, which results in significant reduction in communication overhead when addressing hierarchical problems. We provide performance guarantees for both methods. We validate the theory using numerical experiments on nonsmooth and hierarchical problems.

2 An Incremental Gradient Method for Optimization Problems with Variational Inequality Constraints

Harshal D. Kaushik[1], Sepideh Samadi[2], Farzad Yousefian[2], [1]Bayer, St Louis, MO, [2]Rutgers University, Piscataway, NJ, Contact: sepideh.samadi@rutgers.edu

We aim to minimize a sum of local nondifferentiable convex functions over the solution set of a distributed variational inequality (VI) problem with a monotone mapping. This problem finds an application in the efficiency estimation of transportation and communication networks. We develop an iteratively regularized incremental gradient method where agents communicate over a directed cycle graph to update their iterates using their local information. This method is single-timescale as it does not involve any excessive hard-to-project computation per iteration. We derive convergence rates for the global objective function's suboptimality and the VI constraints' infeasibility measured by a dual gap function. We present a numerical experiment for a transportation network problem to validate our results.

3 An Inexact Conditional Gradient Method for Constrained Bilevel Optimization

Nazanin Abolfazli[1], Ruichen Jiang[2], Aryan Mokhtari[3], Erfan Yazdandoost Hamedani[4], [1]the University of Arizona, Tucson, AZ, [2]University of Texas at Austin, Austin, TX, [3]University of Texas at Austin, Austin, TX, [4]the University of Arizona, Tucson, AZ, Contact: nazaninabolfazli@email.arizona.edu

In this talk, we focus on a class of constrained bilevel optimization problems. For those methods that can handle constrained problems, either the convergence rate is slow or the computational cost per iteration is expensive. To address this issue, in this talk, we introduce a novel single-loop projection-free method using a nested approximation technique. Our proposed method has an improved per-iteration complexity, surpassing existing methods, and achieves optimal convergence rate guarantees matching the best-known complexity of projection-free algorithms for solving convex constrained single-level optimization problems. In particular, when the upper-level objective function is convex, our method converges with the rate of ▯(▯$^{-1}$) and when it is non-convex the convergence rate will be ▯(▯$^{-2}$).

4 Stochastic and Hierarchical Multiagent Optimization

Farzad Yousefian, Rutgers University, Piscataway, NJ

In noncooperative Nash games, equilibria are known to be inefficient. This is exemplified by the Prisoner's Dilemma and was first provably shown in 1980s. We present single-timescale decentralized optimization methods for computing the best Nash equilibrium. We also discuss methods to compute the worst equilibrium.

Optimization and Surrogate Methods for Black-Box Systems

Community Committee Choice Session

Session Chair: Hadis Anahideh, University of Illinois at Chicago, Chicago, IL

1 Scalable Grey-Box Bayesian Optimization

Raul Astudillo[1], Peter Frazier[2], [1]California Institute of Technology, Pasadena, CA, [2]Cornell / Uber, Ithaca, NY, Contact: raul.astudillo@caltech.edu

Bayesian optimization (BO) is a framework for global optimization of expensive-to-evaluate objective functions. Classical BO methods assume the objective function is a black box. However, internal information about objective function computation is often available. Recently, "grey-box" BO methods leveraging such internal information have been proposed. These methods have shown promising results, often improving performance by multiple orders of magnitude. At the same time, however, they are typically computationally challenging and thus limited to problems of moderate "size". In this talk, I will discuss recent advances improving the scalability of grey-box BO.

2 Dynamic Exploration-exploitation Pareto Approach for High-dimensional Expensive Black-box Optimization

Nazanin Nezami[1], Hadis Anahideh[2], [1]University Of Illinois at Chicago, Chicago, IL, [2]University of Illinois at Chicago, Chicago, IL, Contact: nnezam2@uic.edu

Surrogate-based optimization is prevalent in engineering to determine optimal performance parameters for costly simulations. This study proposes a Pareto sampling approach coupled with dynamic discretization for high-dimensional black-box optimization. The proposed Dynamic Exploration-Exploitation Pareto Approach (DEEPA) incorporates dynamic coordinate importance for effective sample generation in high-dimensional solution space. Incorporating dynamic coordinate importance, DEEPA employs model-based and model-agnostic feature selection to enhance sample generation. Perturbing coordinates based on importance probabilities aids convergence to near-optimal solutions. DEEPA's versatility in fixed-batch evaluation environments is demonstrated, outperforming current optimization methods in intricate problems with multiple local minima.

3 Kernelized Lipschitz Constant Estimator: A Non-Linear Lower Bound Construction Approach for Efficient Global Optimization

Mohammadsina Almasi[1], Hadis Anahideh[1], Jay Michael Rosenberger[2], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Texas-Arlington, Arlington, TX

Global optimization is a challenging task due to the complexity of objective functions and high-dimensional search spaces. Lower bounds play a crucial role in guiding optimization algorithms, improving their speed and quality. While Lipschitz constant-based lower bound construction is an effective technique, the quality of the linear bounds depends on the objective's topological properties. Our approach improves upon this by incorporating non-linear kernels to generate higher-quality bounds. We emphasize the importance of using a flexible kernel that can adapt to any function, especially in scenarios where the function is accessible only through a surrogate model. Combining surrogate models and non-linear kernels for Lipschitz constant estimations results in high-quality lower bounds that can contribute to more effective exploration and exploitation.

4 Optimizing Latent Spaces for Mixed Input Domains in Bayesian Optimization

Ng Szu Hui[1], Mingyu Pu[1], Songhao Wang[2], [1]National University of Singapore, Singapore, Singapore; [2]Southern University of Science and Technology, Shenzhen, China

Bayesian optimization (BO) faces significant challenges when applied in mixed categorical and numerical search spaces. The traditional approach to constructing the Gaussian process surrogate and acquisition functions in BO becomes problematic in such mixed-input scenarios. Our study addresses this by exploring encoding methods to convert the mixed inputs into numerical ones in a latent space. Additionally, instead of fixing the latent space, we develop a framework to further learn and search for optimal ways of encoding along with the sequential optimization process. This enables more adaptive and effective latent spaces to be learned and applied as the algorithm sequentially collects more data and optimizes the objective function.

Topics in Bayesian Optimization and Reinforcement Learning

Community Committee Choice Session

Session Chair: Daniel Jiang, Meta, Menlo Park, CA

1 Weakly Coupled Deep Q-Networks

Ibrahim El Shar[1], Daniel Jiang[2], [1]Pittsburgh, PA, [2]Meta, Menlo Park, CA

We propose weakly coupled deep Q-networks (WCDQN), a novel deep reinforcement learning algorithm that enhances performance in structured problems known as weakly coupled Markov decision processes (WCMDP). WCMDPs consist of multiple independent subproblems connected by an action space constraint. Despite this appealing structure, WCMDPs quickly become intractable as the number of subproblems grows. WCDQN employs multiple DQN agents, each addressing a subproblem, combining their solutions to establish an upper bound on the action value. This guides the main DQN agent towards optimality. We show that the tabular version, weakly coupled Q-learning (WCQL), converges almost surely. Numerical experiments show faster convergence compared to DQN/Q-learning and related techniques.

2 Bayesian Optimization with Adaptively-Optimized Early Stopping Rules

Jiayue Wan[1], Peter Frazier[2], Daniel Jiang[3], [1]Cornell University, Ithaca, NY, [2]Cornell / Uber, Ithaca, NY, [3]Meta, Menlo Park, CA, Contact: jw2529@cornell.edu

When Bayesian optimization (BO) is applied in settings where function evaluations return partial data (e.g., machine learning training), early stopping rules can be used to terminate unpromising trials and reduce unnecessary computational cost. However, these stopping rules are typically considered separately from the BO acquisition function, leading to two challenges: (1) poor performance due to lack of consistency between suggested points and the stopping rule and (2) difficulty for practitioners to select the "right" parameters for the stopping rule. In this paper, we present an MDP formulation of the joint BO and stopping problem and propose a lookahead acquisition function for jointly optimizing the suggested points and parameters of the stopping rule.

3 High-Dimensional Bayesian Optimization in Mixedspaces via Nested Random Subspaces

Matthias Poloczek, Amazon, San Francisco, CA

Bayesian optimization (BO) has become a powerful method for the sample-efficient optimization of expensive black-box functions. Use cases arise in AutoML, e.g., when tuning an ML model, in RL when optimizing a policy, etc. Recent advances have scaled BO to dozens of variables and also extended the scope to discrete variables in addition to the usual continuous variables. However, a closer examination reveals that the state-of-the-art suffers from degrading performances or even failures if the instance doesn't meet certain unverifiable properties.

I will show how to leverage nested random subspaces to reliably achieve excellent results on high dimensional problems on continuous and mixed spaces.

Based on joint work with Leonard Papenmeier and Luigi Nardi (Lund University, Sweden).

Optimization with Rare Events

Community Committee Choice Session

Session Chair: Anirudh Subramanyam, The Pennsylvania State University, University Park, PA

1 Optimization Under Rare Chance Constraints

Shanyin Tong[1], Anirudh Subramanyam[2], Vishwas Rao[3], [1]Columbia University, New York, NY, [2]Penn State University, State College, PA, [3]Argonne National Lab, Lemont, IL, Contact: st3503@columbia.edu

Chance constraints provide a framework to mitigate the risk of high-impact extreme events by modifying the controllable properties of a system. The rare occurrence of such events imposes severe sampling and computational requirements on classical methods. This work proposes a novel sampling-free method for solving rare chance constrained optimization problems affected by uncertainties that follow Gaussian mixture distributions. By integrating large deviation theory with bilevel optimization, we propose formulations that can be solved by off-the-shelf solvers. Computational experiments from applications in portfolio management, structural engineering, and fluid dynamics illustrate the broad applicability of our method and its advantages over classical sampling-based approaches in terms of accuracy and efficiency.

2 Randomized Approaches for Optimal Experimental Design

Vishwas Rao[1], Arvind Saibaba[2], Srinivas Eswar[1], [1]Argonne National Laboratory, Lemont, IL, [2]North Carolina State University, Raleigh, NC

This work describe connections between optimal experiment design (OED) for PDE-based Bayesian linear inverse problems and the column subset selection problem (CSSP) in matrix approximation.We derive bounds, both lower and upper, for the D-optimality criterion via CSSP for the independent and colored noise cases.Additionally, we describe ways to interpolate "left-out" sensor data using the "selected" sensors along with the errors in the data completion process. We develop and analyse randomized algorithms which achieve these bounds.Finally, we experimentally verify these results on a model advection-diffusion problem.

3 Rare Event Estimation in High-Dimensional Spaces Through Hamiltonian Mcmc and Inverse Importance Sampling

Elsayed Eshra[1], Kostas G. Papakonstantinou[1], Hamed Nikbakht[2], [1]Penn State, University Park, PA, [2]Risk Management Solutions Inc., Newark, CA, Contact: eme5375@psu.edu

This work presents the *Approximate Sampling Target with Post-processing Adjustment* framework, a computationally efficient method for accurately estimating rare events probabilities, often encountered in optimization under chance constraints. The approximate sampling target, constructed utilizing a cumulative distribution function and the system performance expression, successfully places greater importance on the rare event domain in the random variable space. Our developed Quasi-Newton mass preconditioned Hamiltonian MCMC is then used to efficiently sample the constructed target. To compute the target probability, a post-processing adjustment step is employed to normalize the sampling target, involving a devised *inverse importance sampling* procedure, that utilizes an importance sampling density suggested based on the already acquired samples.

4 Network Cascade Vulnerability Using Constrained Bayesian Optimization

Albert Lam[1], Mihai Anitescu[1], Anirudh Subramanyam[2], [1]Argonne National Laboratory, Lemont, IL, [2]The Pennsylvania State University, University Park, PA, Contact: albert3033@gmail.com

Measures of power grid vulnerability are often assessed by the amount of damage an adversary can exact on the network. However, the cascading impact of such attacks is often overlooked, even though cascades are one of the primary causes of blackouts. This paper explores modifications of transmission line protection settings as candidates for adversarial attacks, which can remain undetectable as long as the network equilibrium remains unaltered. This forms the basis of a black-box function in a Bayesian optimization procedure, where the objective is to find settings that maximize network degradation due to cascading. Our experiments reveal that, even when the degree of misconfiguration is resource constrained, it is still possible to find settings that produce cascades comparable in severity to instances where there are no constraints.

5 Importance Sampling for Optimization with Chance Constraints

Anirudh Subramanyam, The Pennsylvania State University, University Park, PA

Optimization problems with randomly constrained rare events present a significant challenge due to the difficulty of computing the probability that a potential decision meets the random constraints. Importance sampling, a recognized variance reduction method, attempts to alter the probability measure from which the random variables are sampled. However, the issue of selecting a suitable importance distribution tha functions well for all decision variables across a diverse range of problems remains unresolved. Most existing strategies are problem-dependent and require deep knowledge of the system's dynamics. Using recent developments in rare event quantification, this paper presents a generic importance sampling approach that does not suffer from these limitations and is capable of addressing a broad spectrum of chance-constrained problems.

Optimization in Drones and Novel Applications

Community Committee Choice Session

Session Chair: Gino J. Lim, University of Houston, Houston, TX

Session Chair: Yanchao Liu, Wayne State University, Detroit, MI

1 Scheduling Diagnostic Testing Kit Deliveries with the Mothership and Drone Routing Problem

Gino J. Lim[1], Hyung Jin Park[2], Reza Mirjalili[1], Murray J. Cote[3], [1]University of Houston, Houston, TX, [2]Defense Security Support Command, Seoul, Korea, Republic of; [3]Texas A&M University, College Station, TX, Contact: ginolim@uh.edu

We propose a delivery scheduling approach for COVID-19 diagnostic testing kits using a truck and multiple drones with the ultimate goal of minimizing the spread of virus due to human contact. Heuristic algorithms are developed to solve the MIP model faster so that the approach can be practically useful. The experiments show that the proposed method has the potential to significantly reduce human contact; hence, it can reduce disease spread. We observed a 7.5 times reduction on a modified measure of the basic reproduction rate.

2 Mothership-Based Drone Routing and Truck Scheduling Using Branch-And-Price-And-Cut

Reza Mirjalili[1], Gino J. Lim[2], Taewoo Lee[3], [1]University of Houston, TX, [2]University of Houston, Houston, TX, [3]University of Pittsburgh, Pittsburgh, PA

We present a mothership scheduling and multi-visit drone routing problem. The goal is to minimize the total flight duration of drones, including the waiting times of both vehicles. Due to the computational complexity of solving the optimization model, we propose a branch-and-price-and-cut (BPC) method based on Dantzig-Wolfe decomposition. We propose a pruning policy to prevent the unnecessary expansion of BPC, and derive a new lower bound on the number of flights and a valid inequality for wait-hover of vehicles are introduced. A significant improvement in computation time has been observed.

3 Routing Battery-Constrained Delivery Drones in a Depot Network

Yanchao Liu, Wayne State University, Detroit, MI, Contact: yanchaoliu@wayne.edu

We propose a new business model for on-demand package shipment services using drones: customers' shipment orders of arbitrary origins and destinations, payload weights and bid values are collected every five minutes, and available drones from multiple depots are dispatched to fulfill a subset of these orders in a way to maximize profit. A drone path starts from a depot, serves one or more customer orders in sequence, and ends at a depot for battery recharging, which incurs a fixed cost. A compact and a path-based formulation of the dispatch and routing problem are compared, and column generation and brute-force solution approaches are evaluated. Managerial insights gained from an optimization-simulation framework will be discussed.

4 Multiple UAVs' Coverage Path Planning in Rectangular Area Under Windy Conditions

Sina Kazemdehbashi[1], Yanchao Liu[2], [1]Wayne State University, Detroit, MI, [2]Wayne State University, Detroit, MI, Contact: hm3369@wayne.edu

Using drones for surveillance operations comes with its own challenges such as the risk of collision and environmental factors. To deal with these challenges, we develop path planning algorithms to enable a fleet of drones to efficiently search a target area in windy conditions. We first propose a mixed-integer programming model to formulate the problem. Then, to design a practical solution approach, we investigate a special case of the problem where the search area is a rectangular grid. For this special case, we prove that the optimal search time can be calculated using a mathematical formula. We then design an algorithm to obtain the optimal search pattern for multiple drones in polynomial time. Finally, the effectiveness of the algorithms is demonstrated in some simulated scenarios.

CC-North 225A

Applications of Machine Learning Powered Computational Techniques in Transportation Systems

Community Committee Choice Session

Session Chair: Jiawei Lu, 1</sup

1 Leveraging Imitation Learning for Traffic Flow Harmonization in Mixed Autonomy Environment

Zhe Fu, UC Berkeley, Berkeley, CA, Contact: zhefu@berkeley.edu

In this presentation, we explore methods for generating traffic-regulating behaviors by automated driving systems through imitation learning. Imitation learning has become a staple within a number of driving applications, with many replacing rule-based behavioral systems with those trained to imitate human drivers. In dense traffic situations, however, imitating humans alone is likely insufficient, as humans often contribute to the proliferation of traffic congestion. Instead, we construct an expert policy that, in simulation, exploits knowledge of global states of traffic to homogenize the movement of vehicles towards their desirable uniform-flow equilibrium. We then demonstrate that imitation learning techniques can successfully capture such behaviors using only local/decentralized observations and relatively few interactions with the environment.

2 Physics-Informed Neural Networks for Integrated Traffic State and Queue Profile Estimation: A Differentiable Programming Approach on Layered Computational Graphs

Jiawei Lu, Georgia Institute of Technology, Atlanta, GA, Contact: jlu486@gatech.edu

This study presents an integrated framework for physics-informed joint traffic state and queue profile estimation (JSQE) on freeway corridors. The integrated modeling framework aims to maximize the benefits of information from physics-informed analytical traffic flow models and field observations. A nonlinear programming model is formulated for the JSQE problem, taking into account traffic flow models and observations from both corridor and local segment levels. At the corridor level, a fluid queue approximation is employed to model queuing dynamics. To preserve the differentiability of traffic state variables, continuous space-time distribution functions are introduced to model traffic flow variables and partial differential equations. A computational graph is constructed to represent the nonlinear programming model in a layered structure.

3 Bayesian Tucker Tensor Decomposition For Dynamic Origin-destination Demand Analysis

Zihan Wan, Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: 22062327r@connect.polyu.hk

Origin-Destination demand usually appears as a multi-way tensor, useful for mobility companies for taxi deployment or transportation authority for congestion reduction. But spatiotemporal prediction is a challenge due to high dimensionality and temporal patterns. To characterize the uncertainty in O-D demand, we propose a hierarchical Bayesian 3-way tensor decomposition. By using low-rank assumption, our model can characterize features of origins and destinations in an interpretable fashion. Another feature is that posteriors of latent factors enable demand prediction. Due to intractability of exact posteriors, Stochastic Variational Inference techniques are used to find the closest posteriors measured by Evidence Lower Bound. Further, we can develop a more reliable prediction of future O-D demand with quantified uncertainty.

4 Identifying Car-Following Dynamics from Trajectory Data via Automatic Learning

Ohay Angah, Xuegang Ban, University of Washington, Seattle, WA

Most of the commonly used car-following models are based on human knowledge. There may still exist other driving behaviors that can be generalized undiscovered. This study aims to generalize car-following dynamics from data using automatic learning models. We first validate the capability of the automatic learning models using simulation data. The models are then used to discover car-following behaviors from a real trajectory dataset. The aim is to identify a mathematical expression that is able to generalize car-following behaviors. We pre-process and split the trajectory dataset into multiple categories based on driving styles. A coordinate-learning framework is then developed to extract the physical patterns from the split categories.

5 Network-Wide Traffic State Evolution Prediction: Integrating Traffic Dynamics Model and Deep Neural Network

Hanyi Yang, 1</sup

This study develops a macroscopic traffic flow model integrated deep learning framework for traffic state evolution prediction, integrating temporal-spatial flow dependency, traffic flow theory, and data analysis techniques. First, traffic state evolution on every road section is mathematically described by the CTM model given traffic initial and boundary conditions. Next, a temporal-spatial traffic dependency attention (TSTD) recurrent neural network is developed to predict boundary conditions factoring the traffic temporal-spatial dependency. The numerical experiments illustrate that the proposed method predicts the traffic state evolution in a freeway network within 30 minutes with accuracy varying from 75%-95%. It has a better performance compared to the tested baseline models (APTN, Graph CNN-LSTM, and so on).

Learning and Optimization for Emerging Mobility Systems

Community Committee Choice Session

Session Chair: Qi Luo, Clemson University, Clemson, SC

1 Data-Driven Stochastic Programming for Electric Vehicle Charging Station Location with Decision-Dependent Demand Learning

Huangrong Sun[1], Guzin Bayraksan[2], Xian Yu[2], [1]Ohio State University, Columbus, OH, [2]The Ohio State University,

Columbus, OH, Contact: sun.3394@osu.edu
We consider an electric vehicle charging station location problem with uncertain customer demand where the demand depends on the location decisions. We formulate a two-stage stochastic program, where in the first stage, we optimize the location decisions to minimize the investment cost, and in the second stage, we allocate resources to meet the customer demand and minimize the operational cost. We use a regression model to learn the dependence between customer demand and charging station locations and apply an empirical residual-based Sample Average Approximation to solve the two-stage stochastic program. Numerical studies are conducted on synthetic data and real-world data in New York State to evaluate result sensitivity and compare different approaches.

2 Optimal Joint Battery Swapping Van Routing and Battery Redistribution Plans for Mobile On-Demand Charging Service

Lili Du, Jiahua Qiu, University of Florida, Gainesville, FL, Contact: lilidu@ufl.edu

Range anxiety hinders electric vehicle (EV) adoption. On-demand battery swapping, enabling quick replacements, is an emerging solution. However, efficient operation of Battery Swapping Vehicles (BSVs) requires effectively managing demand uncertainty, supply-demand imbalances in the transportation network, and drained battery distribution in the power grid. This paper presents a Model Predictive Control model, embedded with a mixed-integer nonlinear optimizer, to optimize the BSV service in these regards. A deep reinforcement learning and sampling-aided heuristic algorithm was developed to adapt solutions to large-scale instances. Numerical experiments confirmed the algorithm's efficiency and demonstrated the BSV service's robustness against demand uncertainty and heterogeneity.

3 Mixture Model for Contextual Route Choice in Multimodal Transportation Systems

Yan Wu[1], Qi Luo[2], Yuyuan Ouyang[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: yw8@clemson.edu

Predicting route behavior based on trip data becomes a challenging task because of the diversification of intermodal options and latent factors such as trust in the recommended routes. In this paper, we propose an Inverse Mixture Model (IMM) composed of two interconnected components: (1) a set of dynamic route choice models with arc-to-arc transition functions contingent on the contextual traffic conditions, and (2) mixture probabilities determining the selection of route choice models. The mixture probabilities are influenced by the expected value of following recommended routes, thus emulating travel behavior in dynamic and convoluted traffic networks. Two EM algorithms are tailored for estimating IMMs in the following scenarios: (1) mixture probabilities are predetermined upon arriving at the origin, (2) mixture probabilities vary at each intersection.

4 Learning Generalized Mean-Field Games for Day-To-Day Departure Time Choice with Dynamic Population

Ben Wang[1], Qi Luo[2], Yafeng Yin[3], [1]Univerisity of Michigan, Ann Arbor, MI, [2]Clemson University, Clemson, SC, [3]University of Michigan, Ann Arbor, MI, Contact: papaver@umich.edu

We investigate the day-to-day departure time choice (DDTC) problem for travelers, where they choose their modes and departure times to minimize travel costs. Our research uses a customized hierarchical soft actor-critic (HSAC) algorithm, which considers the interactions between travelers in a dynamic game. The algorithm finds an approximate Markovian Perfect Equilibrium (MPE) and sheds light on the impact of emerging mobility and travel information technology on travel behavior. Our findings provide a foundation for promoting socially optimal travel plans through adaptive traffic control policies.

5 Service Network Design with Hub Constraints

Ozgur Satici[1], Iman Dayarian[1], Teodor Gabriel Crainic[2], [1]University of Alabama, Tuscaloosa, AL, [2]Université du Québec à Montréal, Montréal, QC, Canada. Contact: osatici@crimson.ua.edu

This study focuses on the service network design of intra-city operations for courier companies. It proposes a physical network of package drop-off and pick-up hubs within the city, with limited parking and storage capacity. The problem is divided into two phases: Phase I creates itineraries for each commodity, while Phase II constructs vehicle routes based on Phase I outputs. For Phase I, we develop a MIP model and enhance it with network reduction and warmstart techniques. Phase II is formulated as a Vehicle Routing Problem with Time Windows and solved using a Tabu Search-based algorithm. Preliminary tests highlight the effectiveness of the proposed approach, demonstrating potential cost reduction and improved computational efficiency.

Recent Trend in Machine Learning Theory and Its Application in Operations Management

Community Committee Choice Session

Session Chair: Hongyang Zhang, Northeastern University, Boston, MA

Session Chair: Wei Hu, 1</sup

1 Popart: Efficient Sparse Regression and Experimental Design for Optimal Sparse Linear Bandits

Chicheng Zhang, University of Arizona, Tucson, AZ, Contact: chichengz@cs.arizona.edu

In sparse linear bandits, a learning agent sequentially selects an action and receive reward feedback, and the reward function depends linearly on a few coordinates of the covariates of the actions. In this work, we propose a simple and computationally efficient sparse estimation method called PopArt that enjoys a tighter l1 recovery guarantee compared to Lasso in many problems. Our bound naturally motivates an experimental design criterion that is computationally efficient to solve. Based on our novel estimator and design criterion, we derive sparse linear bandit algorithms with improved regret upper bounds upon the state of the art (Hao et al., 2020), especially with respect to the geometry of the given action set. Finally, we prove a matching lower bound for sparse linear bandits in the data-poor regime, closing the gap between upper and lower bounds in prior work.

2 Pseudo-Labeling for Kernel Ridge Regression Under Covariate Shift

Kaizheng Wang, Columbia University, New York, NY

We develop and analyze a principled approach to kernel ridge regression under covariate shift. The goal is to learn a regression function with small mean squared error over a target distribution, based on unlabeled data from there and labeled data that may have a different feature distribution. We propose to split the labeled data into two subsets and conduct kernel ridge regression on them separately to obtain a collection of candidate models and an imputation model. We use the latter to fill the missing labels and then select the best candidate model accordingly. Our non-asymptotic excess risk bounds show that in quite general scenarios, our estimator adapts to the structure of the target distribution as well as the covariate shift. It achieves the minimax optimal error rate up to a logarithmic factor. Pseudo-labels for model selection do not have major negative impacts.

3 Identification of Negative Transfers in Multitask Learning Using Surrogate Models

Hongyang Zhang, Northeastern University, Boston, MA

Multitask learning is widely used in practice to train a low-resource target task by augmenting it with multiple related source tasks. Yet, naively combining all the source tasks with a target task does not always improve the prediction performance for the target task due to negative transfers. Thus, a critical problem is identifying subsets of source tasks that would benefit the target task. This problem is challenging since the number of subsets grows exponentially with the number of source tasks; efficient subset selection heuristics does not always capture the relationship between task subsets and multitask performances. In this paper, we introduce an efficient procedure to address this problem via surrogate modeling. We show that our approach predicts negative transfers much more accurately than existing measures and consistently improves upon existing methods.

4 Nonlinear Benign Overfitting

Wei Hu, University of Michigan, Ann Arbor, MI, Contact: vvh@umich.edu

Benign overfitting is the intriguing phenomenon that a model overfits the noisily labeled training data while still generalizing near optimally. Recent work rigorously proved benign overfitting in a number of settings, but they are limited to linear models or data distributions that are linearly separable. We provide the first benign overfitting result in a nonlinear setting, in which we also show an interesting delayed generalization phenomenon not present in previous work.

5 Advertising Media and Target Audience Optimization via High-Dimensional Bandits

Wenjia Ba[1], Michael Harrison[2], Harikesh Nair[3], [1]University of British Columbia, Vancouver, CA, Canada; [2]Stanford University, Palo Alto, CA, [3]Stanford University, Stanford, CA, Contact: wenjiaba8@gmail.com

This paper introduces a data-driven algorithm, LRDL (Logistic Regression with Debiased Lasso), to automate digital ad-campaigns for advertisers at online publishers. The algorithm actively explores and identifies the optimal audience-ad combination for a campaign from numerous choices, despite very low success probabilities. It addresses challenges like high-dimensional search formulations and prior uncertainty by integrating a multiarmed bandit framework, a Lasso penalty function, a debiasing kernel, and a semi-parametric regression model for cross-learning. Implemented as a Thompson Sampler, LRDL demonstrates superior performance in simulations against several high-dimensional bandit literature benchmarks.

Simulation-based Optimization for UAM Integration

Community Committee Choice Session

Session Chair: Xuan Jiang, 1</sup

1 Evaluation of Vertiport Arrival Operations with the U-Sky Simulator

Carlos Querejeta, Boeing, Madrid, Spain. Contact: Carlos.Querejeta@boeing.com

The development of critical aspects that enable future autonomous UTM operations like tactical deconfliction, contingency management or vertiport operations is still in its infancy and their evolution will undoubtedly involve the analysis of dense traffic simulations suitable to evaluate technical proposals. This presentation showcases the application of Boeing's UTM oriented U-Sky simulator to evaluate vertiport arrival operations. Different methods are considered to manage convergent traffic to vertiports, suitable dense traffic simulations are conducted, and the data analysis of their outcomes is presented to evaluate the impact of the different methods in the efficiency and safety of the operations.Overall, U-Sky is presented as a versatile tool suitable to support the development of key components that support the future autonomous UTM operations.

2 Simulating the Integration of Urban Air Mobility into Existing Transportation Systems: A Survey

Yuhan Tang, University of California, Berkeley, CA

Urban air mobility (UAM) has the potential to revolutionize transportation in metropolitan areas, alleviating congestion and improving accessibility. Integrating UAM into existing systems poses complex challenges, requiring an understanding of its impact on traffic flow and capacity. In our study, we undertake a comprehensive survey of prevailing traffic simulators and evaluate their general capabilities. Subsequently, we identify key challenges and opportunities associated with integrating UAM into urban transportation systems, encompassing the effects on existing traffic patterns and congestion, safety and risk assessment, and potential economic and environmental benefits. By offering an overview of the current state of research related to simulation and UAM, our survey underscores crucial areas necessitating further research and development.

3 Assessing Advanced Air Mobility for Cargo Operations

Nick Gunady, 1</sup

Advanced Air Mobility (AAM) is an emerging aerial transport system that relies on electric aviation. Cargo operations are seen as a potential viable entry into service and a lucrative operational concept due to the lower operating costs of electric aviation. Middle Mile Delivery (MMD) is the segment of cargo logistics within an operator's network between the distribution or ship centers of the operator. To understand the usage of future AAM vehicles for cargo operations in MMD, we utilize a vehicle routing problem to model fleet allocation across several metropolitan areas. Economic sensitivities and environmental impact assessments are presented to compare vehicle and metro-specific implications of this nascent market, and the connection to electrified Last Mile Delivery are considered in the context of system-of-systems operations.

4 UTM V0.1: A Simple System to Keep Drone Traffic Safe

Valentin Polishchuk, Linköping University, LiU, Norrköping, Sweden

We estimate the capacity of very low level (VLL) airspace via simulations. We observe that the probability of occurrence of large conflicts exhibit a phase transition as the traffic density is increased. The traffic density at the phase transition i.e. the capacity, increases with decreasing minimum separation tolerance. This suggests a way to establish UTM v0.1 -- a simple and efficient system which could keep the drone traffic safe while bypassing the complicated operations approval process. Joint work with UC Berkeley

5 Community/Committee'S Choice Submission

Shangqing Cao, 1</sup

Placements of vertiports affect the total addressable market and value proposition of Urban Air Mobility (UAM). We propose a simulation-based optimization scheme with machine learning surrogates to identify the optimal number and locations of vertiports. Our methodology consists of three key stages: (1) Leverage the DBSCAN algorithm to cluster the origins and destinations of UAM passengers. Randomly generate sets of vertiport locations as candidates. (2) Assess the proposed candidates through a simulation model. (3) Construct and tune surrogate machine learning models to create a reliable predictor of the objective function. Use a genetic algorithm to find local optimality. By implementing our method in the San Francisco Bay region, we found a set of vertiport locations that achieve local optimality over all candidates sampled in (1).

Network Analytics

Community Committee Choice Session

Session Chair: John Rios, University of Georgia, Athens, GA

1 How Has Covid-19 Shaken up the Global Supply Chain Networks? - the Role of Location and Firm Performance

John Rios[1], Kang Zhao[2], Elaheh Seyedalikhani[3], Suyong Song[4], [1]University of Georgia, Athens, GA, [2]University of Iowa, Iowa City, IA, [3]University of Iowa, Iowa City, IA, [4]University of Iowa, Iowa City, IA

Maximizing firm value is the ultimate goal of the managers and shareholders. A strong and stable supplier-customer relationship creates value for both trade parties, leading to higher returns for investors of the partner firms. This research implements a stochastic actor-oriented model to analyze the evolution of supply chain networks across different years. We study how various company features (like location or financial performance) and external disruption events (like the COVID-19 pandemic) affect the formation of ties between business partners. While this is an ongoing project, our current results identify changes in companies' mechanisms to select their business partners. Our final goal is to understand how disruptive events change the way companies decide to start businesses with new customers and suppliers or to stop trading with their current ones.

2 A New Index Measuring Occupational Exposure To Artificial Intelligence

Yuanyang Liu[1], Chuanren Liu[1], Tingliang Huang[2], [1]University of Tennessee, knoxville, TN, [2]The University of Tennessee-Knoxville, Knoxville, TN, Contact: yliu191@utk.edu

We develop a new AI index to quantify the occupational exposure to artificial intelligence (AI) technologies. Our methodology utilizes the text embedding vectors to quantify the similarity between occupation descriptions and AI patents. We find that occupations located at the two extremes of the skill distribution are least exposed to AI technologies. Further, for high-skill occupations, those with higher AI index also see the non-routine work activities becoming more important, consistent with the prediction of the routinization hypothesis. However, for low-skill occupations, non-routine tasks become less important in occupations more exposed to AI. These results suggest a possible differential impact of AI on the nature of work for low-skill and high-skill workers.

3 Mining Actionable Insights for Effective Marketing on Social Web Using Context-Aware Multimodal Knowledge-Infused Learning

Ugur Kursuncu[1], Lane Fronczek[2], Manya Rampuria[3], Trilok Padhi[3], Yaman Kumar[4], Valerie L. Shalin[5], [1]Georgia State Unviersity, Atlanta, GA, [2]Georgia State Unviersity, Atlanta, GA, [3]Georgia State Unviersity, Atlanta, GA, [4]Adobe Research, Delhi, India; [5]Wright State Unviersity, Dayton, OH, Contact: ugur@gsu.edu

Marketing a human-centered process exchanging multimodal content (e.g., text/image/video) as behavioral dynamics between marketers and consumers determine the success of a campaign. While online multimodal content provides an enhanced experience to the users, such richness of multimodality also brings the challenge of computational modeling, as the semantic contextual cues span across modalities to make the meaning of the multimodal content. Identifying and incorporating psycho-social cues and contextual connections is crucial in retrieving the true holistic meaning and; thus, more meaningful insights for decision-making. We will discuss our approach for mining actionable insights for effective marketing, challenges and opportunities for building intelligent systems to retrieve insights through multimodal data on the social web.

Machine Learning for Integer Programming

Community Committee Choice Session

Session Chair: KHALIL Elias, University of Toronto, toronto, ON, Canada

1 Faster Multi-Objective Integer Programming with Learned Variable Orderings: A Case Study of Knapsack

Rahul Patel[1], Elias B. B. Khalil[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: rm.patel@mail.utoronto.ca

Binary decision diagram (BDD)-based approaches have achieved state-of-the-art results for multiobjective integer programming. The variable ordering (VO) employed in BDD construction significantly affects its size and the quality of bounds obtained from relaxed/restricted BDDs for single-objective problems. In the context of multiobjective problems, we not only demonstrate the impact of VO on the enumeration time of the Pareto frontier (PF), but also utilize

black-box optimization to identify effective VO strategies that reduce PF enumeration time. However, the computational overhead incurred by black-box optimization outweighs the aforementioned reduction in PF enumeration time. To address this issue, we propose a learning-based approach for VO. Experimental results on Knapsack instances validate the effectiveness of our proposed method.

2 Learn2aggregate: Supervised Generation of Chvatal-Gomory Cuts Using Graph Neural Networks

Arnaud Deza, University of Toronto, Toronto, ON, Canada. Contact: arnaud.deza@mail.utoronto.ca

Recent years have witnessed a number of research efforts to enhance the strength of cutting plane subroutines, specifically cutting plane selection using machine learning (ML). This work has a similar goal by aiming to assist a computationally expensive separator, the Chvatal-Gomory (CG) cut generator, in integer programming (IP) solvers using data-driven analysis. We embed ML into the generation of valid inequalities and show how optimized cut selection can be incorporated into the learning phase for cut generation. Our ML framework uses a graph neural network to generate CG cuts which leverages cut integrality. Although we only focus on CG cuts, our approach can be extended to other families of cuts. Preliminary experiments on synthetic IP instances demonstrate promising results regarding the validity of ML research for cut generation.

3 Pyepo: A Pytorch-Based End-To-End Predict-Then-Optimize Library for Linear and Integer Programming

Bo Tang[1], Elias B. B. Khalil[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: botang@mie.utoronto.ca

In deterministic optimization, all problem parameters are fixed and known. In practice, however, some parameters may be priori unknown but can be estimated. Compared to the traditional two-stage method, end-to-end predict-then-optimize has become an attractive alternative. This work presents the PyEPO package, a PyTorch-based end-to-end predict-then-optimize library, which is the first such generic tool for linear and integer programming. It provides four base algorithms: a convex surrogate loss, a differentiable black-box solver, and two perturbation-based methods, which enable us to conduct experiments comparing end-to-end and two-stage approaches along axes such as prediction accuracy, decision quality, and running time. Furthermore, we extend the framework to a multi-task setting that enables information sharing between tasks for improved learning.

4 A Deep Reinforcement Learning Framework for Column Generation

Khalil Elias, University of Toronto

Column Generation (CG) is an iterative algorithm for solving linear programs (LPs) with an extremely large number of variables (columns). CG is the workhorse for tackling large-scale integer linear programs, which rely on CG to solve LP relaxations within a branch and bound algorithm. Two canonical applications are the Cutting Stock Problem (CSP) and Vehicle Routing Problem with Time Windows (VRPTW). In VRPTW, for example, each binary variable represents the decision to include or exclude a route, of which there are exponentially many; CG incrementally grows the subset of columns being used, ultimately converging to an optimal solution. We propose RLCG, the first Reinforcement Learning (RL) approach for CG. Unlike typical column selection rules which myopically select a column based on local information at each iteration, we treat CG as a sequential decision-making problem, as the column selected in an iteration affects subsequent iterations of the algorithm. This perspective lends itself to a Deep Reinforcement Learning approach that uses Graph Neural Networks (GNNs) to represent the variable-constraint structure in the LP of interest. We perform an extensive set of experiments using the publicly available BPPLIB benchmark for CSP and Solomon benchmark for VRPTW. RLCG converges faster and reduces the number of CG iterations by 22.4% for CSP and 40.9% for VRPTW on average compared to a commonly used greedy policy.

Operationalizing Public Sector Data for Social Good

Community Committee Choice Session

Session Chair: Geri Dimas, Worcester Polytechnic Institute, Worcester, MA

Session Chair: Weixiao Huang, Worcester Polytechnic Institute, Worcester, MA

1 Optimizing Sponsored Humanitarian Parole

Fatemeh Farajzadeh[1], Ryan Killea[2], Alexander Teytelboym[3], Andrew C. Trapp[2], [1]Worcester Polytechnic Institute, WORCESTER, MA, [2]Worcester Polytechnic Institute, Worcester, MA, [3]University of Oxford, Oxford, United Kingdom. Contact: ffarajzadeh@wpi.edu

We introduce a novel algorithmic matching system, RUTH, that relocates Ukrainian refugees to US sponsors for the first time according to their preferences. RUTH (Refugees Uniting Through HIAS) implements Thakral's (2016) Multiple Waitlist Procedure with refugee relocation preferences and sponsor priorities. We analyze whether periodic matching can improve match quality and which locations require the highest sponsor arrival rates in the long run. Our algorithmic design uniquely puts a lot of weight on refugees' preferences, promotes equity and opportunity access for refugee protection and is applicable to other humanitarian parole schemes.

2 Collecting Data in the Human Trafficking Domain: Youth-Informed and Data-Driven Recommendations for Runaway and Homeless Youth in Nyc

Renata Alexandra Konrad[1], Geri Dimas[1], Yaren Bilge Kaya[2], Andrew C. Trapp[1], Kayse Lee Lee Maass[2], Meredith Dank[3], Andrea Hughes[3], [1]Worcester Polytechnic Institute, Worcester, MA, [2]Northeastern University, Boston, MA, [3]New York University, New York, NY, Contact: rkonrad@wpi.edu

Runaway and homeless youth (RHY) are particularly vulnerable to human trafficking (HT) and exploitation, and prevention is a powerful tool for countering trafficking. Access to appropriate housing and associated support services can significantly decrease a youth's likelihood to experience sexual or labor exploitation. We discuss our process and results from collecting over 300 surveys from RHY in New York City (NYC). These data are being deployed in a youth-informed capacity expansion model and benefit to cost-ratio framework for data-driven recommendations. The results of this work are currently being developed into an interactive interface for decision makers in NYC. We underscore the importance of understanding RHY needs by incorporating them to effectively allocate resources and discuss the challenges and lessons learned throughout this process.

3 Data Analytics in the Public Sector: Challenges and Critical Considerations

Geri Louise Dimas[1], Renata Alexandra Konrad[2], Andrew C. Trapp[2], [1]Bryant University, Smithfield, RI, [2]Worcester Polytechnic Institute, Worcester, MA, Contact: gldimas@wpi.edu

Data science and applied analytics are powerful tools that hold immense promise in supporting the operations of governmental agencies, non-governmental and nonprofit organizations. However, implementing these methods in the public sector poses unique challenges that require careful consideration. We open this discussion with first-hand experiences working in domains such as immigration, anti-human trafficking, and social programming to explore the benefits and challenges of data-driven decision-making. Through case studies and practical examples, we will show how data science and applied analytics can help organizations better understand their operations, identify patterns, and improve resource allocation. By leveraging these insights, public sector organizations can make more informed decisions and evaluate the impact of policies and their programs.

4 Operations Research for Addressing Homelessness Crises

Dashi Singham, Naval Postgraduate School, Monterey, CA, Contact: dsingham@nps.edu

We present multiple approaches for employing operations research to develop analytics solutions for communities with large homeless populations. Discrete-event simulation models can track the flow of people through a resource-constrained housing system. Queueing theory approaches assess stability of the system by analyzing blocking mechanics. Simulation optimization can be used to determine the best allocation of investments across specialized housing pathways. A case study using data from the Bay Area in California is presented. We summarize a portfolio of current and future efforts to address homelessness modeling.

Decision Support for the Path to Net-Zero Emissions: Beyond Least-Cost Portfolios
Community Committee Choice Session
Session Chair: Jesse D. Jenkins, ZERO Lab, Princeton University, Princeton, NJ
Session Chair: Michael Lau, Princeton University, Princeton, NJ
Session Chair: Qian Luo, Andlinger Center for Energy and the Environment, Princeton University, Princeton, NJ

1 Measuring Exploration: Review and Comparison of Modelling to Generate Alternatives Methods
Michael Lau, Princeton University, Princeton, NJ, Contact: ml6802@princeton.edu
Modern macro-energy systems (MES) modelling increasingly focuses on outcomes of interest beyond cost. Modelling to Generate Alternatives (MGA) is a method that maps the near-optimal feasible space of an MES model, enabling exploration of technically feasible system outcomes that balance multiple quantifiable or unquantifiable objectives. This research explores three canonical MGA algorithms and constructs an original method, along with a flexible testbed to benchmark their speed and efficacy in mapping the near-optimal feasible space of a series of random linear programs with *n* variables and *2n* constraints. We find the randomized search algorithm increases in efficiency with search dimension and performs the best out of the methods tested.

2 Next-Generation of Energy Modeling at U.S. the Energy Information Administration
Sauleh Siddiqui, Energy Information Administration, Washington, DC
As the energy system evolves and transitions, so should the way we model long-term energy projections. We will go over the latest efforts at the U.S. Energy Information Administration to build a next-generation modeling framework that is open, nimble, and flexible. This new framework will endogenously model uncertainty and consider modern energy issues associated with technology advancement, industrial policy, and community-level impacts.

3 Impacts of Transmission Network Expansion on Air Quality and Public Health

Qian Luo, Andlinger Center of Energy and the Environment, Princeton, NJ, Contact: ql7299@princeton.edu

Reaching net zero emissions economy-wide requires a significant amount of renewable energy in the power sector. To facilitate the integration of this clean energy resource, a major expansion of transmission lines is expected. Prior studies have demonstrated the critical role of grid transmission in power sector decarbonization. However, few investigate public health impacts of transmission expansion. In this work, we use one regional electricity market as a case study to examine how transmission expansion would impact power system planning, smokestack emissions, and public health associated with air pollution in local communities. To do this, we first design scenarios with different levels of transmission availability within the system. Then a state-of-art power system planning model and a reduced-complexity air quality model are combined to analyze the impacts.

4 Computational Advances for Modeling to Generate Alternatives

Gord Stephen, University of Washington, Seattle, WA

Modeling to generate alternatives (MGA) has been recognized as a valuable tool for identifying a broad set of viable energy system designs that can be ranked and filtered according to qualitative criteria, which may defy inclusion in a traditional mathematical optimization framework. However, the vast majority of established MGA approaches require re-solving large optimization problems with adjusted objective functions to generate each alternative. This can be very limiting for large planning problems, the very class of problems for which MGA methods may be most valuable. This presentation will outline a new approach for alternative generation that maintains mathematical guarantees about the viability of generated solutions while avoiding the need to repeatedly resolve expensive optimization problems.

5 Revealing the Effect of Zoning Ordinances and State-Level Land-Use Restrictions in Renewable Resources' Potential

Edgar Virguez[1], Xianxun Wang[2], John Fay[2], Timothy Johnson[3], Dalia Patino-Echeverri[2], [1]Carnegie Institution for Science, Stanford, CA, [2]Duke University, Durham, NC, [3]Duke University, Durham, NC, Contact: edgar.virguez@duke.edu

This study assesses the effect of incorporating land-use parcel-level data and local zoning ordinances when quantifying the resource potential for renewable energy projects. Examining utility-scale solar photovoltaics (PV) as a case study, we perform suitability and supply cost analysis of PV projects in North Carolina, incorporating the classification of more than 2.3 million parcels based on their local zoning ordinances.
Exploring three scenarios that represent conditions ranging from restrictive to favorable, the study finds a substantial reduction of PV resource potential when incorporating land-use and local zoning ordinances, reducing current estimates of land for PV in NC as much as ~8 million acres.
The study's findings highlight the necessity of integrating land-use restrictions into siting models while increasing their spatial granularity.

Energy Analytics and Energy System Modeling

Community Committee Choice Session

Session Chair: Sonja Wogrin, Graz University of Technology, Graz, Austria

1 Towards Renewable Power Systems: Analyzing the Technical and Economic Effects Using a Linked Modeling Framework

Robert Gaugl[1], Mark Sommer[2], Claudia Kettner[2], Udo Bachhiesl[1], Thomas Klatzer[1], Lia Gruber[1], Michael Böheim[2], Kurt Kratena[3], Sonja Wogrin[1], [1]Graz University of Technology, Graz, Austria; [2]Austrian Institute of Economic Research (WIFO), Vienna, Austria; [3]Centre of Economic Scenario Analysis and Research (CESAR), Vienna, Austria. Contact: robert.gaugl@tugraz.at

The transition to renewable power systems is both technically and economically challenging. We take a novel approach by coupling a macroeconomic model of Austria's economy with a technical model of the European power system. With the linked modeling framework, we can provide insights towards the transformation to a highly renewable power system and its impact on emissions as well as its macroeconomic and distributional effects. Using the novel model framework to analyze Austria's renewable electricity transformation shows that gas-fired power plants are still needed in 2030 to balance variable renewable generation. Furthermore, the results show that the investments do not lead to high multiplier effects from a socio-economic perspective.

2 Modeling Novel Electricity Market Products for Management of Net Load Forecast Errors

Elina Spyrou, Imperial College London, London, United

Kingdom. Contact: elina.spyrou@ic.ac.uk

As the integration of variable energy resources increases in power systems around the world, power system operators propose or revise products and services to manage net load forecast errors. Modeling supply of those products by energy-limited resources is challenging. This presentation analyzes net load forecast errors for a realistic case study of ERCOT and concludes with recommendations for product design to leverage flexibility of energy-limited resources for management of net load forecast errors.

3 Load Shifting Versus mFRR: Which One is More Appealing to Flexible Loads?

Peter Gade, DTU

This paper investigates how a flexible TCL can deliver flexibility either in form of manual frequency reserves (mFRR) or load shifting, and which one is more appealing for such a load. A supermarket freezer is considered as a representative flexible load, and a grey-box model describing its temperature dynamics is developed. Taking into account price and activation uncertainties, a two-stage stochastic mixed-integer linear program is formulated to maximize the flexibility value from the freezer, where two solution strategies for mFRR are presented: one with a simple policy and the other one with a dynamically updated policy. Examined on an ex-post out-of-sample simulation, load shifting shows to be more profitable than the provision of mFRR, but is also more consequential for the temperature in the freezer than flexibility provision for mFRR.

4 Time Series Aggregation for Energy System Models

Sonja Wogrin, Graz University of Technology, Graz, Austria

One of the fundamental problems of using optimization models that use different time series as data input, is the trade-off between model accuracy and computational tractability. In this talk, we discuss some typical challenges of time series aggregation methods when used for energy system models.

Modeling and Optimization for Power Grid Resilience Enhancement

Community Committee Choice Session

Session Chair: Feng Qiu, Argonne National Laboratory, Lemont, IL

1 Set Theoretic Approaches for Performance Guaranteed Control in Low Inertia Power Systems

Yichen Zhang, University of Texas at Arlingotn, Department of Electrical Engineerring, Arlington, TX

Most renewable sources are inverter-based and do not respond to grid events. With increasing renewable penetration, it is inevitable for inverter-based resources (IBRs) to provide grid supportive functions like inertia emulation. However, designing such multi-mode IBRs control to guarantee the grid-level performance is challenging. This presentation will demonstrate how to employ backward and forward reachability for such a control design as well as advanced computation approaches for accurate reachability estimation.

2 County-Level Assessment of Behind-The-Meter Solar and Storage to Mitigate Short but Frequent Power Interruptions for Residential Customers

Sunhee Baik, Lawrence Berkeley National Laboratory, Berkeley, CA

Behind-the-meter solar-plus-storage (BTM PVESS) has been adopted to address concerns over electric system reliability and resilience, but its technical benefits are poorly understood. Building on our previous work on resilience value analysis, this paper uses the PVESS dispatch algorithm and Reliability Event Simulator to analyze the impacts of short, frequent power outages. We investigate how battery size, state of charge, climate, load, and outage profiles affect BTM PVESS's ability to meet power demands during interruptions at the county level at 15-minute intervals. Our findings show that BTM PVESS can improve power system reliability, but its ability to provide backup power is mainly influenced by battery power constraints and outage profiles. Finally, we discuss how to evaluate tradeoffs between backup power and competing value streams.

3 Resilience-Oriented Robust Routing Optimization for Smart Grids Under Extreme Events

Luo Xu, Princeton University, Princeton, NJ, Contact: luoxu@princeton.edu

Due to the in-depth interdependence between electric power systems and advanced information systems, extreme weather events may result in cyber-physical coupling failures. Most existing literature control physical power systems. However, as a coupled system, there is still tremendous flexibility in the information system to be explored. We developed a resilience-orient optimization strategy for integrated systems by scheduling the communication routing of power system remedial control services, which can minimize the loss of load in extreme scenarios.

4 Applying a Comprehensive View of Resilience to Power Distribution Network Optimization

Benjamin P. Riley, Prodromos Daoutidis, Qi Zhang, University of Minnesota, Minneapolis, MN, Contact: riley718@umn.edu

Prior works on the resilience of power systems have primarily limited their focus to one type of stressor at a time. In this work, we propose an optimization model that enables distribution system operators to employ a variety of resilience-enhancing measures to respond to a variety of uncertain stressors. In particular, we develop a scenario-based two-stage stochastic program that considers line hardening projects, mobile battery storage systems, mobile ammonia-based energy storage systems, and line switching procedures to respond to line faults, generating unit failures, and demand uncertainty. Computational case studies are performed using the model, and large-scale problem instances are solved using a tailored decomposition algorithm.

AI/ML for Transportation Electrification

Community Committee Choice Session

Session Chair: Diwas Paudel, Tampa, FL

1 A Dynamic Pricing Strategy by EV Charging Hubs in Competitive Environment

Diwas Paudel, University of South Florida, Tampa, FL

As the number of electric vehicles (EVs) on the road continues to grow, EV charging hubs present a lucrative business opportunity. This profitability leads to the emergence of multiple competing EV charging establishments, similar to present-day gas stations, at street corners. To remain competitive, these hubs must dynamically adjust retail prices to attract an adequate number of EVs while ensuring profitability. This paper presents a multi-agent deep reinforcement learning framework for dynamic pricing in competitive EV charging environments. Performance validation is accomplished through a numerical case study, demonstrating the efficacy of the proposed framework in enabling effective pricing strategies for EV charging hubs within a rapidly evolving market.

2 Quantifying the Supply Potential and Value of Vehicle-To-Grid as an Energy Storage

Wonjong Lee[1], Yoonmo Koo[2], [1]Seoul National University, Seoul, Korea, Republic of; [2]Seoul National University, Seoul, Korea, Republic of. Contact: leewing159@snu.ac.kr

Renewable energy (RE) and electric vehicles (EV) are deployed faster than ever to combat the climate crisis. However, there would be mismatch in supply and demand given intermittency of RE and drivers' charging preference. In this situation, vehicle-to-grid (V2G) which allows bidirectional power flow between EV and grid can alleviate the mismatch by selling back power in EVs and absorbing excessive RE generation. However, the supply potential and the effectiveness of V2G as an ES are still unclear. In this research, choice experiment and expansion planning are both used to identify drivers' V2G participation and how much ES could be replaced with V2G. The results show drivers prefer to participate in night but could be encouraged to enroll in evening with higher reward. Also, more than half of ES are replaced (most in short-term ES) with V2G with a decrease in overall cost.

3 Mixed Integer Linear Programming for Critical Mineral-Efficient Fleet Electrification Planning

Jack Weissman[1], Nicolò Daina[2], [1]Center on Global Energy Policy, New York, NY, [2]Columbia University, New York, NY, Contact: jw3764@columbia.edu

Ensuring the security of the critical mineral supply has been at the forefront of geo-strategic aspects of recent transportation electrification policies such as the Inflation Reduction Act in the United States. Furthermore, economic, ethical, and environmental concerns are associated with the unprecedented scale of critical mineral mining required to achieve zero-emission targets. To mitigate such impacts, both policymakers and fleet owners need to explicitly consider the tradeoffs between cost and critical mineral requirements in fleet electrification planning. We present a MILP formulation accounting for these tradeoffs in optimal decisions for vehicles and charging infrastructure configurations.

Data-Driven Optimization and Explainability

Community Committee Choice Session

Session Chair: Alexandre Forel, Polytechnique Montreal, Montreal, QC, Canada

1 Cluster Explanation via Polyhedral Descriptions

Connor Lawless, Cornell University, Ithaca, NY, Contact: cal379@cornell.edu

This talk focuses on the cluster description problem where, given a dataset and its partition into clusters, the task is to explain the clusters. We introduce a new approach to explain clusters by constructing a polyhedron around each cluster while minimizing either the complexity of the resulting polyhedra or the number of features used in the description. We formulate the problem as an integer program and present a column generation approach to search over an exponential number of candidate half-spaces that can be used to build the polyhedra. To deal with large datasets, we introduce a novel grouping scheme that first forms smaller groups of data points and then builds the polyhedra around the grouped data. Compared to state of the art cluster description algorithms, our approach is able to achieve competitive interpretability with improved description accuracy.

2 Explainable Data-Driven Optimization

Alexandre Forel[1], Axel Parmentier[2], Thibaut Vidal[3], [1]MAGI, Polytechnique Montreal, Montréal, QC, Canada; [2]Ecole des Ponts, Champs sur Marne, France; [3]MAGI, Polytechnique Montreal, Montréal, QC, Canada. Contact: alexandre.forel@polymtl.ca

Data-driven optimization uses contextual information and machine learning algorithms to find solutions to decision problems with uncertain parameters. While a vast body of work is dedicated to interpreting machine learning models, explaining decision pipelines involving learning algorithms remains unaddressed. This lack of interpretability can block the adoption of data-driven solutions as practitioners may not understand or trust the recommended decisions. We bridge this gap by introducing a counterfactual explanation methodology tailored to explain solutions to data-driven problems. We introduce two classes of explanations and develop methods to find nearest explanations of random forest and nearest-neighbor predictors. We evaluate our approach by explaining key problems in operations management such as inventory management and routing.

3 Bilevel Optimization for Feature Selection in the Data-Driven Newsvendor Problem

Breno Serrano de Araujo[1], Stefan Minner[2], Maximilian Schiffer[1], Thibaut Vidal[3], [1]Technical University of Munich, Munich, Germany; [2]Technical University of Munich, München, Germany; [3]MAGI, Polytechnique Montreal, Montréal, QC, Canada

We study the feature-based newsvendor problem, in which a decision-maker has access to historical data with demand observations and exogenous features. In this setting, we investigate feature selection, aiming to derive sparse, explainable models with improved out-of-sample performance. Current methods utilize regularization, which penalizes the number of selected features or the norm of the solution vector. As an alternative, we introduce a novel bilevel program and present a MILP reformulation, which we solve to optimality with standard optimization solvers. Our experiments show that the method accurately recovers ground-truth features for instances with a few hundred samples, while other methods often require thousands of samples to obtain similar accuracy. Regarding out-of-sample generalization, we achieve improved or comparable cost performance.

4 Hyperboost: A Scalable Stacking Algorithm for Binary Classification

Ingo Meise, Zuse Institut Berlin, Berlin, Germany. Contact: meise@zib.de

Boosting is a popular, well-interpretable ensemble method. However, the larger the training data set, the harder it gets to (1) fit the training data and (2) apply existing regularization techniques like sparsification and generalization bounds which harms scalability in practice. We circumvent both problems by stacking boosted classifiers. This significantly decreases training error while we still ensure a scalable worst case running time and space complexity. Moreover, our algorithm enjoys a logarithmic approximation guarantee w.r.t. the sparsity of the set of base classifiers. It also iteratively minimizes strong PAC-Bayesian generalization bounds that are formulated as provably small linear programs. In extensive experiments on data sets from LIBSVM, we compare our stacking algorithm to popular ensemble methods like Boosting, Random Forests and XGBoost.

1 Order Stacking in On-Demand Delivery Platforms

N. Bora Keskin, James Scott, Robert Swinney, Duke University, Durham, NC

To increase efficiency, On-Demand Delivery Platforms often “stack” (or batch) orders together and assign them to a single driver to deliver. We investigate the circumstances in which a platform can benefit from allowing the customer to decide whether their order is stacked with other orders or delivered directly for an additional fee. We also investigate the effect this has on customer surplus in equilibrium.

2 Multi-Homing Across Platforms: Friend or Foe

Gerard P. Cachon[1], Tolga Dizdarer[2], Gerry Tsoukalas[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Boston College, Boston, MA, [3]Boston University, Boston, MA, Contact: dizdarer@bc.edu

Multi-homing gives platforms access to a larger pool of supply; however, it also changes the nature of competition between platforms in a market. It is not clear whether this works to the advantage of platforms or not. In light of this, we ask a fundamental question: When is it better for two-sided platforms to pool their workers? We answer this question through a game-theoretic study. We identify the key trade-offs associated with pooling decision and highlight the key role of scale.

3 Community/Committee'S Choice Submission

Zhen Lian, Yale School of Management, New Haven, CT, Contact: zhen.lian@yale.edu

Conventional wisdom in ride-hailing suggests that disclosing trip details to drivers hurts the platform, as drivers become selective about trips ("cherry-picking"). Still, recent shifts in regulations and labor are nudging platforms toward more transparency for drivers. We analyze a platform with two levers towards drivers: the pay, and the transparency of this pay. The platform faces uncertain demand, characterized by multiple demand scenarios. We find that, surprisingly, revealing full information is optimal, providing that the pay is set properly in each scenario. However, if the platform cannot dynamically adjust the pay, then full information can backfire, worse than not sharing any information at all. Our results highlight the intricate relationship between the information policy and the driver pay policy in ride-hailing.

4 Platform Disintermediation: Information Effects and Pricing Remedies

Shreyas Sekar[1], Auyon Siddiq[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of California-Los Angeles, Los Angeles, CA, Contact: auyon.siddiq@anderson.ucla.edu

Many two-sided platforms face the risk of disintermediation, where sellers transact offline with buyers to bypass platform commission fees. While transacting offline allows sellers to avoid paying commission, it also leaves them fully exposed to risky buyers given the absence of the platform's protections. In this work, we examine how disintermediation and information quality -- specifically, the accuracy of the signal sellers receive about a buyer's type -- jointly impact a platform's revenue and optimal commission rate. Our results generate prescriptions for platforms seeking to mitigate revenue losses from disintermediation.

Telecommunication and Network Design

Community Committee Choice Session

Session Chair: Marziehsadat Rezaei, [1]</sup

Session Chair: Sepideh Mohammadi, Lubbock, TX

1 A Compact Formulation and Efficient Solution Procedure for Fixed-Charge Network Flow

Eli Olinick[1], Yulan Bai[2], Ronald L. Rardin[3], [1]Southern Methodist University, Dallas, TX, [2]Towson University, Towson, MD, [3]University of Arkansas, Mckinney, TX, Contact: olinick@lyle.smu.edu

The triples formulation is a compact formulation of multicommodity network flow problems that provides a different representation of flow than the traditional and widely used node-arc and arc-path approaches. We show that the triples formulation significantly reduces the number of variables and constraints in the mixed integer programming formulations of the fixed-charge network flow problem (FCNF). For dense problem instances, the triples-based formulation of FCNF is found to produce better solutions than the node-arc formulation early in the branch-and-bound process. This observation leads to an effective hybrid method which combines the respective advantages of the smaller size of the triples formulation and the stronger linear programming relaxation of the node-arc formulation.

2 A Fairness-Aware Attacker-Defender Model for Optimal Edge Network Operation and Protection

Duong Thuy Anh Nguyen[1], Jiaming Cheng[2], Ni Trieu[3], Duong Tung Nguyen[1], [1]Arizona State University, Tempe, AZ, [2]University of British Columbia, Vancouver, BC, Canada; [3]Arizona State University, Tempe, AZ, Contact: dtnguy52@asu.edu

While various aspects of edge computing (EC) have been studied extensively, the current literature has overlooked the robust edge network operations and planning problem. To this end, this letter proposes a novel fairness-aware attacker-defender model for optimal edge network operation and hardening against possible attacks and disruptions. The proposed model helps EC platforms identify the set of most critical nodes to be protected to mitigate the impact of failures on system performance. Numerical results demonstrate that the proposed solution not only ensures good service quality but also maintains fairness among different areas during disruptions.

3 The Hop-Bounded Steiner Tree Problem with Budget Constraint

Sepideh Mohammadi, Hamidreza Validi, Texas Tech University, Lubbock, TX, Contact: sepideh.mohammadi@ttu.edu

The Steiner tree problem (STP) is an important combinatorial optimization problem with a wide range of applications (e.g., cable routing, chip design, and drug repositioning.) Given a weighted graph with a specific root, the hop-bounded STP with budget constraint seeks to maximize the vertex profits while keeping (i) the distances of vertices from the root in a specific range and (ii) the edge costs less than or equal to the budget. In this talk, we propose a cut-based mixed integer programming (MIP) formulation for the problem and compare its strength with two existing MIP formulations. We also propose multiple procedures that accelerate the solving process. We finally conduct a set of experiments on the benchmark instances to provide a computational comparison between the formulations and to assess the efficacy of the proposed enhancement procedures.

4 The Virtual Network Embedding Problem with Latency Constraints

Marziehsadat Rezaei[1], Hamidreza Validi[2], Illya V. Hicks[3], [1]Texas Tech University, LUBBOCK, TX, [2]Texas Tech University, Lubbock, TX, [3]Rice University, Houston, TX, Contact: marrezae@ttu.edu

We study the virtual network embedding problem with applications in cloud-based and telecommunication systems. This NP-hard problem seeks to find feasible mappings of virtual workloads onto an infrastructure with respect to constraints like capacities, placement, routing, and latency. We propose three mixed integer programming formulations for solving the problem: (i) a path-based model, (ii) a clique-based model, and (iii) a cut-based model. We also discuss the strength of the proposed formulations and the hardness of their corresponding separation problems. We finally present computational results on benchmark instances of the problem.

Quantum Computing and Optimization I

Community Committee Choice Session

Session Chair: Brandon Augustino, Lehigh University, Landing, NJ

1 Universal Quantum Speedups for Branch-And-Bound Algorithms

Shouvanik Chakrabarti, 1</sup

Exact solvers for mixed integer optimization problems are primarily based on the Branch-and-Bound meta algorithm. These solvers have many important applications across science, engineering, and the financial industry. Finding quantum speedups for branch-and-bound is therefore of interest both from an applications perspective, and to demonstrate that quantum speedups in optimization are possible over the classical state-of-art (as opposed to naïve brute force algorithms). In 2015, Montanaro developed an algorithm that was theoretically demonstrated to obtain a quadratic speedup for Branch-and-Bound in terms of the number of nodes explored to find all optimal solutions in the worst case. We develop an algorithm where this speedup is extended to be universal: for almost any choice of search heuristic, and any problem instance, the quantum algorithm explores quadratically fewer nodes than the actual number of nodes explored by the classical equivalent. In particular, we show how the quantum Branch-and-Bound algorithm may be integrated with arbitrary early stopping conditions through an incremental tree search procedure.

2 Hamiltonian-Oriented Quantum Algorithm Design

Jiaqi Leng, Joseph Li, Xiaodi Wu, University of Maryland, College Park, College Park, MD, Contact: xwu@cs.umd.edu

The conventional design of quantum algorithms is centered around the abstraction of quantum circuits, a theoretically appealing but expensive-to-implement model given the limited computing resources of near-term quantum machines. We propose another paradigm where the design of quantum algorithms is directly built on the abstraction of continuous-time Hamiltonian evolution. Namely, we treat quantum machines as programmable and efficient solvers for the Schrodinger equation and directly develop applications on top of that. We showcase that a few leading quantum applications (e.g., quantum walk and quantum PDE solvers) can be re-derived in this way, which share the same features (e.g., efficiency, input/output assumptions) as their known circuit-model counterparts but could be likely implemented on near-term analog quantum simulators with minimal overheads.

3 Quantum Computing for Combinatorial Optimization
Carleton Coffrin, Los Alamos National Laboratory, Los Alamos, NM
This talk will review recent developments in solving combinatorial optimization problems with quantum computing hardware.

4 New Perspectives on Quantum Interior Point Methods
Brandon Augustino, Lehigh University, Bethlehem, PA, Contact: bra216@lehigh.edu
Existing quantum interior point methods seek to speedup their classical counterpart by using quantum linear systems algorithms to solve the Newton linear system at each iteration. While this approach yields polynomial speedups in the dimension, it introduces a dependence on a condition number bound which may prohibit any overall advantage. In this talk we present two new approaches to quantizing IPMs. The first approach draws on a recently established relationship between interior point methods and simulated annealing, while the second seeks to derive a quantum central path.

Emerging Topics in Computational Optimization
Contributed Session
Session Chair: Samiran Kawtikwar, University of Illinois at Urbana Champaign, Urbana, IL

1 New Advances for Quantum-Inspired Optimization
Yu Du, University of Colorado Denver, Denver, CO, Contact: duyu197@gmail.com
The QUBO model has become highlighted as an effective alternative method for representing and solving a wide variety of combinatorial optimization problems. Additional momentum has resulted from the arrival of quantum computers and their ability to solve the Ising Spin Glass problem, another form of the QUBO model. This paper highlights advances in solving QUBO models and extensions to more general PUBO models as important alternatives to traditional approaches. Computational experience is provided that compares the performance of unique metaheuristic solvers NGQ, and NGQ-PUBO for QUBO and PUBO models with the performance of CPLEX and a leading Quantum solver. Extensive results disclose that our solvers outperform both CPLEX and the Quantum Solver by a wide margin in terms of both computational time and solution quality.

2 The Quantum Tortoise and the Classical Hare: Which Problems Will Quantum Computing Accelerate?
Neil Thompson[1], Sukwoong Choi[2], [1]MIT, Cambridge, MA, [2]University at Albany, SUNY, Albany, NY
Quantum computing promises transformational gains for solving some problems, but little to none for others. For firms hoping to use quantum computers now or in the future, it is important to know which problems will benefit. In this paper, we answer this question by analyzing the relative strengths of classical and quantum computers. This analysis then provides insights for which types of problems faced by businesses will benefit from quantum and which will not.

3 Hylac***:*** Hybrid Linear Assignment Solver in Cuda
Samiran Kawtikwar[1], Rakesh Nagi[2], [1]University of Illinois at Urbana Champaign, Urbana, IL, [2]Industrial Enterprise Systems University of Illinois, Urbana, IL, Contact: samiran2@illinois.edu
This paper presents a hybrid GPU-accelerated solver for the Linear Assignment Problem (LAP) that achieves significant performance improvements. The LAP is a fundamental combinatorial optimization problem. The Hungarian algorithm is a well-known approach for solving LAP, with $O(N^4)$ Munkres' and $O(N^3)$ Lawler's implementations having different speed advantages depending on the sparsity of problem instances. The proposed solver, HyLAC, blends the GPU solutions of above implementations and improves memory access and CPU-GPU synchronization. HyLAC achieves a speedup of up to 6.14x over existing GPU solvers for both sparse and dense instances. Additionally, a tiled LAP solver is developed to solve a list of small LAPs, it performs 22.59x faster than existing solvers.

Structuring and Building Multicriteria Decision Model
Community Committee Choice Session
Session Chair: Adiel Teixera de Almeida, Brazil
Session Chair: Eduarda Asfora Frej, Universidade Federal de Pernambuco, Recife, Brazil

1 Choice of Method by Using a Framework for Structuring and Building Multicriteria Decision Models

Adiel Teixeira De Almeida[1], Lucia Roselli[2], Eduarda Asfora Frej[2], Danielle C. Costa Morais[3], [1]Universidade Federal de Pernambuco, Recife PE, Brazil; [2]Universidade Federal de Pernambuco, Recife, Brazil; [3]Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil. Contact: adielta@gmail.com

A Framework for structuring and building multicriteria decision models is discussed. The framework focuses on the decision process, in which the choice of MCDM/A methods is considered. Regarding this matter, compensatory and non-compensatory preferences are analyzed in the preference modeling process. This is considered a first step in choosing the MCDM/A method.

2 Multicriteria Decision Model for Portfolio Selection in Natural Gas Companies

Carolina Lino Martins[1], João Batista Sarmento dos Santos Neto[1], Lucas Borges Leal Silva[2], Eduarda Asfora Frej[3], Adiel Teixeira de Almeida[4], [1]Universidade Federal de Mato Grosso do Sul, Campo Grande MS, Brazil; [2]Universidade Federal do Rio Grande do Norte, Natal RN, Brazil; [3]Universidade Federal de Pernambuco, Recife, Brazil; [4]Universidade Federal de Pernambuco, Recife PE, Brazil. Contact: carolina.lino@ufms.br

The availability of new technology and rising demand have caused the energy sector to undergo restructuring. Due to its adaptability, natural gas can compete with practically all other alternative fuels. Planning its use is extremely difficult, as it depends on multiple criteria. Thus, this study proposes a GIS-Based Multicriteria Decision Support System for portfolio selection in natural gas companies. The study uses the Framework of twelve steps to define potential projects for expanding natural gas distribution networks. The multicriteria model is based on additive aggregation with a benefit-to-cost ratio-based approach and is integrated with a Geographic Information System (GIS). Consequently, companies can benefit from models comprising spatial and multicriteria analytical tools to improve and support strategic decisions to achieve efficient results.

3 A Multicriteria Decision Approach for Ranking Potential Investors in the Economic Development Agency of Pernambuco with the Fitradeoff Method

Geyse da Silva[1], Eduarda Asfora Frej[1], Adiel Teixeira De Almeida[2], [1]Universidade Federal de Pernambuco, Recife, Brazil; [2]Universidade Federal de Pernambuco, Recife PE, Brazil. Contact: eafrej@cdsid.org.br

In this work, a problem of attracting companies for direct investments in the state of Pernambuco, Brazil is addressed. The main goal is to aid the Economic Development Agency of Pernambuco (ADEPE) to rank the potential investors, based on a structured decision process. In order to address the multiple and conflicting objectives inherently involved in this problem, the FITradeoff method is applied, with the use of its Decision Support System. The combination of two preference modeling paradigms - elicitation of decomposition and holistic evaluations - within the structure of the FITradeoff method is widely explored in this work, with a view to show how such integration can bring improvements to the decision process. As a result, a ranking of 25 alternatives that could match the proposal of the Pernambuco state as a win-win investment movement is obtained.

Student Participation in DEI: A Bottom-Up Approach to creating More Diverse, Equitable and Inclusive Departments and Universities

Panel Session

Session Chair: Justin Rist, The Pennsylvania State University, State College, PA

1 Student Participation in DEI: A Bottom-Up Approach to creating More Diverse, Equitable And Inclusive Departments and Universities

Susan E. Martonosi, Harvey Mudd College, Claremont, CA

As existing social, cultural, and educational practices are not inclusive to all learners, they restrict diverse engagement in STEM-based, thus OR/MS, higher education, which is the foundation for our research and development, cultivating equitable and inclusive learning experiences and environments will result in sustainable diversity in OR/MS fields. The “Promising Tomorrow” theme takes a student-focused bottoms-up approach with three strategic panel discussions to develop collaborative and inclusive learning OR/MS communities. Student communities can accelerate Equitable and inclusive OR/MS community development. This panel discussion outlines future collaborative student DEI efforts to strengthen the sense of belonging in our community.

Equity and Fairness in Resource Allocation Settings
Community Committee Choice Session
Session Chair: Faidra Monachou, Harvard University, Cambridge, MA

1 Group Fairness in Dynamic Refugee Assignment
Wentao Weng, MIT, Cambridge, MA
Recent research proposed algorithms that assign refugees and asylum seekers to geographic locations in a manner that maximizes the global average employment. While these algorithms can have substantial overall positive impact, using data from industry collaborators we show that the impact of them can vary widely across key subgroups. Thus motivated, we develop a framework for incorporating group fairness into the dynamic refugee assignment problem. Equipped with our framework, we propose two bid-price algorithms that maximize overall employment while simultaneously yielding provable group fairness guarantees. Through extensive numerical experiments using real-world data, we show that our algorithms can yield substantial improvements in group fairness compared to state-of-the-art algorithms with only small decreases in global performance.

2 Learning Optimal Fair Decision Trees: Trade-Offs Between Interpretability, Fairness, and Accuracy
Nathanael Jo, Stanford University, San Francisco, CA
The increasing use of machine learning (ML) in high-stakes domains creates an urgent need for interpretable, fair, and accurate algorithms. With these needs in mind, we propose a mixed integer optimization (MIO) framework for learning optimal decision trees that can be augmented with arbitrary fairness constraints. In order to better quantify the “price of interpretability”, we also propose a measure of model interpretability called decision complexity that allows for comparisons across ML models. We benchmark our method against existing approaches for fair classification on popular datasets; given a fixed disparity threshold, our method has a price of interpretability of about 4.2 percentage points in accuracy compared to the best performing, complex models. However, our method consistently finds decisions with almost full parity, while other methods rarely do.

3 The Determinants of U.S. College Admission
Allen Sirolly, Columbia Business School, New York, NY
Many colleges and universities in the United States take a “holistic” approach to undergraduate admissions which evaluates applicants on both academic and non-academic dimensions. We use a novel data set--containing students’ application information and admissions outcomes--to quantify the relative importance of these factors across the spectrum of college selectivity and student characteristics. We give evidence that the magnitude of “noise”--the part of admissions outcomes which is not attributable to merit-based factors--is significant, especially at highly selective colleges.

1 Optimizing Food Bank Operations for Equity and Efficiency: A Case Study of Food Bank Quebec
Duygu Pamukcu[1], Julie Paquette[1], Burcu Balcik[2], Marie-Ève Rancourt[1], [1]HEC Montreal, Montreal, QC, Canada; [2]Ozyegin University, Istanbul, Turkey. Contact: duygu.pamukcu@hec.ca
Food banks are long-term continuous aid organizations, vital in combatting food insecurity by collecting and distributing food donations to agencies that then offer them to those in need. However, they encounter several challenges in

their operations, including logistical constraints and the variable nature of food donations. This study delves into the complexities of food bank supply chain operations and aims to develop a decision-support tool to optimize the allocation of diverse donations to the agencies while considering logistical constraints. Also, we consider the long-term equity targets of such organizations while maintaining their operational efficiency, a critical component in providing continuous aid. Leveraging a comprehensive case study of the Food Bank Quebec network, this research seeks to better understand the tradeoffs between the efficient and equitable allocation of diverse food donations over extended periods.

2 Changes in Community Emergency Reporting During the Covid Pandemic

Michelle Seref[1], Onur Seref[2], Christopher W. Zobel[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Blacksburg, VA, Contact: mmhseref@vt.edu

We analyze 311 community emergency calls from Orlando, FL and San Diego, CA over a period spanning 3 months before the Covid Pandemic in the United States through the first 3 months of the pandemic. Using temporal context tracking, we analyze changes to emergency report categories and consider implications to future emergency reporting strategies and resource allocation planning.

3 Modeling and Managing Food Insecurity Through Assessment of Agricultural Practices

Deniz Besik[1], Shital Thekdi[2], Felipe Aros-Vera[3], [1]University of Richmond, Richmond, VA, [2]University of Richmond, Richmond, VA, [3]Ohio University, Athens, OH, Contact: dbesik@richmond.edu

In recent years, innovations in food production have improved efficiencies in agricultural practices, such as through factory farming. However, there is no clear optimal mix between food production practices, given that various food production practices have limited constrained production capabilities and are subject to vulnerabilities to changing conditions. This paper introduces a mathematical framework that aims to minimize the impact of food insecurity, specifically the deprivation from fresh, healthy produce over a period of time. To achieve this, we analyze various agricultural practices, from production to distribution, and their effectiveness in alleviating food insecurity. We present a numerical study on agricultural firms in Central Virginia, serving agricultural products in the form of fresh produce to community members in various neighborhoods.

4 Value of Sorting and Recovery in Post-Disaster Relief Aid Distribution

Mehmet Alegoz[1], Muge Acar[1], F.Sibel Salman[2], [1]Eskisehir Technical University, Istanbul, Turkey; [2]Koc University, Istanbul, Turkey

In-kind donations gathered from the public after a disaster typically consist of an unknown and disorganized composition of both “useful” and “useless” items. Sending the donations directly to the affected people without any pre-processing leads to not only extra shipment and handling costs but also congestion in the disaster areas, and even chaos in local distribution. We investigate the effect of relief aid sorting and subsequent recovery of items that do not fulfill immediate needs under demand, donation quantity, and donation type uncertainties. We propose a supply network configuration with sorting centers for pre-processing and optimize it by a three-stage stochastic programming model. We compare the case of the sorted donations with the case where donations are directly sent to points of distribution to victims. We apply the proposed model to the Istanbul earthquake case under different parameter settings and derive various managerial insights.

5 Offline Incentives and Online Volunteers’ Productivity

Eunae Yoo[1], Gloria Urrea[2], [1]Indiana University, Bloomington, IN, [2]University of Colorado Boulder, Boulder, CO

Online volunteering platforms are valuable tools for mobilizing individuals from around the world to work virtually on projects. However, this type of volunteering is typically a solitary commitment with limited incentives to boost productivity. We study the role of providing offline incentives in the productivity of online volunteers. We collect data from an online volunteering platform that has been giving microgrants to communities worldwide with the goal of providing offline incentives to online volunteers (e.g., training, access to technology, and even monetary incentives). The data allow us to identify the projects and online volunteers who benefit from these offline incentives. Using a difference-in-difference analysis, we investigate the effect of providing offline incentives on online volunteers’ productivity and the evolution of this effect over time.

AI in Service Science

Community Committee Choice Session

Session Chair: Alan Scheller-Wolf, Tepper School of Business, Pittsburgh, PA

Session Chair: Yanhan Tang, 1</sup

1 Online Facility Location: Running Stores on Wheels with Spatial Demand Learning

Junyu Cao[1], Wei Qi[2], Yan Zhang[3], [1]The University of Texas at Austin, Austin, TX, [2]Tsinghua University, Beijing, Canada; [3]McGill University, Montreal, QC, Canada. Contact: yan.zhang13@mail.mcgill.ca

We formulate an online facility location problem, joint with operational-level decisions. The scope of facility location problems continues to expand, while the models of facility location problems have been so far largely restricted to be in a static, offline fashion, prescribing one-shot facility placement based on past and current data on hand. In an online setting, the decision maker is subject to parameter uncertainties. However, they are able to adjust facility locations over time while updating her parameter estimation from historical observations. To this end, we propose an online algorithm that integrates the continuous approximation approach. The algorithm is both computationally efficient and has a near-optimal regret guarantee.

2 Multi-Armed Bandits with Endogenous Learning Curves: An Application to Split Liver Transplantation

Yanhan (Savannah) Tang[1], Andrew A. Li[2], Alan Scheller-Wolf[3], Sridhar R. Tayur[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]CMU Tepper, Pittsburgh, PA, [3]Tepper School of Business, Pittsburgh, PA, Contact: yanhanta@andrew.cmu.edu

Proficiency in many sophisticated tasks is attained through learning by doing. For example, transplant surgeons need to practice difficult surgeries to master surgical skills. This experience-based learning may affect other stakeholders, for example, patients eligible for transplant surgeries. Such a situation illustrates the classical exploration-exploitation tradeoff: A central planner may want to identify and develop surgeons with high aptitudes while ensuring that patients still have excellent outcomes. We formulate a multi-armed bandit model with parametric reward functions to capture endogenous, experience-based learning. We propose the L-UCB and FL-UCB algorithms, prove their O(log t) regrets, and show that they have superior numerical performance compared to standard bandit algorithms when experience-based learning exists.

3 Bayesian Dynamic Pricing and Subscription Period Selection with Unknown Customer Utility

Yuan-Mao Kao[1], N. Bora Keskin[2], Kevin Shang[2], [1]Baruch College, CUNY, New York City, NY, [2]Duke University, Durham, NC, Contact: yuan-mao.kao@baruch.cuny.edu

We consider a provider offering subscription services to customers over a multiperiod planning horizon. The provider has a prior belief about the customers' utility model and updates its belief based on the transaction data of new customers and the usage data of existing subscribers. The provider aims to minimize its regret—the profit loss relative to a clairvoyant who knows the utility model. We first develop a method to resolve the curse of dimensionality in obtaining the clairvoyant's optimal policy. In the absence of full information, we show that a certainty-equivalence policy may perform poorly due to incomplete learning, slow learning, or offering a suboptimal and long contract at the beginning. We design an information-threshold policy that adaptively collects information, and show that this policy achieves asymptotically optimal performance.

4 Aruba: Efficient and Adaptive Meta-Learning with Provable Guarantees

Mikhail Khodak, Carnegie Mellon University, Pittsburgh, PA

Meta-learning has recently emerged as an important direction for multi-task learning, dynamic environments, and federated settings. We present a theoretical framework for designing practical meta-learning methods that integrates natural formalizations of task-similarity with the extensive literature on online convex optimization and sequential prediction algorithms. Our approach, which works by learning surrogate losses bounding the within-task regret of base learning algorithms, enables the task-similarity to be learned adaptively and leads to straightforward derivations of average-case regret bounds that improve if the tasks are similar. We highlight how our theory can be extended to numerous settings, especially for deriving multi-task guarantees for bandit algorithms.

Influencer Marketing

Community Committee Choice Session

Session Chair: Jessie Liu, 1</sup

1 Imbalanced Impact of AI Matching on Influencer Marketing: Implications for Social Media Platforms

Z. Jessie Liu[1], Yi Liu[2], [1]Johns Hopkins University, Baltimore, MD, [2]University of Wisconsin - Madison, Madison, WI,

Contact: jzliu@jhu.edu
This paper examines the impact of adopting an Artificial Intelligence (AI) technology that matches marketers with influencers in social media platforms. We theoretically show that improving AI accuracy may not always benefit the platform. On the one hand, AI enhances the matching between influencers and marketers; on the other hand, it intensifies competition between influencers of different types. Improving such matching technology has an imbalanced impact on influencers: the matching outcome for influencers with a narrower audience ("niche" influencers) is more sensitive to AI accuracy than that for those with a broader audience ("general" influencers). As more niche influencers begin to participate in the marketing campaigns, the general influencers are pressured to reduce their prices, which gives rise to a possible decline in platform revenue.

2 Racial Pay Gap in Influencer Marketing

Amy Pei[1], Yakov Bart[2], Koen Pauwels[3], Chan Kwong[1], [1]Northeastern University, Boston, MA, [2]Northeastern University, Boston, MA, [3]Northeastern University, Newton, MA
Is there a racial pay gap for influencers? Using a novel data set, we find that Black macro-influencers were paid significantly more than their White counterparts in months with increased public attention to racial inequality. In contrast, micro-influencers did not experience any significant changes in pay during the same months. These findings are consistent with firms' virtue signaling during times of predictable visibility of Black influencers. Indeed, we find that the pay for Black-macro influencers did not change when an increase in public attention to racial inequality was triggered by an exogenous shock. Our empirical findings imply that firm response to racial inequality is opportunistic and only benefits more visible Black influencers.

3 Influencers: The Power of Comments

Cristina Nistor[1], Matthew Selove[2], [1]Chapman, Orange, CA, [2]Chapman University, Orange, CA, Contact: nistor@chapman.edu
Many customers choose products based on information from social media influencers. Companies can pay these influencers to promote their products. We develop a model in which customers read an influencer's sponsored post for a mix of entertainment and product information, and those who purchase the product can leave comments for future customers. We derive conditions in which a large celebrity influencer endorses all products, whereas a micro-influencer adopts a policy of endorsing only high quality products. In equilibrium, the micro-influencer screens for high quality products so his followers do not waste time reading informative comments about low quality products. By contrast, the celebrity influencer attracts many uninformative comments, and the value of his endorsement arises solely from generating product awareness.

4 Metaverse is Near: The Impact of Virtual Influencers on Human Influencers

Serim Hwang[1], Xiao Liu[2], Kannan Srinivasan[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]New York University, New York, NY, Contact: serimh@andrew.cmu.edu
Brands partner with AI virtual influencers because they are affordable and exempt from human misconduct (e.g., moral issues, feuds, scandals). However, it is unclear whether virtual influencers complement or displace human influencers. Using Instagram data, deep learning techniques (CNN, autoencoder, DeepFace), and three identification strategies, we study how the entry of virtual influencers affected human influencer jobs. We find that virtual influencers tend to displace previously sponsored human influencers, while complementing those who were not sponsored. Vulnerability to displacement was greatest for older, male, and less-attractive influencers; experience goods did not embrace virtual influencers as much as other categories. Finally, human influencers responded to this AI threat by increasing their usage of human-oriented verbs.

Contemporary Challenges in Technology and Innovation Management

Community Committee Choice Session

Session Chair: Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN

Session Chair: Yasaman Asayesh, 1</sup

1 Peer Effects and Learning with New Technology

Deepanshi Bhardwaj[1], Bilal Gokpinar[2], Ashwini Chhatre[3], [1]University College London, London, United Kingdom; [2]UCL School of Management, London, United Kingdom; [3]Indian School of Business, Hyderabad, India. Contact: deepanshi.bhardwaj.20@ucl.ac.uk
With the growth of new technologies and an increase in the knowledge-intensive nature of work, service agents have become a central part in service delivery and use. Using a unique transaction level dataset of bank-service agents, we investigate how agents adapt to new technologies and whether peers play a role in performance improvement. We find that at the onset of a technological change,

agents with peers adapt better to the new technology as compared to agents working in isolation and exhibit a 4% lower error rate in transactions. However, the peer effects do not hold in the presence of competition. We also find that while a major part of learning rests on an agent's own experience, the experience of peers also plays a critical role in performance improvement.

2 Leveraging the Potential of Outsourcing and Offshoring in Complex Product Development

Ole Frauen[1], Arnd Huchzermeier[2], Jurgen Mihm[3], [1]Volkswagen AG, Wolfsburg, Germany; [2]WHU - Otto Beisheim School of Management, Vallendar, Germany; [3]Insead, Fontainebleau, France

Leveraging the potential of outsourcing and offshoring remains a major challenge in complex product development. It is a question about effectively decomposing and distributing work across geographical and organizational boundaries while providing high quality products. The sourcing decisions must clearly depend on the product's characteristics and the emerging collaborative network. The study is based on an extensive data set containing 380,000 components from 121 vehicle projects of one of the largest car manufacturers worldwide. We demonstrate that a precise distinction between outsourcing and offshoring, as well as the introduction of a network perspective, are crucial to evaluate the effects in more detail.

3 The Development of Precision Medicines: An Economic Impediment or a New Model of Drug Innovation?

Jingwen Yang[1], Anant Mishra[2], [1]Lee Business School, University of Nevada Las Vegas, Las Vegas, NV, [2]Carlson School of Management, University of Minnesota, Minneapolis, MN

We study the development of precision medicines over the last decade. The study finds that precision medicines lead to market expansion. The effects are further strengthened by the availability of companion diagnostics. These findings suggest that the drug market responds to precision medicine innovation despite the concern surrounding the innovation targeting small, segmented drug markets. Overall, precision medicine innovation presents a viable new model of drug innovation departing from the traditional blockbuster innovation approach.

4 The Effect of Relatable Role Models on Increasing Female Participation in Stem Entrepreneurship

Jon Eckhardt[1], Brent Goldfarb[2], Minah Park[1], Subra Tangirala[2], Molly Carnes[1], Jennifer Sheridan[1], Markus Brauer[1], [1]University of Wisconsin–Madison, Madison, WI, [2]University of Maryland, College Park, MD

This study aims to generate greater interest in entrepreneurship for women in STEM through a large-scale field experiment involving incoming freshmen at a Carnegie R1 university. Students were randomly assigned to a relatable or unrelatable role model condition. Preliminary analysis on female and male students indicates that entrepreneurial identity aspiration and self-efficacy were driving the difference in entrepreneurial intention between the two conditions. Female students with STEM interest in the relatable role model condition found the video more relatable, but no significant difference in entrepreneurial intention was observed. We suggest that interventions may have the potential to increase interest in STEM entrepreneurship among undergraduates.

Innovation and Relative Incentives

Community Committee Choice Session

Session Chair: Sanjiv Erat, University of California-San Diego, La Jolla, CA

1 Exclusive or Not? an Experimental Analysis of Parallel Innovation Contests

RAMAZAN Kizilyildirim[1], Ersin Korpeoglu[1], Mirko Kremer[2], Gizem Korpeoglu[3], [1]UCL, LONDON, United Kingdom; [2]Frankfurt School of Finance & Management, Frankfurt, Germany; [3]Eindhoven University of Technology, Eindhoven, Netherlands

We study parallel innovation contests where contest organizers elicit innovative solutions to a set of problems from a group of solvers with limited (financial, time, cognitive) resources. The quality of a solver's solution improves with their effort, yet it is also subject to an output uncertainty. Prior theoretical work shows that organizers should discourage solvers from participating in parallel contests under low output uncertainty. In this case, organizers should benefit from solvers focusing all of their efforts on a single “exclusive” contest rather than splitting them across multiple “non-exclusive” contests. We test this prediction with controlled laboratory experiments. Our main result is that non-exclusive contests are attractive to organizers even in environments with low output uncertainty where contest theory favors exclusive contests.

2 Designing Knowledge-Driven Innovation Contests

Lakshminarayana Nittala[1], Sanjiv Erat[2], [1]University of Dayton, Dayton, OH, [2]University of California-San Diego, La Jolla, CA

We develop a framework for Innovation Contests that explicitly considers knowledge generation and transfer under different modes of learning. We characterize the effort allocation of contestants from a knowledge management perspective and derive insights for optimal contest design.

3 Sequential Product Innovation and Inventory Planning in Startups

Sreekumar R. Bhaskaran[1], Karthik Ramachandran[2], Ankur Goel[3], [1]Southern Methodist University, Dallas, TX, [2]Georgia Institute of Technology, Atlanta, GA, [3]PNC Bank, Pittsburgh, PA, Contact: sbhaskar@mail.cox.smu.edu

While developing innovative and novel products, startups typically use intermediate products as bridges to help them manage the transition and generate revenue to continue the development process. However, the development process for the new product is also risky with several challenges including regulatory obstacles and uncertainty about the product-market fit which can require significant time and resources. However, operational decisions including inventory levels for the intermediate product would have to be made before this uncertainty is resolved. In this paper, we jointly model the inventory and new product development decisions of sequentially improving hardware products developed by startups. Impact of supply disruptions, product architecture and development capability on the startup's transition strategy are also explored.

4 Duration Overlapping and Online Contest Performance

Sanjiv Erat, Xiaofeng Liu, University of California San Diego, La Jolla, CA

With the increasing popularity of online contests, many companies are embracing this approach to source innovative solutions. As the number of contests grows, some need to run concurrently. This study introduces a model that considers multiple solvers and contests, investigating the impact of overlapping durations on contest performance. The findings indicate that overlapping with other contests can result in fewer solvers and lower submission quality, especially when those end prior to the focal contest. Furthermore, the study uncovers a positive externality on submission quantity and quality when the duration overlapping occurs with similar contests. Empirical evidence from a prominent online contest platform supports the analytical model.

Applications of Deep Learning to Real World Problems

Community Committee Choice Session

Session Chair: Bruce Cox, Air Force Institute of Technology, Dayton, OH

1 Transfer Learning for Emotion Classification of Indonesian Tweets

Connor Shaw, Air Force Institute of Technology, OH

This research utilizes Bidirectional Encoder Representation from Transformer (BERT) and Recurrent Neural Networks (RNNs) to perform emotion classification for Indonesian Twitter data. It explores the merits and demerits of both approaches. Ultimately, Bilateral Long Short-Term Memory (Bi-LSTMs) utilizing five emotion classes were able to achieve a macro-level F1 score of 70.83% and a fine-tuned Indonesian BERT performed at 79.1%. This additional performance comes with a longer training time, the requirement of using a pre-trained large language model (LLM), and other attributes discussed in this presentation.

2 Automated Registration of Titanium Metal Imaging of Aircraft Components Using Deep Learning Techniques

Nathan Johnston, Air Force Institute of Technology, OH

Studies have identified a connection between the microtexture regions (MTRs) found in certain titanium alloys and early onset creep fatigue failure of rotating turbomachinery. Microtexture regions are defined by their size and orientation, which can be characterized via scanning electron microscopy (SEM) Electron Backscatter Diffraction (EBSD). However, doing so is impractical at the component-scale. A novel method of characterizing MTRs is needed to qualify new engine components. Researchers in the Air Force Research Lab Materials and Manufacturing Directorate have proposed fusion of two inspection methods (eddy current testing (ECT) and scanning acoustic microscopy (SAM)) to achieve the goal of MTR characterization. Our research focuses on development of a Convolutional Neural Network to automatically register two polarized light microscopy images.

3 Entering Hyperspace: Conditional Hyperspectral Reflectance Image Generation Using Convolutional Neural Networks

Bret Wagner, Air Force Institute of Technology, OH

The Afit Sensor and Scene Emulation Tool (ASSET) produces accurate synthetic electro-optical and infrared (EO/IR) data. ASSET currently uses broadband reflectance inputs to produce a realistic scene. The radiometric accuracy of that scene may by improved through the implementation of hyperspectral reflectance data. This research uses a Pix2Pix generative adversarial network (GAN) and a U-Net convolutional neural network (CNN), trained on pixel matched satellite images to produce synthetic hyperspectral reflectance data. The networks generate multiple narrow band reflectance maps from a single panchromatic image, which ASSET will use as source material for synthetic background signature generation. The contributions herein are relevant to improving ASSET's radiometric accuracy and generating synthetic hyperspectral data sets.

4 Garbage in ≠ Garbage Out: Exploring Gan Resilience to Image Training Set Degradations

Nicholas Crino, AFIT/ENS, Dayton, OH, Contact: nicholas.crino.1@us.af.mil

Generative Adversarial Networks (GANs) are a class of powerful generative models. While research has yielded GAN variants robust to training set shrinkage and corruption, we focus on quantifying the resilience of a GAN architecture to specific modes of image degradation. We determine empirically the effects of 10 fundamental image degradation modes applied to the training image dataset on the Fréchet inception distance (FID) of images generated by a conditional DCGAN. We find that at the ▯ = 0.05 level, brightening, darkening, and blurring are significantly more detrimental to GAN image quality than full data loss, while other degradations are typically safe to keep in datasets. Additionally, we find that only in the case of randomized partial occlusion does the FID of resulting GAN images approach that of the degraded training set for increasing levels of corruption.

Issues in Renewable Energy Auctions and Market Design

Community Committee Choice Session

Session Chair: Joseph Edward Duggan, University of Dayton, Dayton, OH

1 Pricing Indivisibilities in the Investment Problem

Nicolas Stevens, UCLouvain, Louvain-la-Neuve, Belgium

Pricing non-convexities in power markets has been explored vividly in the literature and among practitioners for the past twenty years. The debate has been focused on indivisibilities in short-term auctions, the computational tractability of the pricing proposals and their economic analysis. In this work, we introduce another non-convexity that is less discussed: the indivisibilities in investment decisions. We analyze the problem from a theoretical point of view, characterizing the long-term incentives of the agents. We derive theoretical results relative to the incentives of the participants to deviate from the social optimum when the market grows. We analyze the ability of a capacity market to improve the incentives. We illustrate our findings on a stylized example and numerical simulations conducted on a model that covers the entire European region.

2 Multi-Product Balancing Market and Cross-Border Platforms

Jacques Cartuyvels, UCLouvain, Ottignies-Louvain-la-Neue, Belgium. Contact: jacques.cartuyvels@uclouvain.be

This paper provides a framework for understanding multi-product European balancing markets. We characterize the optimal strategies of price-taking flexibility providers that can participate in sequential capacity auctions for secondary and tertiary reserves, followed by a real-time power auction conducted by the system operator. Equilibria are then derived depending on three market characteristics: (i) the capacity demand curves, (ii) the system operator's activation strategies, and (iii) the imbalance pricing scheme. The results are then extended to the cross-border setting with the integration of balancing platforms.

3 The Effects of Long-Term Market Design Choices on Low-Carbon Electricity System Outcomes

Mark Noll, Argonne National Laboratory, Washington, DC

In this work, we examine how different choices of electricity market design parameters affect market outcomes in low-carbon systems. We apply a least-cost capacity expansion model to a simplified version of the New York power grid to compare system costs and unit-level operational outcomes and profitability under an "energy-only" market design to a "capacity-based" market design that features a reserve margin requirement and lower energy and ancillary service price caps. We enforce an increasing clean energy standard in both cases and capture aspects especially relevant to high-VRE systems, including declining capacity contributions of VRE renewable resources and battery storage and flexible operations of reservoir-based hydro power plants and battery storage.

4 Funding Mechanisms in Green Finance: The Creation of Commitment with Green and Sustainability-Linked Bonds

Philip Zilke[1,2], [1]Leibniz Centre for European Economic Research, Mannheim, Germany; [2]University of Cologne, Cologne, Germany. Contact: philip.zilke@zew.de

I study a problem of moral hazard in corporate funding which arises due to the time lag between funding and investment. The investors decide at which funding terms to invest in the company before the company has to decide in what projects to invest the funding. I show that if investors with green preferences participate in the funding process, the company can benefit from committing to invest in green projects ex ante. In Green Finance, companies can create commitment by the issuance of Green or Sustainability-linked Bonds. If the project's sustainability is observable by the investors ex ante, both bond types yield the same outcome. If investors can only observe the project's sustainability ex post, the outcomes of Green Bonds are distorted due to the information asymmetry. I show that Green Bonds yield more investment in green projects compared to Sustainability-linked Bonds.

The Future of Digital Platforms

Community Committee Choice Session

Session Chair: Jing Peng, University of Connecticut, Storrs, CT

1 Team Purchase as a Marketing Strategy

Huiyan Chen[1], Jing Peng[1], Mengcheng Guan[2], Jianbin Li[2], [1]University of Connecticut, Storrs, CT, [2]Huazhong University of Science and Technology, Wuhan, China. Contact: huiyan.chen@uconn.edu

Team purchase is marketing strategy that encourages customers to purchase discounted products together with friends. Over the past few years, team purchase has become a popular strategy for online sellers to acquire new customers. However, the impact of team purchase on the sales of sellers' other products remains unclear. Using a dataset from an e-commerce platform, we find that that enrolling a few products in team purchase increase the sales of the sellers' other unpromoted products, and this effect varies across different types of sellers. Moreover, we find that the spillover effect exhibits similar heterogeneity at the brand level, except that the spillover effect on highly popular brands can be negative. This finding suggests that the sellers may gain from team purchase at the expense of large brands. We discuss the implications of our findings for sellers and brands.

2 Privacy and Content Contribution of Fact Checkers

Sameer Borwankar, Jinyang Zheng, Purdue University, West Lafayette, IN, Contact: sborwank@purdue.edu

Researchers have studied different solutions for preventing the generation and spread of misinformation on social media. Previous research on crowd-based solutions has shown that such programs effectively improve the quality of the content generated by fact-checkers. But it comes at the cost of the quantity of the content. To avoid such higher costs in terms of reduction in content, Twitter has allowed fact-checkers to do the monitoring anonymously. Our paper studies the effectiveness of this privacy protection feature of the crowd-based Community Notes program on Twitter. Some of the questions we address are:
1. whether the privacy-protecting feature reduces the cost involved in crowd-based fact-checking programs
2. Whether the quality of the content generated by the fact-checkers, after enabling the privacy protection feature, remains the same.

3 Unveiling The Effects Of LLMs: Shifting UGC Contribution In An Online Coding Community

Xinyu Li, Keongtae Kim, The Chinese University of Hong Kong, Shatin, NT, Hong Kong. Contact: xinyu.li@link.cuhk.edu.hk

Large language models (LLMs) like ChatGPT are reshaping content creation and knowledge sharing on user-generated content (UGC) platforms. While they enable AI-assisted content generation and potentially increase interactions among users, concerns arise regarding possible discouraging effects on user participation through increased competition for visibility and eroded trust stemming from an influx of low-quality content. This study presents timely evidence on changes in user contributions following the introduction of ChatGPT. Our findings underscore the necessity of monitoring LLM impacts on UGC platforms and formulating harmonious human-AI collaborations. Overall, this study offers critical insights into the emerging influence of generative AI on UGC platforms.

4 Stimulating Consumption on a Limited Budget with AI vs. Human: Evidence from a Large-Scale Randomized Field Experiment

Chen Liang[1], Tong Shen[1], Chunxiao Li[2], Xi Jing[2], Shuliu Yuan[3], Bin Gu[4], [1]University of Connecticut, Storrs, CT, [2]Shanghai Jiao Tong University, Shanghai, China; [3]T3 Chuxing Technology Co., Nanjing, China; [4]Boston University, Boston, MA, Contact: tong-shen@uconn.edu

This study examines the effectiveness of AI vs. human decision-making in stimulating consumption based on coupons in ride-hailing platforms. Results from a randomized experiment show that both AI and human-optimized coupons can drive consumption effectively, with AI coupons excelling during lower demand periods. Furthermore, we find that human-optimized coupons are highly effective in increasing the ride completion rate for users with low prior coupon redemption rates, whereas AI-optimized coupons are highly effective for users with high prior coupon redemption rates. Our study highlights the importance of designing coupons tailored to specific trip types and user segments.

5 Estimating Online Community Evolvement with Social Networks

Yanhao Wei[1], Wensi Zhang[2], Sha Yang[1], Xi Chen[3], [1]University of Southern California, Los Angeles, CA, [2]The University of Texas at Dallas, Richardson, TX, [3]Zhejiang University, Zhejiang, China. Contact: wensi.zhang@utdallas.edu

Incorporating online community features has become a popular strategy for digital platforms to engage consumers and foster social interactions, highlighting the importance of understanding how online communities form and develop over time. Our paper builds a model that captures the co-evolvement of both online communities and social networks, accommodating rich unobserved heterogeneity at the user level in both communities and networks. To address the computational challenge, we embrace the trend of fusing machine learning techniques with economic modeling of decision-making, utilizing a neural net-based estimator (NNE) to recover our model parameters. We demonstrate the accuracy and scalability of this estimation method through simulation and discuss the implications using real data from online gaming.

Business Analytics with Modern AI/ML

Community Committee Choice Session

Session Chair: Junming Yin, Carnegie Mellon University, Pittsburgh, PA

1 Market Segmentation Using Deep Learning

Wenjun Zhou, University of Tennessee Knoxville, Knoxville, TN

Segmentation is an important task for businesses to understand their customer base. In this presentation, we explore opportunities in using deep learning techniques to conduct market segmentation.

2 Consumer Search and Preference Formation: A Deep Structural Econometric Model

Yicheng Song, University of Minnesota, Minneapolis, MN

We propose a theory-driven deep learning model called Customer Preference Transformer (CPT), which leverages the Transformer model to learn dynamic customer preferences and sequential search theory to model customers' search and purchase decisions. CPT integrates these two building blocks into a unified model that can be estimated via end-to-end learning. Unlike regular deep learning methods, we incorporate economic theory into the model learning process, opening up the black box of the model and providing reasonable interpretations of the formation process of dynamic customer preferences.

3 Someone is Mimicking You: Investigating Competition Network in Social Trading

Ye Liu, University of Washington, Seattle, WA

Social trading platforms are gaining popularity due to their high level of information transparency. While greater information transparency can benefit investors, it also enables strategic investors to mimic original traders' trading strategies with little cost, pretend to be original traders, and compete with other traders. Using data from a leading social trading platform, we investigate the effect of the competition network. We then model the dynamic change of the network and traders' attributes (the number of followers) using the coevolution model.

4 Text Versus Video for Knowledge Communication: Combining Quasi-Experiment and Interpretable Video Analytics

Gujie Li, Jui Ramaprasad, Lauren Rhue, Wen Wang, University of Maryland, College Park, MD, Contact: gujieli@umd.edu

In this study, we examine the effect of video on viewers' psychological processes including cognitive, affective, social, and perceptual process, which are essential for knowledge transfer. Leveraging a quasi-experiment, we find that knowledge communicated in video significantly elicits affective, social, and perceptual process as compared with that in text, whereas they do not differ in evoking cognitive process. We also explore the heterogeneity of knowledge content (fact-based and opinion-based knowledge). We further decompose videos into interpretable audio-visual features and investigate their differential influences on the four psychological processes. Our findings help to offer actionable insights for knowledge content creators, educators, and managers of knowledge sharing platforms.

Recent Development in Modeling Complex Spatial and Temporal Dependent Data

Community Committee Choice Session

Session Chair: Wenbo Wu, The University of Texas at San Antonio, San Antonio, TX

1 A General Spatial-Temporal Framework for Short-Term Building Temperature Forecasting at Arbitrary Locations with Crowdsourcing Weather Data

Renhao Sun, 1</sup

This paper presents a novel approach by utilizing crowdsourcing weather data from neighboring personal weather stations (PWS) to improve the weather forecast accuracy around buildings using a general spatial-temporal modeling framework. Our approach leverages PWS data in addition to public data sources, resulting in finer time and spatial resolutions. Additionally, the proposed model incorporates spatial-temporal correlation information of weather variables between the target building and neighboring PWSs, effectively capturing underlying correlation. To evaluate our framework, we compare it against the benchmark models on temperature forecasting for a building located in San Antonio. Overall, our proposed model framework demonstrates a 50% improvement over persistent model and has a 90% chance to outperform airport forecasts in short-term prediction.

2 On Partial Envelop Approach for Modeling Spatial-Temporally Dependent Data

Reisa Widjaja, 1</sup

Modeling multivariate spatial-temporally dependent data is a challenging task due to the dimensionality of the features and the complex spatial-temporal associations among the data. We use a parsimonious approach by proposing a spatial-temporal partial envelop model to achieve efficient estimations in modeling the spatial-temporal data. We extend our model to a group-wise spatial-temporal partial envelop model to adjust the heterogeneity existing at different locations. We provide both theoretical justifications and conduct thorough empirical simulations to demonstrate the effectiveness of our proposed method. We also apply the proposed model to analyzing the crowdsourcing weather data collected from personal weather stations in the United States.

3 Dimension Reduction for Spatial Regression

Hossein Moradi Rekabdarkolaee, South Dakota State University, Brookings, SD

Natural sciences often utilize regression models for spatial data with highdimensional predictors and moderate sample sizes. Therefore, efficient estimation of the regression parameters is crucial for both model interpretation and prediction. The predictor envelope is a dimension reduction method for linear regression that assumes certain linear combinations of the predictors are immaterial to the regression. While predictor envelopes have been developed and studied for independent data, no work has been done adapting predictor envelopes to spatial data. In this work, we proposed the spatial predictor envelope that provides efficient estimate for regression coefficients while taking spatial autocorrelation into account. The effectiveness of the proposed model is illustrated through simulation studies and real data analysis.

4 Scalable Semiparametric Spatio-Temporal Regression for Large Data Analysis

Ting Fung Ma, University of South Carolina, Columbia, SC

Spatio-temporal data are becoming increasingly abundant in a diverse array of disciplines. Here, we develop a spatio-temporal regression methodology for analyzing large amounts of spatially referenced data collected over time. We specify a semiparametric autoregressive model without the Gaussian assumption and devise a computationally scalable procedure with linear computational complexity. Asymptotic properties are further established that inform the computational procedure to be efficient and scalable. A simulation study is conducted to evaluate the finite-sample properties of the procedure. We illustrate our methodology with a dataset with over 2.96 million observations of land surface temperature, and comparison with an existing approach highlights the advantages of our method.

Stochastic Control and Its Applications in Finance

Community Committee Choice Session

Session Chair: Xuedong He, Chinese University of Hong Kong, Hong Kong

1 Exit Strategies of CPT Gamblers in Asymmetric Random Walks

Sang Hu, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: husang@cuhk.edu.cn

In this paper we consider the optimal stopping strategy of a CPT gambler in an asymmetric casino betting problem. After a geometric transformation on the underlying process, we use the Skorokhod embedding technique with randomization to change the decision variables from stopping times to probability distributions of accumulated gains or loss at exit time. Different from fair betting problem that was studied in He et al. (2019), we show that even in an infinite time horizon the asymmetric gambling problem could be well-posed for a wide range of specifications of probability weighting functions. We also present the optimal solution of randomized path-dependent stopping time in the case of power distortion functions.

2 Strategic Investment Under Uncertainty with First- and Second-Mover Advantages

Min Dai[1], Zhaoli Jiang[2], Neng Wang[3], [1]The Hong Kong Polytechnic University, Hong Kong, China; [2]Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [3]Columbia University, New York, NY, Contact: zljiang@cuhk.edu.cn

We analyze a duopoly real-option entry game where the second mover has a cost advantage over the first mover. The equilibrium solution features five regions. In addition to the option-value-of-waiting and competing-to-enter (first-mover-advantage) regions (Fudenberg and Tirole, 1985; Grenadier, 1996), three new regions appear due to the second-mover advantage: a waiting-to-be-Follower region and two disconnected probabilistic-entry regions. Only when market demand is very high does Follower immediately enter after Leader does. The second-mover advantage causes firms to use state-contingent mixed strategies, significantly delaying their entry timing. Our model generates new predictions, e.g., entry likelihood is non-monotonic in market demand.

3 Recovering Time-Consistency in the Mean-Variance Problem

Cagin Ararat[1], Emre Duzoylum[2], [1]Bilkent University, Ankara, Turkey; [2]University of California Santa Barbara, Goleta, CA, Contact: cararat@bilkent.edu.tr

The dynamic mean-variance problem is a well-studied optimization problem that is known to be time-inconsistent. The main source of time-inconsistency is that the family of conditional variance functionals indexed by time fails to be recursive. We consider the mean-variance problem in a discrete-time setting and study an auxiliary dynamic vector optimization problem whose objective function consists of the conditional mean and conditional second moment. We show that the vector optimization problem satisfies a set-valued dynamic programming principle and is time-consistent in a generalized sense. Finally, we propose a computational procedure that relies on convex vector optimization and convex projection problems, and we use this procedure to calculate time-consistent solutions in discrete market models.

4 Optimal Liquidity Provision on Decentralized Exchanges

Xuedong He[1], Chen Yang[2], Yutian Zhou[1], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Eidgenossische Technische Hochschule Zurich Departement Mathematik, Burwood

Automated Market Makers (AMMs) are a popular type of decentralized exchanges in which users trade tokens with each other directly and automatically through a liquidity pool and a fixed pricing function. Liquidity providers can contribute to the liquidity pool by supplying tokens to the pool and in return they earn transaction fees from users who trade through the pool. We propose a model of optimal liquidity provision in which a risk-averse liquidity provider decides the number of tokens she would like to supply to the pool and trade in an open market and the amount of consumption in multiple periods. We derive the liquidity provider's optimal strategy by dynamic programming and study the impact of the transaction fees and pricing function on the number of tokens supplied by the liquidity provider.

Economics and Computation IV

Award Session

Session Chair: Yanqiu Ruan, Singapore University of Technology and Design, Singapore, Singapore

1 On the Timing of Auctions: The Effects of Complementarities on Bidding, Participation, and Welfare

Hayri Alper Arslan[1], Alex Arsenault-Morin[2], Matthew Gentry[3], [1]University of Texas at San Antonio, San Antonio, TX, [2]Queen's University, Kingston, ON, Canada; [3]Florida State University, Tallahassee, FL

This paper empirically explores how varying the timing of a sequence of auctions affects both bidder behavior and the welfare of procurers and bidders. We develop a structural auction model with endogenous participation in which bidding may be either simultaneous or sequential, and bidders may perceive auctioned objects as either complements or substitutes. We then apply this model to data on auctions for roof-maintenance projects in Montreal. We show that complementarities can account for as high as 17% of the total size of a contract combination. Finally, we develop an algorithm to search a schedule of auctions and show that the total cost of projects can be reduced by more than 8%.

2 Algorithmic Assistance with Recommendation-Dependent Preferences

Bryce McLaughlin, Jann Spiess, Stanford Graduate School of Business, Stanford, CA, Contact: jspiess@stanford.edu

When we use algorithms to produce risk assessments, we typically think of these predictions as providing helpful input to human decisions, such as when risk scores are presented to judges or doctors. But when a decision-maker obtains algorithmic assistance, they may not only react to the information. The decision-maker may view the input of the algorithm as recommending a default action, making it costly for them to deviate, for example when a judge is reluctant to overrule a high-risk assessment of a defendant or a doctor fears the consequences of deviating from recommended procedures. In this article, we consider the effect and design of algorithmic recommendations when they affect choices not just by shifting beliefs, but also by altering preferences. We motivate our model from institutional factors, such as a desire to avoid audits, as well as from well-established models in behavioral science that predict loss aversion relative to a reference point, which here is set by the algorithm. We show that recommendation-dependent preferences create inefficiencies where the decision-maker is overly responsive to the recommendation. As a potential remedy, we discuss algorithms that strategically withhold recommendations, and show how they can improve the quality of final decisions.

3 Choice Architecture, Privacy Valuations, and Selection Bias in Consumer Data

Tesary Lin[1], Avner Strulov-Shlain[2], [1]Boston University, Cambridge, MA, [2]University of Chicago, Chicago, IL

How much are consumers' privacy valuations influenced by choice architecture? How does this influence affect the volume and representativeness of the data shared? To answer these questions, we run an experiment to elicit consumers' valuation for their personal data while randomizing the default option and price anchor that they face. An opt-out default decreases valuations by 14-22% compared to opt-in, while a $0-50 anchor decreases valuation by 37-53% compared to a $50-100 anchor. We find that choice architecture that maximizes the supply of data can have opposite effects on its representativeness: A bias exacerbating effect emerges when consumers' privacy valuations and frame effects are negatively correlated. However, such a volume-maximizing frame may also mitigate the bias by improving sample coverage.

4 A Nonparametric Approach with Marginals for Modeling Consumer Choice

Yanqiu Ruan[1], Xiaobo Li[2], Karthyek Murthy[3], Karthik Natarajan[3], [1]Singapore University of Technology and Design, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Singapore University of Technology and Design, Singapore, Singapore

This paper aims to develop parsimonious models for predicting consumer choice behavior using the marginal distribution model (MDM). By establishing necessary and sufficient characterizations of choice data for consistency with MDM, the paper achieves an exact representation of choice probabilities. Verifying the consistency of choice data with this characterization is equivalent to solving a polynomial-size linear program. MDM strikes a balance between tractability and representational power, allowing a nonparametric prediction approach where data informs marginal distributions based on the task at hand. Inconsistent choice data with MDM leads to solving a mixed integer convex program for the best-fitting MDM. These results extend to the case where the alternatives can be grouped based on the marginal distribution of their utilities.

Operations Planning to Ensure Food Security

Contributed Session

Session Chair: David C. Novak, University of Vermont, Burlington, VT

1 Volunteer Allocation and Route Planning for Non-Profit Food Banks with Fairness Requirements

Maria Cabarcas[1], Faisal M. Alkaabneh[2], Leila Hajibabai[1], Ali Hajbabaie[1], [1]North Carolina State University, Raleigh, NC, [2]North Carolina A&T State University, Greensboro, NC, Contact: mcabarc@ncsu.edu

This research studies the assignment of volunteers to appropriate routes to service centers in a non-profit food network. The problem involves food banks, volunteers, and service locations. The routes include picking up volunteers, taking them to service locations where they assist food-insecure households, and returning them home. The problem is formulated as a specialized network flow model that considers volunteers' unique locations and availability status. The objective is to maximize the number of volunteers assigned to service locations while minimizing the routing cost. To solve this problem, a branch and price based technique is devised. Numerical experiments are conducted to validate the effectiveness of the proposed methodology.

2 A Location Routing Model for Equitable Food Distribution to Insecure Households

Kuangying Li, Maria Cabarcas, Asya Atik, Leila Hajibabai, Ali Hajbabaie, North Carolina State University, Raleigh, NC, Contact: lhajiba@ncsu.edu

This study aims to develop an optimal plan for location and routing of food rescue operations by volunteers considering food supply and demand under resource and vehicle capacity constraints. A multi-objective mixed-integer linear model is formulated that aims to maximize the total demand served and minimize the total travel cost of volunteers. An integrated solution technique based on Lagrangian relaxation and column generation is proposed to solve the problem. The proposed methodology decomposes the problem into location and routing components and solves them iteratively using a case study in Raleigh, North Carolina. The preliminary results indicate that the proposed methodology can solve the problem efficiently and outperform the solutions obtained by a benchmark.

4 Hospital Food Waste: A Stochastic Approach Minimizing Food Waste While Fulfilling Nutritional Requirements Under Different Demand Scenarios

Mariana Arriz-Jorquiera, Jorge Andrés Acuna, Jose L. Zayas-Castro, University of South Florida, Tampa, FL, Contact: arrizjorquiera@usf.edu

Up to 5% of the global environmental damage is contributed by the healthcare system, whose solid waste is 71% produced by hospitals, 10-15% of which is food waste. Not only is food waste a global environmental concern, but it also affects patient nutrition. This talk presents a stochastic approach to building the plates of patients by using a Mixed Integer Programming (MIP) model to minimize food waste, applied under different scenarios of the weekly demand of a 1000-bed Hospital in Florida. The discussion includes the difference between the plates that are built without considering the food waste and the plates that include extra food to cover the loss of nutritional intake when the food is wasted.

5 Transportation-Based Food Accessibility Considering Social Vulnerability

David C. Novak[1], James Sullivan[2], [1]University of Vermont, Burlington, VT, [2]University of Vermont, Burlington, VT, Contact: david.novak@uvm.edu

In this research, we address the lack of analytical research focused on food accessibility in rural communities, particularly with respect to marginalized or vulnerable populations. We develop a measure for identifying the most important roadway components in facilitating access to food and apply the measure in a real-world case setting via agent-based simulation. The case example includes a detailed discussion of data sources, how household origins and grocery destinations are mapped to a GIS, and employs a unique statistical technique to map aggregate publicly available demographic data at the census block level to the household level.

1 Hybrid Classical-Quantum Benders Decomposition for Optimal Edge Network Design

The Duong Do[1], Duong Nguyen[1], Ni Trieu[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: duongdo@asu.edu

This study proposes a mixed-integer linear programming model that addresses the challenge of optimal edge server placement and workload allocation in edge computing, which is known to be NP-hard, meaning that it is computationally complex and difficult to solve. To address this challenge, the study explores the potential of leveraging quantum computing, an emerging computational paradigm that has shown promise in offering more effective solutions to complex problems than classical computing. The proposed approach decomposes the original MILP problem into a quadratic unconstrained binary optimization problem and a linear program subproblem. Extensive numerical results verify that the proposed approach has shown significant performance enhancements in terms of computational time over the classical, indicating the efficiency of the proposed model and algorithm.

2 Optimal Baggage Allowance Design for Passenger Airlines

Prabhupad Bharadwaj, R K Amit, Atul Malik, Indian Institute of Technology Madras, Chennai, India. Contact: pbharadwaj@smail.iitm.ac.in

We propose a stochastic optimization approach to determine baggage allowances for a travel class in a passenger aircraft, with the objective of maximizing expected profit in an uncertain baggage demand scenario. Our analysis incorporates the dynamics of the baggage allowance and its effect on passengers and their baggage demand. Results from a “pooled demand” case with realistic price and cost assumptions show that baggage allowance decisions depend upon baggage handling costs. We extend the model to a two-class capacity-sharing scenario where we demonstrate that a higher allowance is given to the business class. As average fare is also a decision criterion for airlines while calculating total revenue, we treat it as a decision variable for the model and compute the optimal value along with the free baggage allowance for each passenger type (economy and business).

3 Robust Capacity Planning with General Upgrading

Zhaowei Hao[1], Zhenyu Hu[2], Long He[3], JUN JIANG[2], [1]Institute of Supply Chain Analytics (ISCA), Dongbei University of Finance and Economics, Dalian, China; [2]NUS Business School, Singapore, Singapore; [3]George Washington University, Washington, WA, Contact: haozhaowei@dufe.edu.cn

In this paper, we consider the capacity planning problem to decide the initial capacity for multiple products to maximize the expected total profit when general upgrading is allowed. Given the marginal mean and variance information of the demand distribution for each product, we formulate it as a two-stage distributionally robust optimization (DRO) model. We derive a compact binary extended formulation for the extreme points of the dual polyhedron by corresponding the extreme points to the shortest path network. Utilizing such formulation, we provide the polynomially solvable SOCP reformulation.

4 Airport Runway Capacity Expansion Planning Under Stochastic Demand

Qianwen Guo, Florida International University, Miami, FL

The objective of this paper is to propose a stochastic model for the airport runway capacity expansion problem. We seek to minimize the cumulative airport runway system costs over the planning horizon time by determining The dynamic model assumes that demand grows deterministically over time, and the investment decision involves a trade-off between system cost savings and the additional costs of capacity expansion. Numerical analyses show important findings regarding the relationships between investment timing, expansion size, and system cost. The findings suggest that larger expansions require a longer wait for the project to become advantageous over the initial capacity. Insufficient expansion size will lead to limited capacity that cannot meet growing demand, causing delays and cumulative costs.

Perspectives on Integrating AI and Automation into Workforce

Contributed Session

Session Chair: Akram Khattab, The University of Toledo, Rochester, MI

1 AI Divide Versus Inclusion: Evidence from Algorithmic Task Assignment of a Food Delivery Platform

Tae Jung Yoon, Yeonseo Kim, Jiyong Eom, KAIST College of Business, Seoul, Korea, Republic of. Contact: taejung.yoon@kaist.ac.kr

The adoption of AI task assignment systems in gig economy has raised growing concerns about whether the systems benefit all platform stakeholders. In a unique setting of a food delivery platform, we study the impact of AI task assignment on delivery workers' productivity and the quality of customer service. Our results show that the adoption improves worker productivity by nearly 3%, with the improvement primarily concentrated among medium-skilled workers. However, it takes more hours for low-skilled workers to complete extended stacks of orders. For high-skilled workers, there is no apparent benefit or loss. These results indicate that AI task assignment can partially alleviate existing productivity disparities among workers. We also find that the adoption reduces customer waiting time for a single order delivery, but this is not the case for a stacked order delivery.

2 The Moderating Role of Work Autonomy in the Relationship Between AI Advancement and Team Creativity: A Task-Technology Fit Perspective

Meng Zhang[1], Jinlong Zhu[1], Chu-Ding Ling[1], Qin He[2], [1]Renmin University of China, Beijing, China; [2]Capital University of Economics and Business, Beijing, China. Contact: mengzhang@ruc.edu.cn

Despite growing interest in the role of artificial intelligence (AI) in enhancing team creativity, little is known about the conditions that maximize its potential benefits. In this research, we attempt to investigate when and how AI advancement enhances team creativity. Drawing on the task-technology fit theory, we propose that work autonomy moderates the positive relationship between AI advancement and team creativity via perceived AI assistance. Findings based on multisource data from 375 employees in 75 teams supported the hypotheses. These findings suggest that work autonomy can be a significant facilitator in reaping the benefits of AI in a team setting and underscore organizations to enhance team creativity by encouraging work autonomy in conjunction with AI advancement.

4 Employees' Response to Artificial Intelligence

Paul Owusu, University of North Texas, Denton, TX, Contact: paul.owusu@unt.edu

This study explores the emotional responses of individual employees towards the introduction of Artificial Intelligence (AI) in their work. Previous research has focused on the macroeconomic and labor market impacts of AI, but little attention has been given to employees' emotional reactions. Drawing on existing frameworks, the study examines employees' appraisals of AI adoption, their emotional responses, and their subsequent reactions. By investigating the emotional aspects of AI implementation, this research aims to provide valuable insights into the human experiences and perceptions associated with this transformative technology.

5 The Effect of the Automation of Managerial Controls on Organizational Outcomes: An Experimental Examination of the Hidden Costs of AI-Based Controls

Akram Khattab[1], HEBA ABDEL-RAHIM[2], [1]The university of Toledo, Toledo, OH, [2]The university of Toledo, Toledo, OH, Contact: akram.khattab@rockets.utoledo.edu

The reliance on automation and AI in managerial controls in the workplace has been subject to a heavy debate in recent years. Automated workplace controls range from installing a surveillance camera to microchipping employees to track their whereabouts. This study uses a controlled experiment to examine whether and how the automation of managerial controls impacts organizational outcomes. We manipulated between-subjects workplace controls at 3 levels (low, medium, and high automation) and recruited 630 US employees. Results show that the automation of controls increases employee performance, yet, decreases organizational commitment and citizenship while increasing turnover rate. In addition, employees demand higher wage premiums when controls are automated. However, the negative effects of increased control automation are moderated for younger generations.

Carbon Emission Analysis in Supply Chains

Contributed Session

Session Chair: Nuri Onat, University of Qatar, Doha, Qatar

1 Impact Analysis of Environmental Policies on Liner Ship Fleet Planning Under Demand Uncertainty

Yonzheng Jerry Chua[1,2], Irfan Soudagar[3], Szu Hui Ng[4], Qiang Meng[5], [1]National University of Singapore, Singapore, Singapore; [2]Agency for Science and Technology Research, Singapore, Singapore, Singapore;

[3]National University of Singapore, Singapore, Singapore; [4]National University of Singapore, Singapore, Singapore; [5]National University of Singapore, Singapore, Singapore. Contact: e0202647@u.nus.edu

Considerations to decarbonize maritime shipping by implementing the Emissions Trading System (ETS) are underway at the International Maritime Organization (IMO). We propose a fleet planning model accounting for carbon emissions to evaluate the decision-making nuances of a liner company to investigate the short-term impact of the ETS. Numerical experiments are conducted on various proposed policy design parameters. Our findings indicate that, for liner shipping which is cross-regional by nature, regional ETS implementations are inadequate due to carbon leakage; Open ETS policies have limited efficacy, particularly when carbon prices are low; strict carbon purchase caps integrated with robust carbon price-setting mechanisms are critical to designing an effective ETS.

2 Estimate Supply Chain Emission Using Large Language Model

Manikandan Padmanaban[1], Jagabondhu Hazra[1], Ayush Jain[2], Shantanu Godbole[1], Kommy Weldemariam[3], [1]IBM Research Labs, Bangalore, India; [2]IBM Research India, Gurugram, India; [3]IBM Research Labs, Yorktown Heights, NY, Contact: manipadm@in.ibm.com

Estimating the carbon emission embodied in the supply chain product is imperative for understanding the climate impact and its actions. The US Environmentally Extended Input-Output (USEEIO) model provides a carbon emission factor per dollar spend for a set of industry sectors. This provides an opportunity to classify the product transaction data into one of the predefined USEEIO industry classes. But the presence of acronym and the limited words in the transaction data poses a challenge in mapping an expense data to an industry sector. To address this challenge, we propose to incorporate the enterprise specific novel embeddings into the NLP foundation model leveraging enterprise contextual data. This helps to improve the disambiguation with industry abbreviations and the results show an improved accuracy in comparable to annotation by domain expertise.

3 Disambiguation of Product Expense Data for Carbon Emission Estimation

Ayush Jain[1], Manikandan Padmanaban[2], Jagabondhu Hazra[2], [1]IBM Research Labs, Gurugram, India; [2]IBM Research Labs, Bangalore, India. Contact: ayush.jain@ibm.com

4 Scope-Based Corporate Carbon Footprint Accounting and Reporting: Insights from a Real-World Application

Nuri Onat[1], Murat Kucukvar[2], [1]Qatar University, Doha, Qatar; [2]University of Denver, Denver, CO, Contact: nonat@asu.edu

Carbon footprint accounting and reporting have gained tremendous interest in recent years due to the pressing impacts of Global Climate Change. Managing and reducing a company's carbon footprint requires comprehensive systems-based approaches where companies require to map all their value chains and operations, develop important performance metrics, and composite indicators, and adopt integrated data management and visualization approaches. In this research, we present a real-world application of corporate carbon footprint accounting and reporting and demonstrate the benefits of using advanced carbon footprint accounting methods for calculating Scope 3 emissions, the development of composite sustainability indicators, and data visualization.

1 Mean-field Analysis for Load Balancing on Spatial Graphs

Daan Rutten, Georgia Institute of Technology, Atlanta, GA

The analysis of parallel-server load balancing systems has relied heavily on mean-field analysis. A pivotal assumption is that servers are exchangeable. However, modern data-centers have data locality constraints, such that tasks of one type can only be routed to a small subset of servers. An emerging line of research considers load balancing algorithms on bipartite graphs where vertices represent task types and servers, respectively. In this talk, I will present a novel coupling-based approach to establish mean-field approximation for a large class of graphs which includes spatial graphs.

2 Bayesian Design Principles for Frequentist Sequential Learning
Yunbei Xu, Massachusetts Institute of Technology, Cambridge, MA
We develop a general theory to optimize the frequentist regret for sequential learning problems, where efficient bandit and reinforcement learning algorithms can be derived from unified Bayesian principles. We propose a novel optimization approach to create “algorithmic beliefs” at each round, and use Bayesian posteriors to make decisions. This is the first approach to make Bayesian-type algorithms prior-free and applicable to adversarial settings, in a generic, optimal, and efficient manner.

3 Estimate-Then-Optimize Versus Integrated-Estimation-Optimization: A Stochastic Dominance Perspective
Haofeng Zhang, Columbia University, New York, NY
In data-driven stochastic optimization, model parameters of the underlying distribution need to be estimated from data in addition to the optimization task. The integration of the estimation and optimization processes can be readily shown to outperform ``estimate then optimize” when the model is misspecified, while we argue that when the model class is rich enough to cover the ground truth, the performance ordering between the two approaches is reversed for nonlinear problems in a strong sense. Analogous results also hold under constrained settings and when contextual features are available.

1 K-12 Education Outreach in a Post-COVID World
Zihan Zhang, Georgia Tech, Atlanta, GA
In March 2020, the start of the COVID-19 pandemic brought a sea change to K-12 education in the U.S. Every school district was forced into virtual learning overnight. Now that the pandemic is fading into the rear-view mirror, those who value the success of K-12 students have the opportunity to begin anew K-12 education outreach projects. Successful, sustained programs will simultaneously work within longstanding constraints facing public education in this country and leverage new opportunities resulting from pandemic response. Lessons learned from first-hand experience will be discussed.

Machine Learning Applications in Health Care

Contributed Session

Session Chair: Yujia Xie, Georgia Tech, Atlanta, GA

1 Investigating Distance Decay and Social Determinants on Healthcare Outcomes Using Meta-Ensembles Predictive Models in Broome County, Ny

Anemone Kasasbeh[1], Mohammad AlDarabseh[2], Amy Booth[1], Hiroki Sayama[2], [1]United Health Services Hospitals, Inc., Vestal, NY, [2]State University of New York at Binghamton, Binghamton, NY, Contact: akasasb1@binghamton.edu

To improve access to healthcare, issues associated with distance decay and social determinants need to be addressed. In this work we developed an automated Artificial Intelligence application to generate a list of patients who could benefit from interventions to improve their healthcare outcomes. We inspected the effect of distance decay on healthcare outcomes by performing meta-ensembles predictive models. Data used in this paper is retrieved from a local hospital in Broome County, NY. Proposed models were evaluated for generalizability. The stacked Model (RF-NB-Nnet, GBM Top Layer) outperformed the rest of the models. The model identified contributing factors to poor health outcomes, such as unavailability of transportation, no-show rate, insurance type, and travel distance. The developed application is used by population health nurses for outreach purposes.

2 Enhancing Diagnosis and Prognosis of Diseases of Despair: An Attention Network Approach

Haya Alshayji[1], Paul Griffin[1], Soundar Kumara[1], Vasant Honavar[2], [1]The Pennsylvania State University, State College, PA, [2]The Pennsylvania State University, State College, PA, Contact: hka5222@psu.edu

We leverage structured medical claims data of patients suffering from diseases of despair and associated social determinants of health (SDOH) to improve disease diagnosis and prognosis. Utilizing attention network methods, we aim to identify and prioritize critical factors in the complex interplay between patient demographics, medical history, and SDOH, enabling more accurate and personalized treatment recommendations and timely interventions for at-risk individuals.

3 A Bayesian Network Model for Early Detection of Students' Course Failure

Yi Tan, The University of Alabama in Huntsville, Huntsville, AL

Motivated by the need of early detection of students' course failure, we propose a hierarchical Bayesian network model which can be used as a screening tool to assess the immediate probability of course failure for each student throughout the semester. The model takes into consideration of students' demographic information, previous academic records, target course attendance/engagement, and has demonstrated its effectiveness on the UAH 2022-23 academia year data. We also conduct the feature importance analysis, which helps us better understand the mechanism of the students' course failure.

4 Reformulation For TSP Under Clustered Layout

Yujia Xie, Georgia Tech, Atlanta, GA, Contact: yxie@gatech.edu

Traveling Salesman Problem (TSP) aims to find the shortest path while visiting all nodes in a given graph, and it has long been proven hard and computationally challenging to obtain optimal solution when the graph size explodes. However, if the underlying graph reveals special layout, especially modular layouts, we can reformulate the well-known Dantzig-Fulkerson-Johnson MIP formulation to reduce the size of TSP computation. With this reformulation approach, we can effectively bring down the computational cost for solving large-sized TSP instances.

5 Harnessing User-Generated Content and Large Language Models for Depression Analysis on Social Media

Jie Li, Juheng Zhang, University of Massachusetts Lowell, Lowell, MA

Depression, characterized by persistent sadness, hopelessness, and disinterest in activities, is a serious mental health concern. As more individuals express their emotional distress online, we identify and analyze these narratives to understand depression better and evaluate community responses' impact on recovery trajectories. This analysis informs the potential of online interventions in mitigating depression and tailoring strategies for specific depression types. We employ lexicon-based methods, benchmarked with large-language models, to analyze depressive narratives,

offering profound insights into online depression expressions. Additionally, we examine how individual personality traits and user profiles shape emotional expression on social media.

COVID-19 Vaccine Demand and Distribution

Contributed Session

Session Chair: Kuangying Li, North Carolina State University, Raleigh, NC

1 Association Between Vaccination Rates and Covid-19 Health Outcomes in the United States: A Population-level Statistical Analysis

Hongru Du, Samee Saiyed, Lauren Gardner, Johns Hopkins University, Baltimore, MD, Contact: hdu9@jhu.edu

COVID-19 vaccines have been consistently proven to be safe and effective in clinal trials, however the emergence of new variants and other confounding factors make it challenging to determine their real-world effectiveness. We analyzed the association between vaccination rates and COVID-19 severity for 48 states in the U.S. at the population level using Generalized Additive Models (GAMs). We modeled the different COVID-19 variant-driven waves separately while controlling for testing, purpose-specific travel behaviors, underlying population immunity, policies, and critical static factors such as comorbidities, vulnerability, race, and state healthcare expenditures. Our study found a significant inverse association between vaccine uptake and COVID-19 severity across variant waves while assessing the impact of all controlled variables on COVID-19 severity.

2 Getting Hundreds of Thousands Vaccinated Using Optimization to Direct Data-Based Ads

Theodore T. Allen[1], Antor Rashid[2], Long Wang[2], [1]Ohio State University, Columbus, OH, [2]FactSpread, Columbus, OH, Contact: allen.515@osu.edu

In late 2020 and early 2021, we clustered counties with the lowest vaccination rates using integer programming into homogeneous groups. Then, we ran optimally planned experiments sharing different combinations of keywords and charts. We implemented an optimized ad strategy which caused hundreds of thousands to vaccinate proven using intervention analysis.

3 A Location-Allocation Model for Optimizing Covid-19 Vaccine Distribution with Equity Constraints

Kuangying Li, Asya Atik, Dayang Zheng, Leila Hajibabai, Ali Hajbabaie, North Carolina State University, Raleigh, NC

This study presents a maximal covering location problem that aims to minimize the total cost of vaccine distribution and maximize the total number of vaccines allocated to population blocks. Equity constraints are included in the proposed mixed-integer linear model considering age, race, and gender groups. A modified Voronoi diagram technique embedded in a Lagrangian relaxation framework is proposed to solve the problem. A set of empirical case studies in North Carolina and Pennsylvania are conducted based on the real-world data collected from the Centers for Disease Control and Prevention (CDC) and health department websites. The numerical results indicate that the proposed model can solve the problem effectively and outperform those of a column generation-based benchmark.

4 Location Routing Problem in a Megacity

Jihyun Jo, Soundar Kumara, Pennsylvania State University, University Park, PA, Contact: jzj5077@gmail.com

In this study, we address the urgent vaccine distribution problem within a megacity, incorporating a location routing problem. We first compare the solutions from two distinct approaches: the vehicle routing problem and the location routing problem. Furthermore, we assess the solutions derived from two heuristics to solve the location routing problem. The first heuristic approach involves solving the location allocation problem to determine the optimal satellite locations within the network. Subsequently, we determine individual routes using a multi-depot vehicle routing problem. The second heuristic approach entails identifying individual routes within the delivery network first and then determining suitable satellite locations along these routes. During the satellite location finding process, we re-optimize the individual routes to improve the solution.

MSOM Service Operations I

Contributed Session

Session Chair: Ruben Lobel, Airbnb, San Francisco, CA

1 Optimizing Queues when Customers Commit the Sunk Cost Fallacy

Shining WU, Liutao YANG, The Hong Kong Polytechnic University, Hong Kong, China. Contact: liutao.yang@connect.polyu.hk

We study a service system where customers make an enter-or-leave decision before observing the queue and a purchase-quantity decision when they are served. Customers form references of the waiting times and are influenced by the sunk cost/time when making their purchasing decisions. We model this sunk cost fallacy, characterize customers' decisions in equilibrium, and study the firm's optimal operations strategies.

2 Pooled Testing in the Presence of Congestion

Bingnan Lu[1], Saif Benjaafar[2], Benjamin Legros[3], Oualid Jouini[4], [1]National University of Singapore, Singapore, Singapore; [2]University of Minnesota, Minneapolis, MN, [3]EM Normandie, PARIS, France; [4]CentraleSupelec, Gif-sur-Yvette, France. Contact: luke_lu@nus.edu.sg

We study the operation of a testing facility that diagnoses infected individuals. In particular, we focus on how the facility should select the sample pooling size that minimizes the total waiting time for testing results. We model the testing process as a two-stage tandem queueing system with batch service and re-entry. We provide conditions on the disease prevalence rate and the arrival intensity that guarantee system stability (i.e. a finite expected waiting time). We provide analytical expressions for estimating the expected time spent in the system by each sample. We also develop an algorithm to obtain the batch size that minimizes the delay in delivering test results. We show that, in general, the optimal batch size decreases in the prevalence rate and increases in the testing times.

3 A Decision-dependent Optimization Model For Restructuring Bank Networks After Mergers And Acquisitions

Zeyu Wang, George Washington University, Washington, DC, Contact: zywang@gwu.edu

This study introduces a decision-dependent model designed to improve operations for closing and resizing bank branches due to mergers and acquisitions. The model incorporates uncertainties in the customer's choice of new service location that arise from the relocation decisions into the decision-making process. We formulate the scheme as a mixed-integer nonlinear programming (MINLP) problem, then present efficient linearization techniques that transform the model into equivalent mixed-integer linear programming (MILP) formulations.

4 Value-Based Routing: Optimizing Airbnb'S Customer Service System

Ruben Lobel[1], Peggy Shao[1], Ryan Lucas[2], Paul Roeseler[2], David Gamarnik[2], [1]Airbnb, San Francisco, CA, [2]Massachusetts Institute of Technology, Cambridge, MA

Airbnb has over 4 million hosts who have welcomed more than 1 billion guest arrivals around the globe. Whenever guests or hosts have an issue they can't resolve, they contact the Customer Service team through one of many channels. The contact is placed in one of many queues, depending on the predicted contact reason, until an agent is available to provide support. In this research, we propose a redesign of the ticket routing system to optimize long term engagement of the user with the platform. To achieve this, we develop a simulation platform that replicates this complex system. We then build an optimization model that leverages the state of the queues, issue prediction, and the heterogenous skills of the agents to find the best match between contact and agent. Finally, we introduce a novel experimentation framework to validate the model.

Online Decision Making, beyond the Worst-Case Adversaries
Community Committee Choice Session

Session Chair: Nika Haghtalab, 1</sup
Session Chair: Abhishek Shetty, University of California, Berkeley, Berkeley, CA

1 Efficient Sequential Decision Making Through Smoothed Analysis

Abhishek Shetty, University of California, Berkeley, Berkeley, CA

Sequential decision making is often plagued with impossibility results indicating that both its statistical and computational difficulty. Given the importance of these problems, both in theory and practice, a pertinent question is to understand and remedy the source of this difficulty, for real-world instances. Towards this end, we establish novel techniques to analyze online algorithms in the smoothed analysis model. In this setting, the algorithm's input is perturbed slightly by noise. One of our framework is to show that, in this model, online learning is as easy as offline learning, both statistically and computationally. That is, we show that the regret against smoothed adversaries is captured by the offline complexity measure, VC dimension. Furthermore, we design efficient algorithms for online learning, circumventing impossibility results in the worst case.

2 Beyond Iid: Data-Driven Decision-Making in Heterogeneous Environments

Omar Besbes, Will Ma, Omar Mouchtaki, Columbia University, New York, NY, Contact: ob2105@gsb.columbia.edu

How should one leverage historical data when past observations are not perfectly indicative of the future? Motivated by this question, we study a data-driven decision-making framework in which historical samples are generated from unknown and different distributions assumed to lie in a heterogeneity ball with known radius and centered around the (also) unknown future (out-of-sample) distribution on which the performance of a decision will be evaluated. This work aims at analyzing the performance of central data-driven policies but also near-optimal ones in these heterogeneous environments.

3 Adaptive Oracle-efficient Online Learning

Vidya Muthukumar, ISyE Georgia Tech, Atlanta, GA

Classical online algorithms offer optimal performance guarantees but face scalability limitations. Oracle-efficient methods address this by leveraging offline optimization oracles to search through an exponentially-large decision space. However, they encounter challenges in adapting to friendly environments. In this talk, we explore two friendly scenarios: (a) “small-loss” problems and (b) IID data. We provide a new framework for designing online algorithms that are oracle-efficient and adapt well to the small-loss environment, under a particular condition which we call approximability (which is spiritually related to sufficient conditions provided by Dudik et al., (2020)). We identify a series of real-world applications for which approximability holds. We also extend the algorithm to an IID data setting and establish a “best-of-both-worlds” bound.

4 Optimal Robustness-Consistency Tradeoffs for Learning-Augmented Metrical Task Systems

Nicolas Christianson, Junxuan Shen, Adam Wierman, California Institute of Technology, Pasadena, CA, Contact: nchristianson@caltech.edu

We discuss recent developments in the design of learning-augmented algorithms for the metrical task systems problem. In this setting, a decision-maker must choose decisions online to minimize the sum of per-round hitting and switching costs, while incorporating (potentially unreliable) advice from an AI/ML algorithm. The decision-maker seeks to exploit good AI/ML performance while ensuring worst-case guarantees in case of poor AI/ML performance due to, e.g., distribution shift. We propose an algorithm, DART, which obtains an exponential tradeoff between consistency (exploitation of the AI/ML advice) and robustness (worst-case performance), and prove a lower bound showing that this tradeoff is the best obtainable for general decision spaces and cost functions. Nonetheless, we demonstrate several special cases in which improved tradeoffs can be achieved.

Analytics in Revenue Management

Community Committee Choice Session

Session Chair: Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI

1 Collaborative Learning and Decision-Making on Pricing and Recommendation: A Simple Framework for Planning

Junyu Cao, The University of Texas at Austin, Austin, TX

We formulate a collaborative learning and decision-making problem involving contextual information. In current business practices, pricing and recommendation decisions often are made jointly by multiple teams in sequence. The decision-making processes for different teams can be controlled by either a centralized or decentralized planner. We propose a simple collaboration framework that integrates the learning about decision-making in an unknown environment. The main challenge in a decentralized framework is that the decision-making process in other teams is unknown, but the subsequent decisions are mutually dependent. We test our algorithm using real data from JD.com, a large e-commerce retailer. Numerical studies validate the superior performance of the two proposed frameworks for different types of planners.

2 Empirical Investigation of Side Effects of Price Change

Ozalp Ozer[1], Inki Sul[2], Serdar Simsek[3], [1]Amazon, Richardson, TX, [2]Carnegie Mellon University, Pittsburgh, PA, [3]The University of Texas at Dallas, Richardson, TX, Contact: isul@andrew.cmu.edu

Modern day retailers use pricing policies that involve frequent price changes according to a complex algorithm and/or the pricing of competitors. Most academic research leaves room for deeper understanding of customer's perception towards frequent price changes. We assess the impact of a retailer's frequent price adjustments on customers' long term expenditure in the retailer. We take multiple empirical strategies including endogenous treatment model and doubly robust learning to find consistent evidence of negative impact of additional price change. We find additional evidence of non-linear impact of increasing price change magnitude, and dissipating negative effect after multiple price change observations. From our counterfactual analysis, we find that not considering the negative effect of price can lead up to 3.05% of revenue loss per product.

3 Ordering and Ranking Products for an Online Retailer

Zijin Zhang, Hyun-Soo Ahn, Lennart Baardman, University of Michigan, Ann Arbor, MI, Contact: zijinz@umich.edu

In e-commerce, product ranking and display affect customer choices and sales. For retailers who sell items from the inventory they have purchased and owned, product ranking has a profound impact on future demand as well as the amount of inventory to be ordered. In this paper, we show that it is important to consider inventory ordering and product ranking decisions as a joint problem, and study how this can be done. We investigate three widely-used rank-choice models from the literature and we develop tractable solution methods through approximating the choice behavior with a simpler model in a variety of ordering-and-ranking problems. We show that our algorithms results in significant profit gain and can solve problems with a large number of products and generate high-quality solutions when it is not possible to get an optimal solution efficiently with the exact demand model.

4 Voice of the Customer? Negative Review as a Double-Edged Sword

Hanqi Wen[1], Izak Duenyas[2], Joline Uichanco[3], [1]Ross School of Business, University of Michigan, Ann Arbor, MI, [2]University of Michigan-Ann Arbor, Ann Arbor, MI, [3]University of Michigan, Ross School of Business, Ann Arbor, MI, Contact: hanqiwen@umich.edu

Nowadays online reviews have become an important factor in influencing the sales of products, where negative reviews usually hurt sales in the long run. To mitigate the negative impact of critical reviews, a simple solution is to disallow reviews. However, doing so not only removes a convenient channel for unsatisfied customers to complain, but eliminates an important source of feedback that the firm can use to make further improvements to the product. This paper explores the optimal dynamic review management policy when negative reviews have double-edged effects. We find that the net impact of negative reviews and whether a negative review's marginal value in providing feedback is increasing or decreasing in the number of reviews collected together decide the optimal policy. We also extend to consider positive reviews, and simple but effective heuristics are designed.

Design and Operation of Ridesharing Platforms

Community Committee Choice Session

Session Chair: Francisco Castro, UCLA Anderson School of Management, Los Angeles, CA

Session Chair: Hongyao Ma, Columbia University, New York, NY

Session Chair: Chiwei Yan, University of Washington, Seattle, WA

1 Pricing Shared Rides

Chiwei Yan[1], Julia Y. Yan[2], Yifan Shen[3], [1]University of California, Berkeley, Berkeley, CA, [2]University of British Columbia, Vancouver, BC, Canada; [3]University of Washington, SEATTLE, WA, Contact: yan.cw08@gmail.com

Despite ride-hailing services gaining wide popularity, major ride-sharing platforms have long been struggling with maintaining a healthy and profitable shared rides product, a critical product for sustainable urban transportation. We study how smart pricing strategies can help to densify demand and increase adoption. In stylized cases, we show a profit-maximizing policy has a simple closed-form solution and is intrinsically altruistic in improving adoption and cost efficiency compared to status-quo pricing policies. We develop efficient computational approaches to scale this policy to large networks. Experiments using NYC taxi data show promising results.

2 Iterative Network Pricing for Ridesharing Platforms

Chenkai Yu, Columbia University, New York, NY

Ridesharing platforms match riders and drivers, using dynamic prices to balance supply and demand. The origin-based "surge pricing", however, does not depend on the market condition of trip destinations, leading to inefficient trip flows in space and incentivizes drivers to strategize. In this work, we introduce the *Iterative Network Pricing (INP)* mechanism, addressing a main challenge in the practical implementation of optimal origin-destination (OD) based prices, that the model for rider-demand is hard to estimate. Assuming that the platform's surge algorithm clears the market for each origin in real-time, our mechanism updates the OD-based price adjustments week-over-week, using only information immediately observable during the same time window in the prior week. We prove that our mechanism converges to an outcome that is approximately welfare-optimal. Using data made public by the City of Chicago, we illustrate (via simulation) the resulting substantial improvements in social welfare under the INP mechanism.

3 Two-Sided Platform Flexibility

Daniel Freund[1], Sebastien Martin[2], Jiayu (Kamessi) Kamessi Zhao[3], [1]MIT, Boston, MA, [2]Kellogg School of Management, Northwestern University, Evanston, IL, [3]MIT, Canbridge, MA, Contact: dfreund@mit.edu

We study a parsimonious model of two-sided platform flexibility, wherein nodes form random edges in a bipartite graph before a centralized market designer finds a maximum matching. In order to increase the size of the matching, the designer can (at a cost) incentivize parts of the market to be more flexible, thus increasing the chance that they form edges. Surprisingly, in many instances of interest, the optimal solution incentivizes nodes on only one side of the market to be flexible, even when the instance is entirely symmetric. However, when both sides are managed by distinct managers with the same objective, they may face a suboptimal Nash equilibrium in which they incentivize their respective sites equally. In summary, our work initiates the study of multi-sided platform flexibility, and identifies a range of unexpected patterns and technical challenges associated to it.

4 Life Cycle Air Pollution, Greenhouse Gas, and Traffic Externality Benefits and Costs of Electrifying Uber and Lyft

Aniruddh Mohan, Princeton University, Princeton, NJ, Contact: aniruddh@princeton.edu

Uber and Lyft have pledged to fully electrify their ridesourcing fleets by 2030 in the United States. We introduce AgentX, a novel agent-based model built in Julia for simulating ridesourcing with high geospatial and temporal resolution. Using AgentX, we model the life cycle local air pollution, CO_2, and traffic externality benefits and costs of serving rides based on Chicago trip data from 2019-2022 with fully electric vehicles. We estimate that electrification reduces life cycle CO_2 emissions by 40-45% but increases externalities from criteria pollutants by 6-11% on average across our simulations. A novel finding is that electrification may increase deadheading due to additional travel to and from charging stations and this increases congestion, crash risk, and noise externalities by 2-3%. Overall, electrification reduces net external costs to society by 3-11%.

Pricing and Assortment Optimization

Community Committee Choice Session

Session Chair: Anran Li, The Chinese University of Hong Kong, Hong Kong, China

Session Chair: Zhe Liu, Imperial College Business School, London, -, United Kingdom

1 Balancing Risk and Return in Product Line Pricing

Hongmin Li, Scott Webster, Arizona State University, Tempe, AZ, Contact: hongmin.li@asu.edu

Product line pricing in a multi-product environment can be intriguing because the decision affects both the expected profit and the variability of profit. We study firms' pricing decisions with the goal of optimally balancing the expected profit and the risk associated with uncertain customer choices. Two alternative settings are considered: (1) a monopolist managing a complex product line where the firm strategically prices its products based on risk preference; (2) a competitive equilibrium of multiple firms each with distinct risk preference, where we analyze the effect of risk on a firm's competing power and its interaction with market entry cost.

2 Duopoly Price Competition with Reference Effects Under Logit Demand

Mengzi Amy Guo[1], Zuo-Jun Max Shen[2], [1]University of California, Berkeley, Berkeley, CA, [2]University of California Berkeley, Berkeley, CA, Contact: mengzi_guo@berkeley.edu

We consider a duopoly price competition with potential asymmetric reference effects under the MNL model. In the one-shot game, we show the existence and uniqueness of Nash equilibrium (NE) in loss-neutral and loss-averse scenarios, while for the the gain-seeking scenario, the NE exists but may not be unique. We also extend to dynamic games with periods connected by reference price updates. Our analysis examines long-run market dynamics of the repeated game under two practical pricing policies. For fully rational firms employing equilibrium pricing, we show convergence to a stationary Nash equilibrium (SNE) for loss-neutral and loss-averse products, with SNE being unique and independent of initial reference price in the loss-neutral scenario. For firms with bounded rationality using best-response pricing, we prove the same conclusion for short-term memory consumers.

3 Dynamic Pricing Under Stochastic Hawkes Arrival Processes

Longyuan Du[1], Ming Hu[2], Quan Yuan[3], [1]University of San Francisco, San Francisco, CA, [2]University of Toronto, Minneapolis, MN, [3]Zhejiang University, Hangzhou, China. Contact: ldu5@usfca.edu

The paper investigates how a seller adjusts prices to maximize profit under the Hawkes process, where demand is influenced by previous customers. The problem is formulated as a dynamic program, and the optimal pricing strategy is characterized. We show that the optimal intensity increases with the effect of the previous process and decreases over time. The asymptotic analysis shows that the revenue of the stochastic and deterministic problem differ by a constant, and the heuristic that adopts the optimal price in the deterministic problem achieves a performance loss at the scale of a constant. The paper is extended to cover general information spreading and multiple identical products.

APS Student Paper Competition

Award Session

Session Chair: Jose Blanchet, Columbia University, Dallas

1 On the Statistical Benefits of Temporal Difference Learning

David Cheikhi, Columbia University, New York, NY

Given a dataset on actions and long-term rewards, a direct estimation approach fits value functions that minimize prediction error on the training data. Temporal difference learning (TD) instead fits value functions by minimizing inconsistency between estimates made at successive time-steps. For finite state Markov chains, we provide a crisp asymptotic theory of the statistical advantages of TD. First, we show that an intuitive inverse trajectory pooling coefficient completely characterizes the reduction in mean-squared error of value estimates. Depending on problem structure, the gain could be enormous or nonexistent. Next, we prove that there can be dramatic improvements in estimates of the difference in value-to-go for two states: TD's errors are bounded in terms of a novel measure - the trajectory crossing time - which can be much smaller than the time horizon.

2 Bayesian Design Principles for Frequentist Sequential Learning

Yunbei Xu, MIT, Cambridge, MA

We develop a general theory to optimize the frequentist regret for sequential learning problems, where efficient bandit and reinforcement learning algorithms can be derived from unified Bayesian principles. We propose a novel optimization approach to create "algorithmic beliefs" at each round, and use Bayesian posteriors to make decisions. This is the first approach to make Bayesian-type algorithms prior-free and applicable to adversarial settings, in a generic, optimal, and computationally efficient manner. As a major application, we present a novel algorithm for multi-armed bandits that achieves the "best-of-all-worlds" empirical performance in the stochastic, adversarial, and non-stationary environments. And we illustrate how these principles can be used in linear bandits, bandit convex optimization, and reinforcement learning.

3 A New Class of Bounds for Convergence of Markov Chains to Equilibrium

Yanlin Qu, Peter W. Glynn, Jose Blanchet, Stanford University, Stanford, CA

We introduce a unified framework to derive computable convergence bounds for Markov chains. Under this framework, bounds with various rates, ranging from polynomial to exponential, are derived from a single "contractive drift" (CD) condition. These bounds are computable, as all elements are explicitly defined in terms of one-step transition expectations. Various techniques are devised to verify CD for examples from queueing theory and stochastic optimization. For these examples, we obtain sharp bounds that scale correctly with respect to model parameters such as the traffic intensity in queueing models and the step size in optimization algorithms.

4 On the Convergence of Policy Iteration-Based Reinforcement Learning with Monte Carlo Policy Evaluation

Anna Winnicki, University of Illinois at Urbana-Champaign, Urbana, IL

A common technique in reinforcement learning is to evaluate the value function from Monte Carlo simulations of a given policy, and use the estimated value function to obtain a new policy which is greedy with respectto the estimated value function. A well-known longstanding open problem in this context is to prove the convergence of such a scheme when the value function of a policy is estimated from data collected from a single sample path obtained from implementing the policy (see page 99 of Sutton and Barto (2018), page 8 of Tsitsiklis (2002)). We present a solution to the open problem by showing that a first-visit version of such a policy iteration scheme indeed converges to the optimal policy provided that the policy improvement step uses lookahead Silver et al. (2016), Mnih et al. (2016), Silver et al. (2017b) rather than a simple greedy policy improvement. We provide results both for the original open problem, which was stated for the tabular setting, and also present extensions to the function approximation setting, where we show that the policy resulting from the algorithm performs close to the optimal policy within a function approximation error. The key technical contribution in the paper is the following: the proof in Tsitsiklis (2002) relies on policy iteration ideas extended to the stochastic approximation setting when the probability of a visit to any state is known. In our trajectory-based setting, this approach does not work because the number of visits to each state is policy dependent and unknown; therefore, we employ very different ideas by combining contraction properties of the Bellman operator along with stochastic approximation techniques.

Frontiers of Data-Driven Decision-Making

Community Committee Choice Session

Session Chair: Hamsa Bastani, UPenn Wharton
Session Chair: Kan Xu, University of Pennsylvania, Philadelphia, PA

1 The Disparate Impacts of User Strategizing in Recommendation Systems

Chara Podimata, MIT, Boston, MA, Contact: podimata@mit.edu

An important assumption in recommendation systems is that users consume the content they like with no other considerations in mind. But as we document in a large survey, in fact, users choose content strategically in order to influence their future recommendations. We show that at equilibrium differences in users' preferences get accentuated. This effect is very strong among minority users, who must avoid signaling interest in mainstream content to ensure the algorithm will show them content related to their minoritized identities. This puts minorities at a disadvantage; they cannot access mainstream content without the algorithm suppressing their identities. We propose 3 interventions to improve the recommendation quality on average and for minorities. Finally, we describe a methodology to inform applied theory modeling in strategic learning settings with surveys.

2 Optimizing and Learning Sequential Assortment Decisions with Platform Disengagement

Mika Sumida[1], Angela Zhou[2], [1]Marshall School of Business, University of Southern California, Los Angeles, CA, [2]USC Marshall School of Business Data Sciences and Operations, Los Angeles, CA, Contact: zhoua@marshall.usc.edu

We consider a problem where customers repeatedly interact with a platform. At every interaction, the customer is shown an assortment of items and selects among these items according to a Multinomial Logit choice model. The probability that a customer logs onto the platform in the next period depends on the customer's past purchase history. The goal of the platform is to maximize the total revenue obtained from each customer over a finite time horizon. First, we study a non-learning version of the problem with known preferences. We formulate the problem as a dynamic program and prove structural properties of the optimal policy. Next, we formulate a contextual episodic reinforcement learning setting, where the parameters governing consumer preferences and return probabilities are unknown and learned over multiple episodes. We develop an algorithm and provide a regret bound.

3 Online Resource Allocation with Predictions

Lin An, Andrew A. Li, Benjamin Moseley, CMU Tepper, Pittsburgh, PA, Contact: linan@andrew.cmu.edu

An emerging line of work has shown how to incorporate machine-learned predictions into decision-making in a manner that is robust to the accuracy of those predictions. We do this for an online resource allocation problem, under both stochastic and adversarial arrivals. Our main contribution is a single algorithm which, without a priori knowledge of the accuracy of the predictions, achieves the optimal consistency-robustness tradeoff simultaneously for both settings.

4 Stochastic Low-rank Tensor Bandits For Multi-dimensional Online Decision Making

Emma Jingfei Zhang, Emory University, Atlanta, GA, Contact: emma.jzhang@emory.edu

Multi-dimensional online decision making plays a crucial role in online recommendation and digital marketing. In these problems, a decision at each time is a combination of choices from different types of entities. We introduce stochastic low-rank tensor bandits, a class of bandits whose mean rewards can be represented as a tensor, and consider two settings, tensor bandits without and with context. In the first setting, the platform aims to find the optimal decision with the highest expected reward. In the second setting, some modes of the tensor are contexts and the rest are decisions, and the goal is to find the optimal decision given the context. We propose learning algorithms under each setting and analyze their regret bounds. Simulations and analysis of online advertising data show that our algorithms outperform alternative approaches that ignore the tensor structure.

Queueing and Learning

Community Committee Choice Session

Session Chair: Xinyun Chen, Chinese University of Hong Kong, Shenzhen, Shenzhen, China

1 A Two Timescale Evolutionary Game Approach to Multi-Agent Reinforcement Learning

Nan Chen, Chengli Ren, Chinese University of Hong Kong, Shatin N T, Hong Kong. Contact: nchen@se.cuhk.edu.hk

We propose a two-time scale evolutionary game theoretic approach to solving multiagent reinforcement learning (MARL) problems. The new approach incorporates three innovative designs. First, we represent each agent by a population of pure-action-playing individuals and use the action distribution in each population to approximate the agent's mixed policy. Second, we propose a simple optimization based protocol to update policies, avoiding the computationally expensive step of finding the exact equilibrium at each state. Third, the updating of population states and Q-values is set in two different time scales to ensure the convergence. The new approach provably converges to approximate Nash equilibria of MARL problems without imposing the global optima or saddle point conditions, two restrictive assumptions that are typically needed in the literature.

2 Performance of the Gittins Policy in the G/G/1 and G/G/K, with and Without Setup Times

Yige Hong[1], Ziv Scully[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Cornell University, Berkeley, CA, Contact: yigeh@andrew.cmu.edu

How should we schedule jobs with unknown sizes to minimize the mean queue length? In the preemptive M/G/1 queue, we know the Gittins policy is the optimal policy. Recent results also show that Gittins policy is heavy-traffic optimal in M/G/k. But allowing multiple servers is just one way of extending the M/G/1. Does Gittins policy still perform well when there are non-Poisson arrivals or setup times? In this paper, we give the first analysis of the Gittins policy that can handle any combination of (a) multiple servers, (b) non-Poisson arrivals, and (c) setup times, bounding its suboptimality gap in each case. Our results thus cover the G/G/1 and G/G/k, with and without setup times, implying the heavy-traffic optimality in all the systems we consider. Another consequence of our results is that Gittins is optimal in the M/G/1 with setup times at all loads.

3 A Unified Fluid Model for Service Systems with Service Times that Depend on the Delay or the Abandonment Times

Deniz Simsek[1], Achal Bassamboo[1], Ohad Perry[2], Chenguang Wu[3], [1]Northwestern University, Evanston, IL, [2]SMU, University Park, TX, [3]Hong Kong University of Science and Technology, Hong Kong, China. Contact: deniz.simsek@kellogg.northwestern.edu

We propose a unified fluid model to approximate two separate queueing models for service systems: In the first, customers' service times depend on their patience, and in the second, the service times depend on their delay in queue. The unified fluid model is shown to provide accurate approximations for the mean transient dynamics of the queue process, and guidance regarding its stationary behavior. In particular, we show that the fluid model may possess multiple equilibria, some of which are (locally) stable, and others which are unstable. Having more than one stable equilibrium in the fluid model suggests that the stochastic system experiences large oscillations over large time periods and congestion collapse.

4 Steady-State Analysis of Queues with Hawkes Arrival

Guiyu Hong[1], Xinyun Chen[2], [1]The Chinese University

of Hong Kong, Shenzhen, Shenzhen, China; [2]Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: guiyuhong@link.cuhk.edu.cn

We investigate single-server queues with Hawkes arrivals and general service distributions. In specific, we show that under mild conditions, single-server queues with Hawkes arrivals converge to their steady-states in an exponential rate. Since the initial state of Hawkes queues contains future information of arrivals, we develop a semi-synchronous coupling technique to show the exponential ergodicity. As an application of the ergodic rate, we further consider a online learning method for the staffing problem of the Hawkes queues (dubbed GOLiQ-Hawkes) and establish the regret bound of GOLiQ-Hawkes based on the ergodic results. Finally, comprehensive numerical experiments are conducted to contrast the Hawkes queues with conventional GI/GI/1 queues. The results turn out a sharp difference due to the auto-correlation of Hawkes arrivals.

5 Stochastic Approximation MCMC And Online Inference For Dynamic Pricing And Capacity Sizing In Queues

Jiadong Liang[1], Xinyun Chen[2], Xiang Li[3], Zhihua Zhang[3], [1]Peking University, Peking, China; [2]Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [3]Peking University, Beijing, China

In this talk, we explore the application of Stochastic Approximation MCMC (SAMCMC) in optimal control of queueing systems. Unlike traditional SA methods, SAMCMC generates samples using Markovian dependence on current iteration parameters and past samples. Leveraging parameter-dependent Poisson equations, we establish convergence rates and a functional CLT for SAMCMC, and introduce a novel inference method that can be executed streamingly based on this result. Addressing challenges with abstract assumptions regarding SAMCMC's Poisson equation, we propose a practical, testable assumption framework. Through meticulous derivations, we align the queueing setting with these assumptions.Through numerical experiments, we validate our conclusions, highlighting SAMCMC's superior performance compared to benchmark methods.

New Topics in Applied Probability

Community Committee Choice Session

Session Chair: Jamol Pender, Cornell University, Ithaca, NY

1 Queueing for Epidemics

Laurel Newman, Cornell University

While most studies concerning queueing models focus solely on customer behavior in the aggregate, our work draws inspiration from COVID-19 applications and seeks to explore the interaction between customers as a new model for infectious disease spread. Our model considers a queue where a proportion of the arriving population p is infected and the remaining population is susceptible. When an infected person overlaps in the queue with a non-infected customer for more than I units of time, then the non-infected person becomes infected. We compute the probability that a non-infected person becomes infected depending on the model parameters.

2 Overlap Times in the Infinite Server Queue

Sergio Palomo, Cornell University

Imagine, you enter a grocery store to buy food. How many people do you overlap with in this store? How much time do you overlap with each person in the store? In this paper, we answer these questions by studying the overlap times between customers in the infinite server queue. We compute in closed form the steady state distribution of the overlap time between a pair of customers and the distribution of the number of customers that an arriving customer will overlap with. Finally, we define a residual process that counts the number of overlapping customers that overlap in the queue for at least δ time units and compute its mean, variance, and distribution in the exponential service setting.

3 Overlap Times in Two Dimensional Tandem Queue

Ruici Gao, Jamol Pender, Cornell University, Ithaca, NY, Contact: rg585@cornell.edu

In this paper, we investigate overlap times in a two-dimensionalinfinite server tandem queue. Specifically, we analyze the amount oftime that a pair of customers spend overlapping in any station of thetwo dimensional tandem network when the stations have independentand identically distributed service times that follow an exponentialdistribution. Our main contribution is the derivation of the joint taildistribution, the two marginal tail probabilities and several momentsof the overlap times. We extend our results to the non-identicallydistributed case as well. Our results shed light on how customersoverlap downstream in serial queueing systems.

4 Stochastic Models for Double Reservation Parking

Ryan McCleary, Cornell University

We will discuss a stochastic model used to study reservation policies in vehicle sharing systems. The basic set-up for this talk is a station-based car sharing system having N stations, each of which consists of K parking spaces. Users entering the system can either reserve only a car at their starting station and not a parking space at their destination ("single reservation"), or both a car and a parking space ("double reservation"). We will first introduce a Markov process which describes this system, which is of dimension O(N^2), where N is the number of stations. For large N, this becomes computationally infeasible, so we then shift our attention to a process of dimension O(N), which is not Markov. We can, however, prove a convergence theorem relating this lower-dimensional process to a Markov process, which will be the subject of this talk.

5 Waiting for Justice: Stochastic Models for Bail Funds

Jamol Pender, Cornell University, Ithaca, NY

Bail funds have a long history of helping those who cannot afford bail in order to wait for trial at home. They have also had a large impact on the verdict of the defendant. In this talk, we present the first stochastic model for capturing the dynamics of a community bail fund. Our bail fund model integrates traditional queueing models with classic insurance/risk models to represent the bail fund's intricate dynamics. We employ simulation techniques to assess Gaussian-based approximations that estimate the probability of a defendant being denied access to the bail. We also propose a new simulation-based algorithm that leverages a deterministic infusion of capital as a control variable to stabilize the probability that defendants have access to the bail fund. It reveals that our Gaussian-based approximations are suitable for highly active bail funds.

Some Recent Advancements in Simulation

Community Committee Choice Session

Session Chair: Zeyu Zheng, University of California, Berkeley, Berkeley, CA

1 Efficient Input Uncertainty Quantification for Regenerative Simulation

Linyun He[1], Mingbin Feng[2], Eunhye Song[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Waterloo, Waterloo, ON, Canada; [3]Georgia Institute of Technology, Atlanta, GA, Contact: lhe85@gatech.edu

This work tackles quantification of input uncertainty for a regenerative simulation model when its input distributions are estimated from finite data. In particular, our aim is to construct a bootstrap-based confidence interval (CI) with correct coverage for the true simulation output mean performance at a significantly less computational cost than traditional methods. Exploiting the regenerative structure, we propose a k-nearest neighbor (kNN) ratio estimator for the steady-state performance measure at each set of bootstrapped input parameters and construct a bootstrap CI from the computed estimators. Asymptotically optimal choices for k and bootstrap sample size are discussed. We further improve the CI by combining the kNN and likelihood ratio methods. The efficiency of the proposed estimators over the standard estimator are empirically demonstrated.

2 Pseudo-Bayesian Optimization

Haoxian Chen, Henry Lam, Columbia University, New York, NY

Bayesian Optimization is a popular approach for optimizing black-box functions. Its key idea is to use a surrogate model to approximate the objective and quantify the uncertainty for sequential search of query points that balance exploitation-exploration. Gaussian process (GP) has been a primary candidate for the surrogate model, thanks to its Bayesian-principled uncertainty quantification power and modeling flexibility, and has spurred an array of more efficient variants in recent years. In our study, we take a distinct view based on an axiomatic framework that elicits the minimal requirements on any surrogate model to guarantee black-box optimization convergence. Our framework, which we call Pseudo-Bayesian Optimization, substantially enhances the design freedom and subsequently bypasses the scalability issues faced by GP methods.

3 A Tree-Base Continuous Simulation Optimization Procedure

Jianzhong Du[1], Jeff Hong[1], Ying Zhong[2], [1]Fudan University, Shanghai, China; [2]University of Electronic Science and Technology of China, Chengdu, China. Contact: jianzhodu2-c@my.cityu.edu.hk

In this work, tree-based procedures are proposed to solve continuous optimization via simulation (COvS) problems. The procedures search for the optimal solution by adaptively partitioning the design space and allocating more sampling efforts to the area where the optimal solution tends to lie. We establish different lower bounds on the minimax convergence rate for the optimization error when the objective function satisfies different local smoothness assumptions. Then we show that our procedures can solve these problems without necessarily knowing the objective function's smoothness condition and achieve the optimal minimax convergence rates. Numerical results show the procedures are efficient.

Analytics for Sustainable Development

Community Committee Choice Session

Session Chair: Ville Satopaa, INSEAD, Paris, France

1 Improving Transport for People with Reduced Mobility: Leveraging Matheuristics and Analytics to Optimize the Dial-A-Ride Problem in Barcelona

Laura Portell, Helena Ramalhinho, University Pompeu Fabra, Barcelona, Spain. Contact: portell.laura@gmail.com

The rich heterogeneous Dial-a-Ride Problem (rHDARP) is introduced to optimize door-to-door transport for individuals with reduced mobility in Barcelona. Leveraging matheuristics, specifically Iterated Local Search (ILS) and Set Partitioning (SP), we address the multi-constraint problem considering user and vehicle heterogeneity, time windows, ride/waiting times, and accompanying people requirements. We evaluate our approach using a real-world case study of the Transport Service for People with Reduced Mobility in Barcelona, demonstrating its effectiveness in reducing costs and improving service quality compared to existing routes.

2 Vehicle Routing with Stochastic Demand, Service and Waiting Times - a Case of the Food Bank Collection Problem

Meike Reusken, Tilburg University, Tilburg, Netherlands. Contact: m.c.d.reusken_1@tilburguniversity.edu

We present a matheuristic for the capacitated vehicle routing problem with stochastic demand, service and waiting times. The problem is inspired by the donation collection of food banks, where the donated food that needs to be collected only becomes known upon arrival and the time spent on waiting and service depends on the size of the donation. We present a matheuristic that decomposes this problem into its individual decisions to obtain a feasible solution: (i) select the number of districts into which the service area should be divided, (ii) cluster customers into these districts, (iii) plan routes for each district, (iv) enter iterative procedure in case no feasible solution is found. Computational experiments demonstrate that the matheuristic can effectively solve problems sizes of up to 100 consumers and contains practical value to Canadian and Dutch food banks.

3 On the Trade-Offs Between Affordability, Nutritional Value and Environmental Impact of Food Baskets

Melissa Koenen[1], Claudia Damu[2], Marleen Balvert[1], [1]Tilburg University, Tilburg, Netherlands; [2]World Food Programme, Rome, Italy. Contact: m.f.koenen@tilburguniversity.edu

Diet optimization is used by humanitarian organizations such as the World Food Programme to get a cost estimate for a nutritious food basket in a certain region. This analysis helps to identify local food barriers and to propose policies to improve the situation. Besides the affordability and nutritiousness of a food basket, there are many other goals that these baskets should achieve. That is, an ideal food basket should be culturally appropriate, affordable, nutritious and environmentally friendly. In most cases it is not possible to achieve this, as goals can be conflicting. In order to investigate how these different goals interact with each other we use a weighted sum sandwich algorithm to show all trade-offs. In our research we focus on making these trade-offs understandable using visualizations, and we explain what kind of insights can be gained for informing policy.

4 Web-Based Decision-Support System for Integrated Home Care Planning

Jesica De Armas, Bruno Vieira, Helena Ramalhinho, Universitat Pompeu Fabra, Barcelona, Spain

Planning combined home health and social services is a very difficult task for decision-makers due to the high number of working regulations, user-related necessities and the need for synchronizing both types of services. We propose two heuristic methods to optimize routing and scheduling decisions for the synchronized home health and social care problem. We use data from current care providers in Barcelona to build and test our models and provide insights into the trade-off between the associated operating costs, continuity of service and number of unscheduled services. The proposed tool is made available via a web-based decision support system that allows decision-makers to obtain efficient solutions in an intuitive manner.

Applications of OR and Analytics to Socially Impactful Problems

Flash Session

Session Chair: Mechack Ciyola, Lawyer Office, Kinshasa, AZ

1 Fairness and Strategies in Multi-Member Districts

Sanyukta Deshpande[1], Nikhil Garg[2], Sheldon H. Jacobson[3], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]Cornell Tech, New York, NY, [3]University of Illinois Urbana-Champaign, Champaign, IL, Contact: spd4@illinois.edu

Given the well-documented flaws in single-member plurality systems, there's a growing demand for alternatives. This work investigates the viability of the sought-after 'multi-winner ranked choice voting (RCV) system' and its susceptibility to strategic influences. We analyze the feasibility, computability, and effectiveness of employing strategies in RCV. Treating voter data as objects in space, tagged with unique social choice orders, we model game-like dynamics between candidates. They aim to enter preferred regions, using campaign and cooperative strategies. This research sheds light on strategic aspects of multi-winner RCV systems, providing insights for electoral reform.

3 To Convert or to Deter? Combat Counterfeiting in an Emerging Market

Liling Lu, singapore management university, singapore, Singapore. Contact: liling.lu.2018@pbs.smu.edu.sg

"Super fakes" are becoming popular in emerging markets. A brand-name firm may combat counterfeiting by converting the counterfeiters into authorized overseas suppliers, instead of deterring the entry to sell counterfeits. With the option of converting, we investigate under what conditions a brand-name firm optimally chooses to convert the counterfeiter into an authorized overseas source when facing with a licit domestic supplier.

4 Developing a Sustainable Network Design for Agricultural Waste Supply Chain in Ireland

Maryam Roudneshin, Amanda Sosa, University College Dublin, Dublin, Ireland. Contact: rudneshinmaryam@yahoo.com

This paper presented a methodology applying Geographic Information System (GIS) and mathematical programming to design a sustainable supply chain network for converting agricultural waste into high-value-added products. This approach aims to optimize sustainability factors as well as supply chain design. Ireland, as one of the largest agricultural producers in Europe, is considered a case study to validate the proposed methodology.

5 Student Performance Differences in High School Physics Education Using Big Data

Harry Wu, Walter Payton College Preparatory High School, Chicago, IL, Contact: wuharry53@gmail.com

This study uses TIMSS data to identify topic areas where US students perform well or poorly. I developed a unique index to measure the performance in the seven topic areas and three cognitive areas covered in high school curricula. I found that US students perform the worst in magnetism and electromagnetic induction compared to students in other countries. I also found that US students perform better in multiple-choice questions than in critical responses and that their performance in reasoning skills is consistently poor. I identified various contextual variables that may explain student performance and propose leveraging artificial intelligence (AI) strategies in teaching high school physics to improve student performance.

6 Municipal Bond Market Price of Risk

Dan Li[1], Peter Adriaens[1], Romesh Saigal[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: kency@umich.edu

Public water utilities are pivotal in ensuring access to safe drinking water, serving about 90% of the U.S. population. As user fees and tax earnings fall short of maintaining infrastructure, issuing municipal bonds has emerged as the primary financing method for public water infrastructure. The emergence of climate change is reshaping freshwater dynamics, impacting both water resources and the pricing of municipal bonds issued by water utilities. This study presents empirical evidence showcasing the impact of flooding and drought risks on municipal bond spreads. Notably, our research reveals a trend of reduced issuance spreads for water bonds associated with flooding risks since 2013. Furthermore, a scenario analysis based on the Merton model is employed to assess the economic implications of the observed climate risk premium within the domain of water bonds.

4 How Does Executive Incentive Perceptions Mediate the Effect of Environmental Regulations on Green Process Innovation? Moderating Effects of Executive Age and Ownership Type

Hesong REN, Wang Nengmin, Xi'an Jiaotong University, Xi'an, China. Contact: renhesong@stu.xjtu.edu.cn

Green process innovation (GPI) is an efficient way to reduce pollution, but there are no uniform findings on the effect of environmental regulations (EGs) on GPI. Using survey data from 309 Chinese manufacturing firms, we examine how EGs affect GPI, considering the mediating role of executive perceived political incentives (PPIs) and perceived wealth

incentives (PWIs). We also investigate the contingent role of executive age and further explore how these effects vary between state-owned enterprises (SOEs) and privately-owned enterprises (POEs). We find that executive age weakens the positive influences of EGs on both PPIs and PWIs. Additionally, PPIs and PWIs enhance GPI. The partial effect related to PPI is stronger for SOEs, while the partial effect related to PWI is stronger for POEs. This study contributes to the literature by disentangling the effects of EGs on GPI.

Decision Support for Military Air Operations

Community Committee Choice Session

Session Chair: Matthew JD Robbins, Air Force Institute of Technology, WPAFB, OH

1 Evaluating the Joint Reliability of Multiple Distinct Servers for a Comprehensive Military Medical Evacuation Scenario

Virbon Frial, Air Force Institute of Technology, WPAFB, OH, Contact: virbon.frial@afit.edu

The Golden Hour policy requires that the medical evacuation (MEDEVAC) of casualties to medical treatment facilities (MTFs) occurs within an hour from the time of injury. To maximize the number of casualties evacuated within an hour, it is vital that military MEDEVAC planners effectively determine where to locate MEDEVAC facilities, such as mobile aeromedical staging facilities and MTFs, and allocate their associated servers, such as MEDEVAC units and beds. Furthermore, MEDEVAC servers conduct joint operations to ensure successful casualty evacuations. Therefore, we develop an approximate hypercube queueing algorithm and joint-coverage models that consider the dependencies between servers. The results in this research highlight the importance of considering the joint operations of servers within a comprehensive MEDEVAC system to improve system performance.

2 Efficient Dynamic Threat Avoidance Routing for Combat Aircraft in Advanced Framework for Simulation, Integration, and Modeling (AFSIM)

Dante Reid, Lance E. Champagne, Nathan B. Gaw, Air Force Institute of Technology, Wright Patterson AFB, OH

Simulating pre-planned routes and dynamic threat avoidance routing represents a significant problem for operations analysts. Without automated methods to create operationally valid routes, the analyst is faced with hard coding individual routes for aircraft over the entirety of the mission set. This research implemented threat avoidance routing based on Dijkstra's algorithm for aircraft attempting to operate in an anti-access area denial environment capable of dynamically updating the mission route as new threat information is learned. A designed experiment determined the impact of grid parameters on operational effectiveness and computational costs. Results show that the algorithm produced the best operational performance with grid spacing set to 50% of the smallest surface to air missile threat radius without incurring prohibitive computational costs.

3 Predicting Success in United States Air Force Pilot Training Using Machine Learning Techniques

Phillip R. Jenkins, Air Force Institute of Technology, Wright-Patterson Air Force Base, OH, Contact: phillip.jenkins@afit.edu

The US Air Force is struggling with a chronic pilot shortage, and not all pilot candidates are completing the necessary training, which exacerbates the problem. This study uses machine learning techniques to analyze historical data on pilot training candidates to gain insights into their success rates. The study finds that the extremely randomized tree technique can predict candidate success with 94% accuracy, and that degree type and commissioning source are the most important factors in determining success. The findings can inform modifications to future candidate selection criteria and Air Force personnel policies.

4 A Similarity-Based Admission Control Methodology for Experience Replay Within a Deep Reinforcement Learning Algorithm: Solving an Air Battle Management Problem

Joseph M. Liles, Matthew J. Robbins, Brian J. Lunday, Air Force Institute of Technology, WPAFB, OH

This paper introduces a novel similarity-based admission control methodology for the experience replay memory buffer in reinforcement learning problems. By updating the buffer only with sufficiently dissimilar experiences, the efficiency and speed of learning algorithms can be improved. We demonstrate the efficacy of our approach by analyzing an air battle management problem, extending previous work by including navigational waypoints and a probability-of-kill model for enhanced realism. We employ a neural network-based approximate policy iteration algorithm in a unique simulation environment, performing computational experiments to evaluate various algorithm designs. Analysis shows that using a memory buffer with the top 50% most distinct experiences allows a learning algorithm to converge about 10% faster than using prioritized experience replay alone.

5 A Game Theoretic Approach to Search for a Moving Target

Thuy Bui, Rutgers University, Newark, NJ, Contact: tb680@business.rutgers.edu

We present a zero-sum game between a Hider and a Searcher. The Hider places a target in one of n boxes. The target then moves among boxes according to a time-homogeneous Markov chain. Each box i has a detection probability q_i. That is, given the target is in box i, a search of that box will find the target independently with probability q_i. The Searcher picks a search sequence of length m corresponding to the order in which the boxes are searched. The payoff is the probability of finding the target in m searches, which the Searcher wishes to maximize, and the Hider wishes to minimize. We prove the game has a value and each Player has an optimal strategy. We also present the solution of the game for some classes of Markov chains.

Advanced Topics in Biomedical Informatics

Community Committee Choice Session

Session Chair: Haifeng Wang, Mississippi State University, Mississippi State, MS

1 Characterizing the Complex Dynamic Properties of Rem Sleep Using Nonlinear Dynamical System Analysis

Cheng-Bang Chen, University of Miami, Coral Gables, FL, Contact: cxc1920@miami.edu

Rapid eye movement (REM) sleep is a crucial stage of sleep for brain health, but it is difficult to quantify. REM is a complex and dynamic process that requires characterization methods that can capture its complexity and dynamism. While existing approaches, such as power spectrum analysis, have made significant contributions to sleep research, they do not adequately capture the intricate nonlinear and nonstationary dynamic patterns within REM. To address this gap, this research introduces a novel framework based on nonlinear dynamical system analysis to quantify the dynamic properties of REM. The proposed metrics offer an objective and quantitative approach to characterizing REM sleep, enabling further advancements in sleep research.

2 Generating Counterfactual Explanations for Causal Inference Using Generative Modeling

Zhou Siqiong[1], Upala Islam[1], Imon Banerjee[2], Bhavika Patel[2], Ashif Iquebal[1], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Phoenix, AZ, Contact: aiquebal@asu.edu

We leverage the concept of counterfactual explanations to extract causal relationships between various imaging phenotypes, clinical information, molecular features, and the treatment response after neoadjuvant systemic therapy. Our approach is based on learning the sampling distributions of counterfactual instances using a regularized generative adversarial network such that the resulting counterfactuals are realistic. We demonstrate the method on benchmark datasets and a real-world case study on breast cancer.

3 Early Detection of Metastatic Tumor Recurrence Using Brain MRI

Oyekanmi O. Olatunde[1], William M. Duggar[2], David M. Caballero[2], Toms V. Thomas[2], Neha Adari[2], Mohammad T. Khasawneh[1], Hyunsoo Yoon[3], [1]Binghamton University, Vestal, NY, [2]University of Mississippi Medical Center, Jackson, MS, [3]Yonsei University, Seoul, Korea, Republic of. Contact: oolatun1@binghamton.edu

Due to the lack of clarity and standardization among experts regarding the treatment of metastatic brain tumors, it is important to monitor the effectiveness of any treatment plan and update it if necessary. This monitoring task involves predicting metastatic tumor recurrence using a binary classification approach. Therefore, we studied the effectiveness of using tumor radiomic features obtained from MRI to that of using 2D/3D deep neural networks on the ROI from brain MRI and radiotherapy dose. We used data from the University of Mississippi central hospital for this study. Our results show that radiomic features from MRI alone may be sufficient to discriminate stable from recurrent tumors. In addition, we showed different splitting strategies and how they affect the model's ability to learn discriminative feature representations between stable and recurrent tumors.

Advances in Public Sector Operations

Community Committee Choice Session

Session Chair: Vibhuti Dhingra, Schulich School of Business, York University, Toronto, ON, Canada

1 Nudging Patients Towards Cost-Effective Providers: Analysis of an Insurer's Effort-Based and Cash Reward-Based Mechanisms

Mili Mehrotra, University Of Illinois Urbana Champaign, Champaign, IL

Misalignments between patients' choices of providers and those of the health insurance company (HIC) can result in significant costs. Misalignments may occur either because enrollees are unaware of their options or because they do not have an incentive to choose the cost-effective provider. Motivated by emerging mechanisms in the industry, we examine how an insurer can exert effort and/or offer cash rewards to nudge patients towards cost-effective providers. We build an analytical model that captures the salient aspects of an HIC's decision problem while incorporating how enrollees choose providers. With this versatile framework, we analyze the HIC's optimal effort and reward, individually and jointly, under different cost-share structures (i.e., copayment and coinsurance). Comparing the HIC's savings with the effort and cash reward-based approaches, we find that when coinsurance is high, the HIC prefers the effort-based approach. Conversely, the cash reward-based approach is better when coinsurance is low and the price difference between the two providers is high. With copayment, the HIC prefers to use a cash reward when the price difference is high; otherwise, it prefers to exert effort. Thus, neither a reward-only nor an effort only approach uniformly outperforms the other. The two approaches can serve as tactical complements as indicated by the superiority of the joint approach in some cases. This work provides a framework for the HIC to tailor the nudge (effort or reward or both) for different procedures and geographies based on the cost-share structure and the relative magnitude of related costs.

2 Effect of Expedited Payments on Project Delays: Evidence from the Quickpay Reform

Vibhuti Dhingra[1], Volodymyr O. Babich[2], Harish Krishnan[3], Jie Ning[4], [1]Schulich School of Business, York University, Toronto, ON, Canada; [2]Georgetown University, Washington, [3]University of British Columbia, Vancouver, BC, Canada; [4]Case Western Reserve University, Cleveland, OH, Contact: vibhutid@schulich.yorku.ca

Contractors are typically not paid instantaneously upon completing the project tasks and furnishing the invoice. We study the impact of payment timings on project delays. We develop theories that explain how payment duration affects project completion, and generate testable hypotheses. We empirically test these hypotheses using data on U.S. public projects. Our identification strategy uses a policy amendment that expedited payments to certain federal contractors as an exogenous shock.

3 Are Chief Sustainability Officers Guardians Of Environmental Justice? An Empirical Evaluation

Finn Petersen[1], Vibhuti Dhingra[2], Rachna Shah[1], [1]University of Minnesota, Minneapolis, MN, [2]Schulich School of Business, York University, Toronto, ON, Canada. Contact: pet03435@umn.edu

Environmental justice is a pressing issue in the US, as marginalized communities, primarily composed of people of color and those living in poverty, continue to bear the disproportionate burden of pollution and toxic emissions from manufacturing facilities.

Recently, firms have signaled an increased commitment to responsibility and sustainability by appointing Chief Sustainability Officers (CSOs). However, the impact of such appointments on overall sustainability, especially in environmental justice context, remains unclear. We analyze the effects that CSO appointments have on facility-level toxic chemical releases and explore how the effect varies by the type of community in which a facility is located. Our research sheds light on the pivotal role CSOs play in fostering sustainable business practices and mitigating instances of environmental injustice.

4 How Do Private Sector Firms Respond to a Supply Shock from the Public Sector?

Anant Mishra, Carlson School of Management, University of Minnesota, Minneapolis, MN

The study analyzes the response of domestic and foreign firms in the private sector to a sudden reduction in competition from public sector units (PSUs) in India, caused by a suspension of production licenses for vaccine-manufacturing PSUs. The suspension created uncertainty, but domestic firms were able to introduce new products and experience performance gains, while foreign firms did not benefit much. The study suggests that domestic firms' ability to navigate political challenges arising from lack of alignment between national and subnational governments is a key factor in their outperformance of foreign firms. The study highlights that even a transitory and uncertain reduction in competition from the public sector can lead to fundamental market restructuring by domestic firms.

HAS Distinguished Speakers Session 2

Community Committee Choice Session

Session Chair: Jonas Oddur Jonasson, MIT Sloan School of

Management, Somerville, MA
Session Chair: Mariel Sofia Lavieri, University of Michigan, Ann Arbor, MI

1 Optimal Treatment Models: Past, Present and Future

Andrew J. Schaefer, Rice University, Houston, TX

Optimal disease treatment models were first proposed over 50 years ago, and continue to be an active area of research. We summarize the literature, survey the state of the art, and discuss exciting areas of future research.

2 Teaching, Research, and Practice: A Virtuous Cycle in Healthcare

Amy Cohn, University of Michigan, Ann Arbor, MI

For many operations researchers working on healthcare applications in an academic setting, it can be a sizeable challenge to have impact in teaching, research, *and* clinical practice. There just aren't enough hours in the day! My training in optimization, however, has assisted me in maximizing the synergies to be found in building a virtuous cycle where teaching influences and informs (no pun intended) research, which influences and informs practice, which influences and informs teaching, and counter-clockwise as well. I will discuss my experiences working as: a) professor of Industrial and Operations, b) Faculty Director of the Center for Healthcare Engineering and Patient Safety, and c) Chief Transformation Officer of Michigan Medicine, with the hopes of not only sharing my insights but stimulating future discussions amongst attendees.

Behavioral Aspects of Healthcare Operations

Community Committee Choice Session

Session Chair: Craig Froehle, University of Cincinnati, Cincinnati, OH

1 Physician Collaboration and Multisiting: Implications for Care Efficiency in Emergency Departments

Bogdan C. Bichescu[1], Haileab Hilafu[2], Hui Jia[3], [1]The University of Tennessee, Knoxville, TN, [2]University of Tennessee, Knoxville, TN, [3]University of La Verne, La Verne, CA

Effective collaboration is crucial for temporary healthcare teams as it facilitates information sharing and reduces duplicated actions that hinder the care delivery efficiency. This study, based on data from Florida EDs, found that physician collaboration, operationalized based on physician familiarity and partner exposure, has a positive impact on care efficiency, by reducing visit durations and the number of procedures received. Additionally, physician multisiting, which represents a physician's tendency to work at multiple ED locations, weakens the benefits of familiarity but strengthens the benefits of partner exposure. These insights suggest that hospital administrators should consider physician collaboration and multisiting when forming care teams and scheduling shifts.

2 Patient Prioritization in Emergency Departments

Daniel Adelman[1], Thomas Spiegel[2], Kanix Wang[3], Gizem Yilmaz[4], [1]University of Chicago, Booth School of Business, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]University of Cincinnati, Cincinnati, OH, [4]University of Chicago, CHICAGO, IL, Contact: wang2xk@ucmail.uc.edu

In this study, we aim to unravel the decision-making process underlying the assignment of patients to available beds in Emergency Departments (EDs) and examine the ramifications of queue jumping on waiting times and medical outcomes. Leveraging historical data, we train an array of machine learning algorithms to accurately forecast the subsequent patient to be assigned to a bed, evaluate the resulting patient outcomes, and recommend operational refinements. We then assess the impact and externalities of patient prioritization, focusing on waiting times and medical outcomes such as length of stay (LOS), mortality, risk of admission, and ED bounce-backs. This empirical research, conducted within the framework of personalized medicine, offers valuable insights into improving patient prioritization in emergency care settings.

3 Understanding Determinants of Patient Appointment Punctuality

Hedayat Alibeiki, California State University San Marcos, San Marcos, CA

Understanding the causes of patient unpunctuality can help better design the queuing systems and appointment arrival policies. This study aims to investigate the potential factors that may affect the patients' arrival time to their outpatient appointments. Potential factors considered in this analysis include patient appointment characteristics and patient demographic and socio-economic information.

4 Scheduling Effects on Service-Worker Fatigue: Evidence from Emergency Department Physicians

Chia-Chun Yang[1], Craig Froehle[2], Elizabeth Leenellett[3], [1]University of Cincinnati, Cincinnati, OH, [2]University of Cincinnati, Cincinnati, OH, [3]University of Cincinnati, Cincinnati, OH, Contact: craig.froehle@uc.edu

Employee fatigue is known to have deleterious consequences for work quality. Less is known about how scheduling, and shift structure specifically, influences front-line service-worker fatigue. Using primary data collected via a fatigue-monitoring program we developed and implemented in a large hospital's emergency department, we examine how shift duration and timing influence fatigue. We also assess how workers' between-shift activities influence the effectiveness of what should be their fatigue-recovery time. We find both shift structure and downtime activities influence the fatigue experienced by workers, but not always in intuitive ways, and we recommend organizations consider worker fatigue more specifically in their scheduling policies.

5 Capacity Expansion in Emergency Department Network: Impact of Opening Hospital and Hospital-Based Emergency Department on Patient Demand Shift and Operational Performance

Hyun Seok (Huck) Lee[1], Eric Park[2], Timothy H. Rainer[3], Robert Batt[4], [1]Korea University Business School, Seoul, Korea, Republic of; [2]Wake Forest University, Winston-Salem, NC, [3]Li Ka Shing Faculty of Medicine, The University of Hong Kong, Hong Kong Island, Hong Kong; [4]Wisconsin School of Business, UW-Madison, Madison, WI, Contact: parke@wfu.edu

We study how patients respond to easier access to emergency care in the form of new EDs opening closer to their location. Our study exploits individual patient's decision on ED visit choice and tendency and its impact on care outcomes and operational performances due to shift in overall demand and subsequent change in ED congestion levels in two different settings. One ED/hospital opening in a region without any public hospital within 25 km and another ED/hospital opening in a region with already two other EDs within 10 km.

Data-driven Research in Healthcare Operations

Community Committee Choice Session

Session Chair: Masoud Kamalahmadi, University of Miami

Session Chair: Iman Attari, Indiana University, Bloomington, IN

1 A Data-Driven Analytical Framework for the Opioid Prescription Epidemic

Alireza Boloori[1], Soroush Saghafian[2], Stephen Traub[3], [1]University of Washington, Tacoma, WA, [2]Harvard University, Cambridge, MA, [3]Brown University, Providence, RI, Contact: aboloori@uw.edu

Opioid epidemic is attributed to the over-prescription of opioid painkillers. Medical guidelines have urged healthcare providers to lessen opioid prescriptions in their medical practices. This, however, could negatively affect those patients who suffer from acute or chronic pain symptoms. Utilizing commercial insurance claims and encounters data, we (1) analyze the trade-off between the side effects and potential benefits of using pain treatments, and (2) provide an analytical framework that helps physicians in prescribing these treatments.

2 The Benefits-Value-Advisor (BVA) Program for Shoppable Medical Procedures

Jingyao Huang[1], Diwakar Gupta[2], [1]University of Missouri-Kansas City, Kansas City, KS, [2]University of Texas, Austin, TX, Contact: jhhkq@umkc.edu

Large price variation is prevalent for routine medical procedures such as MRI and CT Scan, which has led insurers to introduce payment innovations to reduce the medical expenditure. We focus on one beneficiary-oriented payment innovation, the BVA program, which is designed to steer beneficiaries to low-cost providers. Under the BVA program, insurers exert influence on beneficiaries' provider selection via recommendation effect. In this paper, we first investigate the effectiveness of recommendations under the BVA program and identify the optimal recommendation strategy. Additionally, we point out that the benefit of the BVA program also depends on procedure types and we found that the BVA program has least benefit for critically difficult procedures.

3 Growing the Vaccine Distribution Network During a Pandemic: Implications for Increasing Access

Sukrit Pal[1], Anand Nair[2], Jason Miller[3], [1]Iowa State University, Ames, IA, [2]Northeastern University, Boston, MA, [3]Michigan State University, East Lansing, MI

Hospitals implement different policies to better manage care capacity in environment of uncertain demand. In this study, we investigate one such policy - creation of access controlled

COVID isolation ward - to understand how hospitals exploit such policy to manage their protective equipment inventory and patient care.

4 Traffic Light Allocation Pathway System for Geriatric Patients

Abtin I. Maghsoodi[1], Valery Pavlov[2], Paul Rouse[3], Cameron Walker[4], Matthew Parsons[5], [1]Waikato Health District, Hamilton, New Zealand; [2]University of Auckland, Auckland, New Zealand; [3]University of Auckland, Auckland, New Zealand; [4]University of Aukland, Aukland, New Zealand; [5]University of Waikato, Hamilton, New Zealand. Contact: v.pavlov@auckland.ac.nz

For many geriatric patients access to the acute geriatric ward is critical for their health as their conditions and treatment are complex due to multiple comorbidities and general frailty of such patients. However, the acute geriatric ward purposefully designed and equipped to provide health care at the required level is unavailable for all geriatric patients due to its limited capacity. The complexity of such patients translates to a demanding, complex, and laborious triage process. Considering geriatric patients constitute about 34% of patients the triage process consumes time of some of the most highly qualified medical staff. A data-driven Traffic Light System has been developed that reduces the amount of required human decision-making by 95%.

Leveraging Empirical Data to Improve Health IT and Healthcare Operations

Community Committee Choice Session

Session Chair: Seokjun Youn, University of Arizona, Tucson, AZ

1 Optimal Location of a Remote Dental Unit

Jong Youl Lee[1], Balaraman Rajan[2], Abraham Seidmann[3], [1]Florida International University, Miami, FL, [2]California State University East Bay, Pleasanton, CA, [3]Boston University, NEWTON, MA, MA, Contact: jongyoul.lee@simon.rochester.edu

We explore the economics of a major hospital operating a remote dental unit in a distant rural area. Specifically, we characterize the optimal location of the remote unit and examine the impact of operating a remote dental unit on the profit of a dental hospital. The ideal scenario, from a patient coverage perspective, is to put the remote unit location far enough away that patients accessing the remote unit are distinct from patients accessing the main hospital center to avoid redundancy (market cannibalization). However, we show that such a placement may not always be optimal for the hospital's profit and derive conditions under which the optimal patient coverage for the hospital and the remote unit overlaps. Our findings lead to policy implications for dental care reimbursement and service expansion.

2 Unintended Impact Of Initial Prescribing In Hypnotics Abuse

Manqi Li[1], Xiang Chen[1], Yan Huang[2], [1]Renmin University of China, Beijing, China; [2]Tepper School of Business, Carnegie Mellon University, Pittsburgh, PA, Contact: limanqi@rmbs.ruc.edu.cn

Hypnotics medication misuse is a severe global problem. In this study, we propose the bullwhip effect in chronic disease management, indicating the self-amplifying impact of an initial prescription of hypnotics medication on a patient's long-term outcome. Utilizing a unique prescription dataset, we identify causality between initial prescription dosage and long-term patient outcomes, uncovering the dynamics involved. Mechanism analysis shows that subsequent prescription in follow-up visits may refer to the dosage of the previous prescription, signifying a prominent impact of the initial decision. This study stresses the need for careful dosage decisions in the early stage of the treatment course.

3 Tracking Nosocomial Diseases at Individual Level with a Real-Time Indoor Positioning System

Yong-Hong Kuo[1], Chun Hung Cheng[2], Ziye Zhou[3], [1]The University of Hong Kong, Pokfulam Road, Hong Kong; [2]Logistics and Supply Chain MultiTech R&D Centre (LSCM), Hong Kong, Hong Kong; [3]The Chinese University of Hong Kong, Shatin, Hong Kong. Contact: yhkuo@hku.hk

Healthcare-associated infections (HAIs) pose a significant risk during infectious disease outbreaks like SARS, as they can spread through person-to-person contact or within healthcare facilities. To address this issue, we propose a novel methodology that models HAIs at an individual level and integrates real-time positioning technologies for effective outbreak control. We tested our approach using four months of human tracking data from a hospital that experienced a major SARS outbreak in 2003. Our evaluation results demonstrate that our framework outperforms existing models in characterizing macro-level phenomena such as the number of infected people and epidemic threshold. Our work highlights the importance of personalized modeling for controlling HAIs and provides a promising avenue for future research in this area.

4 From One Goal to Another: Understanding the Dynamic Mechanism of Goal Pursuitin Mobile Health Platforms

Chenxi Guo[1,2], Qiuju Yin[1], Zhijun Yan[1], Seokjun Youn[2], Wei Chen[2], [1]Beijing Institute of Technology, Beijing, China; [2]University of Arizona, Tucson, AZ, Contact: sarahguocx@hotmail.com

Goal pursuit are important for improving public health management. Existed literature reveals the change of user motivation in single and hierarchical goal pursuit. However, the change of user healthful activity in mHealth platforms is composed of multiple non-hierarchical goal-pursuing processes, which remains limited. This paper proposes a dynamic approach (hidden Markov model) to reveal 1) how user motivation change in the process of goal pursuit, especially moving to the next goal; 2) how previous goal (including the outcome and user feedback) affects the next goal pursuit. We identify three motivation states, and show that the characteristics of previous goal affect users' pursuit of the next goal differently across states. The findings offer implications for platform managers on how to encourage users to pursue goals and build sustainable online platforms.

Emerging Applications of Machine Learning in Healthcare

Community Committee Choice Session

Session Chair: Caleb Bugg, Georgia Tech, Decatur, GA
Session Chair: Gian-Gabriel P. Garcia, Georgia Institute of Technology, Atlanta, GA

1 Clustered Multi-Task Learning for Prediction of Adverse Pregnancy Outcomes

Sun Ju Lee, Gian-Gabriel Garcia, Georgia Institute of Technology, Atlanta, GA, Contact: julee@gatech.edu

In clinical prediction models, combining individual indicators into a composite outcome can help overcome issues associated with single outcomes such as low predictability and low prevalence. However, this may obscure relationships between predictors and single outcomes, and may limit the clinical utility of the prediction model as diagnoses may have different etiologies addressed by different interventions. We aim to resolve this trade-off by developing an optimization framework to simultaneously cluster related outcomes and learn model parameters for each cluster. We apply our formulation to indicators comprising maternal and neonatal morbidity and demonstrate that our approach can aid interpretability by finding underlying groups of related tasks and deriving an interpretable set of predictors.

2 Studying and Fixing Machine Learning Racial Bias in Medical Appointment Scheduling

Michele Samorani, Santa Clara University, Santa Clara, CA

In an effort to increase clinic efficiency, state-of-the-art scheduling algorithms use patients' individual no-show predictions when scheduling medical appointments. By combining in such way machine learning and optimization, though, these algorithms inevitably result in undesirable racial disparities, because patients' race tend to be correlated with their no-show risk. Published and ongoing work shows, for example, that black patients are disproportionately placed in overbooked appointment slots, or that they are scheduled farther in the future than the rest of the patients. In this talk, I will give an overview of recent working and published papers that study and attempt to fix racial disparity in appointment scheduling.

3 Implementing Federal Food Service Guidelines In Federal And Private Worksite Cafeterias In The United States Improves Human And Planetary Health

Caleb Bugg[1], Gian-Gabriel P. Garcia[1], Yang Yang[1], Karen R. Siegel[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University, Atlanta, GA, Contact: caleb.bugg@isye.gatech.edu

This modeling study estimates the potential impact of adherence to US Food Service Guidelines for Federal Facilities and further dietary substitutions on the carbon footprint and healthfulness of food menus offered by federal facilities in the United States. First, we built a food database that links food items with their greenhouse gas emissions (GHGEs), nutritional content, and healthfulness using multiple data sources. Next, we used this food database to parameterize a linear programming optimization model to estimate the impact on human and planetary health of (a) shifting from current adherence to FSGs to complete (100%) adherence and (b) shifting within food groups from less healthy to more healthy foods (for example, within the protein foods group, shifting from beef to chicken or from chicken to legumes).

4 On Time-dependent Workloads in Service Processes

Donald Lee[1], Hao Ding[2], Sokol Tushe[1], Diwas S. KC[1], [1]Emory University, Atlanta, GA, [2]Emory University, Decatur, GA

The empirical operations literature have shown that the service process of customers is state-dependent, with a primary focus on the relationship between patient length-of-stay and workload in emergency departments (ED). Traditionally, the state of the workload is either measured at the beginning of service, or the average workload over the course of the stay is used. Recognizing that the state of the workload is not time-static but actually varies over time, this paper provides empirical evidence from the ED setting that the patient service rate is both state- and time-dependent. Through two applications, we demonstrate that time-dependency is a first-order concern. First, we show how accounting for time-dependent workloads can potentially resolve an open question regarding the relationship between service speed and workload. Specifically, the literature has identified a number of seemingly contradictory findings. We show that this could be due to a statistical artefact of using static workloads in the estimation. Second, we use a naturalistic ED staffing simulation to demonstrate significant performance improvements gained from employing a state- and time-dependent service process model over one that only accounts for state-dependency.

Emerging Topics in Logistics

Community Committee Choice Session

Session Chair: Sibel Alumur Alev, University of Waterloo, Waterloo, ON, Canada

1 The Value of the Multi-Period Solution Revisited: How to Model Time in Capacitated Location Problems

Hannah Bakker[1], Stefan Nickel[2], [1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]Karlsruhe Insitute of Technology, Karlsruhe, Germany. Contact: stefan.nickel@kit.edu

Location decisions are often long-lasting and multi-period models have received considerable attention. The price to pay for the increased flexibility in decision-making is increased complexity. When facilities are capacitated, multi-period models impose additional restrictions regarding when to use resources. The value of the multi-period solution (VMPS) was introduced to quantify the benefit of shifting to a multi-period model by setting its objective value in relation to that of a static counterpart. We discuss how relaxing time-dependent constraints and deriving periods from the problem's data allows decision-makers to exploit the benefits of increased flexibility while limiting the drawbacks of multi-period modeling. We conclude that more does not necessarily translate to better when it comes to modeling time.

2 Multi-Period Hub Location with Shipment Consolidation and Time-Definite Transportation

Khaled M. Shah[1], Sibel A. Alumur[1], James H. Bookbinder[2], [1]University of Waterloo, Waterloo, ON, Canada; [2]University of Waterloo, Toronto, ON, Canada. Contact: jbookbinder@uwaterloo.ca

In this study, we jointly decide on locations of hubs, consolidation of shipments, and inventory holding. A fleet with different vehicle capacities and costs is used for inter-hub transportation. Inventory space at hubs is limited, demand between O-D pairs is distributed over a multi-period horizon, and there are promised times for delivery. We formulate a MIP model to decide the optimal hub locations, allocation of demand nodes to hubs, inventory to be held at hubs, and types and the number of vehicles to be dispatched on inter-hub links in different periods. We propose a solution methodology that incorporates a shipment consolidation subproblem embedded in a variable neighborhood search heuristic. We evaluate the performance of the model and algorithm by numerical experiments on a realistically prepared data set to derive managerial insights.

3 Sustainable Hub Location Under Uncertainty

Gita Taherkhani[1], Mojtaba Hosseini[2], Sibel Alumur[3], [1]Loyola University, Chicago, IL, [2]University of Iowa, Iowa City, IA, [3]University of Waterloo, Waterloo, ON, Canada. Contact: gtaherkhani@luc.edu

In this paper, we study the sustainable design of hub networks under uncertainty for truckload and less-than-truckload transportation. We develop a model in which, in addition to transportation and hub installation costs, the carbon tax is also explicitly included in the objective function. Moreover, to ensure that the total amount of greenhouse gas emissions emitted by trucks does not exceed the carbon cap, we incorporate an emission limit on the entire transportation network. To provide a more reliable solution framework for this problem, we take the demands as stochastic parameters and then develop a Benders-decomposition-based algorithm coupled with a sample average approximation scheme for solving our stochastic problem.

4 Data-Driven Hub Network Design for Ridesharing

Gita Taherkhani[1], Bissan Ghaddar[2], Sibel Alumur[3], [1]Loyola University, Chicago, IL, [2]Ivey Business School, London, ON, Canada; [3]University of Waterloo, Waterloo, ON, Canada. Contact: sibel.alumur@uwaterloo.ca

We study the design of ridesharing hub networks to promote shared transportation. Given a set of passenger trips in an urban area, the problem is to determine the origins and destinations of a fixed number of ridesharing connections to maximize the potential users of the system. The problem is formulated as a maximal covering hub arc location model and solved to optimality using Benders decomposition. Additionally, two data-driven clustering-based methodologies are adapted and implemented to compare with the solutions of the optimization model. All methodologies are tested using the New York City taxi trip data. Several computational experiments are conducted to compare optimization and data-driven approaches under key performance metrics.

Platform Economy and Socially Responsible Operations

Community Committee Choice Session

Session Chair: Yunlong Peng, Tsinghua University, Beijing, China

Session Chair: Chong Zhang, Tilburg University, Tilburg, Netherlands

1 The Impact of Image Quality in Review Platforms: Theory, Evidence, and Managerial Implications

Jiawei Chen[1], Yunke Mai[2], Chong Zhang[3], [1]Shanghai University of Finance and Economics, Shanghai, China; [2]University of Kentucky, Lexington, KY, [3]Tilburg University, Tilburg, Netherlands. Contact: c.zhang@tilburguniversity.edu

In this paper, we utilize a data-driven approach to study sellers' visual marketing decisions on service rating platforms. In particular, by applying image processing and machine learning techniques on a dataset collected on Yelp, we estimate the quality of photos posted by restaurants and establish its connection with the qualities of restaurants (reflected by ratings and reviews). We find that restaurants with higher ratings prefer to post photos, and more interestingly, the quality of photos is shown to have different impacts on customer reviews depending on restaurants' service qualities. Building upon this interesting data finding, we establish a quality disclose model that captures the key tradeoff behind the data observations in order to provide managerial insights and inform optimal visual marketing decisions for restaurants.

2 Reusable Packaging Program with Consumer Engagement

Yunlong Peng[1], fei gao[2], Jian Chen[3], [1]University of Warwick, Coventry, United Kingdom; [2]Indiana University Bloomington, Bloomington, IN, [3]Tsinghua University, Beijing, China. Contact: Yunlong.Peng@wbs.ac.uk

In this paper, we consider a firm selling in a market where some eco-conscious consumers start to use their own reusable containers to reduce the waste of single-use packaging. Two different strategies have been adopted by firms in practice to promote the use of reusable packaging: (i) offering incentives (including monetary and pro-environmental incentives) and providing their own reusable packaging to consumers. We develop a stylized model to study the effectiveness of such two strategies and examine their environmental implications.

3 Will Diversity Equity and Inclusion Commitment Improve Manufacturing Firms' Market Performance?

Chris Lo[1], Fei Li[2], Christopher S. Tang[3], Yi Zhou[4], [1]Hong Kong Polytechnic University, Hong Kong, China; [2]Hong Kong Polytechnic University, Hong Kong, China; [3]ucla, Los Angeles, CA, [4]Monash University, Caulfield East, Australia. Contact: kwan.yu.lo@polyu.edu.hk

As the U.S. faces changing demographics, Diversity, Equity, and Inclusion (DEI) becomes crucial for firms to meet regulations, attract talent, and enhance performance. However, limited research exists on DEI's implications, especially for manufacturing. We studied the effects of DEI commitment on 233 publicly traded manufacturing companies using Signaling Theory and event study methodology. Our analysis covered 311 DEI announcements from 2014-2022, revealing positive abnormal stock returns during the announcement period, particularly for strong DEI announcements or those through domestic media. We also compare U.S. and China results for a global DEI management perspective.

Emergency Department Operations

Community Committee Choice Session

Session Chair: Lesley Meng, Yale School of Management, Yale University, New Haven, CT

1 Emergency Department Boarding: Quantifying the Impact of Inpatient Admission Delays on Patient Outcomes and Downstream Hospital Operations

Huifeng Su[1], Lesley Meng[1], Rohit Sangal[2], Edieal J. Pinker[1], [1]Yale School of Management, Yale University, New Haven, CT, [2]Yale School of Medicine, Yale University, New Haven, CT, Contact: huifeng.su@yale.edu

Emergency Department (ED) boarding refers to the delay in transfer experienced by admitted patients from ED to inpatient units. Using an instrumental variable design, we find that on average, longer boarding times lead to longer hospital stays and a higher chance of escalation in care. Our findings also reveal that the impact of boarding differs across patients, suggesting that considering such heterogeneity when assigning inpatient beds could improve the patient flow

2 Improving Emergency Department Flow: A Predictive Model for Ambulance Diversion

Chenhao Zhou[1], Temidayo Adepoju[2], David Dreyfus[3], Christine Ramdin[4], Erin Muckey[4], Anthony Rosania[4], Lewis Nelson[4], Akiva Dym[4], [1]Rutgers Business School, Newark, NJ, [2]Rutgers Business School, Newark, NJ, [3]Rutgers University, Newark, NJ, [4]Rutgers New Jersey Medical School, Newark, NJ, Contact: chenhao.zhou@rutgers.edu

This study delves into internal and external factors prompting ambulance diversion in Emergency Departments (EDs), an issue exacerbated by the rise in ED visits and uninsured patients. We extend the scope beyond prior research that largely focused on internal factors, utilizing patient-level longitudinal data for a holistic understanding. Leveraging artificial intelligence and machine learning, we analyze a wide spectrum of variables from our institution's health records while respecting privacy. Our objective is to establish a measurable pre-diversion threshold for proactive management of ambulance diversions, with implications for improving patient flow and overall healthcare efficiency.

3 Does Machine Learning Improve Operational Efficiency? Evidence from the Design of an Emergency Department Vertical Processing Unit

Agni Orfanoudaki, Oxford University, Oxford, United Kingdom

Many hospitals have been experimenting with innovative patient flow designs to address the emergency department (ED) overcrowding challenge. A promising approach is to separate patients who can be served vertically and route them to a different area, termed the Vertical Processing unit, also known as the Rapid Medical Assessment (RMA) unit. However, successful implementation of this design significantly depends on understanding which patients should be routed to the RMA unit. We develop and validate a machine learning model that accurately predicts when an arriving patient can be served in the RMA unit. Subsequently, we propose an analytical model to minimize the average patient length of stay in an RMA-based ED. Our results suggest that the proposed RMA design outperforms traditional patient flow approaches due to the dynamic and efficient use of ED resources.

4 The Cost of Task Switching: Evidence from Emergency Departments

Yiwen Jin[1], Yige Duan[2], Yichuan Ding[3], Mahesh Nagarajan[4], Garth Hunte[5], [1]University of British Columbia, Sauder School of Business, Vancouver, BC, Canada; [2]Vancouver School of Economics, UBC, Vancouver, BC, Canada; [3]McGill University, Montreal, QC, Canada; [4]University of British Columbia, Vancouver, BC, Canada; [5]University of British Columbia, Vancouver, BC, Canada. Contact: yiwen.jin@sauder.ubc.ca

Emergency department (ED) physicians treat patients of different symptoms and constantly switch between tasks. Using comprehensive data sets on patient visits and lab tests in two collaborating EDs, we examine the impact of task switching on physician productivity, quality of care, and patient routing. To address endogenous patient selection, we construct an instrumental variable using the exogenous composition of waiting patients. We find a 10% increase in physicians' switching frequency reduces the number of patients treated per hour by 8.65% -11.53%, with no significant influence on quality. By exploring the heterogeneous switch costs among different patient pairs, we propose a data-driven queue management method to best partition patients into two queues. In the simulation, we find implementing the proposed two-queue system reduces average waiting time by 38%.

5 Predicting Short-Stay Patients in the Emergency Department

A. Cecilia Zenteno, Massachusetts General Hospital, Boston, MA, Contact: azentenolangle@mgh.harvard.edu

Emergency Department overcrowding is a widespread concern amongst hospital leaders. A significant contributor to this congestion is created by patients who have been admitted, but who are waiting for an inpatient bed to become available. In this work, we propose to establish a different pathway for ED patients who are predicted to have a short length of stay upon admission (2 days maximum). Our goals are i) to minimize disruptions in care of this patient population, and ii) opening scarce ED and inpatient beds for more complex patients. Our predictive model, which uses patients' clinical, administrative, and demographic data, has been validated by a group of hospital physicians. It has a sensitivity of 65%, a positive predictive value of 62%, and is 79% accurate. This proposal is in the process of being implemented at Mass General Hospital.

Community Committee Choice Session

Session Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

Session Chair: Youngsoo Kim, University of Alabama, Tuscaloosa, AL

1 Influence of Customer Financing Choices on Retail Demand and Pricing Decisions

Panos Kouvelis[1], Wenhui Zhao[2], [1]Washington University in St. Louis, St. Louis, MO, [2]Shanghai Jiao Tong University, Shanghai, China. Contact: zhaowenhui@sjtu.edu.cn

We study the pricing decision of a retailer selling a product to her customers, who can make the purchase with a credit card at a prespecified interest rate, or through a "buy now pay latter" (BNPL) service offered by a third-party provider at a zero interest rate but with a fixed amount of payment within a prespecified number of installments. If a customer cannot meet an installment requirement, the service provider has to stop his service till the time the customer can clear the outstanding balance. To offset such risks, the service provider will ask for a price discount from the retailer. We build demand models of the two customer financing modes, and analyze the optimal pricing decisions of the retailer. Interestingly, we show that the BNPL service may not necessarily attract more demands and generate more profits than the credit card financing mode.

2 Fintech Lending, Open Banking, And Consumer Manipulation

Yangguang Wang[1], Zhengping Wu[2], Fasheng Xu[3], [1]Syracuse University, Syracuse, NY, [2]Syracuse University, Syracuse, NY, [3]Syracuse University, Long Island City, NY, Contact: ywang784@syr.edu

Credit invisibles, consumers with limited (blank) credit histories and low credit scores, make up nearly 20 percent of the U.S. adult population. Long marginalized from mainstream credit services, they are more vulnerable to withstand financial shocks and face inconveniences in fundamental life aspects such as renting an apartment, not to mention encountering barriers to accessing to equitable financial opportunities. Open banking seems to provide a way to improve financial inclusion, especially for these credit invisibles. We study the impact of open banking on consumer behaviors regarding the manipulation of alternative data, and the consequential effects on lending decisions within the fintech sector. Additionally, we analyze its influence on the welfare of borrowers and lenders, as well as its role in reshaping competition within the lending market segment.

3 Towards Moderate Representation Balancing for Credit Policy Evaluation

Qi Wu, Yiyan Huang, City University of Hong Kong, Kowloon Tong, Hong Kong. Contact: qiwu55@cityu.edu.hk

Credit policy evaluation presents profitable opportunities for E-commerce platforms through improved decision-making. The core of policy evaluation is estimating the causal effects of the policy on the target outcome. However, selection bias presents a key challenge in estimating causal effects from real-world data. Some recent causal inference methods attempt to mitigate selection bias by leveraging covariate balancing in the representation space to obtain the domain-invariant features. However, over-balancing representations may result in the loss of domain-related information. This paper introduces a novel model to achieve moderate representation balancing to do policy evaluation. The extensive experimental results on benchmark datasets and a newly introduced credit dataset show a general outperformance of our method compared with existing methods.

4 Securing Payment from a Financially Distressed Buyer

Philipp J. Schneider[1], Isik Bicer[2], Thomas A. Weber[1], [1]EPFL, Lausanne, Switzerland; [2]York University Schulich School of Business, Toronto, ON, Canada. Contact: philipp.schneider@epfl.ch

When contracting with buyers that may become financially distressed, suppliers are exposed to an invoice-default risk. Based on Compustat data we identify a reduced-form model that relates salient operational and financial parameters to the default-risk premium. We derive the buyer's optimal ordering policy, as well as the effective risk premium paid by the otherwise risk-neutral supplier. Furthermore, we investigate the effects of the product's profit margin and of agency conflicts related to other debtors on the supplier's default-risk premium and the buyer's financial leverage.

Recent Advancement of Stochastic Modeling for Service Systems

Community Committee Choice Session

Session Chair: Yue Hu, University of Chicago, Chicago, IL
Session Chair: Antonio Castellanos, Technion – Israel Institute of Technology, Nesher, Israel

1 Optimal Allocation of Resources to Reduce Risk of Fall in Hospital

Jared Chiu, Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

Falls among inpatients are one of the most frequently reported safety incidents at hospitals. In this work, we investigate the optimal allocation of interventions (e.g., equipments or human resources) to reduce the risk of falls. We first use observational data from a large hospital to estimate the impact of various interventions on risk of falls. We then leverage these results to determine the optimal allocation of interventions under resource constraints.

2 Proactive Patient Treatment in Sepsis

Chia-Hao Chang[1], Vineet Goyal[1], Carri Chan[2], [1]Columbia University, New York, NY, [2]Columbia Business School, New York, NY, Contact: cc4626@columbia.edu

Sepsis is an emergent medical condition where body's immunological responses cause end-stage organ dysfunction and death. In a typical year, around three hundred and fifty thousand people died of sepsis in the United States. Its high mortality renders the timeliness of detection and treatment crucial. Some recent evidence has shown that providing early treatment to patients before they develop sepsis may lower their mortality. Due to the scarcity of the medical resources, such early treatment may cause congestion and block the urgent need from the patients developing sepsis. In this work, we consider a discrete-time Markov model where a policy maker decides the number of patients to treat proactively. Motivated by the structural insights from fluid approximation, we propose a state-dependent threshold policy. We justify our policy by showing its asymptotic optimality.

3 Analysis and Improvement for Eviction Enforcement

Baris Ata, Yuwei Zhou, University of Chicago, Chicago, IL, Contact: Yuwei.Zhou@chicagobooth.edu

Eviction proceedings are a critical component of the housing sector, and it is the legal responsibility of the Cook County Sheriff's Office (CCSO) to enforce them. The CCSO receives an average of 13,000 eviction requests annually. Besides the high volumes of requests, efficiently allocating resources such as labor and vehicles to fulfill these requests is an immense challenge. We model the eviction process using a Brownian Control Problem with dynamic control capability. However, solving the problem numerically to identify the optimal policy is still challenging, because the problem is high-dimensional due to its spatial nature. To overcome this challenge, we propose an approach that solves HJB equations using deep neural networks. Using this solution, we propose a policy for the queueing system and illustrate its effectiveness in a simulation study.

Sunday, October 15, 4:00 PM - 5:15 PM

Waste Reduction in Food Supply Chains

Community Committee Choice Session

Session Chair: Nicholas C. Petruzzi, University of Wisconsin-Madison, Madison, WI
Session Chair: Karthik Murali, Oregon State University, Corvallis, OR

1 The Impact of Online Sales on Perishable Product Waste in Grocery Retail

Parisa Shahsavand, Dorothee Honhon, The University of Texas at Dallas, Richardson, TX, Contact: parisa.shahsavand@utdallas.edu

We consider an omnichannel retailer satisfying demand from in-store and online consumers from the same in-store inventory. The retailer has to decide between FIFO and LIFO fulfilment methods for online orders up to an age-threshold. We study the impact on waste of an increase in the proportion of online consumers.

2 Strategic Sell-By Dates: Implications for Retail Food Waste

Karthik Murali[1], Aditya Vedantam[2], Nicholas C. Petruzzi[3], [1]Oregon State University, Corvallis, OR, [2]State University of New York at Buffalo, Williamsville, NY, [3]University of Wisconsin-Madison, Madison, WI, Contact: karthik.murali@oregonstate.edu

Grocery stores in the U.S. throw away 16 billion tons of food each year due to expiration. In this study, we develop a game-theoretic model to examine the strategic motivations behind a manufacturer's choice of sell-by dates and the corresponding implications for food waste at the retail level. We examine the role of supply chain structure as well as

inventory issuing policies on the sell-by date decision. Finally, we identify mechanisms that policy makers can implement to reduce food waste in the supply chain.

3 Multiplicity in Product Expiration Dates and Food Waste in Retail Stores

Nitish Jain[1], Ashish Kabra[2], Varun Karamshetty[3], [1]London Business School, London, United Kingdom; [2]University of Maryland-College Park, College Park, MD, [3]National University of Singapore, Singapore, Singapore. Contact: akabra@umd.edu

Perishable products with multiple expiration dates contribute to expiration waste (EW) in food retailers. Consumers tend to choose units with later expiration dates, resulting in waste of units with sooner expiration dates. Retailers use strategies like price markdowns and inventory rotation to reduce this waste, but lack awareness of its extent. This study presents the first large-scale evidence of the contribution of multiple-dates-led expiration waste (MDEW) to overall waste. The study introduces a novel methodology that calculates its lower and upper bounds. For a large dataset from a European retailer, the study finds that MDEW contributes 21-52% of the EW. This research provides a basis for academic investigation and offers a practical method for measuring MDEW in store operations.

4 Improving Smallholder Welfare And Productivity While Preserving Natural Capital

Dan Andrei Iancu, Erica Plambeck, Xavier Warnes, Stanford University, Stanford, CA, Contact: daniancu@stanford.edu

Smallholder farmers in developing economies produce more than 50% of the world's food calories and often live on the fringe of poverty. With agricultural supply chains acting as a prominent driver of tropical deforestation, increasing the welfare and productivity of smallholders can be a crucial driver for reducing worldwide poverty and hunger and preserving the natural environment. We study the optimal design of incentive schemes in agricultural supply chains to best balance these goals. We propose a detailed operational model of household decision-making that includes land clearing, production, and consumption decisions, as well as uncertainty and liquidity constraints. We characterize the optimal policies and analyze different incentive schemes that allow us to derive practical implications for public and private stakeholders.

New Technologies in Operations Management

Community Committee Choice Session

Session Chair: Yao Cui, Cornell University, Ithaca, NY
Session Chair: Jingchen Liu, Nanjing University, Nanjing, China

1 Blockchain Adoption And Greenwashing

Yuze Li[1], Pnina Feldman[2], Gerry Tsoukalas[2], [1]Questrom School of Business, Boston University, Boston, MA, [2]Boston University, Boston, MA, Contact: yuzeli@bu.edu

Recently, some brands have started to adopt blockchain technology to certify the sustainability claims of their products. While blockchain technology has advantages such as tamper-resistance and transparency, it also suffers from weaknesses such as data input integrity issues. Given the advantages and weaknesses of blockchain, we examine the strategic aspects of blockchain adoption for certifying green products and examine its impact on greenwashing in practice. Using a stylized model, we demonstrate that, although blockchain certification can increase the environmental quality of products, it may also induce incentives for firms to engage in greenwashing. In addition, blockchain certification may lead to reduced profitability for the firm, reducing the incentives to adopt blockchain technology.

2 Invoice Tokenization for Deep-Tier Payables Finance

Jing Hou[1], Burak Kazaz[2], Fasheng Xu[2], [1]Nanjing University, Nanjing, China; [2]Syracuse University, Syracuse, NY

Invoices from tier-1 suppliers to the downstream anchor manufacturer can be tokenized onto a blockchain. The tier-1 suppliers are then able to split and transfer the tokens to their own (tier-2) suppliers, enabling deep-tier suppliers to sell tokens and access financing at more affordable rates based on the anchor manufacturer's credit rating. This paper investigates how invoice tokenization impacts the multitier supply chain's decisions and profits under different supply network configurations and contractual forms.

3 Predictive 3D Printing with IoT

Yue Zhang, Pennsylvania State University, University Park, PA

We consider a scenario where a 3D printer supplies a critical part to multiple machines that are embedded with sensors and connected through IoT. Our framework can help inform investment decisions regarding IoT/embedded sensors and support the development of scheduling tools for predictive 3D printing.

4 Resale with Non-Fungible Tokens
Yao Cui[1], Jingchen Liu[2], [1]Cornell University, Ithaca, NY, [2]Nanjing University, Nanjing, China
In this paper, we study NFTs as a novel means to facilitate resale. We characterize market conditions for NFTs to create value over traditional resale markets and prescribe how to design NFT features (such as the royalty fee) to maximize its value.

OR/MS Applications in Practice - I
Community Committee Choice Session
Session Chair: Mustafa Can Camur, General Electric Research, New York, NY

1 Integrated Production and Buffer Planning Under Demand and Supply Uncertainty in the High-Tech Manufacturing Industry: A Case Study at ASML
Tijn Fleuren, Yasemin Merzifonluoglu, Maarten Hendriks, Renata Sotirov, Tilburg University, Tilburg, Netherlands
This paper proposes an integrated methodology to optimize tactical production planning and strategic buffer placement in high-tech manufacturing supply chains. Long production lead times, component commonality in the network, non-stationary and volatile demand, and supply uncertainty all complicate the decision-making. We introduce a framework that combines a mathematical programming-based rolling horizon procedure to optimize the production planning under uncertainty, and a heuristic approach to search for efficient buffer policies. In this way, we explicitly consider the interplay between optimal production planning and buffer allocation in capacitated systems. In a large-scale case study at our industry partner ASML, we overview current buffer planning practices and provide a comparison study to demonstrate the real-world benefit of our approach.

2 An Optimization Framework for Efficient and Sustainable Logistics Operations via Transportation Mode Optimization and Shipment Consolidation: A Case Study for GE Gas Power
Mustafa Can Camur, General Electric Research, New York, NY, Contact: can.camur@ge.com
GE Gas Power sources parts for its gas & steam turbines from multiple suppliers in Asia. These parts are transported to the USA using multiple modes of transportation including Full Container Load (FCL), Less than Container Load (LCL), and air-transport with varying lead times and costs. We present an optimization model backed by predictive modeling and a novel heuristic approach to develop a parts transportation plan to minimize cost while ensuring that the parts arrive at the destination within their respective deadlines.

3 An Empirical Investigation into the Prevalence and Impacts of Complicating Environmental Factors in Applied Analytical Modeling
Michael Gorman, University of Dayton, Dayton, OH

Previous research (Gorman, 2021) describes ten contextual complications that exist in the application of applying analytical models and how they impact the models and modeling approaches themselves. These complications are pervasive, and because the affect the constructs of the modeler, must be better understood by researchers in order to increase the robustness, appropriateness and usefulness of the models themselves. This research surveys the extent of the presence of these factors and the extent to which they affected modeling efforts in 70 different published applications via an author survey. It finds that the factors are pervasive and their importance to the appropriateness and success of the modeling efforts are high. Further, it finds a strong interaction factor between them. As a result, it would seem that a line of research geared towards identifying and overcoming these factors would aid in the application of analytical models.

4 An Overview of Research Programs to Drive Sustainability, Resiliency and Efficiency in GE Aerospace Enterprise Operations

Banu Gemici-Ozkan, Ph.D., General Electric, Niskayuna, NY

Our team of dedicated researchers brings together diverse expertise that combine physics-based first principals with domain specific business constraints and provide prescriptive decision support for enterprise challenges faced in design, manufacturing and service operations. Common to all these problems is digital twinning approach where structured and unstructured sensor data is fused to extract state information which in turn then integrated with model-based system representations to provide realistic representation of complex systems. Examples of data science, ORMS applications will be shared within three research pillars: 1) multi-tier sourcing for aircraft engine production, 2) engine maintenance and service operations and 3) minimizing climate impact of airline operations.

Quadratic, Polynomial, and Semidefinite Optimization

Community Committee Choice Session

Session Chair: Boshi Yang, Clemson University, SC
Session Chair: Hao Hu, Clemson University, Clemson, SC

1 Facial Reduction for Semidefinite Relaxations of Combinatorial Optimization Problems

Hao Hu, Boshi Yang, Clemson University, Clemson, SC, Contact: hhu2@clemson.edu

We propose an efficient implementation of FR algorithms for SDP relaxations of combinatorial optimization problems. Our innovative approach is to leverage the combinatorial and the polyhedral structures behind its SDP relaxations. The key idea is that the feasible set of the semidefinite program is a relaxation for the lifted feasible set of the associated problem. Thus, it is possible to connect certain geometric properties between these feasible sets. Our strategy is to derive these relevant properties from the underlying CO problem directly. As a result, this allows us to facially reduce its semidefinite relaxation more efficiently and effectively.

2 Dual Nonnegativity Certificates in Polynomial Optimization

Dávid Papp, Maria M. Davis, North Carolina State University, Raleigh, NC, Contact: dpapp@ncsu.edu

We study the problem of computing optimal sum-of-squares (SOS) lower bounds for positive polynomials over a compact semialgebraic set, circumventing the conventional semidefinite programming reformulation. In the first part of the talk, we introduce the concept of *dual certificates*, which allows us to interpret vectors from the dual of the SOS cone as rigorous nonnegativity certificates. The second part of the talk will feature some algorithmic and theoretical applications, including a simple iterative method for computing the optimal SOS lower bound with a polynomial-time computational cost per iteration and linear rate of convergence, and which can also be turned into an efficient method in exact (rational) arithmetic.

3 Semidefinite Representable Reformulations for Two Variants of the Trust-Region Subproblem

Sarah Kelly, Clemson University, Central, SC

We consider two specific variants of the trust-region subproblem and provide exact semidefinite representable reformulations. The first is over the intersection of two balls; the second is over the intersection of a ball and a special second-order conic representable set. The reformulations obtained are based on partitions of the feasible regions into sub-regions with known lifted convex hulls.

Advances in Mixed Integer Linear and Nonlinear Programming

Community Committee Choice Session

Session Chair: Jean-Philippe P. Richard, University of Minnesota, Minneapolis, MN

1 Robust Modeling Approach for Effective Multi-Period Fuel Treatment in South-East Australia

Tomas Lagos[1], Nam Ho-Nguyen[2], Dmytro Matsypura[2], Oleg A. Prokopyev[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]The University of Sydney, Sydney, Australia

Wildfires pose grave risks to human life, health, and infrastructure. To address these challenges, proactive fuel treatment strategies are crucial before each fire season. However, managing fuel treatment resources in south-east Australia becomes problematic due to species protection and forest maturity considerations. We extend our previous work and introduce a robust modeling approach for devising multi-year treatment strategies. Our robust mixed-integer optimization model incorporates worst-case scenarios of fuel growth and treatment effects, offering adjustable uncertainty levels.

2 The Terminator: An Integration of Inner and Outer Approximations for Solving Regular and Ambiguous Chance Constrained Programs via Variable Fixing

Nan Jiang, Weijun Xie, Georgia Institute of Technology, Atlanta, GA, Contact: nanjiang@gatech.edu

We present a novel approach to enhance the effectiveness of solving regular and ambiguous chance constrained programs with empirical reference distributions. These programs can be, in general, reformulated as mixed-integer programs (MIPs) by introducing binary variables for each scenario, indicating whether a scenario should be satisfied. While existing methods have focused on either inner or outer approximations, this paper fills this gap by proposing a scheme that effectively combines these approximations via variable fixing. By probing the restricted outer approximations and comparing them with the inner approximations, we derive optimality cuts that significantly reduce the number of binary variables, fixing them to either one or zero. Our numerical results demonstrate the clear advantages of our approach in terms of computational time and solution quality.

3 Matrix Completion over Gf(2)

Akhilesh Soni, Jeffrey T. Linderoth, Jim R. Luedtke, Daniel Pimentel-Alarcon, University of Wisconsin-Madison, Madison, WI, Contact: linderoth@wisc.edu

We discuss integer-programming-based approaches to doing low-rank matrix completion over the finite field of two elements. We are able to derive an explicit description for the convex hull of an individual matrix element in the decomposition, using this as the basis of a new formulation. We also derive valid inequalities involving multiple matrix elements. Computational results showing the superiority of the new formulation over a natural formulation based on McCormick inequalities with integer-valued variables, and an extended disjunctive formulation arising from the parity polytope are given.

4 Variable Selection for Kernel Two-Sample Tests

Jie Wang[1], Santanu Dey[2], Yao Xie[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA

We consider the variable selection problem for two-sample tests, aiming to select the most informative variables to distinguish samples from two groups. To solve this problem, we propose a framework based on the kernel maximum mean discrepancy (MMD). Our approach seeks a group of variables with a pre-specified size that maximizes the variance-regularized MMD statistics. This formulation also corresponds to the minimization of asymptotic type-II error while controlling type-I error, as studied in the literature. We present mixed-integer programming formulations and offer exact and approximation algorithms with performance guarantees for linear and quadratic types of kernel functions. Experimental results demonstrate the superior performance of our framework.

5 Convexification Techniques For Logical Implication Constraints Involving Cardinality Requirements

Jean-Philippe P. Richard[1], Mohit Tawarmalani[2], Jinhak Kim[3], [1]University of Minnesota, Minneapolis, MN, [2]Purdue University, West Lafayette, IN, [3]Northern Illinois University, Dekalb, IL

Cardinality requirements and implications between groups of distinct variables are pervasive in applications and are often modeled through the use of integer programming techniques. We describe a general constructive scheme that allows for the convex hull of sets involving logical implication constraints relating the cardinality of groups of variables to be derived in a higher dimensional space. We also discuss aspects of projecting the formulations. We provide simple illustrative applications of the scheme, which subsume existing results in the literature.

Optimization of Networks' Design, Expansion, and Investment

Community Committee Choice Session

Session Chair: Zhaomiao Guo, University of Central Florida, Orlando, FL

1 Scheduling In Project Networks With Various Resource Types

Nicklas Klein, Mario Gnaegi, Norbert Trautmann, University of Bern, Bern, Switzerland. Contact: norbert.trautmann@unibe.ch

We consider scheduling in a project network, whose nodes correspond to activities which require two types of resources for execution: renewable resources representing, e.g., staff members or equipment; and production and consumption resources representing, e.g., the project budget. We present a mixed-integer linear programming formulation which significantly outperforms state-of-the-art models from the literature.

2 Correspondent Banking Network Optimization

NIMA Safaei, Scotiabank, Toronto, ON, Canada

Correspondent Banking (CB) Network refers to a network of financial institutions providing cross-border payment services for customers through different channels such as SWIFT, Fedwire, etc. We employ the mathematical programming approach in conjunction with the graph theory to optimize a CB network. Optimizing the network requires decisions to be made to onboard, terminate or restrict the bank relationships to optimize the size and overall risk of the network. This study provides theoretical foundation to detect the components, the removal of which does not affect some key properties of the network such as connectivity and diameter. We find that the correspondent banking networks have a feature we call k-accessibility, which helps to drastically reduce the computational burden required for finding the above mentioned components.

3 A Generalized Disjunctive Programming Formulation for Generation and Transmission Expansion Planning

Kyle Skolfield, John Siirola, Sandia National Laboratories, Albuquerque, NM, Contact: kyle.skolfield@asu.edu

Joint generation and transmission expansion planning (GTEP) is a challenging problem to solve, especially at the necessary scales, given its large number of discrete decision variables. The ongoing shift of the national energy system to inverter-based resources (IBRs) including renewables and storage amplifies the difficulty and necessity of solving this difficult problem. Furthermore, these resources are not properly valued in current GTEP formulations. This talk proposes a novel generalized disjunctive programming formulation using the unique capabilities of the Pyomo Python package to solve GTEP while appropriately valuing IBRs. SNL is managed and operated by NTESS under DOE NNSA contract DE-NA0003525.

4 Information System Design in Transportation Network

Zhaomiao Guo[1], Weijun Xie[2], [1]University of Central Florida, Orlando, FL, [2]Georgia Institute of Technology, Atlanta, GA

Effective information sharing through vehicle-to-infrastructure technologies is a promising approach to improve traffic mobility. While studies have shown the benefits of information sharing, few have investigated the optimal design of information sharing locations over transportation network. To address this issue, we propose a bilevel mathematical model to optimally determine the information sharing locations in the upper level considering the drivers' decentralized routing behavior in response to the information received in the lower level. To solve this bilevel problem, we present a novel value-decomposition algorithm based on cutting plane methods. The proposed model can provide insights for transportation planners to strategically design information sharing locations to minimize network congestion and information infrastructure costs.

5 Convex Hull Pricing in Electricity Markets: Evidence from a Large Us Iso

Panagiotis Andrianesis[1], Dimitris Bertsimas[2], Michael C. Caramanis[1], William W. Hogan[3], [1]Boston University, Boston, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Harvard University, Belmont, MA, Contact: panosa@bu.edu

We discuss the theory and application of convex hull pricing in non-convex electricity markets. In a recent work, we validated the proof-of-concept of a tractable, highly parallelizable, and exact method for convex hull price computation with guaranteed finite convergence, relying on Dantzig-Wolfe decomposition and Column Generation, and we illustrated how this approach provides intuition on the underlying price formation rationale. In this work, we provide evidence from the application of our method to a large US ISO, accounting for all applicable characteristics of the market participants and a fully granular network model, and we further elaborate on "cheap" performance-boosting techniques.

Sunday, October 15, 4:00 PM - 5:15 PM

First-order Methods for Stochastic Programming

Community Committee Choice Session

Session Chair: Jiaming Liang, Yale University, NEW HAVEN, CT

1 Inexact Bundle Method for Two-Stage Stochastic Programming

Baoyu Zhou[1], Haihao Lu[2], John R. Birge[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Chicago Booth School of Business, Chicago, IL, [3]University of Chicago, Chicago, IL, Contact: zbaoyu@umich.edu

We propose an inexact bundle method for solving two-stage stochastic programming problems that arise from important application areas including revenue management and power system. We consider the setting that it is intractable to compute true objective function and gradient information, and instead only estimates of objective function and gradient values are available. Under common assumptions, the algorithm generates a sequence of iterates converging to a neighborhood of optimality, where the radius of neighborhood depends on the level of inexactness from stochastic objective function estimates. The numerical results demonstrate empirical performance of our proposed algorithm.

2 Asymptotic Normality and Optimality in Nonsmooth Stochastic Approximation

Liwei Jiang[1], Damek Davis[2], Dmitriy Drusvyatskiy[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, ITHACA, NY, [3]University of Washington, Seattle, WA, Contact: lj282@cornell.edu

In their seminal work, Polyak and Juditsky showed that stochastic approximation algorithms enjoy a central limit theorem for solving smooth equations. Moreover, it has since been argued that the asymptotic covariance of the method is best possible among any estimation procedure in a local minimax sense of Hajek and Le Cam. A long-standing open question in this line of work is whether similar guarantees hold for important non-smooth problems, such as stochastic nonlinear programming or stochastic variational inequalities. In this talk, we show that this is indeed the case.

3 Variance Reduction and Low Sample Complexity in Stochastic Optimization via Proximal Point Methods

Jiaming Liang, Yale University, NEW HAVEN, CT

This paper studies novel variance reduction techniques in stochastic convex composite optimization via proximal point methods. It applies those techniques to obtain improved sample complexity in high probability results without assuming the standard light-tail conditions such as sub-Gaussian noise distributions. The paper develops both accelerated and unaccelerated proximal point methods based on the understanding that Nesterov's acceleration method can be regarded as an accelerated version of the proximal bundle method. Another interesting result of the paper is that it establishes the iteration complexity of Nesterov's acceleration method with the restart technique in the deterministic setting.

4 Optimal And Parameter Methods For Gradient Minimization In Convex Optimization

Jimmy Zhang[1,2], Yuyuan Ouyang[3], Guanghui Lan[4], [1]MIT, Boston, MA, [2]Northeastern University, Cambridge, MA, [3]Clemson University, Clemson, SC, [4]Georgia Institute of Technology, Atlanta, GA, Contact: jimmy_zhang@gatech.edu

We introduce novel algorithms for finding solutions with small gradient norms in convex smooth optimization. Our approach guarantees a solution with a small (projected) gradient norm using only $O(1)\sqrt{L/\epsilon}$ gradient evaluations. Our results match the state-of-the-art for unconstrained problems and are new for problems with simple feasible sets, composite functions, or nested functions. Notably, we resolve the open question of optimally solving smooth strongly convex problems in a parameter fashion, without knowing the strong convexity modulus.

Optimization and Learning Models for Design and Operation of Microgrids

Community Committee Choice Session

Session Chair: Alexander Zolan, National Renewable Energy Laboratory, Austin, TX

1 Nash Bargaining Game for Cooperative and Operational Decisions for Microgrids with Hydrogen Integration Flexibility Options

Yolanda Matamala[1], Kevin Melendez[2], Hadi Charkhgard[3], Felipe A. Feijoo[4], [1]Pontifica Universidad Católica de Valparaíso, Valparaíso, Chile; [2]UNIVERSITY OF SOUTH

FLORIDA, TAMPA, FL, [3]University of South Florida, Tampa, FL, [4]Pontificia Universidad Católica de Valparaíso, Valparaiso, Chile. Contact: yolanda.matamala.a@mail.pucv.cl

Trading of electricity among connected microgrids has the potential to reduce the dependency on the independent system operator, which in turn reduces the use of fossil fuels. In this paper, we study the bargaining among microgrids solution for reducing the dependency on fossil fuels in periods with peak electricity demand. The bargaining game is modeled at the upper level of a Stackelberg model. We modeled an optimal power flow with endogenous prices in the lower level. The computational study on a 14-bus network shows that electricity trading between microgrids increases operational stability while minimizing operational costs. Finally, we showed that this kind of market achieves a fair distribution of the generated profit for all participating microgrids while reducing the network prices.

2 Assessing Fast Charging Station Requirements Under Varying EV Travel Demand and Weather Conditions with Integration of Distributed Energy Resources

Hamid Mozafari[1], Kunle Adeyemo[1], Mehrnaz Ghamami[2], Annick Anctil[1], Ali Zockaie[1], Jessica Crawford[3], [1]Michigan State University, East Lansing, MI, [2]Michigan State University, Okemos, MI, [3]Michigan Department of Environment, Great Lakes, and Energy, Lansing, MI, Contact: mozafar1@msu.edu

The rapid growth of the electric vehicle (EV) market share requires an extensive network of EV direct current fast charging (DCFC) stations and a responsive power distribution system. After simulating the future EV travel and energy demand of Michigan's intercity network, this study developed an optimization approach to find the optimum number and location of required DCFC stations throughout Michigan. Due to the varying travel demand and weather conditions over the seasons, the power demand of each charging station may unpredictably change, which causes problems for both the stations and utility providers. Applying the proposed optimization model, this study finds the optimum capacity of DERs, such as SLBs, in each charging station by integrating EV second-life batteries (SLBs) and other distributed energy resources (DERs) to respond to the uncertain energy demand.

3 Design and Dispatch of a Microgrid with Heterogeneous Heating Loads

Alexander Zolan, National Renewable Energy Laboratory, Austin, TX, Contact: alexander.zolan@nrel.gov

We introduce REOpt, an open-source web tool that obtains cost-minimizing distributed energy resource designs subject to meeting electrical, heating, and cooling loads with or without a utility connection for residential and commercial customers. We present an extension to include multiple heating loads of different quality and demonstrate the impact of this extension on design selection.

Recent Theory and Applications in DRO 1

Community Committee Choice Session

Session Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN

Session Chair: Eojin Han, Southern Methodist University, Dallas, TX

1 Robust Contextual Portfolio Optimization with Gaussian Mixture Models

Yijie Wang[1], Grani Adiwena Hanasusanto[2], Chin Pang Ho[3], [1]The University of Texas at Austin, Austin, TX, [2]University of Illinois Urbana-Champaign, Urbana, IL, [3]City University of Hong Kong, London, United Kingdom

We consider the portfolio optimization problem with contextual information that is available to better quantify and predict the uncertain returns of assets. Motivated by the regime modeling techniques for the finance market, we consider the setting where both the uncertain returns and the contextual information follow a Gaussian mixture distribution. This problem is shown to be equivalent to a nominal portfolio optimization problem where the means and the covariance matrix are adjusted by the contextual information. We further propose the robust contextual portfolio optimization problem to alleviate the sensitivity of model parameters to the given data. Finally, we conduct a numerical experiment in the US equity markets to demonstrate the advantage of our proposed model against other benchmark methods.

2 Distributionally Ambiguous Multistage Stochastic Integer and Disjunctive Programs: Applications to Sequential Two-player Interdiction Games

Sumin Kang[1], Manish Bansal[2], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech., Blacksburg, VA, Contact: suminkang@vt.edu

We study the generalizations of multistage stochastic mixed-integer programs (MSIPs) with distributional ambiguity, namely distributionally risk-receptive and risk-averse multistage stochastic mixed-integer programs (denoted by DRR- and DRA-MSIPs). These frameworks have applications in non-cooperative Stackelberg games involving two players, namely a leader and a follower, with uncertainty in the impact of the decisions made by the leader. We present cutting plane-based and reformulation-based approaches for solving DRR- and DRA-MSIPs to optimality. In addition, we introduce multistage stochastic disjunctive programs with(out) distributional ambiguity and present algorithms for solving them. To assess the performance of the algorithms for MSIPs, we consider instances of multistage maximum flow and facility location interdiction problems.

3 A Finitely Convergent Decomposition Algorithm for Distributionally Robust Two-Stage Convex Programming Problem

Fengqiao Luo[1], Shibshankar Dey[1], Sanjay Mehrotra[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: shibshankardey2025@u.northwestern.edu

We develop a finitely convergent decomposition algorithm for general mixed-integer convex problem applicable to distributionally robust two-stage convex program. This decomposition algorithm separates binary variables from integer and continuous variables, respectively acting as first and second stage variables. A finitely convergent branch-cut-union algorithm is first proposed for the second stage problem leveraging a parametric cut generation oracle. We then generate valid optimality cut using cut-generating-linear-program and show decomposition algorithm's finite convergence. Computational results with Wasserstein ambiguity set shows the superiority of branch-cut-union based decomposition approach compared to its no-cut counterpart, an extension to Luo and Mehrotra [Mathematical Programming 196:673-717, 2022] for convex program setting.

4 K-adaptability In Two-stage Distributionally Robust Optimization: A Primal Perspective For Explainability

Yiling Zhang[1], Eojin Han[2], [1]University of Minnesota, Minneapolis, MN, [2]Southern Methodist University, Dallas, TX, Contact: yiling@umn.edu

In this talk, we investigate the K-adaptability problem for two-stage distributionally robust optimization, which pre-selects K candidate second-stage decisions and then implements the best of them when the uncertainty is revealed. With given candidate policies, we provide an exact conic reformulation from a primal perspective building on characterizing conditional moments of second-order conic representable ambiguity sets. This conic reformulation enables to obtain K-adaptable policies with improved explainability in persistency and objective contribution of each candidate solution. Based on the conic reformulation, we derive an exact mixed-integer bilinear program for K-adaptability problems and a mixed-integer linear program when uncertainties are binary.

CC-North 224A

Fair Learning and Optimization

Community Committee Choice Session

Session Chair: Qing Ye, Georgia Tech, Atlanta, GA

1 Multistage Fair Classification from Observational Data

Zhuangzhuang Jia[1], Grani Adiwena Hanasusanto[2], Phebe Vayanos[3], Weijun Xie[4], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]University of Illinois Urbana-Champaign, Urbana, IL, [3]University of Southern California, Los Angeles, CA, [4]Georgia Institute of Technology, Atlanta, GA

We focus on the multistage fair classification problem, which is a common scenario in many relevant applications where there is a predetermined limit or budget on the number of candidates that can be selected at each stage. We propose several optimization models with a fairness constraint that encourages the classifier to be fair in view of the equality of opportunity criterion. To remove the selection bias at each stage, we use the Inverse Probability Weighting method from causal inference. Finally, we provide numerical evidence demonstrating the effectiveness of our proposed approaches in mitigating unfairness on both synthetic and real datasets.

2 Fair Machine Learning in Healthcare

Na Zou, Qizhang Feng, Texas A&M University, College Station, TX

Due to the digitization of healthcare data and advancements in computing power, machine learning methods are increasingly being used in the healthcare domain. However, machine learning methods inherit and even amplify existing health disparity issues, leading to fairness issues such as unequal distribution of healthcare resources or disparity in diagnostic accuracy across demographic groups. In this talk, we bridge the gap between fair machine learning and healthcare disparities by defining the problem of fairness in healthcare, identifying its sources, and categorizing fair machine learning algorithms. Specifically, we provide a comprehensive classification of the fairness measures, introduce the various biases and algorithms. It is concluded by identifying additional challenges and outlining a number of promising new directions.

3 Dr-Fermi: A Stochastic Optimization Framework for Distributionally Robust Fair Empirical Risk Minimization

Sina Baharlouei, Meisam Razaviyayn, University of Southern California, Los Angeles, CA, Contact: baharlou@usc.edu

The majority of the developed fair machine learning algorithms rely on the assumption that the training and test data have similar distributions. In the presence of distribution shifts, fair models may behave unfairly on test data. Further, the proposed mitigation solutions are either designed based on the assumption of having access to the causal graph describing the interaction of different features or knowing the exact type of the distribution shift apriori. This work proposes the first distribution-shift-agnostic fairness framework with convergence guarantees for both full-batch and stochastic first-order optimization methods. The framework is based on a distributionally robust optimization problem under L_p norm uncertainty sets with respect to the Exponential Renyi Mutual Information (ERMI) as the measure of fairness violation.

4 Distributionally Fair Stochastic Optimization Using Wasserstein Distance

Qing Ye[1], Grani Adiwena Hanasusanto[2], Weijun Xie[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Illinois Urbana-Champaign, Urbana, IL

The conventional stochastic program under an empirical population treats each individual equally and optimizes an aggregated objective, which, unfortunately, can be rather unfair when the entire population consists of multiple groups. This paper generalizes the demographic parity fairness notion using Wasserstein distance and proposes a framework that searches for the fairest near-optimal decision. The proposed formulation is proven to be NP-hard in general and shown to be nonconvex. Fortunately, by exploring the properties of Wasserstein distance, we formulate the problem as a mixed-integer program and develop asymptotic optimal lower and upper bounds to generate fair and efficient decisions. The framework can be applied to a range of fair decision-making problems.

Drone Delivery Operations

Community Committee Choice Session

Session Chair: James Campbell, University of Missouri - St. Louis, Saint Louis, MO

1 Facility Location Decisions for Drone Delivery: A Literature Review

Okan Dukkanci[1], James Campbell[2], Bahar Kara[3], [1]European University Viadrina, Frankfurt (Oder), Germany; [2]University of Missouri - St. Louis, Saint Louis, MO, [3]Ihsan Dogramaci Bilkent University, Ankara, Turkey

This study presents a comprehensive literature survey on facility location problems for drone delivery. The main goals of this review are to identify and categorize fundamental facility location problems associated with drone delivery and to provide a connection between the studies from different research fields that consider similar problems. We first discuss and classify the various types of facilities used for drone and hybrid vehicle-drone delivery systems, including drone bases, charging stations, rendezvous points, and riding points. The literature is then reviewed and categorized based on the types of facilities modeled, the drone operations and the location space. Each category is analyzed in terms of the modeling approach, decisions, objective functions, constraints and additional features. The talk will also present some future research directions.

2 National-Level Vaccine Distribution with Drones: Strategic Locations and Multi-Modal Network Design

Shakiba Enayati, James Campbell, Haitao Li, University of Missouri - Saint Louis, St Louis, MO, Contact: senayati@umsl.edu

This presentation addresses the use of drones to deliver vaccines to hard-to-reach populations using a novel optimization model to strategically design a multimodal vaccine distribution network. Our research incorporates multiple drone types, recharging of drones, a cold chain travel time limit, transshipment delays for switching transport modes, and practical limits on the vaccine paths and drone trips. The goal is to locate facilities (distribution centers, drone bases, and relay stations) and design vaccine paths to minimize transportation costs, including the fixed costs for facilities and transportation links and variable costs for transportation through the network. Results are shown for a case study of childhood vaccine delivery in Vanuatu, a South Pacific Island nation.

3 Local Vaccine Delivery with Drones: Multi-Modal and Hierarchical Network Design and Routing

Bahar Kara[1], Meltem Peker[2], Shakiba Enayati[3], James Campbell[4], Haitao Li[4], [1]Ihsan Dogramaci Bilkent University, Ankara, Turkey; [2]Bilkent University, Ankara, Turkey; [3]University of Missouri - Saint Louis, St Louis, MO, [4]University of Missouri - St. Louis, Saint Louis, MO, Contact: bkara@bilkent.edu.tr

This study addresses vaccine delivery within one health zone for hard-to-reach regions. This requires simultaneously determining the location of facilities (distribution centers, permanent clinics and drone bases) and hierarchical vaccine delivery routes from distribution centers to remote clinics. We consider drones as part of a multimodal transport system that must coordinate with the outreach trips of healthcare workers. The goal is to minimize the total transportation costs including the fixed costs and variable costs for transportation through the network. The model incorporates limits for the cold chain and drone ranges. We show results for a case study of distributing childhood vaccines in Vanuatu, a South Pacific Island nation.

4 Applications and Research Avenues for Drone-Based Models in Post-Disaster Response Logistics

Trilce Encarnacion[1], Diana Gineth Ramirez-Rios[2], [1]University of Missouri- St. Louis, Saint Louis, MO, [2]University at Buffalo, Buffalo, NY, Contact: tencarnacion@umsl.edu

Disaster response efforts operate under conditions characterized by significant disruptions to transportation infrastructure. The lack of ground transportation access to impacted areas presents a challenge that drones could address. In this research, we survey the literature to identify potential research directions of drone-based logistics that can address the challenges brought on by disasters, focusing on the critical emergency support functions that can benefit from these new technologies. This presentation provides a starting point for researchers interested in developing OR/MS models to address these challenges.

CC-North 225A

Large-scale Data Analytics for Transportation Systems - Session I

Community Committee Choice Session

Session Chair: Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA

1 On Drivers' Routing Behavior Under Incidents: Fusing System-Level and Individual-Level Data in Networks

Haocheng Duan, Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA, Contact: haocheng@andrew.cmu.edu

Understanding drivers' re-routing behavior under incidents is crucial when predicting incident impacts on the large-scale network. This research proposes a data-driven approach leveraging data from roads, incidents, and GPS traces of probe vehicles. The route choice model under incidents is first validated and tested in a small synthesized network. It is then applied to learn drivers' re-routing choices in the real-world using data collected in the Washington DC region in 2020.

2 A Physics-regularized, Multi-task Gaussian Process With Multiple Kernel Learning To Uncover Mobile Data Generation Processes

Ekin Ugurel, Shuai Huang, Cynthia Chen, University of Washington, Seattle, WA, Contact: ugurel@uw.edu

Passively-generated mobile data has grown increasingly popular in the travel behavior (or human mobility) literature. We propose a novel generative machine learning framework to model individual mobile data using multi-task Gaussian processes (GP). Since data generation processes of such datasets are highly heterogeneous, we further propose a data-driven multiple kernel learning approach to determine the optimal composite kernel for each individual. Finally, we augment our approach using physics-based information such as average segment speeds and directions to reduce variance and bias in model estimation. Our numerical results demonstrate the potential of the proposed framework to uncover individual mobile data generation patterns.

3 Tfs-Dgan: Multi-View Temporal Factorizations-Based Dynamic Adaptive Generative Adversarial Networks for Hybrid Recovery of Missing Traffic Data

Zilin Huang[1], Jinlong Li[2], Lunhui Xu[2], Sikai Chen[1], [1]University of Wisconsin-Madison, Madison, WI, [2]South China University of Technology, Guangzhou, China. Contact: zilin.huang@wisc.edu

Recovering missing traffic data is crucial for intelligent transportation systems. However, current methods often fail to fully capture complex spatio-temporal correlations, which leads to suboptimal results. In this research, we introduce a novel hybrid framework, TFs-DGAN, that combines dynamic adaptive generative adversarial networks (DA-GAN) with multi-view temporal factorizations (TFs) to effectively impute missing data by modeling these correlations. The proposed

TFs-DGAN integrates all stage-optimized residuals through local feedback, ultimately yielding the best data repair results. By utilizing DA-GAN for data generation and TFs to refine temporal properties, our method significantly outperforms state-of-the-art baseline models in terms of accuracy, stability, and efficiency, based on tests with two publicly available traffic datasets.

4 Data-driven Quantification Of The Resilience Of Enforcement Policies On Transportation Systems: A Comparative Study Of Two Major Winter Storms In Buffalo, New York

Eren Kaval[1], Zilin Bian[2], Kaan Ozbay[2], [1]New York University, Brooklyn, NY, [2]New York University, Brooklyn, NY, Contact: ek3433@nyu.edu

Understanding traveler policy compliance is significant, especially in emergency disaster instances, where enforcement policies can impact the safety of the public. This study aims to investigate the regulation power policies retain during disruptive and deadly winter storms. A comparative study using the disruptive events of November and December 2022 blizzards in Buffalo is conducted. A novel concept in the field of policy research, LoR_p (Loss of Resilience of Policy) inspired by evacuation studies, is introduced to describe how the power of an enforcement policy evolves between the time it is issued and lifted. Results are analyzed using a change detection and spatial modeling framework on a neighborhood level to associate LoR_p with spatial and socioeconomic variables, understand their effects on LoR_p and study the factors affecting resilience of various policies.

5 Dynamic Routing Games for Connected and Autonomous Vehicles with Traffic Congestion: A Mean Field Game Approach

Eunhan Ka, Satish V. Ukkusuri, Purdue University, West Lafayette, IN, Contact: kae@purdue.edu

Large urban areas struggle with severe traffic congestion. Connected and Autonomous Vehicles (CAVs) can alleviate traffic congestion via road efficiency improvements. However, simulating traffic dynamics through dynamic routing games encounters scalability hurdles, warranting a Mean Field Game (MFG) approach. This study presents an MFG method for multi-player dynamic routing involving CAVs, addressing scalability issues and integrating game theory. We evaluate the proposed method on the Sioux Falls network and perform a sensitivity analysis for CAV penetration rates. The results show that CAVs effectively reduce network travel costs and impact routing decisions, resulting in alleviated congestion. Furthermore, as CAV penetration rates rise, the mean-field equilibrium policy converges toward the Nash equilibrium policy of the MFG.

On-Demand Urban Logistics

Community Committee Choice Session

Session Chair: Zhengtian Xu, The George Washington University, Washington

Session Chair: Kenan Zhang, ETH Zurich, Zurich, Switzerland

1 Modeling and Managing an On-Demand Meal Delivery System

Anke Ye[1], Kenan Zhang[2], Xiqun Chen[1], Michael G.H. Bell[3], Simon Hu[1], [1]Zhejiang University, Hangzhou, China; [2]ETH Zurich, Zurich, Switzerland; [3]the University of Sydney, Sydney, Australia. Contact: ankeye@intl.zju.edu.cn

This paper proposes a theoretical framework to characterize an on-demand meal delivery (ODMD) system featured by bundling delivery and sharing couriers among restaurants. This framework makes the first attempt to allow bundling delivery for more than two orders among multiple restaurants in market analysis. It provides managerial insights for the stakeholders in the system. The developed model consists of a physical model describing the delivery process for bundled orders and an aggregated market model characterizing the demand and supply equilibrium. Analysis and numerical experiments are conducted to examine the market equilibrium characteristics and evaluate the performance of the ODMD system under the platform's maximum profit policy.

2 Exploiting Modularity in Co-Modal Passenger-Freight Transportation: A Market-Driven Approach

Hongyu Zheng[1], Jiayang Li[1], Jane Lin[2], Marco Nie[1], [1]Northwestern University, Evanston, IL, [2]University of Illinois-Chicago, Chicago, IL, Contact: hongyuzheng2024@u.northwestern.edu

Co-modal passenger-freight transportation refers to sharing infrastructure/capacity between passenger and freight transportation systems that may be independently owned and operated. This paper proposes a market-driven approach to co-modality that takes advantage of the autonomous modular vehicle (AMV) technology. As AMVs can easily join to form a train, transit operators can utilize them as buses with dynamically adjustable capacity. This flexibility allows the operator to efficiently address temporal demand variations using heterogeneous fleets. Meanwhile, the operator can gain revenue by renting spare AMVs to a freight carrier to supplement last-mile delivery operations during the off-peak period. Our goal is to understand the various trade-offs in such a system and analyze the optimal strategies for all participants under different market mechanisms.

3 Dynamic Order Fulfillment in Autonomous Last-Mile Delivery with Demand Uncertainty

Linxuan Shi, Zhengtian Xu, Miguel Lejeune, The George Washington University, Washington, DC, Contact: shilx@gwu.edu

The logistics industry has eyed on autonomous solutions, such as delivery robots and drones, as a promising future for last-mile delivery. For the problem we picture, a fleet of automated delivery vehicles is deployed for fulfilling the delivery requests that arrive with stochastic time, location, and urgency. Given an operational context with discrete delivery waves, we adopt a Model Predictive Control (MPC) framework to address the dynamic order fulfillment in a rolling horizon. A two-stage stochastic program is formulated to minimize the total expected delays and energy consumption, and an integer L-shaped method is adapted for efficient solutions.

4 Deep Reinforcement Learning to Assess the Potential Gains of Cooperating with Competitors in Meal Delivery Markets

Azadeh Gharibreza Yazdi, Vadim Sokolov, Elise Miller-Hooks, George Mason University, Fairfax, VA

This talk presents a job assignment algorithm using multi-agent deep reinforcement learning (MDRL) concepts for assessing the possible gains that can be obtained from a meal delivery company (MDC) from cooperating with competitors. The potential gains are assessed on numerical examples in a simulated environment built on data from real-world operations.

Data Science and Machine Learning Applications

Community Committee Choice Session

Session Chair: Maryam Jafaripakzad, 1</sup

1 Enhancing Open-World Recognition: An Innovative Framework for Robust Detection of Unknown Instances

Mohammad Noroozi, Ankit Shah, University of South Florida, Tampa, FL, Contact: mnoroozi@usf.edu

Our talk focuses on open-world object recognition, examining in and out-of-distribution instances. We propose an innovative framework integrating image processing, generative adversarial network-based data augmentation techniques, and object detection models. Facilitating automated annotation and enhancing dataset diversity, our approach ensures reliable object detection performance. Rigorous experiments validate accurate detection, advancing the field and providing insights for diverse domains.

2 A Multi-Agent Reinforcement Learning Approach to Identify Optimal Intervention Options for 'Ending the HIV Epidemic'

Dinesh Sharma[1], Ankit Shah[1], Chaitra Gopalappa[2], [1]University of South Florida, Tampa, FL, [2]University of Massachusetts, Amherst, Amherst, MA

The U.S. government's 'Ending the HIV Epidemic' initiative aims to reduce HIV incidence by 90% by 2030. A significant challenge in identifying an optimal intervention policy to achieve this goal is that, because of disparities in infections across geography, one policy is not suitable for all, but because of geographical dynamics of infection spread, analyses to identify optimal policies cannot be conducted independent to each jurisdiction. To address this, we propose a multi-agent reinforcement learning framework that identifies jurisdiction-specific optimal policies, using an environment that simulates a national population as a composition of 96 interacting sub-jurisdictions. We evaluate alternative objective functions, minimizing costs and disease burden, and minimizing disease burden.

3 Predictive Models for ICU Admission Classification and Length of Stay Forecasting: Methodological Exploration and Feature Engineering in Healthcare Analytics

Maryam Jafaripakzad[1], Jorge Andrés Acuna[2], Jose L. Zayas-Castro[2], [1]University of South Florida, Tampa, FL, [2]University of South Florida, Tampa, FL, Contact: maryamjafaripakzad@usf.edu

This study follows a sequential prognostic approach to classify patients' hospital length of stay. For this purpose, we examine the impact of incorporating new features from two classifiers in two steps. We conducted a sensitivity analysis to determine the appropriate specifications for incorporating new features into each sequence classifier training, enhancing accuracy at each step. Moreover, we assessed the impact of diverse feature engineering and model training techniques to optimize our approach. These findings hold promising implications for refining patient management strategies and optimizing resource allocation in healthcare.

4 The Skill-Fit Model: Utilizing Skills to Advance Machine Learning Based Job Recommendation Systems

Alon Atzil[1], Hila Chalutz-Ben Gal[2], [1]Tel Aviv University, Tel Aviv, Israel; [2]Tel Aviv University, Tel Aviv, Israel

The growing practice of utilizing Machine Learning based Job recommendation systems (JRS) has become a major component in talent management. However, recent disruptions in the labor force (e.g. flexible work, freelancing, gig work) result in the need to adopt a Skill-Fit Model. For this purpose, we present an analysis of the ML based JRS literature and propose a synthesized approach to analyze and model skills. Our results indicate that some JRS features may benefit from the Skill-Fit Model thus may be adopted by ML-enabled JRS in order to achieve improved performance. This study contributes to the understanding and systematically developing skills - based JRS to support the new world of work.

5 Comparison Of Object Detection Methods Under Different Weather Conditions Using Multimodal Data

Mehrsa Mashhadi[1], Nicolas Bustos[2], Susana Lai-Yuen[1], Sudeep Sarkar[1], Tapas K. Das[1], [1]University of South Florida, Tampa, FL, [2]University of South Florida, TAMPA, FL, Contact: mehrsamashhadi@usf.edu

Thermal images are increasingly being used to complement visible images and to improve the performance of object detection models. While visible images provide detailed scene information, thermal images capture temperature information and are less affected by lighting conditions. However, adverse weather can affect object detection and current approaches lack uniform evaluation due to the use of different private datasets. In this work, we evaluate two object detection methods, YOLOv7 and Vision Transformers, on a publicly available multimodal dataset and under different weather conditions. The aim is to provide insights to assist in the design of more robust object detection methods under adverse weather conditions.

6 Wireless Signal Prediction Using Deep Learning Models

Abdullah Konak[1], Michael Bartolacci[2], Simon Delattre[3], [1]Penn State Berks, Reading, PA, [2]Penn State Berks, Bethlehem, PA, [3]Penn State, State College, PA, Contact: konak@psu.edu

Modeling wireless signal coverage in areas where measurements are difficult to record can be daunting. We utilized a deep autoregressive model and a convolutional neural network model trained on a synthetic floor plan dataset to accurately extrapolate signal coverage across such spaces without using specific information about antennae placements or floor plan designs.

Data-driven Methods for Analyzing the Terminal Airspace

Community Committee Choice Session

Session Chair: Go Nam Lui, 1</sup

1 Vision-Based Decision Support for Improved Situational Awareness in General Aviation

Rahul Rathnakumar, Yongming Liu, Arizona State University, Tempe, AZ, Contact: rrathnak@asu.edu

Commercial aviation safety has seen remarkable progress thanks to improvements in Air Traffic Management technology and stringent regulations. These developments have resulted in safety standards that surpass those in General Aviation (GA) operations. In this work, we propose a novel data-driven decision support system to improve GA pilot situational awareness. Specifically, we leverage image data along with weather decriptors to build an uncertainty-aware neural network model to detect potential weather threats that can lead to a loss of situational awareness. The proposed model is compared against multiple baselines, showing some interesting benefits that adding additional contextual data brings to predictive performance. Finally, this work highlights some key challenges that models need to address to provide reliable decision support for GA pilots.

2 Data-Driven Environmental Assessment for Airport Operation Inside Terminal Airspace

Go Nam Lui[1], Dajung Kim[1], Kai Kwong Hon[2], Rhea Patricia Liem[1], [1]The Hong Kong University of Science and Technology, Sai Kung, Hong Kong; [2]Hong Kong Observatory, Tsim Sha Tsui, Hong Kong. Contact: gnlui@connect.ust.hk

This work proposes a data-driven approach to derive environmental assessment metrics for airport operations within terminal airspace. We incorporate flight information, flight trajectory, and weather data to quantify the fuel consumption status, noise pollution status, and adverse weather resilience for an individual airport. With the application of data-driven methodologies including Bayesian hierarchical model, we develop interpretable metrics to evaluate airport operations and identify opportunities for sustainable improvements. The proposed metrics can inform decision-making and promote a more advanced sustainable assessment of airport operations within terminal airspace.

AI in Supply Chain Management

Community Committee Choice Session

Session Chair: Huihui Chi, EM Lyon, Écully, France
Session Chair: Haipeng Chen, William & Mary, Williamsburg, VA

1 Collective Learning: Resolving AI Explainability and Supply-Side Asymmetries in Airbnb Hosting

Rodreck David[1], Fatemeh Saadatmand[2], Shiyuan Liu[3], [1]EMLYON Business School, Lyon, France; [2]IT University of Copenhagen, Copenhagen, Denmark; [3]Stockholm School of Economics, Stockholm, Sweden. Contact: rdavid@em-lyon.com

As a digital platform that connects hosts and guests for short-term rental housing, Airbnb relies on AI algorithms to match various supply and demand parameters. This ‘matching’ process is highly driven by algorithms that are often opaque, making it challenging for hosts to navigate the asymmetries created by them. Using advanced text analyses, this study examined over 6 years of Airbnb hosts’ forum activity data with a temporal bracketing of key events. The analysis reveals that, through collective learning, hosts gain insights into the intricate mechanisms of Airbnb’s algorithms and fine-tune their listings to enhance their visibility, pricing, guest preferences, etc. The findings underscore the significance of collective learning in enhancing AI explainability and mitigating supply-side asymmetries associated with “black box” algorithms.

2 Models and Algorithms for a Dynamic Multi-Trip Vehicle Routing Problem with Time Windows

Xukun Qin[1], Hui Li[1], Zhiya Zuo[2], Xi Wang[1], [1]Central University of Finance and Economics, Beijing, China; [2]City University of Hong Kong, Kowloon Tong, China. Contact: 2022212400@email.cufe.edu.cn

Reinforcement learning (RL) has been studied in the field of information systems and proposed in public administration related to pandemic control. However, policymakers have been hesitant due to concerns such as reliability and ethical implications. Drawing on the AI trust theory, this study aims to address this dilemma by proposing a framework for designing a trustworthy RL-based policy support system. Through a design science approach, specific components, such as multi and guided rewards are introduced to enhance people’s trust in building the IT artifact. The findings will shed light on the complex interrelationships between public internal change, pandemic status, and government protest policy in the context of a public health crisis, which will contribute to greater transparency and accountability in the design of RL-based AI systems.

3 Recommendation System with Delay Option: Should Retailerrecommend Out-Of-Stock Products?

Huihui Chi[1], Wei Zhou[2], Howard Zhong[2], [1]EM Lyon, Écully, France; [2]ESCP Business School, Paris, France

When shortage happens, recommending out of stock products to consumers seems inappropriate and meaningless intuitively. However, the stockout message also reveals the products’ popularity and the customers’ strong desire in placing orders. Therefore, in this paper, we develop a newsvendor model for multi-products with different replenishment periods. A recommendation algorithm is embedded to adjust the demand in the model. First, we consider the option of substitution for out-of-stock products. Alternatively, as a second option, we add the substitution option as well as the waiting option for out-of-stock products. For evaluation, we test our model with by combining simulation and a dataset collected from a British store. Our preliminary results demonstrate that the addition of waiting option in recommendation strategy yields higher profits and is favored.

4 Dynamic Feature-Based Newsvendor

Zexing Xu[1], Ziyi Chen[2], Xin Chen[3], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]University of Utah, Salt Lake City, UT, [3]Georgia Institute of Technology, Atlanta, GA, Contact: zexingx2@illinois.edu

In this paper, we investigate the dynamic feature-based newsvendor problem within a multi-period inventory control setting featuring backlogged demands. Highlighting the significance of feature information and a multi-stage decision-making framework, we introduce novel algorithms and techniques to tackle the problem’s challenges. The proposed Contextual Value Iteration (CVI) algorithm exhibits efficacy across diverse scenarios, supported by performance analysis, including generalization bounds and sample complexity, as well as numerical experiments.

5 Complex Contagion Influence Maximization: A Reinforcement Learning Approach

Haipeng Chen[1], Bryan Wilder[2], Wei Qiu[3], Bo An[3], Eric Rice[4], Milind Tambe[5], [1]William & Mary, Williamsburg, VA, [2]Harvard University, Los Angeles, CA, [3]Nanyang Technological University, Singapore, Singapore; [4]University of Southern California, Los Angeles, CA, [5]Harvard University, Cambridge, MA, Contact: hchen23@wm.edu

Influence maximization (IM) aims to find a set of seed nodes in a social network that maximizes the influence spread. While most IM problems focus on classical influence cascades which assume that individual influence cascade probability is independent of the number of neighbors, recent studies show that many influence cascades follow a pattern called complex contagion (CC), where cascade probability is much higher when more neighbors are influenced. Nonetheless, there are very limited studies on complex contagion influence maximization (CCIM). This is partly because CC is non-submodular, the solution of which has been an open challenge. We propose the first reinforcement learning (RL) approach to CCIM that uses the CCIM problem structure. Empirical results show that our approach achieves state-of-the-art performance on 9 real-world networks.

Machine Learning and Optimization in Power Systems

Community Committee Choice Session

Session Chair: Tanneau Mathieu, Georgia Tech

Session Chair: Pascal Van Hentenryck, ISyE Georgia Tech, Atlanta, GA

1 End-To-End Feasible Optimization Proxies for Large-Scale Economic Dispatch

Wenbo Chen[1], Mathieu Tanneau[1], Pascal Van Hentenryck[2], [1]Georgia Tech, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: wchen616@gatech.edu

The paper proposes a novel End-to-End Learning and Repair (E2ELR) architecture for training optimization proxies for economic dispatch problems. E2ELR combines deep neural networks with closed-form, differentiable repair layers, thereby integrating learning and feasibility in an end-to-end fashion. E2ELR is also trained with self-supervised learning, removing the need for labeled data and the solving of numerous optimization problems offline. E2ELR is evaluated on industry-size power grids with tens of thousands of buses using an economic dispatch that co-optimizes energy and reserves. The results demonstrate that the self-supervised E2ELR achieves state-of-the-art performance, with optimality gaps that outperform other baselines by at least an order of magnitude.

2 Multiperiod Stochastic Security-Constrained Economic Dispatch: A Systematic Study

Haoruo Zhao, Mathieu Tanneau, Pascal Van Hentenryck, Georgia Institute of Technology, Atlanta, GA, Contact: hzhao306@gatech.edu

US Independent System Operators co-optimize energy and reserve dispatches every five minutes to minimize operating costs while meeting physical and regulatory constraints. However, due to the growing penetration of renewable energy generation, the current single-period, deterministic, security-constrained economic dispatch (SCED) formulations struggle to manage operational uncertainty effectively. This project proposes a multi-period stochastic look-ahead (SLAD) formulation to explicitly consider uncertainty in real-time markets. An accelerated Benders' decomposition is utilized to solve the formulation efficiently. The approach is evaluated on an industry-size transmission grid, and the numerical results demonstrate that SLAD significantly improves reliability and reduces costs, saving approximately 2% on high net load days compared to SCED.

3 Bucketized Active Sampling for Acopf Optimization Proxies

Michael Klamkin, Georgia Tech, Atlanta, GA, Contact: klam@isye.gatech.edu

This paper considers optimization proxies for Optimal Power Flow (OPF), i.e., machine-learning models that approximate the input/output relationship of OPF. Their training requires significant data, each instance necessitating the (offline) solving of an OPF. To meet market-clearing requirements, this paper proposes Bucketized Active Sampling (BAS), a novel active learning framework that aims at training the best OPF proxy within a time limit. BAS partitions the input distribution and uses an acquisition function to determine where to sample. Numerical experiments are conducted on large power grids, benchmarking different BAS strategies against classical approaches wherein training data is generated offline. Overall, BAS achieves the same or better accuracy but does so in half the compute time.

4 Online Risk Assessment with Optimization Proxies

Mathieu Tanneau[1], Pascal Van Hentenryck[2], [1]Georgia Tech, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA

The increased penetration of renewable energy and distributed energy resources is fueling an increase in operational uncertainty in modern power grids.To manage this uncertainty, grid operators must continuously monitor and manage risk. This, in turn, requires tools that can quantify risk in a real-time fashion.

This talk presents how optimization proxies, i.e., machine learning models that approximate the input-output mapping of an optimization problem, offer a scalable tool for real-time risk assessment. Numerical results on an industry-size system will be presented.

Data-Driven Innovations in OR Education

Community Committee Choice Session

Session Chair: Jeroen Belien, KU Leuven, Brussel, Belgium

Session Chair: Thomas A. Grossman, University of San Francisco, San Francisco, CA

1 Prescriptive Analytics in the Data Analysis Pipeline

Alice Paul, Brown University, Providence, RI

Practical Data Analysis is a required course for Biostatistics Masters and PhD students. Last year, the course focused around a semester-long project on foodborne illness in collaboration with a Co-Chair of the Healthy People 2030 Foodborne Illness Reduction Committee. The project goal was to use insights from a national foodborne pathogens database to help drive action on foodborne illness prevention. A key challenge of this project was shifting the student perspective to a prescriptive one: needing to frame their analyses to help make data-driven decisions. I'll talk about how using large, messy data helped to drive home the course concepts and give lessons learned in integrating project-based learning and prescriptive analytics into a data science course.

2 Using an Excel Error as a Teaching Tool

Eric Logan Huggins[1], Ivan G. Guardiola[2], [1]Fort Lewis College, Durango, CO, [2]Fort Lewis College, Durango, CO, Contact: huggins_e@fortlewis.edu

Performing linear regression in Microsoft Excel is relatively easy and fast. The software calculates the slope, y-intercept and coefficient of determination (r^2) and creates a graph of the data and best-fitting line automatically. An option exists to force the y-intercept to zero, which makes sense in some cases, but the resulting output is glaringly wrong - the r^2 value is incorrect, tending to increase even though the line is a worse fit! One of our students discovered this in class, boldly questioning the accuracy of MS Excel output. We discuss what the error is, how to fix it, and how to use this error as a teaching tool in two ways: first, that students should always double check results from any software and second, as a means to better explain what correlation is and how to calculate it.

3 Gilp: An Interactive Tool for Visualizing the Simplex Algorithm

Henry W. Robbins[1], David B. Shmoys[2], Samuel Gutekunst[3], David P. Williamson[2], [1]Uber, New York, NY, [2]Cornell University, Ithaca, NY, [3]Bucknell University, Weston, CT, Contact: hwr26@cornell.edu

The Simplex algorithm is a fundamental topic in many Operations Research courses. While it relies on intuitive geometric ideas, the computationally-involved mechanics of the algorithm can obfuscate a geometric understanding. Here, we present gilp, an easy-to-use Simplex algorithm visualization tool designed to explicitly connect the mechanical steps of the algorithm with their geometric interpretation. We provide an extensive library with example visualizations, and our tool allows an instructor to quickly produce custom interactive HTML files for students to experiment with the algorithm (without requiring students to install anything!). The tool can also be used for interactive assignments in Jupyter notebooks, and has been incorporated into a forthcoming Data Science and Decision Making interactive textbook.

4 The Flair Game: Teaching Newsvendor and Inventory Pooling in One Classroom Session

Jeroen Beliën[1], Stefan Creemers[2], [1]KU Leuven, Brussel, Belgium; [2]IESEG, Aarschot, Belgium. Contact: jeroen.belien@kuleuven.be

We present the Flair game: an Excel-driven classroom game for teaching the concepts of newsvendor and inventory pooling in one 2-hour class. The game stimulates active participation and peer learning through a competitive setting with a dynamic team size formation. Since 2016, the game has been used successfully for a wide range of education: from undergraduate to executive teaching.

5 Moneyball for Murderball: A Teaching Case on Using Analytics to Construct Lineups in Wheelchair Rugby

Timothy Chan[1], Craig Fernandes[1], Albert Loa[1], Nate Sandholtz[2], [1]University of Toronto, Toronto, ON, Canada; [2]Brigham Young University, Provo, UT, Contact: nsandholtz@stat.byu.edu

Motivated by the problem of lineup optimization in wheelchair rugby (WCR), this case covers descriptive, predictive and prescriptive analytics. The case is presented from the perspective of a new assistant coach of Canada's national WCR team, who has been tasked by the head coach to use analytics to improve their lineups. While the data and actors are fictitious, they are based on real data and discussions with the national team coach and sport scientists. To solve the case, students must conduct data wrangling, regression modeling, and optimization modeling. These three steps are tightly linked, as the data wrangling is needed to prepare the data for regression, and the regression outputs are used as parameters in the optimization. As such, students build proficiency in developing an end-to-end solution approach for a complex real-world problem.

Computational Methods for Uncertainty Quantification I/II

Community Committee Choice Session

Session Chair: Moses Chan, Northwestern University, Evanston, IL

1 Bayesian Model Mixing Of Computer Simulators

John Yannotty[1], Thomas Santner[2], Richard Furnstahl[1], Matthew Pratola[3], [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH, [3]The Ohio State University, New Albany, OH, Contact: yannotty.1@buckeyemail.osu.edu

Multiple computer simulators are often used to study complex physical systems. Each simulator may have varying accuracy across the input domain. One strategy is to mix the predictions from the simulators using a linear combination with input-dependent weights. Recent work focused on mixing EFT Nuclear Physics models using weight functions modeled by Bayesian Additive Regression Trees (BART). In this work, we propose a tree-based model for mixing arbitrary simulators. One limitation of the BART-based weight functions was their piecewise constant form. We incorporate probabilistic path assignments which leads to smooth predictions of the weight functions and physical system, while also achieving more appropriate uncertainty quantification, all in a matrix-free formulation. The methodology is demonstrated on motivating Nuclear Physics and Climate problems.

2 Online Nonparametric Surrogate Models for Scientific Computation

Hengrui Luo, Lawrence Berkeley National Laboratory, Berkeley, CA

Online surrogate modeling, where the observed dataset keeps accumulating, is becoming an increasingly important topic in statistics, mathematics, and data science research. In this seminar talk, we will introduce the Gaussian process (GP) regression, and how we can use it as a Bayes online nonparametric surrogate to approximate the "black-box performance function" arising in scientific computation. Using the Gaussian process model, we will illustrate several novel research projects inspired by related scientific computation applications. In particular, we will discuss extensions of surrogate models when there exists discontinuous responses (motivated by exascale computing) and structured variables (motivated by functional data simulation). We will also point out several ongoing theoretical and applied challenges when working with online surrogates.

3 Uncertainty Quantification for Bayesian Optimization

Rui Tuo[1], Wenjia Wang[2], [1]Texas A & M University, College Station, TX, [2]Hong Kong University of Science and Technology (Guangzhou), GuangZhou, China

Bayesian optimization is a class of global optimization techniques. It regards the underlying objective function as a realization of a Gaussian process. Although the outputs of Bayesian optimization are random according to the Gaussian process assumption, quantification of this uncertainty is rarely studied in the literature. In this work, we propose a novel approach to assess the output uncertainty of Bayesian optimization algorithms, in terms of constructing confidence regions of the maximum point or value of the objective function. These regions can be computed efficiently, and their confidence levels are guaranteed by newly developed uniform error bounds for sequential Gaussian process regression. Our theory provides a unified uncertainty quantification framework for all existing sequential sampling policies and stopping criteria.

4 Simulation Surrogate for Stochastic High-Dimensional Outputs with Heterogeneous Error

Moses Chan, Matthew Plumlee, Northwestern University,

Evanston, IL, Contact: mosesyhc@u.northwestern.edu
Gaussian processes are a popular surrogate choice in place of an expensive simulation model. Many modern simulation models are stochastic, for example agent-based models, meaning that a different output is returned each time (even) at the same input. In the case of a simulation output that is high-dimensional with potentially heterogeneous error structure, approximations are often the method researchers resort to, due to the exploding computational cost associated with the large covariance matrix. We propose a novel Gaussian process model that allows a rich representation of the covariance matrix and offers exact while efficient inference.

Structured Data Analysis in Healthcare Applications

Community Committee Choice Session

Session Chair: Xin Zan, University of Florida, GAINESVILLE, FL
Session Chair: Xiaochen Xian, University of Florida, GAINESVILLE, FL

1 Scalable Dependent Dirichlet Process Mixture Model via Parallel Mcmc

Ning Dong, Dongping Du, Texas Tech University, Lubbock, TX, Contact: ndong@ttu.edu
Bayesian nonparametric methods such as the Dirichlet Process Mixture Model (DPMM) have been widely used in survival analysis. A compelling challenge for solving Bayesian nonparametric models is the high computational cost, especially when dealing with large datasets and high-dimensional parameter spaces. Parallel MCMC algorithms have been developed to speed up the computation. However, none of them applies to the posterior inference in DPMM. This study develops a scalable DPMM via parallel MCMC, which divides the massive data set into small subsets and aggregates the subsets' posteriors to approximate the true posterior. The DPMM generates discrete posteriors that allow aggregation without sampling to minimize information loss. The model is validated by simulation studies and a medical dataset, which shows good computational efficiency and accuracy.

2 Concurrent Data Assimilation for Model-Guided Learning of Cardiac Potassium Channel Activities

Haedong Kim, The Pennsylvania State University, University Park, PA, Contact: huk344@psu.edu
Potassium channels (K_v) play critical roles in the cardiac conduction system. Although there are various K_v isoforms, only the sum of their activities can be measured in the form of currents (I_{Ksum}). Most existing studies estimate K_v kinetics via curve-fitting procedures, but are limited because: 1) curve-fitting decomposition only relies on the shape of current traces, which does not discern the underlying kinetics and interactions of K_v isoforms; 2) I_{Ksum} traces only be fitted for one clamp voltage at each time. Here, we develop a novel concurrent data assimilation method that calibrates computer models to decompose and delineate kinetics of K_v isoforms with multiple voltage-clamp responses simultaneously. Experimental results show that the proposed method effectively handles cellular dynamics in multiple responses.

3 Weakly Supervised Deep Learning for Monitoring Sleep Apnea Severity Using Coarse-Grained Labels

Xin Zan[1], Di Wang[2], Changyue Song[3], Feng Liu[4], Xiaochen Xian[5], Richard Berry[5], [1]University of Florida, GAINESVILLE, FL, [2]Shanghai Jiaotong University, Shanghai, China; [3]Stevens Institute of Technology, Cedar Grove, NJ, [4]Stevens Institute of Technology, Hoboken, NJ, [5]University of Florida, Gainesville, FL, Contact: xxian@ufl.edu
Sleep apnea is a common sleep disorder suffered by a large population. Current automatic apnea detection methods relying on supervised learning require massive well-labeled training data, which is usually unavailable due to the high labeling cost. This work establishes a weakly supervised deep learning framework using only coarse-grained labels indicating apnea presence to automatically derive fine-grained labels representing the latent apnea severity. A novel knowledge-enhanced dual-granularity consistency loss, which simultaneously considers the consistency between coarse- and fine-granularity and the incorporation of clinical knowledge, is designed to allow the proposed method to accurately estimate fine-grained apnea severity in real time with significantly reduced labeling costs, extending the reach of sleep apnea monitoring to larger population.

4 Multi-Branching Temporal Convolutional Network with Tensor Data Completion for Diabetic Retinopathy Prediction

Zekai Wang[1], Suhao Chen[2], Tieming Liu[3], Bing Yao[4], [1]The University of Tennessee. Knoxville, Knoxville, TN, [2]South Dakota School of Mines and Technology, Rapid City, SD, [3]Oklahoma State University, Stillwater, OK, [4]The University of Tennessee Knoxville, Knoxville, TN, Contact: zwang142@vols.utk.edu

Diabetic retinopathy (DR) is a microvascular complication of diabetes, and it is the leading cause of vision loss among working-aged adults. Due to the low compliance rate of DR screening and expensive medical devices for ophthalmic exams, many DR patients fails to seek medical attention until DR develops to irreversible stages. The systematically collected electronic health record (EHR) data provide an great opportunity to develop inexpensive tools for DR detection. This paper proposes a Multi-branching Temporal Convolutional Network with Tensor Data Completion (MB-TCN-TC) to model the multivariate longitudinal EHRs for DR prediction. Experimental results show that MB-TCN-TC effectively captures complicated variable interactions in the longitudinal clinical data by accounting for missing value and imbalanced data issues and outperforms existing methods.

1 Explaining The Variability In The Profiles Of Ratings Of Perceived Exertion For A Dynamic Upper Extremity Task: A Functional Regression Approach

Setareh Kazemi Kheiri, State University of New York at Buffalo, Buffalo, NY

Musculoskeletal disorders (MSDs) are prevalent among warehouse order-pickers due to repetitive tasks impacting the upper extremities. Our study delves into fatigue dynamics of these extremities to aid intervention strategies. Using data from 14 participants, we created models based on varied tasks, and exertion levels reported via Borg's scale as the functional response variable. Muscular activity was tracked using wearable sensors. Through a functional regression approach, our analysis indicated that models integrating sensor data outperformed others. Additionally, extracting sensor data features using functional principal component analysis excelled in explaining the model variability compared to statistical features from signals.

2 Analytical Study On Direct Ink Writing Process

Wuyang Chen[1], Chenyu Xu[1], Chi Zhou[2], Hongyue Sun[1], [1]University of Georgia, Athens, GA, [2]University at Buffalo, Buffalo, NY, Contact: wuyang.chen@uga.edu

Direct Ink Writing (DIW) boasts numerous advantages over other additive manufacturing techniques, including porous structure, material versatility, and multi-material printing. Despite these benefits, the complexity of the process presents significant challenges and limitations. This study aims to systematically investigate the DIW process including setup building, experimental design, and data analysis, and to find the optimal system control solution for the process in the future.

3 Development of a Hybrid-Sampling Method for Wafer Test Data Considering Spatial Characteristics of Wafer: A Case Study on Latent Defect Detection Model Development

Young-Mok Bae, Kwang-Jae Kim, POSTECH, Pohang, Kyungbuk, Korea, Republic of. Contact: ymbae@postech.ac.kr

The complexity and diversity of defect mechanisms challenge latent defect detection after the wafer test. Recent studies have focused on machine learning models for latent defect classification using wafer test data, but the need for high-speed, accurate classification may limit their industrial application. This study proposes a hybrid sampling method considering spatial attributes on the wafer. Under-sampling employs a one-dimensional convolutional neural network autoencoder for spatial learning, while over-sampling uses the Synthetic Minority Over-sampling Technique on inadequately learned samples. Case studies show that this hybrid approach, paired with traditional machine learning, enhances latent defect detection and reduces training time, and thus potentially aiding in actual cost-effective wafer testing.

4 An Integrated Offline and Online Optimization Framework for Large Scale Additive Manufacturing

Lu Liu[1], Feng Ju[1], Seokpum Kim[2], [1]Arizona State University, Tempe, AZ, [2]Oak Ridge National Lab, Oak Ridge, TN

In the large-scale additive manufacturing process, applying an optimization model to ensure proper layer temperature plays an important role in producing high-quality products. Currently, there are two major studies available, but both have drawbacks when practiced solely. Therefore, an integrated approach by taking advantage of two methods is proposed. When printing based on the optimal layer time

suggested by an offline design, the real-time information captured by the IR camera is considered in the online control to make further adjustments to the layer time.

1 Risk-Informed Resilience Enhancement of Transmission Grids Against Ice Storms

Chenxi Hu, The University of Hong Kong, Hong Kong, China

This work proposes a resilient-oriented planning model for transmission systems against ice storms. The model integrates the predictive information to enhance system resilience through a more informed allocation of resources in anticipation of extreme events. Considering the operation strategies changes under normal and extreme conditions, the model adopts a dual-objective approach to achieve trade-offs during different stages. The model is formulated as a stochastic mixed-integer linear problem. The first stage makes line hardening decisions, as well as the optimal sitting and sizing of energy storage. The second stage evaluates the risk-informed operation costs by taking into account both the normal and the emergent operation stages, respectively. Case studies demonstrate the effectiveness of the proposed model.

2 The Impacts of Uncertainties from Renewables on Dyanmic Response of Power Systems

Chengxi Liu, China

This presentation proposes a novel method based on arbitrary Polynomial Chaos (aPC) to evaluate how parameter and variable uncertainties, like climate or weather, impact the dynamic response of power systems. The method defines a set of orthogonal polynomials that approximate the relationship between the sources of uncertainties, such as the power generation of renewable energy resources determined by climate or weather, and the system dynamic response. Measurement data can be directly utilized to construct the aPC model without any prior knowledge of the probability distribution of the uncertainty. A whitening transformation method is also integrated to decouple the correlated data sets and thus avoid errors caused by distribution fitting. Finally, to avoid numerical issues common to polynomial chaos methods, the k-means++ clustering is embedded in the aPC.

3 Multi-Stage Stochastic-Robust Power System Generation Expansion Planning Under Heterogeneous Uncertainties

Rongpeng Liu, McGill University, Montreal, QC, Canada. Contact: rpliu@eee.hku.hk

This work addresses wind power generation expansion planning (WPGEP) problems with heterogeneous uncertainties. First, we divide the heterogeneous uncertainties into long-term (climate change-induced) wind resource evolution uncertainties and short-term decision-dependent wind power output uncertainties. A multi-stage stochastic-robust optimization model is proposed to handle WPGEP problems and derive optimal expansion decisions. In this model, the long-term uncertainties and short-term decision-dependent uncertainties are depicted by weighted scenarios and decision-dependent ellipsoidal uncertainty sets, respectively. In order to solve the proposed model, we develop a modified parametric C&CG algorithm and analyze its convergence. Testing results verify the effectiveness of the proposed model and solution method.

4 Enhancing the Grid's Resilience by Optimal Hardening and Maintenance

Bo Zeng[1], Zhengsong Lu[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: bzeng@pitt.edu

A Grid's resilience can be improved by employing costly hardening decisions or implementing frequent but less costly maintenance operations.

5 Climate-Adaptive Transmission Network Expansion Planning Considering Evolutions of Resources

Yixuan Chen, The University of Hong Kong, Pok Fu Lam, Hong Kong

The unpredictable climate change introduces ambiguity into the system, since the weather-sensitive resources would evolve with the climate and gradually exhibit a different distribution from the past in an uncertain manner. Lack of considering this climate-induced ambiguity in transmission network expansion planning (TNEP) may cause misunderstanding of future operational scenarios. Aiming at a higher security operation level under climate change yet

less line investment, this paper proposes a climate-adaptive TNEP, which is a robust TNEP equipped with a climate-adaptive uncertainty set (CUS).
Determination of the CUS involves three steps. First, model future unknown distribution under climate change. Specifically, the climate-driven evolution is quantified by an evolutionary distance between historical and future true distributions, while the future unknown distribution is then modeled by a distance-based ambiguity set; Second, determine the CUS which has a minimal volume yet a desired confidence level by a parametric Wasserstein distance-based distributionally robust optimization (p-WDRO); Third, solve the p-WDRO by a data-clustering-incorporated reformulation. After the CUS is determined, the overall climate-adaptive TNEP is solved by a modified C&CG method. Simulations are conducted on three test systems with practical data, which demonstrate that the climate-adaptive TNEP can improve operational security under climate change while reducing investment costs.

Advancing Energy Systems Optimization Modeling and Analysis: Tackling Key Challenges for Planning, Operations, and Implementation

Community Committee Choice Session

Session Chair: Anderson de Queiroz, North Carolina State University

Session Chair: Andeson Queiroz, 1</sup

1 Exploring Illustrative Decarbonization Pathways Under near Cost-Optimal Futures for the United States

Aditya Sinha, NC State University, Raleigh, NC

Real-world energy system pathways deviate greatly from deterministic least-cost scenarios. Modeling to generate alternatives can identify a diverse set of near-cost-optimal net-zero CO_2 futures for the United States energy system. We find that nearly all future net-zero pathways result in the rapid expansion of solar and wind power generation, substantial reductions in petroleum use, and near elimination of coal combustion. In contrast, nuclear power and coal with carbon capture and sequestration are highly adopted in a small subset of pathways. Exploring correlations of technology adoption across pathways, allow us to identify coupled technologies, as well as counterintuitive relationships resulting from energy system interactions. Our results demonstrate that significantly varied pathways are available for deep decarbonization at comparable system costs.

2 Scenario Analysis for Energy Storage Technologies in Energy System Optimization Models Adopting Different Time Scales and Cost Projections

Matteo Nicoli, Politecnico of Torino / NC State University, Torino, Italy. Contact: matteo.nicoli@polito.it

This work focuses on the assessment of the possible role of storage technologies in the future energy system. Its goal is to capture the dynamics of short-term operation within hourly discretization and connect this into long-term capacity expansion decision-making. Storage technologies can play a role in enforcing the reliability and flexibility of energy systems with high shares of intermittent sources. We integrate techno-economic data for storage processes in Energy System Optimization Models and present the methodology adopted to represent the infra-annual dynamics. Results present storage penetration within supply and demand sectors under alternative conditions: policy scenarios, model time scale refinement, and cost projections.

3 Nuclear-Renewable-Storage Systems: Enhancing Planning and Operations of Integrated Energy Systems

Binghui Li, Jianqiao Huang, Idaho National Laboratory, Idaho Falls, ID, Contact: binghui.li@inl.gov

Nuclear-renewable-storage integrated energy systems (IES) are multi-carrier energy systems that include not only electricity but also other forms of demands. Because individual IES components must observe their thermo-physical limits, including ramp rates, start-up, and shut-down time, we formulate operations of the IES as an optimization model by minimizing the total operations costs subject to physical limits of all constituent components. In addition, we develop a data-driven approach to improve the computational performance of the economic dispatch model by using reinforcement learning, where an agent is rewarded by meeting demands and penalized otherwise when shifting to the next state.

4 Energy Systems Capacity Expansion Planning Under the Risk of Hurricane Damage

Victor Faria[1], Anderson Rodrigo de de Queiroz[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina Central University, Raleigh, NC, Contact: vaduraes@ncsu.edu

Capacity expansion planning in energy systems aims to identify the most cost-effective combination of resources to meet future energy demand, considering various factors like policies, fuel prices, and technology expenses. Despite the substantial damages caused by extreme weather events to power and energy systems, these are rarely incorporated into the scenarios of capacity expansion studies. This project aims to reduce this gap by using stochastic programming to better understand the changes in electricity cost and system planning infrastructure, given the incorporation of hurricane scenarios in an energy system optimization model for the North Carolina energy system.

Transmission, Generation and Storage Long-Term Expansion Planning

Community Committee Choice Session

Session Chair: Enzo E. Sauma, Pontificia Universidad Catolica de Chile, Santiago, Chile

1 Green Ammonia Production in Chile: An Optimization-Based Model for Computing the LCOA

David Pozo[1], Enzo E. Sauma[2], [1]European Commission, Joint Research Centre (JRC), Petten, Netherlands; [2]Pontificia Universidad Catolica de Chile, Santiago, Chile

Green ammonia, a potential game-changer in the global effort to combat climate change, is a carbon-free chemical compound made by combining hydrogen and nitrogen. This sustainable alternative to traditional ammonia production has garnered significant attention due to its potential to serve as both an energy carrier and a key component in various industrial processes.

We introduce a methodology for calculating the Levelized Cost of Ammonia (LCOA) and assess the techno-economic feasibility of green ammonia production in Chile, identifying optimal locations for facilities based on renewable energy availability. Our numerical experiments demonstrate that the LCOA for green ammonia production in various locations positioning Chile as a competitive player in the global market.

2 Adaptive Two/Multi-Stage Stochastic Energy Infrastructure Expansion Planning

Yuang Chen[1], Beste Basciftci[2], [1]Georgia Tech Shenzhen Institute, Shenzhen, China; [2]University of Iowa, Iowa City, IA, Contact: yuang.chen@gatech.edu

Two-stage and multi-stage stochastic optimization are commonly used for energy infrastructure expansion planning when future demand is uncertain. The two-stage model has a strict static investment policy that is predetermined at the outset, whereas the multi-stage model has a flexible fully adaptive policy but must be adapted for each time period. To address the limitations of both models, this talk introduces a new stochastic expansion planning model called adaptive two/multi-stage stochastic programming, which lies between a two-stage and a multi-stage stochastic model. The number of adaption times for investment decisions to adapt to underlying uncertainty is fixed. The model determines the optimal adaption times while keeping the investment policy static otherwise. Results from a case study in Rwanda demonstrate the effectiveness of the proposed models.

3 Transmission Benefits and Cost Allocation Under Ambiguity

Han Shu, Jacob Mays, Cornell University, Ithaca, NY, Contact: hs2226@cornell.edu

Large-scale expansion transmission infrastructure would bring economic, reliability, and environment benefits. However, it is challenging to allocate costs for such shared infrastructure investments roughly in proportion to benefits, particularly when faced with uncertainty. To address this challenge, the article proposes a multistage stochastic mixed-integer transmission and generation co-optimization model with binary decisions for transmission expansion. Our mathematical analysis reveals that load is the only long-term beneficiary of transmission expansion. Benefit assessment for a transmission expansion project is carried out by comparing the optimal surplus with a counterfactual scenario where that specific project is constrained. The transmission expansion cost is then allocated in proportion to the expected benefits in a long-term horizon.

4 Long-Term Power Expansion Considering Hydrogen Production

Enzo E. Sauma[1], Javier Jorquera-Copier[1], Álvaro Lorca[2], Stefan Lorenczik[1], Matias Negrete[1], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile; [2]Pontificia Universidad Catolica de Chile, Atlanta, GA, Contact: esauma@ing.puc.cl

We formulate and implement a model that co-optimizes, from a system-wide perspective, the expansion of the H_2 industry and the expansion of the associate power system, when considering the main technical features of both the power system operation and the H_2 production, and use such a model to adequately asses the economic and environmental impacts of green H_2 production on the Chilean power system infrastructure investments. In doing that, we formulated a model that co-optimizes the expansion of the H_2 industry and the expansion of the associate power system, considering the main technical features of both the power system operation and the H_2 production. We used the proposed model to analyze the interactions between the main Chilean power system and H_2 industry, assessing the economic and environmental impacts of green H_2 production on the Chilean power system.

New Algorithms for Power System Operation

Community Committee Choice Session

Session Chair: Daniel Bienstock, Columbia University, New York, NY

1 GravitySDP: A Solver for Sparse Mixed-Integer SDPs

Hassan Lionel Hijazi, Los Alamos National Laboratory, Los Alamos, NM

In this talk, we will introduce GravitySDP, a new solver for sparse mixed-integer semidefinite programming. Experiments on academic benchmarks and energy applications will be presented.

2 Advances in Solving Large-Scale Grid Optimization Problems

Andy Sun, MIT, Cambridge, MA

Operation of large-scale electric power grids imposes challenging optimization problems. In this talk, we will review some of these challenges and new advances in computational methods for dealing with nonconvex constraints, discrete variables, and multiple decision periods. We will demonstrate that large-scale grid optimization problems of real-world sizes can now be solved to obtain high-quality solutions.

3 Recursive Restoration Refinement: A Fast Heuristic for Near-Optimal Restoration Prioritization in Power Systems

Line Roald[1], Noah Rhodes[1], Carleton Coffrin[2], [1]University of Wisconsin - Madison, Madison, WI, [2]Los Alamos National Laboratory, Los Alamos, NM, Contact: roald@wisc.edu

The prioritization of restoration actions after large power system outages impacts how quickly power can be restored. Fast and intuitive heuristics for restoration prioritization most often result in low-quality restoration plans, while mathematical optimization tools that find high-quality restoration plans are too slow to be applied to restoration planning problems of practical interest. To close this quality vs compute time gap we propose the Recursive Restoration Refinement heuristic for power system restoration. This heuristic produces near-optimal restoration plans up to 1,000 times faster than other state-of-the-art methods on a range of test cases with up to 500 buses and 700 damaged components. The recursive restoration refinement algorithm is available as part of the open-source software package, PowerModelsRestoration.

4 Linear Formulations for AC-OPF

Matias Villagra, Columbia University, NYC, NY, Contact: mjv2153@columbia.edu

In this talk, we present a pure LP-based approach for quickly proving lower bounds of challenging AC-OPF instances. Our cutting-plane algorithm leveraged cuts generated from structural properties of the network.

5 Physics-Informed Machine Learning for Electricity Markets

Robert Ferrando[1], Laurent Pagnier[2], Robert Mieth[3], Zhirui Liang[4], Yury Dvorkin[5], Daniel Bienstock[6], Michael Chertkov[1], [1]University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]Princeton University, Princeton, NJ, [4]Johns Hopkins University, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD, [6]Columbia University, New York, NY, Contact: rferrando@math.arizona.edu

We present a physics-informed, market-aware machine learning-driven algorithm to solve the DC optimal power flow problem. Namely, we employ active set learning to construct a system of linear equations whose solution is equivalent to the primal and dual solution of DC-OPF. The scheme, which we refer to as physics-informed, market-aware, active-set OPF (PIMA-AS-OPF), is validated on the New York ISO 1814-bus system, with results shown for different unit commitment, levels of wind penetration, and levels of noise. In addition, we demonstrate that the LMPs and dispatches adhere to established principles of market design, including revenue adequacy and cost recovery. Finally, we discuss how similar ML-driven schemes may be developed for unit commitment, which is mixed-integer and thus inherently more challenging in nature than DC-OPF.

Data-Driven Optimization and Explainability II

Community Committee Choice Session

Session Chair: Alexandre Forel, Polytechnique Montreal, Montreal, QC, Canada

1 Adversarially Robust Decision Tree Retraining

Benoit Duval, Claudia Bongiovanni, Thibaut Vidal, MAGI, Polytechnique Montreal, Montréal, QC, Canada. Contact: claudia.bongiovanni@polymtl.ca

Decision trees are widely used for creating transparent, explainable, and interpretable models. However, their effectiveness is limited when faced with noisy data and uncertainty due to their inflexible partitioning scheme. To address this, we propose a post-learning procedure for re-training robust decision trees. This procedure incorporates data re-labeling, node re-splitting, and node pruning, formulated as a mixed integer program. We evaluate its efficiency on benchmark instances from the literature and compare it to full enumeration and established adversarially-robust methodologies.

2 Applications and Limitations of Reinforcement Learning in Operations Management

Magnus Josef Maichle[1], Nikolai Stein[2], [1]University of Würzburg, Würzburg, Germany; [2]University of Wuerzburg, Wuerzburg, Germany. Contact: magnus.maichle@uni-wuerzburg.de

We propose a versatile reinforcement-learning-based approach that can effectively solve multiple inventory management problems. Our approach extends existing research in two ways: First, we show that our approach not only works in univariate, but also in multivariate settings with many co-variates (features). Second, we demonstrate the approach's applicability to a larger problem class, including problems with fixed ordering costs that have not been considered previously. Based on numerical experiments we show that this generic approach yields very good results, even when compared to previous data-driven approaches that are engineered towards each individual data and problem instance.

3 A Flexible Framework for Data-Driven Optimization Using Level-Set Kernel Weights

Kai Guender, Felix Schmidt, Julius-Maximilians-University Wuerzburg, Wuerzburg, Germany. Contact: kai.guender@uni-wuerzburg.de

We propose a framework for solving various classes of data-driven optimization tasks using a re-weighting of data samples based on point estimation similarity under contextual features. Our approach can utilize any state-of-the-art machine learning model for point estimation, scales efficiently with the number of samples, and can be applied to both univariate and multivariate problems. We can prove asymptotically optimal behavior under mild assumptions; the results of extensive numerical experiments with real world data suggest strong performance.

On-Demand Transportation Services with Innovative Technology

Community Committee Choice Session

Session Chair: Xiaotang Yang, University of Minnesota, Minneapolis, MN

1 General Coupled Morning-Evening Traffic Equilibria with Rideshare and Ride-Hailing Services

Wei Gu[1], Michael Zhang[2], Maged M. Dessouky[3], Jong-Shi Pang[1], [1]University of Southern California, LOS ANGELES, CA, [2]University of California-Davis, Davis, CA, [3]University of Southern California, Los Angeles, CA, Contact: weig@usc.edu

We develop general equilibrium models to capture the influence of the emerging rideshare and ride-hailing services on traffic congestion and travelers' choice behavior in a coupled morning-evening commute framework. The models are formulated as variational inequalities. Then the existence of an equilibrium solution is investigated, and we provide the conditions on the model parameters under which the equilibrium will be unique. Furthermore, we prove that the travelers' disutility of our coupled models will not be worse than that of decoupled modeling approaches. The proposed models are validated with numerical experiments on the Sioux-Falls network.

2 Distance-Based Fee Design of On-Demand Delivery

Manlu Chen[1], Mingliu Chen[2], Ming Hu[3], Jianfu Wang[4], [1]Renmin University of China, Beijing, China; [2]Columbia University, New York, NY, [3]University of Toronto, Minneapolis, MN, [4]College of Business, City University of Hong Kong, Kowloon, Hong Kong. Contact: chenmanlu@

rmbs.ruc.edu.cn

The rapid growth of e-commerce has fostered booming instant delivery services. To examine the impact of the pricing scheme of on-demand delivery services, we consider a vendor that serves customers' online requests and charges a two-part delivery fee, consisting of a uniform base fee and a variable fee that depends on delivery distance. Compared to optimal flat delivery fee, the vendor can serve a broader region and increase profit and social welfare by charging more distant customers a lower delivery fee. When considering customer valuation heterogeneity, the delivery price design becomes more complex and depends on customer density. We also explore the effect of a self-pickup option implemented by the vendor and find that introducing the self-pickup option can enhance system throughput and lead to a win-win for vendor and customers compared to delivery-only operations.

3 Flying High with Improved Data: How an Instructor Training Workshop Boosting Pilot Competency Assessment

Qingyin GE[1], Jussi KEPPO[1], Chuan Hoo TAN[2], Hong Ming TAN[1], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: qingyin.g@u.nus.edu

Data informativeness is crucial for effective data-driven decision-making. In the context of evaluating pilots' competencies within an international airline, we identify a tendency for evaluators to attribute extremity to both ends of the scale, leaving the scores congregating at the mid-point, particularly for skills that are non-technical. To address this challenge, we conducted workshops to educate instructors on grading criteria and the current unvaried grading scale. Utilizing a difference-in-differences approach with a multi-period synthetic control, we find a 29% improvement in the grading variation after the workshops, resulting in a more informative reflection of the pilots' competence. Our findings highlight the efficacy of instructor training in the pilot programs and provide policy implications for enhancing data informativeness.

Network Models in Optimization and Their Applications

Community Committee Choice Session

Session Chair: Yajun Lu, Jacksonville State University, Jacksonville, AL

1 Welfare-Oriented and Public Health-Aware Disaster Sheltering Network Design

Mohamed R. Salama, Min Kyung Lee, Yuehwern Yih, Purdue University, West Lafayette, IN, Contact: salamam@purdue.edu

The inferior conditions that disaster victims commonly experience at public shelters may drive them to refuse evacuation. Moreover, the possible spread of infectious diseases inhibits them further from using such shelters. Therefore, in this study, a four-echelon network design is developed to allow for small-capacity shelters that can enhance both the welfare and public health of evacuees. A two-stage stochastic mixed-integer linear programming model is formulated to select opening nodes in each of the four network echelons under different disaster scenarios, in addition to determining the logistical operations. The national network of shelters in the United States is used as a case study to demonstrate the proposed network design and solution approach.

2 Identifying High Mortality Rate Disease Clusters In Comorbidity Graphs

Parisa Vaghfi Mohebbi[1], Baski Balasundaram[2], Yajun Lu[3], Zhuqi Miao[4], Ramesh Sharda[2], Pankush Kalgotra[5], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Stillwater, OK, [3]Jacksonville State University, Jacksonville, AL, [4]SUNY-New Paltz, New Paltz, NY, [5]Auburn University, Auburn, AL, Contact: parisa.vaghfi_mohebbi@okstate.edu

Mortality rate is the fraction of expired patients who had a particular group of diseases. The knowledge of high mortality rate disease clusters can enable healthcare providers to develop tailored interventions that improve patient outcomes and overall quality of care. This talk will discuss our ongoing work on finding cliques of comorbid diseases that correspond to high mortality rates among a given patient population. To tackle this, we explore two approaches: (i) a mixed-integer programming formulation that maximizes a single fractional objective subject to linear constraints, and (ii) an extension of the classical Bron-Kerbosch (BK) enumerative algorithm. We will report results from our experiments with both approaches on large-scale datasets derived from patient electronic healthcare records.

3 Combining Heuristics and Optimization in Kinaxis RapidResponse Supply Chain Planning

Carsten D. Jordan[1], Dan Vlasie[2], Ingrid Bongartz[3], Sergei Krutelevich[3], Yankai Zhang[3], [1]Kinaxis, San Diego, CA, [2]Kinaxis, Boston, MA, [3]Kinaxis, Ottawa, ON, Canada.

Contact: cjordan@kinaxis.com
Some supply chains involve expensive production on the lower BillOfMaterial levels and distribution on higher levels, across many sites and SKUs. We present an approach where we use heuristic planning on the higher levels and optimization on the lower BillOfMaterial levels. We show the advantages of this approach in a life science supply chain in the Kinaxis RapidResponse software.

4 On Atomic Cliques in Temporal Graphs
Yajun Lu[1], Zhuqi Miao[2], Parisa Sahraeian[3], Baski Balasundaram[3], [1]Jacksonville State University, Jacksonville, AL, [2]SUNY-New Paltz, New Paltz, NY, [3]Oklahoma State University, Stillwater, OK, Contact: ylu@jsu.edu
Atomic cliques were introduced recently to analyze disease progression in temporal comorbidity graphs. Informally, an atomic clique is a clique that is unsplittable over time---the clique is either present or absent entirely and no parts of it appears in the temporal graph unless the entire clique is present. We consider the atomic counterpart of the classical maximum clique problem in this paper. Our main contribution is a polynomial-time algorithm that transforms the maximum atomic clique problem to the maximum clique problem on an auxiliary graph. We report results from our computational studies that demonstrate the effectiveness of this transformation in solving the maximum atomic clique problem in comparison to direct integer programming based approaches.

Quantum Computing and Optimization II

Community Committee Choice Session

Session Chair: Brandon Augustino, Lehigh University, Landing, NJ

1 Graph Decomposition Technique for Solving Combinatorial Optimization Problems with Variational Quantum Algorithms
Moises Ponce[1], Rebekah Herrman[1], Phillip Lotshaw[2], Sarah Powers[2], George Siopsis[1], Travis Humble[2], James Ostrowski[1], [1]University of Tennessee Knoxville, Knoxville, TN, [2]Oak Ridge National Laboratory, Oak Ridge, TN, Contact: rherrma2@utk.edu
The quantum approximate optimization algorithm (QAOA) has the potential to approximately solve complex combinatorial optimization problems in polynomial time. However, current noisy quantum devices cannot solve large problems due to hardware constraints. In this talk, we introduce an algorithm that decomposes MaxCut graphs into reduced problems and solves them using QAOA. We discuss algorithm performance on a collection of test graphs. On average, the algorithm requires approximately 88% fewer qubits than QAOA requires to solve the original MaxCut instances. Furthermore, solving the reduced problems improves the approximation ratio by approximately 125% compared to directly solving the original problems.

2 Quantum Approximate Optimization for Constrained Combinatorial Problems
Phil Lotshaw, ORNL, Oak Ridge, TN
Quantum alternating operator ansätze (QAOA) are being explored as potential approaches to obtain quantum computational advantages in approximately solving combinatorial optimization problems. QAOA typically addresses unconstrained optimization problems, while constrained optimization is relatively less explored. Here we analyze two QAOA approaches to handle constraints in simple instances of binary integer linear programming problems. The first approach uses penalty terms to transform the problem into an unconstrained version; the second approach enforces constraints within the circuit, with auxiliary variables and a smaller number of penalty constraints. We assess the benefits and tradeoffs inherent to these approaches and quantify their performance and scaling.

3 Quantum Approximate Optimization Algorithm Applied to a Classically Intractable Problem
Ruslan Shaydulin, JPMorgan Chase, New York, NY
The Quantum Approximate Optimization Algorithm (QAOA) has attracted a lot of interest as a promising algorithm for solving combinatorial optimization problems on quantum computers. We numerically evaluate the performance of QAOA on a classically intractable problem. We discuss the implications of our findings to the problem of understanding the potential of quantum computers to assist in solving hard optimization problem.

New Perspectives in Multiple Criteria Decision Making

Community Committee Choice Session

Session Chair: Mohammad Ghaderi, Pompeu Fabra

University, Barcelona, Spain
Session Chair: Salvatore Greco, University of Catania, Catania, Italy

1 Selection of a Representative Sorting Model in a Preference Disaggregation Setting: Existing Procedures, New Proposals, and Experimental Comparison

Milosz Kadzinski, Michal Wojcik, Krzysztof Ciomek, Poznan University of Technology, Poznan, Poland. Contact: milosz.kadzinski@cs.put.poznan.pl

We consider preference disaggregation in the context of multiple criteria sorting. Given the multiplicity of sorting models compatible with indirect preferences, selecting a single, representative one can be conducted differently. We review several procedures for this purpose, aiming to identify the most discriminant, average, central, parsimonious, or robust models. Also, we present three novel procedures that implement the robust assignment rule in practice. The performance of fourteen procedures is verified on problem instances with different complexities. The results of an experimental study indicate the most efficient procedures in classification accuracy, reproducing the DM's model, and delivering the most robust assignments.

2 A New Ordinal Regression Procedure for Multiple Criteria Decision Aiding

Salvatore Greco[1], Maria Barbati[2], Isabella Lami[3], [1]University of Catania, Catania, Italy; [2]Università Ca' Foscari Venezia, Venezia, Italy; [3]Politecnico di Torino, Torino, Italy. Contact: salgreco@unict.it

We define a new elicitation procedure to handle Decision Makers (DMs) preferences. The preferences are elicited by conjugating the deck of cards method with the ordinal regression approach allowing the DM to provide preference information in terms of ranking and pairwise comparison of some reference alternatives in terms of intensity of preference. Then, the score ofthe reference solutions obtained through the deck of the cards method is used as a basis for an ordinal regression procedure. We show how this methdology can be usefully applied to different forms of a value function such as weighted sum, Choquet integra, additive value function.

3 XIMEA-DRSA: A New Interactive and Explainable Evolutionary Multiobjective Optimization Method

Roman Slowinski[1], Salvatore Corrente[2], Salvatore Greco[2], Benedetto Matarazzo[2], [1]Poznan University of Technology, Poznan, Poland; [2]Department of Economics and Business, University of Catania, Catania, Italy. Contact: roman.slowinski@cs.put.poznan.pl

XIMEA-DRSA is a new interactive evolutionary multiobjective optimization method guided by preferences of the user modeled in terms of "if ..., then ..." decision rules. Besides guiding the search process, the decision rules can be read as arguments explaining the user's preferences. In this way, the user has a chance to understand how their assessment of a small sample of solutions in the preference elicitation phase is translated into guidelines for the algorithm in the optimization phase. This is a distinctive aspect of an eXplainable Interactive Multiobjective Evolutionary optimization Approach (XIMEA). Decision rules are induced from the preference information using the Dominance-based Rough Set Approach (DRSA). XIMEA-DRSA was tested on benchmark problems, both continuous and combinatorial ones, showing a very good performance.

4 Preference Disaggregation: A Probabilistic View

Moha Ghaderi[1], Milosz Kadzinski[2], [1]Pompeu Fabra University, Barcelona, Spain; [2]Poznan University of Technology, Poznan, Poland. Contact: mohammad.ghaderi@upf.edu

The preference disaggregation paradigm concerns the construction of utility or value functions from the preference information supplied by a decision maker, typically in the form of qualitative judgments and holistic pairwise comparisons of decision alternatives. The extant literature often starts with a utility function, involving various specification and distribution assumptions, and takes the form of mapping utility vectors to choice probabilities. We argue that defining preferences in terms of choices can be problematic for generating insights into the underlying choice process and it assumes away various boundedly rational behavioral patterns such as context-dependency since it arrives at a preference relation endogenously. We provide an alternative approach where utilities are merely quantification mediums that facilitate handling preferences.

MIF Paper Competition 2023

Community Committee Choice Session

Session Chair: Michelle M. Alvarado, University of Florida, Gainesville, FL

1 Joint Client Selection and Contract Design for A Risk-Averse Commodity Broker in a Two-Echelon Supply Chain

Belleh Fontem, University of Massachusetts Lowell, Lowell, MA
We study an expected payoff maximization problem for a risk-sensitive broker aiming to evaluate the merits of designing and underwriting an option contract on a traded commodity with geometric Brownian motion spot price trajectories. The broker's objective is jointly to (i) choose a so-called trigger price function that will fundamentally define the option contract, and (ii) select a value-maximizing set of client firms to whom the broker will offer the contract. We reformulate the problem as a bilevel program whose continuous relaxation we transform into a single-level, univariate problem. Then, we use real-world data to study the implications of violating a certain constraint that implicitly bounds the optimal trigger price.

2 Learning Product Rankings Robust to Fake Users
Negin Golrezaei, Massachusetts Institute of Technology, Cambridge, MA
Online platforms heavily rely on product rankings to influence customers, who often focus on top items. Platforms use customer data for ranking learning. However, this can incentivize some sellers to manipulate rankings. We address this, studying platforms with indistinguishable real and fake data points. Our effective algorithms work for platforms aware or unaware of the number of fake data points, ensuring optimal robust rankings and surpassing existing methods. Our approach includes novel strategies like product-ordering graphs and multi-level learning.

3 Monitoring Policy in the Context of Preventive Treatment of Cardiovascular Disease
Daniel Felipe Otero Leon, Harvard Medical School, Boston, MA
Preventing chronic diseases is an essential aspect of medical care. Physicians focus on monitoring risk factors and prescribing necessary medication. Monitoring too frequently may be unnecessary and costly; on the other hand, monitoring the patient infrequently means the patient may forgo needed treatment and experience adverse events. We propose a Markov decision process to define monitoring policies. To build our model, we use EHR longitudinal observational data from patients seen in the U.S. Veterans Affairs health system. We use our model to study policies for whether or when to assess the need for cholesterol-lowering medications. We further use our model to investigate the role of sex and race in optimal monitoring policies.

How OR Scholars Successfully Collaborate with Public Institutions? A Panel Discussion

Panel Session

Session Chair: Gemma Berenguer, Universidad Carlos III de Madrid, Getafe, Spain

1 How OR Scholars Successfully Collaborate with Public Institutions? A Panel Discussion
Gemma Berenguer, Universidad Carlos III de Madrid, Getafe, Spain
This session will describe different public sector OR collaborations between academics and public sector institutions.

2 Panelist
Yuehwern Yih, School of Industrial Engineering, Purdue University, W Lafayette, IN

3 Panelist
Mahyar Eftekhar, Arizona State University, Tempe, AZ

4 Panelist
Ravi Anupindi, University of Michigan, Ann Arbor, MI

5 Panelist
Jessica Heier Stamm, Kansas State University, Manhattan, KS

Sunday, October 15, 4:00 PM - 5:15 PM

Analytics for Railway Operations

Contributed Session

Session Chair: Md Gulam Kibria, Georgia Institute of Technology, Clarkston, GA

1 Planning Service Protocols for Extra-Long Trains
Jesus Osorio[1], Shiyu Shen[2], Yanfeng Ouyang[3], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Urbana, IL, [3]U of Illinois at Urbana-Champaign, Urbana, IL
Metro systems are becoming overly saturated by the ever-increasing travel demand in many megacities, which results in overcrowded stations, excessive delays, and unsafe rider

anxieties. The concept of extra-long trains (i.e., trains longer than station platforms) was recently proposed in the literature as a promising way to increase metro line capacity without additional infrastructure construction. This talk presents a general modeling and solution framework to optimize train block configuration and operation protocols for extra-long trains under arbitrary demand distributions and platform settings. Numerical experiments, including both hypothetical and real-world cases, are conducted to demonstrate the applicability and effectiveness of the proposed framework. In addition, a set of sensitivity analyses are performed to draw managerial insights.

2 Real-Time Decision Support for Human-Machine Interaction in Digital Railway Control Rooms

Léon Sobrie[1], Marijn Verschelde[2], [1]Ghent University, Ghent, Belgium; [2]IÉSEG School of Management, Lille, France. Contact: leon.sobrie@ugent.be

In digital railway control rooms, traffic operators can on-the-spot choose to use automation. As these choices are frequently suboptimal, we propose a real-time decision support tool to improve human-machine interaction (HMI) at Infrabel, Belgium's railway infrastructure company. The tool provides descriptive, predictive and prescriptive analytics on both expected and desirable HMI at the 15-minute level for each workstation. We benchmark clustering-based approaches for the descriptives, and machine and deep learning approaches for the predictions. To obtain prescriptions, we compare the predictions of HMI with their desirable counterparts. SHAPley values are deployed to foster model explainability and we document a generational difference in the distance between expected and desirable HMI.

3 Explainable Real-Time Predictive Analytics on Employee Workload in Digital Railway Control Rooms

Léon Sobrie[1], Marijn Verschelde[2], Bart Roets[3], [1]Ghent University, Ghent, Belgium; [2]IÉSEG School of Management, Lille, France; [3]Infrabel, Brussels, Belgium. Contact: m.verschelde@ieseg.fr

Workload peaks/lows impact employee well-being. We propose real-time predictive employee workload analytics as decision support for management in an environment with variable and imbalanced workload: the digital railway control rooms of Infrabel. The granularity of the data facilitates an analysis of the multiple dimensions of workload at the 15-minute level. We perform an extensive benchmark between well-known Machine Learning and Deep Learning models to predict the presence and magnitude of various workload dimensions. We leverage SHAPley values to obtain both local and global explainability. Further, we show the value for adequate explainability of disentangling the presence and magnitude of workload. The proposed model is implemented as a proof of concept for explainable decision support within the company of focus.

4 Incentive Design to Shift Car Users to Transit Under TNC-Transit Partnerships

Md Gulam Kibria[1], Srinivas Peeta[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA

Qualitative studies suggest that transportation network companies (TNCs) can increase transit catchment area through partnerships with transit agencies by addressing the first-and-last mile problem. This study explores monetary and non-monetary incentive designs to shift car users to transit by utilizing the increased transit catchment area under TNC-transit partnerships. We propose mathematical models to maximize societal benefit and the associated user-level incentive designs in an integrated system in which TNCs provide first-and-last mile connections to transit stops.

Sunday, October 15, 4:00 PM - 5:15 PM

Diversity, Equity, Inclusion, and Justice in Services

Community Committee Choice Session

Session Chair: Muge Yayla Kullu, University of Central Florida, Orlando, FL

1 Promising Tomorrow: Students' Well-Being Focused Transformative Bottoms-Up Approach for Inclusive Stem Higher Education

Mihir Mehta, Penn State University, State College, PA

OR/MS equitable and inclusive higher education learning experiences are vital for realizing sustainable diversity in OR/MS fields. The "Promising Tomorrow" theme takes a student-focused bottoms-up approach. With three strategic panel discussions, it promotes students' well-being through positivity, productivity, and prosperity goals. The mental health session discusses practices for creating a positive learning environment through pedagogy. The neurodiversity session leverages executive functioning to promote productivity with informative and compassionate mentoring guidelines. The student DEI participation sessions outline future collaborative student DEI efforts for the prospering sense of belonging in OR/MS communities.

2 Redrawing Attendance Boundaries to Foster More Racially and Socioeconomically Diverse Schools

Nabeel Gillani, Northeastern University, Boston, MA, Contact: n.gillani@northeastern.edu

Most U.S. school districts draw “attendance boundaries” to define catchment areas that assign students to schools near their homes, often recapitulating neighborhood segregation by race and socioeconomic status in schools. This talk describes applications of combinatorial optimization to redraw school attendance boundaries in ways that foster more racially, ethnically, and socioeconomically integrated schools. We highlight findings from both country-wide simulations and school district outreach, as well as close collaborations with school district partners, to discuss both challenges and opportunities in using operations research methods to foster more diverse, integrated, and equitable educational environments.

3 Exploring Equity in Social Media Communication for Crisis Management by Water Utilities

Khalid K. Osman[1], Rohit Valecha[2], Arkajyoti Roy[3], Kasey M. Faust[4], [1]Stanford University, Stanford, CA, [2]UTSA, San Antonio, TX, [3]The University of Texas at San Antonio, San Antonio, TX, [4]University of Texas at Austin, Austin, TX, Contact: osmank@stanford.edu

This study investigates whether water utility communications in the US during a crisis are accessible by historically disenfranchised populations. Specifically we explored user engagement with utilities’ messages in non-dominant languages for information regarding utilities’ resources in the form of financial assistance. We examined water utility social media communications during the COVID-19 pandemic using 180,000 tweets from 338 water utilities nationwide. Using a dynamic panel data model, we found that tweets written in Spanish led to positive engagement for financial assistance-related information in Hispanic counties. This finding highlights that in vulnerable communities, social media can be considered as a trusted source for seeking financial assistance information from official organizations when it incorporates non-dominant languages.

4 Dynamic Exception Points for Fair Liver Allocation

Mustafa Akan, Musa Celdir, Sridhar Tayur, Carnegie Mellon University, Pittsburgh, PA

There are disparities in access to livers based on transplant patients’ height - which disproportionately affects women across ethnicities, in addition to Hispanics and Asians broadly - because they can receive transplants from a smaller pool of available deceased donors for medical reasons. We analyze fairness within the current US liver allocation system. We propose a simple adjustment - providing additional (exception) points based on height and MELD score - that can be easily implemented in practice, which materially reduces the disparity without sacrificing overall efficiency.

5 Impact Of Power Distance On Gender Gap In Economic Participation: The Moderating Effects Of Educational Attainment And Masculinity

Muge Yayla Kullu[1], A. Melih Kullu[2], [1]University of Central Florida, Orlando, FL, [2]Florida Southern College, Lakeland, FL, Contact: muge@ucf.edu

Gender diversity in the workforce has proven its benefits. While there has been considerable progress over the last century regarding the women’s status in society, the gender gap in the business world has endured. Women hold jobs that are inferior and pay less and occupy less seats up in the hierarchy. In this paper, we aim to understand the impact of national culture on gender gap in the workforce. We focus on the power distance dimension that studies inequalities in a society. In addition, we also examine how increased education and reduced masculinity helps with reducing the observed gender gap.

Sunday, October 15, 4:00 PM - 5:15 PM

Product and Process Innovation in Healthcare

Community Committee Choice Session

Session Chair: zhili Tian, Univ. of Houston, Myrtle Beach, SC

Session Chair: Anh Tuan Ninh, College of William and Mary, Department of Mathematics, Williamsburg, VA

1 Optimal Enrollment in Late Stage New Drug Development with Learningof Drug’s Efficacy for Group Sequential Clinical Trials

zhili Tian[1], Gordon B. Hazen[2], Hong Li[3], [1]Univ. of Houston, Houston, TX, [2]Northwestern University, Evanston, IL, [3]Univ. of California, David, CA, Contact: zhili.a.tian@gmail.com

The cost for developing a new drug is close to $2.6 billion in early 2010’s. The efficacy of a candidate drug, patient enrollment, and the market exclusivity period (MEP) are uncertain. Slow enrollment leads to increased costs, canceled trials, and lost potential revenue. Firms hope to detect efficacy vs. futility of the candidate drug early to save development costs in group-sequential-design trials. We developed a dynamic program with learning of a drug’s efficacy and MEP. We update a drug's efficacy by Bayes' rules. Our optimal policies can assist firms effectively conduct clinical trials considering competition from other drugs in the marketplace. Firms can use the properties of the value function to select late-stage trials for their drug-development project portfolios and use our model in simulation to select their trial design parameters.

2 Modeling Patient Recruitment In Clinical Trials
Anh Tuan Ninh, William and Mary, Department of Mathematics, Williamsburg, VA, Contact: atninh@wm.edu
Forecasting patient enrollment is of paramount importance in trial monitoring, as it provides decision-makers with crucial information about the anticipated number of recruits and the expected recruitment timeline. In this study, we present both an exact and an approximated formula for calculating the number of recruits at a given time and the recruitment time in a multi-center trial.

3 Analysis Of Compensation Contracts For Providers Inclinical Studies
Xueze Song[1], Mili Mehrotra[2], Tharanga Kumudini Rajapakshe[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]University Of Illinois Urbana Champaign, Champaign, IL, [3]University of Florida, Gainesville, FL, Contact: xuezes2@illinois.edu
To improve participant retention, the clinical study sponsors often provide monetary payments to participants and compensate providers (investigators and coordinators) for their efforts. In this work, our goal is to examine the cost performance of three widely adopted compensation contracts—fixed (FC), linear (LC), and condition linear (CLC) in improving participant retention. To this end, we analyze a sponsor's decisions regarding monetary payments and providers' efforts under a centralized model, and identify the optimal contracts for the providers under the two decentralized team structures: (i) the sponsor-investigator (SI) model and (ii) the outsourcing (OM) model.

4 Food Safety And Sustainable Practices In Hunger Relief Organizations: Analysis Of Current And Potential Partnerships
Naimur Rahman Chowdhury[1], Rashik Intisar Siddiquee[2], Abdullah Al Nadim[3], Naurin Zoha[2], Ricky Owusu[4], Motunrayo Ogunmola[5], Julie Simmons Ivy[6], Shona D. Morgan[7], Lauren Berrings Davis[5], [1]North Carolina State Universoty, Raleigh, NC, [2]North Carolina State University, Raleigh, NC, [3]North Carolina State University, Raleigh, NC, [4]North Carolina A&T State Universoty, Greensboro, NC, [5]North Carolina A&T State University, Greensboro, NC, [6]University of Michigan, Ann Arbor, MI, [7]North Carolina A&T State University, Greensboro, NC, Contact: nchowdh2@ncsu.edu
Under the United Nation's Sustainable Development Goals, increasing concern for sustainability has motivated many hunger relief organizations to focus on environmental responsibilities as well as maintain food safety for holistic well-being. The aim of this paper is to analyze critical attributes in the domains of sustainable practices and food safety and create a predictive framework for hunger-relief companies to make critical decisions on collaboration and partnership with other hunger-relief organizations. First, we train a machine learning model with rating of different sustainability attributes of existing collaborators. The trained model is then used to measure relative ranking of potential partners for future collaborations.

Innovation and Technology Management in Supply Chains

Community Committee Choice Session

Session Chair: Shubhobrata Palit, Georgia Institute of Technology, Rochester, NY

1 Effects of Responsive Pricing on Product Quality and Profitability in a Decentralized Channel
Chongguang Liu[1], Baojun Jiang[2], Yannan Jin[1], Hang Wei[1], [1]Shanghai University of Finance and Economics, Shanghai, China; [2]Washington University in St. Louis, St. Louis, MO, Contact: chongguang@wustl.edu
We build an analytical model to study how the retailer's responsive pricing affects the manufacturer's quality-investment decision and firms' profitability. We find that if the consumers' valuation for quality is sufficiently homogeneous, the retailer's responsive pricing will dampen the manufacturer's quality investment; otherwise, the retailer's responsive pricing will induce the manufacturer to increase its quality investment. We find that if the consumers in the market are sufficiently but not extremely homogeneous, the retailer's responsive pricing will force the manufacturer to set a higher wholesale price, which results in a lose-lose outcome. However, if the consumers in the market are very heterogeneous, the retailer's responsive pricing will induce the manufacturer to set a lower wholesale price, which results in a win-win outcome.

2 Innovation and Technological Knowledge Utilization in Supply Networks

Shubhobrata Palit[1], Manpreet Singh Hora[2], Soumen Ghosh[2], [1]Esade Business School, Barcelona, Spain; [2]Georgia Institute of Technology, Atlanta, GA, Contact: shubhobrata.palit@esade.edu

We focus on a buyer as a source of technological knowledge for a supplier and examine factors that make a supplier utilize technological knowledge from the buyer. Specifically, we study buyer innovation, technological similarity between a supplier and a buyer, a supplier's dependence on a buyer, and buyer-supplier size asymmetry, and how these factors interrelate in influencing the extent of the knowledge utilization from the buyer by the supplier.

Platform Data Mining for Consumer and Social Good

Community Committee Choice Session

Session Chair: Mariia Petryk, George Mason University, Gainesville, FL

1 Twitter Word-of-Mouth and NFT Sales

Katsiaryna Siamionava, Pei-yu Chen, Arizona State University, Tempe, AZ

In the recent years, non-fungible token (NFT) marketplace has rapidly expanded. Despite the public interest for NFTs, predicting success of NFT campaigns or specific digital assets remains a complex task. Prior research indicates the importance of non-financial factors in the NFT valuation prediction (Kapoor et al. 2022; Vasan, Janosov, and Barabási, 2022). We contribute to this research domain by examining the link between the social media word-of-mouth (WOM) on Twitter and NFT sales on OpenSea, one of the largest NFT platforms worldwide. We leverage Koat.ai analytics to extract valuable Twitter WOM dimensions. The outcomes of the study will contribute to the understanding of social influence on NFT sales and will inform NFT campaign strategies.

2 The Efficacy of Need-Based Attentional Interventions in Educational Crowdfunding

Amin Sabzehzar[1], Gordon Burtch[2], Yili Kevin Hong[3], Raghu Santanam[4], [1]Tulane University, New Orleans, LA, [2]Boston University, Boston, MA, [3]University of Miami, Pinecrest, FL, [4]Arizona State University, Tempe, AZ, Contact: asabzehzar@tulane.edu

The ability of the platforms to direct donors' attention toward disadvantaged student groups is predicated on the assumption that donor audiences hold no stereotypes toward underrepresented students. We explore the consequences of attentional interventions from the platform to support disadvantaged student groups. Leveraging data from DonorsChoose.org, we first report evidence that fundraisers benefiting lower-income and minority students receive systematically lesser funding, conditional on project characteristics and amounts requested. Subsequently, we examine the causal effect of a platform-implemented intervention to draw attention to student beneficiaries' poverty and minority status in the form of an 'equity-focus' project label.

3 Consumer Complaints Analysis

Reihane Boghrati[1], Amir Sepehri[2], Pei-yu Chen[1], [1]Arizona State University, Tempe, AZ, [2]ESSEC, Paris, France

Theory suggests when customers voice their complaints to businesses, they seek either psychological recompense (e.g., apology) and/or financial compensation (e.g., refund). We used the Safer Products Database (SPDB), a dataset of consumer complaints and corresponding company responses, to train a classifier for predicting financial and psychological labels. We then ran an experiment to measure the effect of match/mismatch between what consumers seek and what companies offer.Together, the field study and experiment have significant implications for companies. Although consumers are happy with financial compensation, companies cannot provide financial compensation to every customer due to limited resources. By utilizing the machine learning model, companies can classify consumer complaints and allocate their resources more effectively.

4 Designing NFT Collections: An Exploration of Trait Distribution and Diversity

Ehsan Valavi[1], Harang Ju[1], Madhav Kumar[2], Sinan Aral[1], [1]Massachusetts Institute of Technology, Boston, MA, [2]MIT, Cambridge, MA

The meteoric rise of non-fungible tokens (NFTs) has opened up a new frontier for digital art and collectibles. This paper focuses on the design of NFT collections, specifically exploring the distribution of traits and their impact on the perceived value and attractiveness of a collection. Through a comprehensive analysis of existing NFT collections and an examination of the principles of rarity and diversity, we offer insights and guidelines for artists and creators to design appealing and valuable NFT collections.

5 How E-Wom Influences Blockchain-Based Fundraising: The Role of Linguistic Elements

Wei Xiong[1], Siwei Zhu[2], [1]Mercer University, Atlanta, GA, [2]Minnesota State University Moorhead, Moorhead, MN
Prior literature has investigated the impact of eWOM on fundraising. However, there is a lack of discussion on how linguistic elements in eWOM may affect the fundraising performance. Different linguistic elements may trigger different types of eWOM and therefore show heterogeneous influence. Distinguishing between emotional eWOM and informational eWOM, we examine 4 linguistic elements of tweet posts with conservatism and ambivalence related to emotional eWOM while lexical uniqueness and readability related to informational eWOM. Drawing on the context of blockchain-based fundraising, our empirical analysis indicates that conservatism, ambivalence and lexical uniqueness negatively affect fundraising outcomes, while readability positively affects fundraising outcomes. The findings offer valuable insights for entrepreneurs to take advantage of eWOM.

Data Analytics in Digital Platforms

Community Committee Choice Session

Session Chair: Onur Seref, Virginia Tech, Blacksburg, VA

Session Chair: Derya Ipek Eroglu, 1</sup

1 Examining the Impact of Tailoring on Perceived Social Support of a Conversational Agent

Sagar Mahesh Badve, Alan Gang Wang, Wenqi Shen, Virginia Tech, Blacksburg, VA
Advancement in conversational artificial intelligence (AI) has created opportunities for using conversational technologies such as chatbots in various domains. A recent development is the sophisticated conversational agent ChatGPT which has found widespread applications since its launch. Researchers have argued its usefulness and ethical implications in the healthcare domain, specifically mental healthcare. Based on anthropomorphism and communication literature, this research examines the effects of tailoring a conversational agent's cues that use ChatGPT as its underlying mechanism. Particularly, we examine the effect of tailoring responses and avatars of the conversational agent on the user's perceived social support in mental healthcare. Our research also provides guidelines on ethically using ChatGPT to assist in mental healthcare.

2 When the Views Change: Design-Motivated Persuasive Communication on a Reddit Community

Derya Ipek Eroglu[1], Onur Seref[2], Michelle Seref[2], [1]SUNY Brockport, Brockport, NY, [2]Virginia Tech, Blacksburg, VA
Digital spaces allow more people to be connected while paradoxically leading to more polarization. Online environments fostering good faith discussions and diverse opinions could mitigate this problem, a good example of which is the ChangeMyView community of the Reddit platform. If a redditor is successful in persuasion, they receive Delta, a reward system with a specific purpose. We seek answers to two phenomena in the CMV community: challenger strategies to persuade the OP and the way the OP processes the comments and changes her view. With a mixed-methods research design, we explore challengers' persuasion strategies and incorporate these strategies into our theoretical model. We utilize content analysis in the qualitative analysis to find themes of persuasion, and we incorporate these themes into our theoretical model and quantitative analysis.

3 Temporal Context Tracking

Onur Seref, Michelle MH Seref, Christopher W. Zobel, Virginia Tech, Blacksburg, VA, Contact: seref@vt.edu
We present a visualization framework for observing changes in context over time in a time stamped text corpus. We introduce different methods to keep track of the local maxima of a three dimensional surface induced by two dimensional points that represent small units of text from the corpus using a kernel function. We use several combinations of popular methods for vectorization and dimensionality reduction to produce the representative points. We apply our framework to a corpus of 311 calls around the onset of the COVID pandemic to study the drastic shift in the reports.

Sunday, October 15, 4:00 PM - 5:15 PM

Novel Policy Applications of Natural Language Processing (NLP)

Community Committee Choice Session

Session Chair: Kwan-Yuet Ho, Leidos, Columbia, MD

Session Chair: Weifeng Zhong, Mercatus Center at George Mason University, Arlington, VA

1 Propaganda and Foreign Policy Change in China: Text Analysis of People'S Daily Content During International Crises

Weifeng Zhong, Mercatus Center at George Mason University, Arlington, VA

The People's Daily is at the nerve center of China's propaganda system, and existing research has shown that propaganda changes often precede domestic policy changes. This paper extends this insight to the realm of foreign policy. We collect data on official foreign coverage in the People's Daily before, during, and after international crises involving Chinese military or economic coercion from 1990 to 2022. Using a set of natural language processing techniques, we analyze the text to detect changes in how China's state media prioritize their foreign coverage. We hypothesize that the desire to shape public opinion through propaganda and to tie hands during international bargaining will allow us to detect changes in foreign coverage corresponding to escalation and de-escalation of international crises. The analysis will reveal the extent to which the Chinese government (i) preemptively shapes public attitudes towards a target state before the initiation of military conflicts or economic sanctions or (ii) retroactively spins foreign coverage to manage public opinion during the crisis.

2 Calibration in Categorizing Scientific Documents

Kwan-Yuet Ho, Ledos, Columbia, MD

Model calibration in natural language processing (NLP) supervised learning problem is necessary when a probability of the classification result is important for downstream analysis. These probabilities can be estimated using the model output scores directly. In this talk, the example of Assisted Referral Tool (ART), a tool to categorize scientific grant proposals, is demonstrated to see how the model results are calibrated and the quality of the calibration be measured.

Sunday, October 15, 4:00 PM - 5:15 PM

CC-West 105B

Networks, Org Structure, and Media for Business Decisions

Community Committee Choice Session

Session Chair: Yuan Yuan, Purdue University, West Lafayette, IN

1 Network Interventions to Reduce Hate Speech on Twitter

Eaman Jahani[1,2], [1]UC Berkeley, Berkeley, CA, [2]University of Maryland, College Park, MD, Contact: eaman@umd.edu

There are growing concerns about the prevalence of hate content on online social media platforms. Several companies have embarked on content moderation as a way to combat online hate speech. The evidence on the effectiveness of these punitive measures is mixed. In contrast, community-driven interventions rely on the existing social capital in networks and can potentially be more long-lasting. This randomized control study evaluates and compares the effectiveness of network-based interventions aimed at reducing hate speech on Nigerian Twitter. We view online hate content as an ecosystem with supply and demand, and test whether an intervention targeting hate producers is more effective than targeting their consumers. The experiment enables us to compare the effectiveness of producer-only and consumer-only campaigns while taking spillovers into consideration.

2 Workers' Propensity to Return to Office: A National Survey

Y. Jessica Cheng, Y. Jasmine Wu, Noshir Contractor, Northwestern University, Evanston, IL, Contact: jasminewu@u.northwestern.edu

The COVID-19 pandemic prompted a major shift to remote and hybrid work, and many organizations are eager to bring workers back to in-person work. While past research has examined gender, commute time, and geographic factors as predictors of worker propensity to telecommute, this study examines worker propensity to return to the office in the post-pandemic world. Through a national survey distributed in the US and China between December 2020 and March 2021, we collected data on workers' willingness to return to the office and their work relations networks. Results of random forest and logistic regression models show that outdegrees of advice and friendships relations in their work teams are important predictors of their propensity to work in person. This research informs organizational policies and practices promoting collaborative hybrid workplaces.

3 Examining Co-Attendance Patterns in Hybrid Work Environments

Marie-Laure Charpignon[1], Yuan Yuan[2], Dehao Zhang[3], Longqi Yang[3], Fereshteh Amini[3], Sonia Jaffe[3], Sid Suri[3], [1]MIT, Cambridge, MA, [2]Purdue University, West Lafayette, IN, [3]Microsoft, Redmond, WA, Contact: mcharpig@mit.edu

Hybrid work introduces new challenges regarding the synchronization of in-office workdays. We quantified co-attendance patterns among employees at a large US

technology company using anonymized building access data. We employed a two-way fixed effects model to investigate the association between an employee's presence in the office and that of their manager and teammates. Employee in-person attendance was 29% higher (7.7pp) when managers were present. Similarly, a one standard deviation increase in the share of an employee's teammates being present boosted their attendance by 16% (4.2pp). Our findings were consistent across multiple countries, emphasizing the importance of peers in driving employee attendance across different geographical and socio-cultural contexts. These empirical results provide evidence of partial coordination in hybrid work settings.

4 Ai-Enhanced Collective Intelligence: A Transactive Systems Framework

Pranav Gupta, University of Illinois, Urbana-Champaign, Champaign, IL, Contact: pranavgu@illinois.edu

AI-powered machines increasingly mediate our collective managerial, economic, and cultural actions. How do we know that such a socio-technical system as a whole, a complex web of hundreds of human-machine interactions, is performing to its potential? I discuss a holistic approach to designing and studying the dynamics of such socio-technical systems. Drawing a parallel to cognitive architectures that describe the key components and processes of an individual agent's decision-making, we describe and extend a candidate socio-cognitive architecture, the Transactive Systems Model of Collective Intelligence, that articulates the key components and processes underlying collaboration in human-AI systems.

5 Habits In Social Media Use: Entropy As A Habit Measure

Amir Tohidi[1], Dean Eckles[2], Ali Jadbabaie[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT, Cambridge, MA, [3]University of Pennsylvania, Philadelphia, PA, Contact: atohidi@mit.edu

This talk introduces an innovative methodology for quantifying habitual behavior in the context of social media usage. By leveraging entropy as an implicit measure of regularity, this study aims to uncover the intricate relationship between habit formation and digital routines. Through empirical analyses, we establish the validity of the entropy metric, demonstrating its effectiveness in capturing distinct behavioral patterns beyond mere frequency. Our results highlight the nuanced connection between entropy and future app engagement, indicating a positive association for lower entropy values and a significant decline for excessively irregular patterns. These offer practical insights for managing digital habits and advances our comprehension of how habits manifest in the digital realm and provides a robust tool for predicting long-term user behavior.

CC-West 105C

Data Science and Design Science in Information Systems

Flash Session

Session Chair: Hongyi Zhu, UT San Antonio, San Antonio, TX

Session Chair: Victor Benjamin, [1]</sup

1 Using Computational Design Science and Contrastive Self-Supervised Learning to Link Vulnerabilities and Their Remediations

Steven Ullman, University of Arizona, Tucson, AZ, Contact: stevenullman@arizona.edu

Advanced cyberinfrastructure has received millions of dollars in funding to support high-impact organizational and scientific applications. However, open-source software supporting cyberinfrastructure can contain thousands of vulnerabilities and expose cyberinfrastructure to attacks from malicious hackers. Moreover, cybersecurity analysts often struggle remediating vulnerabilities since vulnerability data is often unlabeled and incomplete. This research adopts the computational design science paradigm to develop a novel contrastive self-supervised learning-based artifact to link unlabeled vulnerabilities with their remediations. Experiment results indicate that operating in a self-supervised manner and capturing contextual text features and vulnerability metadata enhances vulnerability remediation linking.

2 Early Detection of Healthcare Misinformation

Minjia Mao, University of Delaware

The growth of the internet greatly influences the spread of misinformation in public, including healthcare misinformation. During the COVID-19 infodemic, a large amount of fake news pieces has caused social panic and weakened the effect of pandemic countermeasures. Existing automatic learning-based detection methods require manual fact-checking for labeling news instances for both true and fake. However, labeled information in healthcare in the early stage is not sufficient due to lacking labor force and expert knowledge. Consequently, our research aims to find an early detection model of healthcare misinformation by leveraging knowledge from other domains.

3 Leverage "Future Information" in Finance Market Prediction with Multi-Task Learning

Yu Zhu, University of Utah, Midvale, UT

When predicting the finance market (e.g., stock price), the predictors must come from the past, i.e., to predict the price on day *t*, we can only use data before *t*, otherwise the model will cheat. In this talk we show that it is possible to leverage "future information"—information that has predictive power on the outcome but is generated *after* time *t*—while *avoiding* cheating. For example, to predict the stock price after the release of quarterly earnings, we can use the *post*-earnings-release stock demand, since demand is strongly associated with price. To achieve that, we adopt the multi-task learning framework and use such future information as model outputs instead of inputs.

4 How Machine-Generated Ratings and Social Exposure Affect Human Reviewers: Evidence from Initial Coin Offerings

Yingxin Zhou[1], Keongtae Kim[2], Ling Xue[1], [1]Georgia State University, Atlanta, GA, [2]The Chinese University of Hong Kong, Shatin, Hong Kong. Contact: yzhou46@gsu.edu

While machine-generated information is prevalent, its impact on human ratings remains understudied. This study exams the influence of increased social exposure and different experiences on human experts' ratings relative to machine-generated ratings (MGRs) in the context of online professional ratings of initial coin offerings (ICOs). Leveraging an ICO rating platform's interface design change, we find that increased social exposure leads experts with advisor experiences to lower ratings and rate below and closer to MGRs. Besides, increased social exposure leads human experts with team member experiences to rate closer to MGRs, without significantly affecting their rating levels. Overall, increased social exposure drives human experts to conform to MGRs, possibly correcting humans' rating biases.

5 Systemic Fairness

Arindam Ray[1], Balaji Padmanabhan[1], Lina Bouayad[2], [1]University of South Florida, Tampa, FL, [2]Florida International University, Miami, FL, Contact: arindamray@usf.edu

Machine learning algorithms are increasingly used to make or support decisions in a wide range of settings. With such expansive use there is also growing concern about the fairness of such methods. Prior literature on algorithmic fairness has extensively addressed risks and in many cases presented approaches to manage some of them. However, most studies have focused on fairness issues that arise from actions taken by a (single) focal decision-maker or agent. In contrast, most real-world systems have many agents that work collectively as part of a larger ecosystem. This paper develops formalisms for firm versus systemic fairness and calls for a greater focus in the algorithmic fairness literature on ecosystem-wide fairness - or more simply systemic fairness - in real-world contexts.

6 Empirical Investigation of Software Security Vulnerabilities Present in Human and Machine Generated Code

Agrim Sachdeva, Indiana University, Bloomington, IN

Our study conducts an empirical analysis that examines potential vulnerabilities in human-generated versus machine-generated code. Using open-source machine-generated code datasets, and vulnerability scanners, we provide insights into the relative security strengths and weaknesses of machine and human generated code. Our research aims to inform safer software development practices and enhance the robustness of AI-generated code.

7 Multi-Modal Retrieval-Based Chest X-Ray Report Summarization

Xingmeng Zhao, Tongnian Wang, Anthony Rios, The University of Texas at San Antonio, San Antonio, TX, Contact: xingmeng.zhao@utsa.edu

Radiology report summarization aims to automatically provide concise summaries of radiology findings, reducing time and errors in manual summaries. However, current methods solely summarize the text, which overlooks critical details in the images. Unfortunately, directly using the images in a multimodal model is difficult. Multimodal models are susceptible to overfitting due to their increased capacity, and modalities tend to overfit and generalize at different rates. Thus, we propose a novel retrieval-based approach that uses image similarities to generate additional text features. We further employ few-shot with chain-of-thought and ensemble techniques to boost performance. Overall, our method achieves state-of-the-art performance across multiple metrics.

8 How Online Reviews Create Distortion: Uncovering the Real Demand

Wenya Shen, Arizona State University, AZ

Online shopping remains a growing market in the retail industry; however, customers face uncertainty about product attributes without the opportunity to evaluate them physically when purchasing. The uncertainty often leads to demand distortion, a scenario when customers purchase products that do not meet their expectations or fulfill their needs. Despite the severe problems caused by demand distortion, there has been a limited understanding of the formation of demand distortion and how to mitigate it. This motivates us to develop a framework that can integrate both purchase and return information to understand the source of demand distortion and the associated market outcomes. This study not only provides practical implications for adjusting firm strategies but also examines the societal impact on the environment from the counterfactual analysis.

9 Social Context Behind Visual Content - a Multimodal Approach

Shuang Gao, Victor Benjamin, Pei-yu Chen, Arizona State University, Tempe, AZ

In recent years, the trend of social media analytics has moved from text format to visual format. For visual analytics, most machine vision models are set up to recognize objects, but usually not able to understand the social context behind it. However, human readers can understand the intention and react with their likes and comments, which may contain their understanding. Therefore, we proposed to leverage the crowd wisdom from selected comments to help the machine in intention classification. The model enables practitioners to detect image threads with specific intentions. Organizations can collect product feedback and brand perceptions concerning themselves and their competitors from large volumes of data, and across vast lengths of time.

Using Data for Socially Responsible Operations

Community Committee Choice Session

Session Chair: Rakesh Reddy Mallipeddi, Th Ohio State University, Columbus, OH

Session Chair: Subodha Kumar, Fox School of Business, Temple University, Philadelphia, PA

1 Modeling Single-Donor Organ Chain Exchange: Optimization Framework for Analyzing Transplant Success

Rakesh Reddy Mallipeddi[1], Chelliah Sriskandarajah[2], Jon M. Stauffer[2], Yunxia Zhu[3], [1]Th Ohio State University, Columbus, OH, [2]Texas A&M University, College Station, TX, [3]University of Nebraska-Lincoln, Lincoln, NE, Contact: yunxia.zhu@unl.edu

An optimal matching problem to maximize transplant success rate is investigated in the context of single donor organ exchange, where one living donor's organ is transplanted to a single patient. In such exchanges, multiple medical compatibility criteria pose a serious challenge for matching a patient with compatible donor. The objective of these exchanges is to increase matching donors with patients requiring organs with maximum transplant success rate. In order to facilitate this organ matching, we use chain mechanism to increase the number of patient-donor matches with maximum success rate for patients receiving transplants. We formulate a general optimization framework for obtaining the chain that maximizes the success rate of patients receiving transplants taking into account multiple compatibility criteria.

2 AI-Powered Personalized Grocery Service

Jingchen Cao[1], Xiaowei Bao[2], Antoine Atallah[3], [1]Hungryroot, San Francisco, CA, [2]Hungryroot, Portland, OR, [3]Hungryroot, Seattle, WA, Contact: xiaowei.bao@hungryroot.com

When shopping for groceries, composing a diverse weekly shopping cart can be challenging. Here we introduce the innovative approach of Hungryroot in revolutionizing the grocery shopping experience using artificial intelligence and machine learning techniques. Our comprehensive solution encompasses a robust data collection framework, advanced statistic analysis and modeling, and a multi-objective mix-integer programming model, which adeptly balances essential objectives like taste, convenience, nutrition, cost, and suitability. In addition, this solution generates personalized offerings for groceries and recipes that cater to each customer's distinct preferences and goals, making shopping for and planning healthy food easier than ever.

3 Online Harassment Toward Transgender Across Social Media Platforms: An Examination of Victim Mental Health Using Deep Learning Methods

Siying Guo[1], Edwin (Yuchen) Wang[2], [1]Wayne State University, Detroit, MI, [2]Kean University, Union, NJ

This research aims to address the prevalent issue of online harassment (OH) towards transgender individuals by utilizing deep learning techniques to automatically identify and analyze harmful images on social media platforms. The proposed deep convolutional neural network model is developed to detect and classify various forms of OH. By examining the typologies, factors, mental health consequences, and coping strategies associated with OH, this study provides valuable insights into the experience of the transgender community. The constructed dynamic decision support system (DDSS) enables effective detection of OH while ensuring user privacy, and can inform the development of interventions, policies, and technologies.

Machine Learning in Finance

Community Committee Choice Session

Session Chair: Markus Pelger, Stanford University, Stanford, CA

1 Agent-Based Market Simulators: Mean-Field Games and Generative Adversarial Networks

Renyuan Xu, University of Southern California, Los Angeles, CA, Contact: renyuanx@usc.edu

Deep-learning-based market simulators have garnered significant attention for generating realistic financial scenarios, yet they often overlook interactions among market participants. This can lead to issues such as unrealistic back-testing performance when market impacts are ignored. In contrast, multi-agent simulation (MAS) allows for incorporating vital interactions among agents, shedding light on how the dynamics arise from traits of individuals and the underlying environment. However, the performance of existing MAS methods is limited when dealing with a large number of agents.
In this talk, we tackle the scalability challenge by applying mean-field approximations. Additionally, we employ generative adversarial networks to construct market simulators. The talk will cover both theoretical developments and empirical performance.

2 Inference for Large Panel Data with Many Covariates

Markus Pelger, Jiacheng Zou, Stanford University, Stanford, CA, Contact: jiachengzou@stanford.edu

This paper proposes a novel testing procedure for selecting a sparse set of covariates that explains a large dimensional panel. Our method provides correct false detection control while having higher power than existing approaches.
We develop inferential theory for large panels with many covariates by combining post-selection inference with a novel multiple testing adjustment. Our data-driven hypotheses are conditional on the sparse covariate selection. As an easy-to-use and practically relevant procedure, we propose Panel-PoSI, which combines the data-driven adjustment for panel multiple testing with valid post-selection p-values of LASSO. In an empirical study, we select a small number of asset pricing factors that explain a large cross-section of investment strategies. Our method dominates the benchmarks out-of-sample due to its better size and power.

3 Asset-Pricing Factors with Economic Targets

Svetlana Bryzgalova[1], Victor DeMiguel[1], Sicong Li[1], Markus Pelger[2], [1]London Business School, London, United Kingdom; [2]Stanford University, Stanford, CA, Contact: ali@london.edu

We propose a method to estimate latent asset-pricing factors that incorporates economically motivated targets for both cross-sectional and time-series properties of the factors. Cross-sectional targets may capture the shape of loadings (monotonicity of expected returns across characteristic-sorted portfolios) or the pricing span of exogenous state variables (macroeconomic innovations or intermediary-based risk factors). Time-series targets may capture overall expected returns or mispricing relative to a benchmark reduced-form model. Using a large-scale set of assets, we show that these targets nudge risk factors to better span the pricing kernel, leading to substantially higher Sharpe ratios and lower pricing errors than conventional approaches.

4 Estimating Market Liquidity from Daily Data: Marrying Microstructure Models and Machine Learning

Yuehao Dai, Ruixun Zhang, Peking University, Beijing, China. Contact: 2201110080@pku.edu.cn

We apply machine learning to estimate market liquidity by combining human-engineered liquidity proxies based on microstructure models and widely available low-frequency (daily) data. Nonlinear machine learning models can effectively estimate high-frequency spread from the raw low-frequency data alone, achieving better performances than human-engineered proxies. In addition, combining these proxies and the raw low-frequency data further improves performance. The machine learning models can be interpreted using feature importance scores, partial dependence plots, and Shapley values. The latter two show nonlinear relationships otherwise not captured by prior approaches. Our results suggest that significant improvements in liquidity estimation can be achieved by combining human knowledge and machine.

Operations Planning for Autonomous Entities

Contributed Session

Session Chair: Yiduo Huang, University of California-Berkeley, Berkeley, CA

1 A Machine Learning Enhanced Multi-Robot Path Planning Protocol for AMR Intralogistics

Zekun Liu, Seokcheon Lee, Purdue University, West Lafayette, IN, Contact: louiszekunliu@gmail.com

Multi-Robot Path Planning (MRPP) plays a critical role in the fleet management of Autonomous Mobile Robots (AMR) Intralogistics, influencing conflict incidence and informing task allocation through travel time predictions. However, traditional methods use deterministic Multiagent Pathfinding (MAPF) algorithms or assume arbitrary delay probabilities in static planning scenarios, failing to address real-world uncertainties. We propose a real-time, reservation-based MRPP protocol coupled with a machine learning-based time estimator. This innovative approach reduces replanning and timeouts, enhancing task scheduling accuracy and ensuring that AMRs execute tasks as planned.

2 Truck-Heterogeneous Sidekicks Cooperative Traveling Salesman Problem with Battery Swapping and Parcel Handover Between Delivery Robots and Unmanned Aerial Vehicles

Joohang Kang, Byoungil Choi, Joonyup Eun, Korea University, Seoul, Korea, Republic of

In the aftermath of the economic crisis following COVID-19, the unmanned delivery is still attractive due to its relatively cheap operational costs. This study proposes a model that employs a truck and heterogeneous sidekicks (i.e., delivery robots and unmanned aerial vehicles) cooperatively. The distinction of the model from the existing models is that an unmanned aerial vehicle can swap batteries and receive parcels from delivery robots as well as the truck to perform additional deliveries. In this talk, the concept and mathematical formulation are presented. In addition, a tailored heuristic to solve large number of customer cases within a reasonable computation time are proposed. The effectiveness of the model and managerial implications are demonstrated based on numerical experiments.

3 Drone-Truck Arc Routing Problem: A Single-Drone-Single-Truck Case

Sung Hoon Chung, Emad Alenany, Binghamton University, Binghamton, NY, Contact: schung@binghamton.edu

We address a Drone-Truck Arc Routing Problem (DT-ARP) for which an integer programming model is proposed. To solve the model, a heuristic method is used following the route-first, cluster-second approach in which the best combination of launch and recover nodes for each edge associated with best savings is selected. We use multiple initial truck tours and use local search (LS) and Simulated Annealing (SA) for the selection of the initial truck solution. Numerical examples are presented to discuss the effectiveness of the proposed model and heuristic for DT-ARP.

4 Flow-Based Integrated Assignment and Path-Finding for Mobile Robot Sorting Systems

Yiduo Huang[1], Zuo-Jun Max Shen[2], [1]University of California-Berkeley, Berkeley, CA, [2]University of California Berkeley, Berkeley, CA, Contact: yiduo_huang@berkeley.edu

In robotic sorting systems, mobile robots are used to sort incoming parcels by destination. In this study, we propose an integrated assignment and path-finding method for robots in such sorting systems. The method has two parts: offline and online. In the offline part, we represent the system as a traffic flow network, develop an approximate delay function using stochastic models, and solve the min-cost network flow problem. In the online part, robots are guided through the system according to the calculated optimal flow split probability. The online calculation of the method is decentralized and has linear complexity. Our method gives the approximated system-optimal traffic assignment rather than an equilibrium flow assignment. According to our simulations, our method can achieve 10%-20% higher throughput than zoning or random assignment.

Optimization of Autonomous Transportation Systems

Contributed Session

Session Chair: Sina Bahrami, University of Michigan, Ann Arbor, MI

1 Bi-Objective Optimization for Scheduling of Connected and Autonomous Vehicles at a Reservation-Based Intersection Considering Efficiency and Safety

Muting Ma[1], Zhixia Li[2], Matthew Hudnall[3], Mesut Yavuz[3], [1]The University of Alabama, Tuscaloosa, AL, [2]University of Cincinnati, Cincinnati, OH, [3]University of Alabama, Tuscaloosa, AL

Efficiency and safety at a reservation-based intersection are two conflicting objectives with respect to scheduling the connected and autonomous vehicles (CAVs). When CAVs cross the intersection as a platoon, the efficiency of the intersection improves, whereas the collision risk increases. In terms of balancing these two conflicting objectives, a bi-objective optimization model is proposed by obtaining an optimal platoon size of CAVs. An efficient frontier approach is exploited where the simultaneous maximization of efficiency and minimization of collision risk is desired. The efficient frontier is constructed via an exact dynamic programming algorithm. The optimal platoon size is obtained under different thresholds of efficiency and safety. Scheduling and trajectory planning insights for CAVs are provided in terms of grouping vehicles into a platoon.

2 Coordinated Platooning and Adaptive Routing with Reinforcement Learning

Xi Xiong[1], Maonan Wang[2], Dengfeng Sun[3], Li Jin[4], [1]Tongji University, Shanghai, China; [2]The Chinese University of Hong Kong, Shenzhen, China; [3]Purdue University, West Lafayette, IN, [4]Shanghai Jiao Tong University UM Joint Institute, Shanghai, China. Contact: xi_xiong@tongji.edu.cn

Platooning connected and autonomous vehicles has the potential to reduce both congestion and fuel consumption. While previous work has extensively examined platooning in static networks, this project delves into the interaction among vehicles and presents a reinforcement learning framework specially designed for platooning in dynamical networks. We explore coordinated platooning in conjunction with adaptive routing within networks. To achieve this, we decouple the action space and use reinforcement learning to estimate travel times for routing purposes. This estimation can subsequently be utilized in the threshold-based policy for coordinated platooning. The results obtained demonstrate the superiority of our approach compared to traditional methods, especially in dynamically changing networks.

3 Lane-Change Behavior of Human-Driven Vehicles in Mixed-Flow Traffic: A Driving Simulator Study

Yongyang Liu[1], Srinivas Peeta[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: liuyongyang@gatech.edu

Connected and autonomous vehicles (CAVs) and human-driven vehicles (HDVs) will coexist on roads in the future, creating mixed-flow traffic. The heterogeneity of HDVs' lane-change (LC) behavior can significantly impact CAV operations and degrade CAV control performance. This driving simulator-based study investigates HDVs' LC behavior in mixed-flow traffic and analyzes differences in their lane change behaviors involving HDVs and CAVs. Behavior evolution is also factored as HDVs' LC behavior may evolve after human drivers gain more experience in driving alongside CAVs.

4 Optimal Investment in Driving Automation: Onboard vs. Roadside Sensors

Mohammadamir Ahmadian[1], Sina Bahrami[2], Mehdi Nourinejad[1], Yafeng Yin[2], [1]York University, North York, ON, Canada; [2]University of Michigan, Ann Arbor, MI, Contact: sinab@umich.edu

Connected automated vehicles are a rapidly advancing technology that has the potential to revolutionize traffic. CAVs use information collected by their sensors to make motion decisions. Each CAV sensor information can be complemented by information shared by other CAVs through vehicle-to-vehicle (V2V) or roadside sensors through vehicle-to-infrastructure (V2I). Exploiting the setting of a CAV-exclusive corridor, we investigate optimal investment in roadside sensors or connectivity to minimize travel time. Our analysis shows that roadside unit investment is beneficial for low traffic flow, and when the traffic flow is over some threshold, connectivity investment to enable V2V can be more effective than roadside units.

1 Advancing Root Cause Analysis with Causal Inference Using Boosting Trees and Topological Data Analysis

Janhavi Giri[1], Attila Lengyel[1], Edward Kibardin[2], [1]Intel Corporation, Folsom, CA, [2]DataRefiner, London, United Kingdom. Contact: janhavi.giri@intel.com

Causal inference is vital across many fields, but it's challenging due to confounding effects, selection bias, and other factors. Machine learning techniques, such as boosting trees, is helpful because it handles high-dimensional data and nonlinear relationships. Topological Data Analysis (TDA) is also promising, as it uncovers complex structures and patterns in data. We propose a novel framework for causal inference that combines boosting trees and TDA. We use boosting trees to estimate causal effects and TDA to identify potential causal pathways and mechanisms. Our approach provides accurate causal inference and deeper insights into the data.

2 Using Decision Trees to Explain Machine Learning Models

Tom Grant, SAS Global Academic Program, Cary, NC, Contact: tom.grant@sas.com

Machine Learning Algorithms can be powerful tools in complex analytic models. However, using a Machine Learning Model is considered "Black Box" technique, where the relationships between inputs and target cannot be directly communicated for explanatory purposes. The appeal of using traditional statistical models (such as Regression) because the magnitude and directional impact (positive or negative) of each model input can be determined, often over-rules the use of Machine Learning models (particularly in observational studies).Using Decision Trees after a Machine Learning model is built, can help remove most of the ambiguity that comes with these "Black Box" algorithms.The combination of Machine Learning and Decision Trees allows the modeler to take advantage of the flexibility and strength of the algorithms without losing the interpretability.

3 Evaluation Imputation in a Two-Way Table of Means for Training Data Construction

Atousa Arzanipour[1], Sigurdur Olafsson[2], [1]Iowa state university, ames, IA, [2]Iowa State University, Ames, IA, Contact: arzani@iastate.edu

The process of predictive machine learning starts with a training dataset. For each of two predictor variables and a response variable, the training dataset can be converted into a two-way table where the rows and columns are each of the predictor variables and the values of each cell are the value of the response variable corresponding to those predictor variables. This two-way table can be highly sparse with a lot of missing values where each missing value represents an observation that could have been possibly made but hasn't. The values for missing observations can be constructed using imputation methods. This research study imputation methods in two-way tables to investigate how they can be used for constructing new data points when the two-way table is converted back to the training dataset then analyze how well such data construction improve quality of predictive models.

4 Optimal Feature Split in Classification Models with Dependency

Daniel B. D. Abib[1], Cristian Bravo[1], Raffaella Calabrese[2], Maria Oskarsdottir[3], [1]University of Western Ontario, London, ON, Canada; [2]University of Edinburgh, Edinburgh, United Kingdom; [3]University of Reykjavik, Reykjavik, Iceland. Contact: dbarboza@uwo.ca

In this work, we estimate a model with more than one source of dependency in the form of a multilayer graph, then develop a two-step method to split the features of a dataset into two blocks for subsequent modeling, which is necessary to avoid endogeneity. Examples of such sources of dependency could be geographical distance and money transfer between companies.We show that including multiple sources of dependency between individuals might improve the performance of classification models. For this, we combine Generalized Method of Moments estimation of spatial models with a branch and bound algorithm that searches for the best feature split, and test our methodology to measure the correlated credit risk of a set of small businesses.

5 Enhancing Machine Learning Performance with Instance-Based Data Collection

Aida Khosh Raftar Nouri, Memorial university, St Johns, NL, Canada. Contact: akhoshraftar@mun.ca

Advancements in machine learning (ML) performance are increasingly reliant on data diversity. Traditional class-based data collection methods, however, can limit this diversity due to their predefined categories and attributes, potentially leading to an inadequate representation of complex subjects. In contrast, instance-based data collection captures a more comprehensive attributes, thereby enhancing the accuracy and reliability of ML models. By identifying the most relevant attributes and potential confounders, and avoiding

overfitting, instance-based methods offer a richer data source for feature selection. Emphasizing the potential of instance-based data collection, this study highlights its role in improving ML performance across various applications, providing a more accurate, diverse, and effective approach for data gathering in the ML field.

1 Does Draft Currency Promote Competitive Balance? an Empirical Investigation of the National Football League 2002-2021

Michael A. Lapre[1], Elizabeth M. Palazzolo[2], [1]Vanderbilt University, Nashville, TN, [2]Lazard, New York, NY, Contact: m.lapre@vanderbilt.edu

In the NFL draft, teams take turns selecting entering players. The draft is a market mechanism designed to promote competitive balance as the NFL assigns draft positions to teams in reverse order relative to last season's performance. Teams frequently trade draft picks. We use several market valuations of draft picks to define original draft currency as the total value of draft picks available before any trades and final draft currency as the total value of picks used after all trades. For the 2002-2021 period, counter to the intent of the draft, we find that original draft currency does not affect the probability of reaching the playoffs, but final draft currency does. Usage of outdated market valuations by most teams can help explain how the best team has used draft-pick trades to remain among the strongest teams over two decades thereby perpetuating competitive imbalance.

2 Advances by Female Athletes from the Ancient Olympics to the Present and Fairness in Gender Inclusiveness

Raymond Stefani, California State University, Long Beach, Lake Forest, CA

In the ancient Olympics and early modern Olympics, emphasis was on men. By the 1970s, the female/male velocity ratio of Olympic champions in running and swimming reached the lean-to-weight ratio for women, indicative of reaching equal training and efficiency. Born with testosterone creating testes (which influence lean-to-weight ratio) instead of ovaries, testosterone restrictions are required of Castor Semenya and other intersex female athletes who were simply born that way. Conversely, it is quite fair to place no restrictions on muscular weight throwers and African distance runners with high lean-to weight ratios and oxygen capacity who also were born that way. It is fair to place testosterone restrictions on men transitioning to become female athletes. They are probably already undergoing hormone therapy, but it is important to make such restriction age sensitive.

3 Moving the Needle from Confusing to Consequential: Making the Most of Sports Examples in the Classroom

Keith A. Willoughby[1], Kent J. Kostuk[2], [1]University of Saskatchewan, Saskatoon, SK, Canada; [2]Engcomp, Saskatoon, SK, Canada

We enjoy deploying sports examples in the classroom. These examples enable us to discuss a key concept, enhance classroom understanding, or nurture student curiosity about the applicability of analytical approaches. Despite some students who feverishly dive into these classroom examples, we have observed challenges. For instance, a sports-based example may present a completely unknown environment to some students. We describe strategies for conveying curriculum content, while ensuring that a focus on sports examples does not deter student learning.

4 Sports Betting Markets and the Football Power Index

Thomas Robbins, East Carolina University, Greenville, NC

Major analytics organizations have developed and promoted a predictive model known as a Football Power Index. In this talk we examine 2 models, the ESPN FPI, and the 538.com ELO model. We discuss how they work, how accurate they are, and how they fare relative to sport betting markets. We investigate what they tell us about semi-strong efficiency in sports betting markets.

1 Revenue Management in Video Games and with Fairness

Xiao Lei, University of Hong Kong, New York, NY

Video games are the largest and fastest-growing segment of the entertainment industry, yet have received limited attention from the operations community. This thesis explores revenue management and matchmaking problems in video games, focusing on loot boxes, player engagement, and fairness issues. We consider optimal pricing and design of loot boxes, aiming to maximize revenue while providing customer protection. We also explore managing player engagement through optimal matchmaking policies and AI bots, using optimization and real data. Finally, we address the inequality induced by price discrimination in e-commerce platforms, considering fairness regulations and their impact on social welfare.

2 Social Choice for Social Good: Proposals for Democratic Innovation from Computer Science

Paul Gölz, Cornell University, Ithaca, NY

Driven by shortcomings of current democratic systems, practitioners and political scientists are exploring democratic innovations, i.e., institutions for decision-making that more directly involve constituents. In this thesis, we support this exploration via three approaches: we design practical algorithms for use in democratic innovations, we mathematically analyze the fairness properties of proposed decision-making processes, and we identify extensions of such processes that satisfy desirable properties

3 Uncertainty in Service Systems: Performance Measure Estimation and Optimization Methods for Contact Centers with Information Uncertainty

Antonio Castellanos, Israel Institution of Technology, Haifa, Israel

In the quest to improve services, companies offer customers the opportunity to interact with their agents using texting. This has become a favorite channel of communication for customers with companies. However, text-based contact centers face operational challenges. Via data analysis of two North American contact centers, we find that the usual ways of analyzing and measuring quality in call centers give biased estimations of performance levels. The reason for this is the way customers and employees behave in these systems, which creates various types of information uncertainty. In this thesis we identify the main sources of such uncertainty and develop methods to cope with them. We do this by combining statistical and optimization methods.

4 Experimental Design and Decision-Making in Marketplace Platforms

Hannah Li, Columbia, New York, NY

Online platforms rely on experiments to aid decision-making. However, in marketplace platforms, prior work shows that treatment effect estimates can be biased due to interference, or users interacting with each other. This dissertation develops a structural modeling method to study interference in marketplace experiments. The work finds two main results that are helpful for practitioners: (1) Supply and demand imbalance balance is a primary factor determining which side of the market (supply or demand) should be randomized to minimize bias. (2) The work introduces a novel experimental design using Two-Sided Randomization and associated estimators that achieve relatively low bias in a wide range of supply and demand imbalance regimes.

5 Adaptivity, Structure, and Objectives in Sequential Decision-Making

Sean Sinclair, Massachusetts Institute of Technology, Cambridge, MA

We will consider designing methods for sequential decision-making (bandits, reinforcement learning) that leverage auxiliary data sources (imitation learning, exogenous datasets, geometric assumptions) based on the themes of adaptivity, structures, and objectives. We will specialize this framework in areas including memory management, fair resource allocation, and cloud computing. Central to this, we will additionally discuss our open-source code instrumentation and methodology to analyze the multi-criteria performance of algorithms on these problems.

1 The Power of Simple Menus in Robust Selling Mechanisms

Shixin Wang, The Chinese University of Hong Kong, Hong Kong, China

We study the robust screening problem with a finite menu size. Our framework characterizes the optimal selling mechanisms and the corresponding competitive ratio across various menu sizes and ambiguity sets of the buyer's valuation distributions, such as support, mean, and quantile ambiguity sets. We show that a selling mechanism with a small menu already yields a competitive ratio comparable to the optimal robust mechanism with infinite options in the menu. Remarkably, a menu size of merely two can significantly enhance the competitive ratio compared to deterministic pricing, which establishes a favorable trade-off between theoretical performance and implementation simplicity.

2 Compact Formulations for Low-rank Functions with Indicator Variables

Andres Gomez, University of Southern California, Los Angeles, CA

We study the mixed-integer epigraph of a special class of convex functions with nonconvex indicator constraints, which are often used to impose logical constraints on the support of the solutions. The class of functions we consider are defined as compositions of low-dimensional nonlinear functions with affine functions. Extended formulations describing the convex hull of such sets can easily be constructed via disjunctive programming, although a direct application of this method often yields prohibitively large formulations, whose size is exponential in the number of variables. In this paper, we propose a new disjunctive representation of the sets under study, which leads to compact formulations with size exponential in the dimension of the nonlinear function, but polynomial in the number of variables. Moreover, we show how to project out the additional variables for the case of dimension one, recovering or generalizing known results for the convex hulls of such sets (in the original space of variables). Our computational results indicate that the proposed approach can significantly improve the performance of solvers in structured problems.

3 Quantifying Spatial Under-reporting Disparities in Resident Crowdsourcing

Nikhal Garg, Cornell Tech, New York, NY

Modern city governance relies heavily on crowdsourcing to identify problems such as downed trees and power-lines. A major concern is that residents do not report problems at the same rates, with heterogeneous reporting delays directly translating to downstream disparities in how quickly incidents can be addressed. Measuring such under-reporting is a difficult statistical task, as, by definition, we do not observe incidents that are not reported or when reported incidents first occurred. Thus, low reporting rates and low ground-truth incident rates cannot be naively distinguished, and reporting delays are unobserved. We develop a method to identify (heterogeneous) reporting delays, without using external ground truth data. Our insight is that rates on duplicate reports about the same incident can be leveraged to disambiguate whether an incident has occurred with its reporting rate once it has occurred. Using this idea, we reduce the question to a standard Poisson rate estimation task -- even though the full incident reporting interval is also unobserved. We apply our method to over 100,000 resident reports made in New York City and to over 900,000 reports made in Chicago, finding that there are substantial spatial disparities in how quickly incidents are reported, even after controlling for incident characteristics -- some neighborhoods report three times as quickly as do others. These spatial disparities correspond to socio-economic characteristics: in NYC, higher population density, fraction of people with college degrees, income, and fraction of population that is White all positively correlate with reporting rates. Finally, leveraging a collaboration with the NYC Department of Parks and Recreation, we demonstrate how estimating reporting delays leads to practical insights and interventions for more equitable, efficient government service.

Innovative Healthcare Service Delivery Models

Contributed Session

Session Chair: Marco Bijvank, University of Calgary, Calgary, AB, Canada

1 Insurance Coverage for Telehealth Services and Analysis of Appointment Scheduling Metrics for Selected Healthcare Specialties

Aysenur Betul Cengil, Burak Eksioglu, Sandra D. Eksioglu, University of Arkansas, Fayetteville, AR

The COVID-19 pandemic triggered policy changes in 2020, allowing insurance companies to reimburse telehealth services, which led to increased telehealth use. However, with many emergency rules ending in 2022, there is a concern about a potential decrease in telehealth services. This study examines telehealth use in Arkansas from 2020 to 2022. We employed statistical tools to compare the number of telehealth and in-person visits for specific specialties and investigated insurance coverage trends for each. Our evaluation also included a procedure to calculate appointment performance metrics such as waiting time and appointment length. We presented our results for specific specialties to highlight the potential benefits of telehealth.

2 Telemedicine: Not Just If, But How It Bridge Healthcare Equity

Saif Benjaafar[1], Xiaonan Li[2], Hai Wang[3], Xiaotang Yang[1], [1]University of Minnesota, Minneapolis, MN, [2]Tongji University, Shanghai, China; [3]Singapore Management University, Singapore, Singapore. Contact: 1830336@tongji.edu.cn

Disparities in the distribution of healthcare resources have long created a chasm between urban and rural hospitals. Urban hospitals suffer from overcrowding, while their rural counterparts face underutilization. In this study, we leverage a queueing game model to delve into patients' choices, considering factors such as the hospital's critical care capability, travel costs, waiting durations, and patients' health perceptions. Our findings underscore the potential of telemedicine to re-balance this inequity. By channelling a portion of the urban hospital's capacity to serve rural patients via telemedicine, urban congestion can significantly decrease. Our research further elucidates the conditions required for this rebalance and offers actionable insights for optimizing telemedicine integration, ensuring both societal benefit and healthcare equity.

3 Managing Capacity Reservation for Low-Priority Strategic Patients

Guanlian Xiao[1], Marco Bijvank[2], [1]Vrije Universiteit Amsterdam, Amsterdam, Netherlands; [2]University of Calgary, Calgary, AB, Canada. Contact: marco.bijvank@haskayne.ucalgary.ca

We study a healthcare system that operates two parallel tracks, i.e., a shared track and a dedicated track, to serve two priority classes of patients. High-priority patients are assigned to the dedicated track for prompt service following a FCFS principle. When the dedicated track is relatively busy, high-priority patients are diverted to the shared track with a non-preemptive priority over low-priority patients. Low-priority patients are strategic, and they choose to join the waiting queue on the shared track, or to balk from the system. Their join-or-balk decision is made based on the utility of joining after obtaining delay information. In our study, we consider two types of expected waiting time information to be revealed to low-priority patients: long-term expected waiting time, and real-time expected waiting time.

Session Chair: Ashish Chandra, Illinois State University, Bloomington, IL

1 Enhancing State-Level Unemployment Rate Forecasts Using Google Trends Data

Levent Bulut[1], Islam Rizvanoghlu[2], [1]University of North Texas, Frisco, TX, [2]NRG Energy, Houston, TX

In this study, we incorporate the generalized additive model (GAM) into the time-series models to forecast and nowcast the monthly state-level unemployment rate statistics in the U.S. from January 2004 to April 2023. Our focus is on utilizing Google Trends data, which provides real-time, high-frequency, and state-specific information. As job search is a requirement for eligibility to receive unemployment insurance benefits in 49 out of the 50 states, we explore whether Google Trends data can enhance the accuracy of state-level unemployment rate forecasts compared to data on initial claims and other factors. Our findings indicate a significant correlation between searches for unemployment-related phrases and state-level unemployment rates

2 A Study on Distributionally Robust Optimization with Changeable Ambiguity Sets

Zhengsong Lu[1], Bo Zeng[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: zs.lu@pitt.edu

We study DRO (Distributionally Robust Optimization) models with complex ambiguity sets that can be modified, including those defined by moment inequities and the Wasserstein metric.

3 Bayesian Kernelized Tensor Factorization as Surrogate for Bayesian Optimization

Lijun Sun, McGill University, Montreal, QC, Canada. Contact: lijun.sun@mcgill.ca

4 A Generative Neural Network Based Surrogate Model for Displacement Estimation for Topology Optimization in B-Spline Space

Congfang Huang, UW Madison, Madison, WI, Contact: chuang286@wisc.edu

This work establishes a generative neural network-based surrogate model for estimating displacements in topology optimization within the B-spline space. The model aims to improve the efficiency of the optimization process by providing accurate displacement predictions.

5 Risk Minimization for Network Traffic Engineering

Ashish Chandra[1], Mohit Tawarmalani[2], [1]Illinois State University, Bloomington, IL, [2]Purdue University, West Lafayette, IN, Contact: achand6@ilstu.edu

We introduce a new two-stage model for integrated quantile functions. This framework leads to a bilinear optimization problem (P), a special case of which reveals a new model for the VaR minimization problem. We discuss various techniques to under- and over-estimate the optimal value of (P), in turn developing new lower and upper-estimators for VaR. We also consider chance-constraint programs (CCP). Utilizing the overestimates we construct for (P), we develop convex inner approximations for the CCP.

1 Estimating Demand for Crowdsourcing the Last-Mile Delivery in Rural Areas (North Dakota) Using Optimization Techniques for Commuters from Urban Areas

Sumadhur Shakya[1], Joseph Gerard Szmerekovsky[2], [1]California State University Monterey Bay, Seaside, CA, [2]North Dakota State University, Fargo, ND, Contact: sshakya@csumb.edu

We estimate the feasibility of crowdsourcing commuters from urban areas for making deliveries to rural areas of North Dakota. Origins are consolidated pickup points from the nearest urban center while a set of rural areas where a certain percentage of the population receives frequent deliveries, as the destinations. Demand is estimated with random assignment of drivers, origins, destinations, etc. Commuter attributes such as compensation, and increased travel time/distance, are used to predict the number of potential drivers that can be crowdsourced to make deliveries. Finally, we propose a matching process to pair the willing commuters with packages for delivery, aiming to optimize a cost or profit function and/or maximize the number of packages delivered. This matching strategy is likely to minimize costs and increase overall efficiency in the delivery process.

2 Enabling Electric Cooking Supply Chain Using Digital Twin

Sanket Mishra, Jayendran Venkateswaran, Indian Institute of Technology Bombay, Mumbai, India. Contact: jayendran@iitb.ac.in

Digital twin is used to help activate a sustainable supply chain (SC) for electric cooking in rural India. A system dynamics simulation model was initially developed incorporating material, information & cash flows of a local SME & its distribution network. The SC network provides IoT-based electric induction stoves with cookware to rural households and help their transition from biomass cooking to e-cooking. Simulation based risk analysis of demand-side & supply-side interventions (behavior nudging, consumer finance, awareness, service network, carbon credits) was done to develop a 2-year business plan. The digital twin then monitors SC network performance & aids in rapid plan-do-check-act cycles to maximize profit & household adoptions. Digital twinning process, along with learnings from the implementation will be discussed.

3 Appointment Interval Sizing at a Pediatric Dentistry

Yao Li[1], Jan A. Van Mieghem[2], Itai Gurvich[3], [1]Kellogg, Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, [3]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: yao.li@kellogg.northwestern.edu

We look for the best appointment length to minimize patient waiting time and care provider idleness and overtime in slot-based appointment systems. As a benchmark, we consider the stationary problem utilizing the limiting distribution in a D/G/1 queue. In practice, professional offices (such as dental clinics) start the day empty and exhibit substantial transient behavior. (In fact, in the pediatric dental clinic we studied, steady state is never approached.) Therefore we focus on transient analysis, derive analytically the optimal appointment length in a recursive form and shows the optimal length grows as patient number in the system increases. Real-world data from a pediatric dentistry clinic is used, extending results to multiple patient classes.

The Electric Grid in Evolution: Data, Optimization, and Risk-Taking

Keynote Session

1 The Electric Grid in Evolution: Data, Optimization, and Risk-Taking

Daniel Bienstock, Columbia University, New York, NY

Power systems i.e., power grids around the world are now in the midst of an accelerating change that will deliver far more knowledge- and data-aware operations in the coming decade. This evolution is spurred by a need for more investment as equipment ages, by increased consumption of power around the world, and, principally, by increased volatility in real-time behavior due to ramped-up renewable penetration and to participation in power systems by prosumers, i.e., entities that can both generate and consume power. The latter two factors contribute correlation patterns that may be opaque to traditional power systems operators. In this talk we will discuss the state-of-the-art of a number of critical technical areas in this domain, including the computation of power flow patterns (a nonlinear, nonconvex optimization problem), financial engineering aspects already seen today, and appropriate data science that can be harnessed to effectively stress test power system operations.

Sunday, October 15, 5:25 PM - 6:15 PM

Making Good Decisions with Wrong Models

Keynote Session

1 Making Good Decisions with Wrong Models

Jose Blanchet, Stanford University, Stanford, CA

Our capacity to access massive data sets and computing resources at scale has enabled the application of OR/MS methods in data driven decision making. But what is the impact of decisions that are made when the data is corrupted or possibly contains anomalies? Or when the deployment/prescription environment is different from the training/learning environment? These situations appear similar in the sense that direct data driven OR/MS approaches lead to making decisions based on wrong models, but, as we shall discuss, they are fundamentally different conceptually. In this talk, we will discuss the differences and provide a disciplined yet practical approach to dealing with these types of problems.

1 Optimizing Walmart's Outbound Supply Chain from Strategy to Execution - A Grocery Case Study

Mingang Fu[1], Tiantian Nie[2], Xiaojie Wang[2], Jing Huang[2], Prakhar Mehrotra[2], [1]Walmart, Palo Alto, CA, [2]Walmart, Sunnyvale, CA

As the largest retail distribution operation in the US, Walmart has always been at the forefront of building optimization capabilities to empower its supply chain from strategy to execution. A set of scalable optimization models have been adopted to determine the optimal network and transformational roadmap for the next decade. For daily operations, a truck routing and load planning optimization system was built. With grocery network alone, the strategy work impacts at least $10 billion investment in transformation, and the system contributes $60 million direct savings in year 2022.

Sensitivity Analysis

Tutorial Session

Session Chair: Douglas R. Shier, Clemson University, Pittsboro, NC

1 Sensitivity Analysis

Emanuele Borgonovo, Bocconi University, Milano, Italy

A primary activity in operations research and the management sciences is the creation of quantitative models to support decision making. The presence of complex architectures, makes tools for explainability and interpretability essential to reinforce stakeholders' trust in the model forecasts and increase transparency. This tutorial reviews the role of sensitivity analysis as a toolset for interpreting and communicating model results. We examine the evolution of sensitivity analysis in the management sciences and analyze available methods through the lens of four primary analysis goals: factor prioritization (or feature importance), trend determination, interaction quantification, and stability (robustness). We present a variety of techniques, starting with local methods and moving on to global methods.

Provalis Research

Technology Tutorial

1 Machine Learning in Text Analytics: Do We Really Need Deep Learning?

Normand Peladeau, Provalis Research, Montreal, QC, Canada. Contact: npeladeau@provalisresearch.com

The renewed enthusiasm for artificial intelligence (A.I.) and, more particularly, for techniques based on deep learning and other forms of neural networks, means that we are trying to apply these latest techniques to all problems requiring a supervised or unsupervised form of learning. But this unprecedented wave of interest often makes us forget there are other forms of machine learning that have proven themselves over time. During this presentation we will compare certain forms of machine learning with and without the contribution of neural network techniques in order to assess the importance and the nature of a possible contribution (if any). To do this, we will examine different tasks in the field of automatic language processing, namely topic modeling, automatic word disambiguation, and the development of semantic lexicons. We will also try to identify in which context an approach based on neural networks or deep learning deserves consideration.

Monday, October 16, 8:00 AM - 9:15 AM

Frontiers of Adaptive Learning and Approximations for Sequential Experiments

Community Committee Choice Session

Session Chair: Anand Kalvit, Columbia Business School, New York, NY

1 Experimenting Under Stochastic Congestion

Xu Kuang[1], Shuangning Li[2], Ramesh Johari[3], Stefan Wager[4], [1]Stanford Graduate School of Business, Stanford, CA, [2]Harvard, Cambridge, MA, [3]Stanford University, Stanford, CA, [4]Stanford GSB, Stanford, CA

While randomized experiments have been effective in gaining causal insights and prescribing policy improvements in many domains, using them to study stochastic congestion has proven challenging. In this work, taking a standard queueing system as a benchmark model of congestion, we study how to conduct randomized experiments in a service system that has a single queue with an outside option. We study switchback experiments and a local perturbation experiment, and demonstrate that the estimator from the local perturbation experiment is asymptotically more accurate than the estimators from the switchback experiments by taking advantage of the structure of the queueing system.

2 Diffusion Approximations for Online Content Moderation

Amir A. Alwan, Rene A. Caldentey, Amy R. Ward, Tingrui Shi, The University of Chicago Booth School of Business, Chicago, IL, Contact: amir.alwan@chicagobooth.edu

The surge in user-generated content on social media platforms has made online content moderation an increasingly challenging problem. To effectively moderate online content, most platforms rely on both artificial intelligence (AI) and human moderators. The AI system is trained using labels assigned by human moderators in order to improve its content classification accuracy. We adopt a Bayesian learning and queueing framework to model the online content moderation problem. In a regime of high frequency and low informativeness, we derive a diffusion approximation for our model and investigate the trade-off between the speed of learning of different content types and the operations of managing a human moderation system.

3 Optimal Policies in Bandit Experiments

Karun Adusumilli, University of Pennsylvania, Heidelberg

We provide a decision theoretic analysis of bandit experiments. Using diffusion asymptotics, we define suitable notions of asymptotic Bayes and minimax risk. For normally distributed rewards, the minimal Bayes risk can be written as the solution to a 2nd-order partial differential equation (PDE). Using a limit of experiments approach, we show that this PDE characterization also holds asymptotically under both parametric and non-parametric distributions of the rewards. In doing so, we describe the state variables it is asymptotically sufficient to restrict attention to, and thereby suggest a strategy for dimension reduction. The PDEs characterizing minimal Bayes risk can be solved efficiently using sparse matrix routines. The optimal Bayes and minimax policies substantially dominate existing methods such as Thompson sampling and UCB, often by a factor of two.

4 Improved Asymptotics for Multi-Armed Bandit Experiments Under Optimism-Based Policies

Anand Kalvit[1], Assaf Zeevi[2], [1]Stanford University, Stanford, CA, [2]Columbia University, New York, NY

This work provides new asymptotic results for UCB-based multi-armed bandit algorithms, leading to several important insights. Among these, it is shown that arm-sampling rates under classical UCB are asymptotically deterministic, regardless of the problem complexity. This discovery facilitates the first complete characterization of the worst-case regret of UCB, as well its “diffusion limit” performance. Among other things, these findings reveal profound distinctions between UCB and Thompson Sampling such as an “incomplete learning” phenomenon characteristic of the latter.

Learning against Uncertainty in Revenue Management

Community Committee Choice Session

Session Chair: Mingxi Zhu, Stanford University, Stanford, CA

1 Bayesian Demand Learning and Revenue Management Under Limited Capacity

Mihalis Markakis[1], Marcos Serrano-Mayor[2], [1]IESE Business School, Barcelona, Spain; [2]Stanford University, Stanford, CA, Contact: marcossm@stanford.edu

Under limited capacity, the optimal price and quantity decision is primarily driven by the total demand rate during the sales season. When demand is unknown, the seller may need adjust its revenue management policy over time as it learns the arrival rate. We formulate the dynamic optimization problem under Bayesian learning. We solve it analytically when there is one unit of capacity for sale, and develop effective heuristics for the multi-unit case. Surprisingly, we find that lack of information pushes the seller to opt for a low-volume, high-margin position for a longer time, and only reduce margins close to the end of the season, as opposed to earlier which would accelerate learning.

2 Sequential Search with Acquisition Uncertainty

David Brown, Cagin Uru, Duke University, Durham, NC, Contact: cagin.uru@duke.edu

We study a variation of the classical Pandora's problem in which a decision-maker (DM) sequentially explores alternatives from a given set and learns their values while trying to acquire the best alternative. The variations in the model we study are (i) alternatives randomly become unavailable during exploration and (ii) the DM's ability to acquire a remaining alternative is uncertain and depends on a chosen offer price. Such acquisition uncertainties arise in many applications, including housing search, hiring problems, and e-commerce, but greatly complicate the search problem. We develop simple greedy policies based on static sequencing and a single threshold value. We show that our policies (a) are asymptotically optimal in high multiplicity regimes with many alternatives and (b) obtain at least 1-1/e ≈ 63.2% of the optimal value under a broad set of conditions.

3 Robust Mean Field Control in Revenue Management

Sirui Lin, Stanford University, Stanford, CA, Contact: siruilin@stanford.edu

Our method provides a robust strategy with mean field control and applies to the revenue management of a large number of objects.

4 Data Sharing Under Competition

Mingxi Zhu, Stanford University, Stanford, CA

The advent of the digital era has brought about an exponential growth in data generation, leading to a significant rise in the value and importance of data for firms across industries. With the increasing recognition of data as a strategic asset, firms are confronted with the decision of whether to share their data with competitors, thereby potentially compromising their competitive advantage, or withhold it to maintain exclusivity at the expense of potential collaborative benefits. This paper proposes a novel model that investigates how market competition influences firms' data sharing incentives and decisions, and provides equilibrium data sharing and contingent competition strategies for firms competing in the same market. The results presented in this paper provide insights for firms seeking to optimize their data sharing decisions in competitive markets.

Recent Advances in Online Learning and Data-Driven Decision Making

Community Committee Choice Session

Session Chair: Divya Singhvi, New York University, New York, NY

1 The Multi-Armed Bandit Problem with K Types

Anand Kalvit[1], Assaf Zeevi[2], [1]Stanford University, Stanford, CA, [2]Columbia University, New York, NY, Contact: ak4076@columbia.edu

We consider a stochastic multi-armed bandit (MAB) problem endowed with a "large" collection of arms containing exactly K arm-types. Each type is characterized by a distinct mean reward and occurs with an unknown probability in the universe. Furthermore, the type of an arm remains unobservable throughout the game. Oblivious to statistical properties of realized rewards (other than [0,1]-boundedness), the decision maker must maximize her cumulative expected payoffs over n rounds of play. While the description suggests a great degree of similarity to the classical MAB problem, properties of performance bounds and salient aspects of algorithm design are quite distinct from the latter, as are key primitives that determine complexity along with the analysis tools needed to study them. We propose adaptive algorithms for this setting achieving rate-optimal "regret" w.r.t. n.

2 The Product Replacement Problem in Fashion: Addressing Manager Behavior and Demand Uncertainty

Manuel Manuel Moran-Pelaez[1], Tamar Cohen-Hillel[2], Georgia Perakis[3], [1]MIT Operations Research Center, Cambridge, MA, [2]UBC Sauder School of Business, Vancouver, BC, Canada; [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: georgiap@mit.edu

Fast fashion retailers offer a wide range of trendy options that are updated frequently. The quick turnover translates into the need to make swift and frequent assortment and inventory decisions to optimize profit. We refer to this as the product replacement problem. The problem involves two decision-makers, with headquarters introducing new items and store managers deciding which current items to remove. We develop optimal and interpretable policies for both decision-makers by accounting for different incentives and uncertainties around the other party's behavior and demand. We show an improvement of 6%-8% in profit when incentives are aligned and of 2%-4% when headquarters adopt a pessimistic policy in terms of manager's behavior.

3 Temporal Fairness in Learning and Earning: Price Protection Guarantee and Phase Transitions

Qing Feng, Cornell University, Ithaca, NY, Contact: qf48@cornell.edu
Motivated by the prevalence of "price protection guarantee", which allows a customer who purchased a product in the past to receive a refund from the seller during the price protection period, we study the impact of such policy on algorithm design for dynamic pricing with initially unknown demand. We consider a setting where a firm sells a product over a horizon of T time steps. For this setting, we characterize how the value of M, the length of price protection period, can affect the optimal regret of the learning process. We first establish the optimal regret by first establishing a fundamental impossible regime with novel regret lower bound instances, then propose an algorithm LEAP to match this lower bound up to logarithmic or even doubly logarithmic factors (under the two-price case). Our results reveal the surprising phase transitions of the optimal regret with respect to M.

4 The Effects of Organic Waste Bans: An Analysis of U.S. Waste Disposal from 2005-2020

Fiori Anglou[1], Robert E. Sanders[2], Ioannis Stamatopoulos[3], [1]University of Texas Austin, Austin, TX, [2]UC, San Diego, Los Angeles, CA, [3]The University of Texas at Austin, McCombs School of Business, Austin, TX, Contact: fiori.anglou@mccombs.utexas.edu
We estimate the effects of organic waste bans on waste diversion from landfills using annual county- and state-level waste-disposal and composting data from 36 U.S. states from 2005 to 2020. This is the first study that empirically studies the effect of organic waste bans. We use a synthetic controls design and placebo inference to estimate the statistical power of the dataset. Using synthetic controls we estimate the treatment effects and compare them against the expected regulatory effect. Contrary to policymakers' expectations, we find evidence of a null effect of the bans on total waste diverted from landfills. Our findings suggest that current organic waste bans may not effectively reduce waste disposal as expected or promote waste diversion, namely composting, indicating a need for further research on alternative policy mechanisms.

New Frontiers in Online Ad Auctions

Community Committee Choice Session

Session Chair: Yeganeh Alimohammadi, Stanford University, Stanford, CA

1 Multi-Channel Autobidding with Budget and Roi Constraints

Yuan Deng[1], Negin Golrezaei[2], Patrick Jaillet[3], Jason Cheuk Nam Liang[4], Vahab Mirrokni[5], [1]Google, NYC, NY, [2]MIT, Cambridge, MA, [3]M.I.T., Cambridge, MA, [4]MIT Operations Research Center, Cambridge, MA, [5]Google Research, New York, NY
In online advertising, advertisers procure ad impressions on multiple platforms, or so-called channels, such as Google Ads, Meta Ads Manager, etc., each of which consists of numerous auctions. We study how an advertiser maximizes total conversion while satisfying aggregate return-on-investment (ROI) and budget constraints across all channels. In practice, an advertiser authorizes a channel to procure impressions on her behalf: the advertiser can only utilize two levers on each channel, namely setting a per-channel budget and per-channel target ROI. In this work, we first analyze the effectiveness of each of these levers for solving the advertiser's global multi-channel problem. We then present an efficient learning algorithm that produces per-channel budgets and target ROI whose resulting conversion approximates that of the global optimal problem.

2 Auction Design in the Auto-Bidding World

Andres Perlroth, Google Research
Over the past few years, more and more Internet advertisers have started using automated bidding to optimize their advertising campaigns. This enables advertisers to simply provide high-level constraints and goals to an automated agent (a.k.a auto-bidder), which optimizes their auction bids on their behalf. The auto-bidders objective is to maximize value instead of profits which makes classic results in auction design no longer applicable to this context. In this talk, we focus on important results of auction design in the auto-bidding world. We discuss how bidding is related to the truthfulness property of the auctions; how different auctions might affect advertisers' incentives in reporting their constraint to the auto-bidders. We also discuss how the presence of auto-bidders affects optimal auction design in the multi-channel setting.

3 Modeling Pricing Strategies for Subscriptions in Service-Based Industries

Rojin Rezvan, University of Texas at Austin, Austin, TX
Subscription-based selling models are popular in many service-based industries, providing the customers with different options to access services such as streaming, delivery, etc. In this work, we explore how customers behave

when they have options to buy subscriptions over a period of time, or pay per use. We analyze how the sellers should optimally price these options, and examine the distribution of customer purchases between these two sources. We propose ways to model buyer behavior, regarding utility and willingness to pay for services by considering factors such as value of service, usage patterns, budget constraints and past purchases. Furthermore, we address the seller's perspective and discuss how the seller should set the prices for pay-per-use and subscription, and whether it is best to provide each or both of them when the objective is maximizing revenue.

4 Improved Online Contention Resolution For Matchings And Applications To The Gig Economy

Mohammad Roghani[1], Tristan Pollner[1], Amin Saberi[1], David Wajc[2], [1]Stanford University, Stanford, CA, [2]Google Research, Mountain View, CA, Contact: roghani@stanford.edu

Motivated by applications in the gig economy, we study approximation algorithms for a sequential pricing problem. Given a bipartite graph of workers and jobs, the platform offers prices to workers for job matches. Our aim is to maximize revenue or social welfare. We propose an efficient Random-Order Online Contention Resolution Scheme (RO-OCRS) approximation algorithm for matching. This yields a 0.456-approximation for the sequential pricing problem. We further extend our results to settings where workers can only be contacted a limited number of times and show how to achieve improved results for this problem.

Experimentation in Industry

Community Committee Choice Session

Session Chair: Andrew T. Zheng, Massachusetts Institute of Technology, Boston, MA

Session Chair: Tianyi Peng, Massachusetts Institute of Technology, Cambridge, MA

1 Optimizing Audio Recommendations for the Long-Term

Daniel Russo, Columbia University, New York, NY

We study the problem of optimizing a recommender system for outcomes that occur over several weeks or months. We begin by drawing on reinforcement learning to formulate a comprehensive model of users' recurring relationships with a recommender system. Measurement, attribution, and coordination challenges complicate algorithm design. We describe careful modeling -- including a new representation of user state and key conditional independence assumptions -- which overcomes these challenges and leads to simple, testable recommender system prototypes. We apply our approach to a podcast recommender system that makes personalized recommendations to hundreds of millions of listeners. A/B tests demonstrate that purposefully optimizing for long-term outcomes leads to large performance gains over conventional approaches that optimize for short-term proxies.

2 Experimentation and Beyond at ByteDance

Xinyuyang Ren, Huang Yang, ByteDance Inc., San Jose, CA

At ByteDance, its in-house experimentation platform has successfully leveraged the power of null-hypothesis significance testing to prompt data-driven decision making that fostered products like TikTok, Lemon8, Douyin and etc. to reach their popularity as of today. In the meantime, the platform is also facing growing challenges of conducting experiments in complex environments with interference, high-dimensional bandits, and infeasibility of randomization. ByteDance has been searching for dynamic, automatic, and observation-friendly solutions with a few that have been in production and demonstrated business values.

3 Correcting for Interference in Experiments: A Case Study at Douyin

Tianyi Peng, Massachusetts Institute of Technology, Cambridge, MA

Interference is a common issue in experiments on two-sided content marketplaces like Douyin (China's TikTok equivalent). We address this problem by formulating interference inference as policy evaluation. We propose a novel Monte-Carlo estimator, utilizing "Differences-in-Qs" (DQ) techniques. Our estimator achieves second-order bias in treatment effect while being sample-efficient. Theoretical contributions include a generalized Taylor expansion theory extending DQ to major MDP formulations. On the practical side, we implement our estimator on Douyin's platform, creating a plug-and-play solution for real-world interference. It offers robust, low-bias, low-variance treatment effect estimates, computationally cheap uncertainty quantification, and reduces MSE by 99% compared to existing alternatives.

Learning and Optimization in Nonstationary Environments

Community Committee Choice Session

Session Chair: Daniel Russo, Columbia University, New York, NY

Session Chair: Seungki Min, KAIST, Yuseong-gu, Korea, Republic of

1 An Information-Theoretic Analysis of Nonstationary Bandit Learning

Seungki Min[1], Daniel Russo[2], [1]KAIST, Daejeon, Korea, Republic of; [2]Columbia University, New York, NY, Contact: skmin@kaist.ac.kr

In nonstationary bandit learning problems, the decision-maker must continually gather information and adapt their action selection as the latent state of the environment evolves. In each time period, some latent optimal action maximizes expected reward under the environment state. We view the optimal action sequence as a stochastic process, and take an information-theoretic approach to analyze attainable performance. We bound limiting per-period regret in terms of the entropy rate of the optimal action process. The bound applies to a wide array of problems studied in the literature and reflects the problem's information structure through its information-ratio.

2 Non-Stationary Bandit Learning via Predictive Sampling

Benjamin Van Roy[1], Yueyang Liu[1], Kuang Xu[2], [1]Stanford University, Stanford, CA, [2]Stanford Graduate School of Business, Stanford, CA

Thompson sampling has proven effective across a wide range of stationary bandits. However, we demonstrate that it may not perform well when applied to non-stationary bandits. We attribute such failures to the fact that the algorithm does not account for how quickly acquired information loses its usefulness due to non-stationarity. Based on this insight, we propose methods to create algorithms that prioritize the acquisition of durable information and deprioritize information that quickly loses its usefulness. Predictive sampling is one example of such an algorithm. We establish a Bayesian regret bound that applies to any agent, and subsequently apply it to predictive sampling. Notably, the regret bound depends on a concept we call predictive information, which measures the cumulative amount of durable information.

3 Multi-Armed Bandit Meets Time Series Forecasting

Djallel Bouneffouf[1], Qinyi Chen[2], Negin Golrezaei[3], [1]IBM Research, New York, NY, [2]MIT, Cambridge, MA, [3]Massachusetts Institute of Technology, Lexington, MA, Contact: djallel.bouneffouf@ibm.com

Multi-armed bandit (MAB) problems are mainly studied under two extreme settings known as stochastic and adversarial. These two settings, however, do not capture realistic environments such as search engines and marketing, in which rewards stochastically change in time. Motivated by that, we introduce a dynamic MAB problem with stochastic temporal structure, where the expected reward of each arm is governed by an auto-regressive (AR) model. Due to the dynamic nature of the rewards, simple "explore and commit" policies fail, as all arms have to be explored continuously over time. We formalize this by characterizing a per-round regret lower bound. We present an algorithm whose per-round regret almost matches our regret lower bound. Our algorithm relies on two mechanisms: (i) alternating between recently pulled arms and unpulled arms with potential, and (ii) restarting.

4 Non-Stationary A/B Tests

Yuhang Wu[1], Zeyu Zheng[1], Guangyu Zhang[2], Zuohua Zhang[2], Chu Wang[2], [1]University of California, Berkeley, Berkeley, CA, [2]Amazon, Seattle, WA, Contact: wuyh@berkeley.edu

A/B tests, also known as online randomized controlled experiments, have been used at scale by data-driven enterprises to guide decisions and test innovative ideas to improve core business metrics.Meanwhile, non-stationarities, such as the time-of-day effect and the day-of-week effect, can often arise nonparametrically in key business metrics involving purchases, revenue, conversions, customer experiences, etc. We discuss in this presentation the impact and challenges of non-stationarities on A/B tests. We then discuss some scenarios where such impact and challenges can be appropriately addressed.

Decision Making Under Uncertainty

Community Committee Choice Session

Session Chair: Yilun Chen, CUHK Shenzhen, West New York, NJ

1 Contextual Linear Optimization with Bandit Feedback

Yichun Hu[1], Nathan Kallus[2], Xiaojie Mao[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, Long Island City, NY, [3]Cornell University, New York, NY, Contact: yh767@cornell.edu

Contextual linear optimization (CLO) uses predictive observations to reduce uncertainty in random cost coefficients and improve performance. An example is stochastic shortest path with random edge costs. Existing work on CLO focuses on data with fully observed cost coefficients, but in many applications we can only see the realized cost of a historical decision, that is, just one projection of the random cost coefficient vector. We study two classes of algorithms for CLO with this so-called bandit feedback: estimate then optimize, where we learn a predictive model and plug predictions into the linear optimization; and induced empirical risk minimization, where we fit the predictive model to directly optimize downstream performance of the policy it induces. We relate the new regret bounds to the full feedback case and demonstrate the dependence on a coverage condition.

2 Allocating Emission Permits Efficiently via Uniform Linear Mechanisms

Xingyu Lin[1], Jiaqi Lu[2], [1]the Chinese University of Hong Kong (Shenzhen), Shenzhen, China; [2]the Chinese University of Hong Kong (Shenzhen), Shenzhen, China. Contact: thulujq@gmail.com

We study the problem of allocating emission permits in an emissions trading system and provide efficiency guarantee of simple uniform linear allocation mechanisms in the broad class of component-wise concave mechanisms. It was well accepted in the literature that the equilibrium consumer surplus and social welfare are not affected by the initial lump-sum allocation of emission permits in a deterministic system without trading fractions. We show that this is no longer the case under more general allocation mechanisms. In particular, for N firms operating under Cournot competition that differs in their abatement abilities, uniform linear permit allocation mechanisms are the most efficient, i.e., achieve the maximum consumer surplus and emission reduction. Numerical experiments show that the benefit of uniform linear mechanisms compared to constant ones can be large.

3 Restless Bandits with Average Reward: Breaking the Uniform Global Attractor Assumption

Weina Wang, Carnegie Mellon University, Pittsburgh, PA, Contact: weinaw@cs.cmu.edu

We study the infinite-horizon Restless Bandit problem with average reward. Prior work on asymptotic optimality relies on the complicated uniform global attractor property (UGAP). In this paper, we propose Follow-the-Virtual-Advice, a simulation-based framework that produces a policy with an $O(1/\sqrt{N})$ optimality gap. In discrete time, we assume a simpler synchronization assumption, covering non-UGAP problem instances. More notably, in continuous time, our result only requires the standard unichain condition. Our work gives the first asymptotic optimality result without UGAP.

4 Decision-Making with Side Information: A Causal Transport Robust Approach

Luhao Zhang, 1</sup

We consider stochastic optimization with side information where, prior to decision-making, covariate data are available to inform better decisions. We propose to consider a distributionally robust formulation based on causal transport distance. Compared with Wasserstein metric, the causal transport distance is better at capturing the information structure revealed from the conditional distribution of random problem parameters given the covariate values. We derive a dual reformulation for evaluating the worst-case expected cost and show that the worst-case distribution in a causal transport distance ball has a similar conditional information structure as the nominal distribution. When optimizing over all decision rules, we identify a new class of robust optimal decision rules when the cost function is convex with respect to a one-dimensional decision variable.

Digital Twin Revolution: Advancing the Frontiers of Large-Scale and High-Fidelity Simulation

Community Committee Choice Session

Session Chair: Tianyi Peng, Massachusetts Institute of Technology, Cambridge, MA

Session Chair: Andrew T. Zheng, Massachusetts Institute of Technology, Boston, MA

1 Efficient Algorithm for Large-Scale Online Fulfilment Simulation

Joren Gijsbrechts[1], Tianyi Peng[2], [1]Portuguese Catholic University, Lisbon, Portugal; [2]Massachusetts Institute of Technology, Cambridge, MA

We develop a parallel simulator that evaluates fulfillment policies of large-scale online retailers. The fulfillment problem consists of deciding from which fulfillment center to supply incoming orders in an online fashion. Fulfillment centers carry inventory of many items but have a maximum daily available processing capacity, which is shared across items. We develop an efficient simulator that paralellizes the evaluation of fulfillment policies across items, which may naturally violate the joint processing capacity constraint. We iteratively solve these violations and show that our algorithm converges in a small amount of iterations. We obtain bounds on the expected running time of our parallel algorithm, as well as a sequential benchmark, and validate our findings in an extensive numerical experiment. By adopting our algorithm, firms may significantly reduce their computational effort to optimize their fulfillment decisions.

2 Improving Supply Chain Resiliency Using a Digital Twin

David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA, Contact: dslevi@mit.edu

We report the impact of leveraging a Digital Twin on improving supply chain resiliency. This includes quantifying the level of resiliency, identifying hidden risk and developing mitigation strategies.

3 Optimizing Supply Chain Inventory Management Through Large-Scale Simulation: Challenges and Lessons Learned

Zhuojie Huang, Nike Inc, Beaverton, OR

This research explores the opportunities to develop large-scale simulation system for inventory management and presents challenges and lessons learned. Key challenges are discussed, including decision granularity, system interactions and dynamics, demand forecasting, replenishment policies, and optimization algorithms. Lessons learned from practical implementations provide insights into the trade-offs between model complexity and outcome precisions. The research emphasizes the importance of addressing challenges related to data accuracy and computational efficiency to achieve effective simulation outcomes. Additionally, we explore collaborative frameworks between the analytics team and the business team to facilitate the effective utilization of simulation model outcomes in informing and guiding business strategy.

Sequential Learning in Simulation

Community Committee Choice Session

Session Chair: Eunhye Song, Georgia Institute of Technology, Atlanta, GA

1 Optimizing Input Data Collection for Ranking and Selection

Taeho Kim, Eunhye Song, Georgia Institute of Technology, Atlanta, GA, Contact: esong32@gatech.edu

We consider a Bayesian ranking and selection problem under input uncertainty when all solutions share the common input models. We assume that there are multiple independent input data sources from which data can be collected at a cost to reduce input uncertainty. To optimize the data collection, we first show that the most probable best (MPB)—the solution with the largest posterior probability of being optimal (posterior preference)—is a strongly consistent estimator for the true optimum. We investigate the optimal asymptotic static sampling ratios from the input data sources that maximize the exponential convergence rate of the MPB's posterior preference. A sequential sampling rule that balances the simulation and input data collection effort is created and demonstrated. The proposed algorithm stops with posterior confidence in the solution quality.

2 Approximate Gaussian Process Regression with Pairwise Comparison Data

Efe Sertkaya[1], Ilya O. Ryzhov[2], [1]University of Maryland, College Park, MD, [2]University of Maryland, College Park, MD, Contact: sertkaya@umd.edu

We use approximate Bayesian inference, together with Gaussian process regression, to create a new estimator for an unknown function in a situation where we can only observe pairwise comparisons of function values at different inputs. Preliminary experimental results suggest that, although information is heavily censored in this setting, it may still be possible to learn the local and global minima of the underlying function. We discuss possible sampling criteria, and explore the performance of the "probability of improvement" strategy numerically.

3 Data-Driven Optimal Allocation via Balancing Empirical Large Deviations in Sequential Selection

Ye Chen, Virginia Commonwealth University, Richmond, VA, Contact: ychen24@vcu.edu

The ranking and selection problem is a classic mathematical framework about identifying the best alternative from multiple alternatives through sampling them. However, the uncertainty about sampling distributions in the ranking and selection problem has been relatively overlooked and related research is just starting to gain momentum recently. We for the first time propose an efficient data-driven nonparametric tuning-free sequential budget allocation strategy under completely unknown sampling distributions. Furthermore, we theoretically prove that our methodology achieves the optimal allocation specified by large deviation analysis. Especially, we propose a new efficient point estimation approach for estimating the optimal large deviation rates and theoretically demonstrate its validity.

Healthcare Analytics for Social Good

Community Committee Choice Session

Session Chair: Zhaowei She, Singapore Management University, Singapore, Singapore

Session Chair: Leon Xu, [1]</sup

1 First Dose or Second Dose? A Study of Vaccination Policy with Supply and Capacity Constraints

Miao Bai[1], Qi (George) Chen[2], Cuihong Li[1], [1]University of Connecticut, Storrs, CT, [2]London Business School, London, United Kingdom. Contact: miao.bai@uconn.edu

We study the problem of allocating limited vaccine supply over time between first-dose and second-dose usage with vaccine administration capacity constraints. Based on the stylized SIR model, our analytical and numerical results establish the value of strategically delaying the vaccination campaign and prioritizing second-dose usage before switching to prioritizing first-dose usage.

2 The Impact of Changing Queue Ranks on Patient Processing in the Emergency Department

Lu Wang[1], Mazhar Arikan[2], Suman Mallik[2], [1]Ball State University, Muncie, IN, [2]University of Kansas, Lawrence, KS, Contact: wang@bsu.edu

We examine the impacts of changing queue rank on patient processing in the ED using empirical investigation. We demonstrate that the additional arrivals of patients that occur close to the end of waiting time contribute to the queue rank changes. Such additional arrivals and changing queue ranks affect the patient waiting time significantly.

3 Medical Inequality: Helping Vulnerable Hospitals

Wei Gu[1], Meng Li[2], Qiang Li[3], [1]University of Science and Technology Beijing, Beijing, China; [2]University of Houston, Houston, TX, [3]Wilfrid Laurier University, Waterloo, ON, Canada. Contact: qli@wlu.ca

In this study, we take advantage of an exogenous event--the introduction of outside experts and examine the impact of the program on service efficiency and service quality for the hospital and physicians. We find that the program has significantly improved the efficiency and quality of medical services provided by them.

4 Beyond Words: Unveiling The Effect Of Physician'S Use Of Audio Communication In Online Healthcare Communities

Xunyu Chen[1], Yeongin Kim[2], Seokjun Youn[1], [1]University of Arizona, Tucson, AZ, [2]Virginia Commonwealth University, Richmond, VA, Contact: syoun@arizona.edu

The digital transformation has made online healthcare communities (OHCs) a vital hub for exchanging healthcare information. Many OHCs now implement multimodal channels (e.g., voice, visual) to enhance physician-patient communication. Despite this evolution, we lack a systematic understanding of how these new communication mediums could influence the interactants involved. We leverage social support theory, social exchange theory, and communication theories, to empirically examine the potential implications of audio communication for OHC physicians and patients. We offer insights for OHC design by revealing the potential of audio communication to enhance user utility. We also advise physicians on the benefits of audio communication in online practice.

Enabling Data-Centric Operations for Decision Dominance

Community Committee Choice Session

Session Chair: David Bierbrauer, Army Cyber Institute, U.S. Military Academy, West Point, NY

1 Data-Driven Assessment of Information Environments: Unveiling Bias Without Human Expertise

Iain Cruickshank, Army Cyber Institute, West Point, NY

The significant role of online information in shaping outcomes is evident in recent events like U.S. National Elections and the COVID-19 Pandemic. Efforts to understand the online information environment have been extensive, but critical gaps persist. Media bias still relies on subjective human assessments, while existing methods are often limited to English or Western media. Computational techniques focus on sentiment and network interactions, neglecting conversations and bias. This presentation introduces novel techniques leveraging advancements in natural language processing, network science, and graph convolutional neural networks. These techniques analyze bias using actual data, eliminating subjective expertise and regional assumptions, providing a fresh approach to understanding the online information environment.

2 Data-Efficient Federated Learning for Edge Network Intrusion Detection

David A. Bierbrauer[1], Mikal Willeke[2], Nathaniel D. Bastian[3], [1]Army Cyber Institute, U.S. Military Academy, West Point, NY, [2]U.S. Military Academy, West Point, NY, [3]United States Military Academy, West Point, NY, Contact: david.bierbrauer@westpoint.edu

Advancements in the use of deep learning using raw network traffic payloads for network intrusion detection systems enable cybersecurity professionals to maintain an advantage over adversaries. However, the evolution of the modern battlefield towards the Internet of Battlefield Things (IoBT) consisting of many interconnected networks, sensors, and devices necessitates more distributed paradigms capable of handling heterogeneous distributions of data. To ensure decision dominance for the IoBT, we propose a data-efficient federated learning (FL) framework that updates and distributes a global intrusion detection model. Initial results using resource-limited devices achieved over 93\% accuracy with the global model. We expand on this by implementing FL strategies on more realistic IoBT network configurations while exploring asynchronous learning methods.

3 Measuring Classification Certainty for Safety-Critical Applications

Alexander Berenbeim[1], Nathaniel D. Bastian[2], Iain Cruickshank[3], Susmit Jha[4], Robert Thomson[3], [1]Army Cyber Institute, USMA, Highland Falls, NY, [2]United States Military Academy, West Point, NY, [3]Army Cyber Institute, West Point, NY, [4]SRI International, Menlo Park, CA, Contact: alexander.berenbeim@westpoint.edu

Quantitative characterizations and estimations of uncertainty are of fundamental importance in optimization and decision-making processes, particularly in safety-critical settings. We propose intuitive scores, which we call *certainty* and *doubt*, that can be used in both a Bayesian and frequentist machine learning framework to assess and compare the quality and uncertainty of predictions of classification models across different modalities and model architectures. Further, using certainty scores, we can assess a model's *competence* in addition to accuracy to assess model reliability, as well as perform out-of-distribution detection.

4 Cyber Creative Generative Adversarial Network for Novel Malicious Packets

John A. Pavlik[1], Nathaniel D. Bastian[2], [1]Army Cyber Institute, West Point, NY, [2]United States Military Academy, West Point, NY, Contact: john.pavlik@westpoint.edu

Benign network traffic and malicious cyber attacks are always evolving and changing, meaning that the existing datasets for training a Network Intrusion Detection System (NIDS) quickly become obsolete. We investigate generative ML modeling for network packet synthetic data augmentation to improve NIDS detection of novel, but similar, cyber attacks. We develop a Cyber Creative Generative Adversarial Network (CCGAN), inspired by previous generative modeling to create new art styles from existing art images. The goal is to create network packet payloads that appear malicious but from novel distributions of cyber attack classes. CCGAN can increase a NIDS baseline accuracy on a novel malicious class from 79% to 97% with a minimal degradation in accuracy on benign classes (98.9% to 98.7%).

Emeriging Topics in Artificial Intelligence: Methods and Applications

Flash Session

Session Chair: Christopher M. Rump, Bowling Green State University, Bowling Green, OH

1 Should I Trust ChatGPT to Review My Program?

Mark Sherman, Carnegie Mellon University, Pittsburgh, PA, Contact: mssherman@sei.cmu.edu

ChatGPT is one of hottest new machine-learning based systems to appear on the Internet. ChatGPT can both create and analyze computer source code. The CERT program at the Software Engineering Institute has an extensive collection of insecure programs. We have used some of these assets to learn how ChatGPT would analyze vulnerable programs. In this talk, we share what we observed about the capabilities of ChatGPT in recognizing and fixing security problems in computer source code.

2 Internet Disrupted Journalism's Rendezvous with AI

Deepti Singh[1], Rohit Nishant[2], Vivek Singh[3], Robert D. Austin[4], [1]California State University - Long Beach, Long Beach, CA, [2]Université Laval, Quebec, QC, Canada; [3]University of Missouri–St. Louis, St. Louis, MO, [4]Ivey Business School, London, ON, Canada. Contact: deepti.singh@csulb.edu

The widespread availability of high-speed Internet and content dissemination through social networks have disrupted traditional journalism and its norms. Competition for clicks and the rush to publish have plagued online news outlets. These outlets are experimenting with generative AI-based tools like ChatGPT for content creation as these tools become more prevalent. We empirically analyze elements of the structural components of the articles written by AI and contrast them with articles written by humans within the same categories. Analyzing the corpus of web-published articles with human and AI authors and we conduct an empirical analysis to explore the differences and shortcomings in the creative processes of journalism in the new world order in progress under the influence of AI.

3 Value-Oriented Loss Function Tuning for Timeseries Forecasting in Energy Markets

Ruben Smets[1], Jean-François Toubeau[1], Mihaly Dolanyi[2], Kenneth Bruninx[3], Erik Delarue[1], [1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Université de Mons, Mons, Belgium; [3]TU Delft, Delft, Netherlands. Contact: ruben.smets1@kuleuven.be

In complex markets with a high amount of uncertainty, such as balancing markets, significant forecast errors are inevitable. Recently, the paradigm of value-oriented forecasting is gaining traction. While these techniques typically require a specific implementation dependent on the application, we propose a generally applicable value-oriented methodology for training time series forecasters. We achieve this by introducing a generalized loss function with a continuous exponent and variability component, and leveraging the maximum downstream value as the selection criterion in the hyperparameter tuning step. The proposed methodology is tested on the optimal control of different types of energy storage systems in the Belgian balancing market. We show that our methodology outperforms traditional benchmarks with 13% to 106% in terms of out-of-sample profit.

4 A Deep Learning Approach for High-Dimensional Time Series Forecasting

Ali Sarabi, Arizona State University, tempe, AZ, Contact: asarabi1@asu.edu

Time series forecasting is a challenging problem in various academic fields, particularly as model predictions become less accurate over longer periods. In many real-world applications, hierarchical structures exist between different time series that cannot be ignored. Graph Neural Network (GNN) models have shown great potential in addressing these relational dependencies. In this study, we present a deep neural network that utilizes graph convolution to capture inter-series dependencies and employs a Transformer to capture intra-series temporal relationships. This framework enables accurate short and long-term predictions, offering potential benefits in various domains.

5 Mining a Lottery for a Favorable Jackpot

Christopher M. Rump, Bowling Green State University, Bowling Green, OH, Contact: cmrump@bgsu.edu

A lottery offers rare opportunities for a favorable wager with a positive expected ticket value. We test various data mining methods for predicting when such opportunities may arise. Two parsimonious models - a logistic regression and a classification decision tree - are shown to make very good predictions for favorability of a wager on the next lottery drawing. These models are practical for a bettor in that they only utilize easily estimated ticket sales for the previous rolled-over jackpot and the size of that cash jackpot prize.

Frontiers in Behavioral Operations Management

Community Committee Choice Session

Session Chair: Anyan Qi, The University of Texas at Dallas, Richardson, TX

1 Human-Centric AI for Sequential Decision-Making

Park Sinchaisri, University of California, Berkeley, Berkeley, CA

Algorithmic recommendation systems are becoming increasingly crucial in supporting decisions in several domains, but there remains a gap between what is technically possible and what is utilized. Human biases are difficult to override, and people often erroneously mistrust effective recommendations after experiencing failure or when facing uncertainties. Recommendation content is also highly crucial, as bridging the gap between intuitive and ideal behavior is necessary to create the most powerful recommendation systems. We study how to best design a recommendation system that acknowledges human biases in the face of uncertainties to induce efficient behavior in complex sequential decision tasks. Our experimental studies also offer insights into the dynamics of human compliance with machine-generated recommendations.

2 Increasing Food Access Through Scheduled Grocery Delivery

Yeonjoo Lee, Karen L. Donohue, University of Minnesota, Minneapolis, MN, Contact: yjlee@umn.edu

The ability to access food is a significant concern for many low-income urban households in the United States. While online grocery delivery has the potential to improve food access, the high delivery fees and markup pricing typical of most instant delivery models pose critical cost barriers for the low-income population. This study examines how a scheduled delivery model, which consolidates nearby grocery orders and delivers on a weekly schedule, can better support the food access for under-served customers. Scheduled delivery may lower the shipping fee through increased operational efficiency, and improve customer grocery consumption behaviors, such as healthy food consumption, by creating an environment for planning. Using field data and experiments, we study the potential operational and customer well-being benefits of this new grocery delivery model.

3 Team Building and Incentive Design in Collaborative Projects

Ruth Beer[1], Anyan Qi[2], Ignacio Rios[2], [1]Baruch College, CUNY, New York, NY, [2]The University of Texas at Dallas, Richardson, TX

We explore factors affecting worker productivity in collaborative projects and what incentives promote the highest worker performance. We also explore another widely used managerial practice utilized by firms seeking to improve workers' performance in collaborative projects: team-building activities. We first derive predictions with an analytical model, and we then test these predictions with a behavioral experiment.

Cancer Modeling Within the CISNET Consortium ? The OR experience

Community Committee Choice Session

Session Chair: Iakovos Toumazis, The University of Texas MD Anderson Cancer Center, Houston, TX

1 The Engage Framework for Personalizing Lung Cancer Screening

Iakovos Toumazis, The University of Texas MD Anderson Cancer Center, Houston, TX, Contact: itoumazis@mdanderson.org

Lung cancer screening guidelines, such as the US Preventive Services Task Force (USPSTF), determine eligibility based on categorical age and smoking history. Selecting individuals for screening using a risk prediction model have been shown to be more effective and more cost-effective than the USPSTF guidelines. Using validated models developed within the Cancer Intervention and Surveillance Modeling network (CISNET), we developed the individualized lung cancer screening decisions (ENGAGE) framework, a partially observable Markov decision process (POMDP), that optimizes screening at the individual-level. We present the ENGAGE framework and compare the optimal policy against existing guidelines.

2 Using Collaborative Simulation Modeling to Develop Health Policy: A Case Study of Breast Cancer Screening Guidelines for Women with Down Syndrome

Oguzhan Alagoz, University of Wisconsin-Madison, Madison, WI, Contact: alagoz@engr.wisc.edu

Although randomized controlled trials (RCTs) are the most reliable form of evidence for health policy decisions, they may not be practical when making decisions that affect a small number of patients. In such cases, simulation modeling can be used to fill in the gaps in evidence. In this presentation, we explain how two established models from the National Cancer Institute's Cancer Intervention and Surveillance Modeling Network (CISNET) were used to develop mammography screening guidelines for women with Down syndrome. These women have a lower risk of breast cancer and significantly shorter life expectancies compared to women without Down syndrome. Our findings indicate that the traditional mammography screening guidelines recommended for average-risk women are not optimal for women with Down syndrome.

3 Dynamic Designs for Calibration of Mathematical Models: Application in Bladder Cancer Population Modeling

Thomas Trikalinos, Brown University, Providence, RI, Contact: thomas_trikalinos@brown.edu

The Cancer Intervention and Surveillance modeling Network (CISNET) Bladder Cancer Site uses two independently developed population-level mathematical models to address important questions in bladder cancer detection and control. Calibration of such models to data from cancer registries and individual- and aggregate-level datasets is a computationally expensive task. I will describe active learning explore-exploit algorithms to efficiently generate experimental designs for model calibration and their comparison with state-of-science approaches.

4 Robustness Analysis of Colorectal Cancer Colonoscopy Screening Strategies

Pedro Nascimento de Lima[1], Carolyn M. Rutter[2], Christopher Maerzluft[2], Jonathan Ozik[3], Nicholson Collier[3], [1]RAND Corporation, Arlington, VA, [2]Fred Hutchinson Cancer Center, Seattle, WA, [3]Argonne National Laboratory, Lemont, IL, Contact: plima@rand.org

This study uses the CRC-SPIN microsimulation model to perform a stress test of currently-recommended colorectal cancer (CRC) screening strategies. First, we extend CRC-SPIN to include birth-cohort effects allowing adenoma incidence to increase in later birth-cohorts and to estimate natural history parameters. We then conduct a large-scale experiment evaluating 26 screening strategies while accounting for uncertainty stemming from natural history, colonoscopy sensitivity, and the youngest age of adenoma occurrence. Finally, we identify non-dominated screening strategies and report posterior credible intervals for LYG, the number of colonoscopies needed, and incremental effectiveness ratios. We find that existing CRC screening policy recommendations are robust to the uncertainties considered in this study.

Practice-driven Healthcare Research in Collaboration with Hospitals and Clinicians

Flash Session

Session Chair: Pooyan Kazemian, Case Western Reserve University, Cleveland, OH

1 Personalized Treatment Decisions for Type 2 Diabetes: Balancing Health Benefits and Costs

Pooyan Kazemian, Case Western Reserve University, Cleveland, OH

Type 2 diabetes is a chronic disorder characterized by insulin resistance and high blood glucose levels, leading to complications in various organs. Type 2 diabetes affects 30 million Americans, with rapidly increasing prevalence projected for the future. While metformin is commonly used as a first-line treatment, many patients require additional medications. Traditional and newer classes of medications offer varying efficacy and side effects, with newer options showing superior benefits but at higher costs. The optimal treatment plan for each patient remains uncertain, as clinical guidelines often provide generalized recommendations. In this context, we developed mathematical and simulation models to help inform personalized treatment decisions based on patient-specific factors, aiming to maximize health benefits while considering costs.

2 Provider Scheduling in a Urology Clinic to Maximize Patient Access

Jennifer Mason Lobo[1], Ayca Erdogan[2], Bjorn Berg[3], Hyojung Kang[4], Matthew Clements[5], Stephen Culp[1], Tracey Krupski[1], [1]University of Virginia, Charlottesville, VA, [2]San Jose State University, San Jose, CA, [3]University of Minnesota, Minneapolis, MN, [4]University of Illinois Urbana-Champaign, Champaign, IL, [5]Lahey Health, Burlington, MA, Contact: jem4yb@virginia.edu

Assigning clinic days to urology providers in academic and large group practices is challenging given numerous scheduling constraints: evaluation and management visits, office or operating room procedures/surgeries, teaching, trainee mentorship, committee work, and outreach activities. We present an integer programming model for scheduling providers for clinic shifts in order to maximize patient access to appointments. We present results for a case study with an academic urology clinic, lessons learned from implementing the model generated schedule, and trends in the number of encounters and relative value units (RVUs, a measure that informs reimbursement for physician services) before and after the change in scheduling.

3 Impact Of Hospitalist Compliance With Providing Medically-Ready-for-Discharge Date

Keely Dwyer-Matzky[1], Dessislava Pachamanova[2], Vera Tilson[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Babson College, Wellesley, MA, [3]University of Rochester, Rochester, NY, Contact: dpachamanova@babson.edu

We report on the impact of a program implemented in a large hospital system where health care providers were requested to estimate and record the Medically-Ready-for-Discharge Date in the electronic health records for hospitalized patients to facilitate efficient hospital stays.

4 Modeling Liver Acceptance Decision Making in Transplantation Using Continuous-Time Markov Decision Processes

Jiahui Luo[1], Wesley Javier Marrero[1], Mariel Sofia Lavieri[2], David W. Hutton[2], Neehar D. Parikh[2], [1]Dartmouth College, Hanover, NH, [2]University of Michigan, Ann Arbor, MI, Contact: jiahui.luo.th@dartmouth.edu

Markov Decision Processes (MDPs) are a collection of mathematical models designed to offer optimal solutions for sequential decision-making problems under uncertainties. The process of decision-making in organ transplantation typically involves uncertainty in the timing and qualities of the organ offers, and the health conditions of patients. To represent the decision-making process of accepting or declining organ offers tailored to an individual candidate on the liver transplantation waiting list, we develop a continuous-time finite-horizon Markov decision process (MDP) model. In this work, we solve the model using data from the Organ Procurement and Transplantation Network (OPTN) to maximize the expected total survival of the candidate in the liver transplantation waiting list.

5 Infection Aware Nurse Staffing

Buyun Li[1], Jonathan Eugene Helm[2], Pengyi Shi[3], Kurt M. Bretthauer[2], [1]Kelley School of Business; Indiana University, Bloomington, IN, [2]Indiana University, Bloomington, IN, [3]Purdue University, West Lafayette, IN, Contact: libu@iu.edu

We study the nurse staffing problem with the awareness of nurse absenteeism caused by the transmission of infectious diseases. In collaboration with Indiana University Health (one of the largest healthcare providers in the Midwest), we find empirical evidence for factors that are contributing or preventing nurses' absenteeism caused by in-hospital infection. Using these factors, we construct a random graph model to capture the transmissions from all sources. The random graph model is able to capture the interaction between operation decisions and disease transmission.

This allows us to perform counterfactual analysis to identify effective operational strategies for protecting nurses and providing patient care. We also offer a novel estimation method for the random graph model which accounts for the unobservable number of nurses in the incubation and infection time.

6 To Open or Not to Open: Efficient Scheduling and Capacity Management for Diagnostic Services

Maureen Canellas[1], Joyce Luo[2], Dessislava Pachamanova[3], Georgia Perakis[2], [1]University of Massachusetts Medical School, Worcester, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Babson College, Wellesley, MA

The management of diagnostic services is a challenging task for hospital systems. Unmet demand is often carried over and pushed into the weekend, which is inefficient for the hospital and increases patient waiting times. In collaboration with a large Level I Trauma hospital, we use robust machine learning (ML) and optimization methods to provide more efficient policies for satisfying demand for diagnostic services (i.e. MRI scans, echocardiograms) among competing patient classes. We address uncertainty in demand and appointment lengths using data-driven uncertainty sets based on predictions from ML models. We also consider capacity adjustments like modifying the hospital's scan opening schedule or staffing distribution. Our work draws analogies to traditional inventory theory, as we aim to minimize daily patient demand carryover.

Healthcare OM: Nonprofit and Public Sector Perspectives

Community Committee Choice Session

Session Chair: Can Zhang, Duke University, Durham, NC

1 Indication-Based Pricing for Multi-Indication Drugs

Elodie Adida, University of California - Riverside, Riverside, CA, Contact: elodie.goodman@ucr.edu

Many pharmaceutical drugs have multiple indications, for which they offer a varying degree of benefit for patients. Yet, in the current US pricing system, the price of the drug is the same regardless of the indication for which it is prescribed. We use a modeling approach to analyze how indication-based pricing compares to uniform pricing for the manufacturer's profit and investment incentives, the patients' access to the drug and benefit, and the payer's coverage incentives and objective. We find that under indication-based pricing, the drug manufacturer earns higher profits and has stronger incentives to invest in a new indication, while the payer has stronger incentives to cover the drug, compared to uniform pricing. However, indication-based pricing may hurt the patient demand, patient utility and the payer's objective.

2 Impacts of a Non-Profit Intermediary on Reliability of Drug Supply

Hyoduk Shin[1], Junghee Lee[2], Jennifer K. Ryan[3], Daewon Sun[2], [1]UC-San Diego, La Jolla, CA, [2]University of Notre Dame, Notre Dame, IN, [3]University of Nebraska - Lincoln, Lincoln, NE, Contact: hdshin@ucsd.edu

Drug shortages have become increasingly common and costly in the U.S., particularly for generic drugs. In recent years, non-profit organizations dedicated to enhancing the reliability of the drug supply have begun to enter the pharmaceutical supply chain, alongside traditional for-profit intermediaries, such as group purchasing organizations. We study the impact of a non-profit intermediary on the market structure, health care providers' surplus, and reliability of supply in the context of a single drug that is vulnerable to shortages. We find that the introduction of a non-profit intermediary will not necessarily improve the surplus of health care providers. We also investigate the impact of the reimbursement rate as a lever to improve the reliability of supply and find that a non-profit intermediary is a more cost-effective mechanism to achieve the same result.

3 The Role of Market Interventions to Increase Access of Health Commodity in LMIC: A Case of the IPAQT

Parshuram Hotkar[1], Sarang Deo[2], Mohammed A. Rahman[1], [1]Indian School of Business, Hyderabad, India; [2]Indian School of Business, Hyderabad, India. Contact: parshuram_hotkar@isb.edu

Low and medium income countries (LMICs) face challenges to provide access to health commodities. This paper examines the role of market interventions like IPAQT in India, which was established to lower the price of TB diagnostic tests by negotiating with manufacturer and coordinating with private labs. We use a game-theoretic model to investigate the feasibility and sustainability of such market-transforming interventions. We show that internal price control mechanisms like the IPAQT will increase consumption more than external price control mechanisms like regulatory set price caps when there is heterogeneity in the private labs market. The research aims to generalize the economics of market-transforming interventions and provide guidelines for intervention designs to increase access to health commodities in LMICs.

4 Strengthen Blood Transfusion System in Africa: Inspire and Enhance Blood Donation Willingness by Utility-Based Blood Drive Planning

Yiqi Tian[1], Bo Zeng[2], Jayant Rajgopal[1], Bopaya Bidanda[1], Pratap Kumar[3], Juan Puyana[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Strathmore University Business School, Nairobi, Kenya; [4]University of Pittsburgh Medical School, Pittsburgh, PA, Contact: yit30@pitt.edu

Blood transfusion is a critical medical intervention that saves millions of lives every year. However, in many parts of Africa, blood transfusion services are under-resourced and face a range of logistical and operational challenges. This presentation proposes a two-stage blood drive planning approach that utilizes decisions to improve the blood transfusion system in Africa. By integrating decision-dependent uncertainty sets into the planning process, the proposed approach can influence the behavior of donors in the system. The presentation provides a detailed overview of the approach, highlighting its key features and advantages, and presents examples of how it can be applied in practice.

Statistical and Machine Learning Methods in Healthcare

Community Committee Choice Session

Session Chair: Raaz Dwivedi, Harvard and MIT, CAMBRIDGE, MA

Session Chair: Kyra Gan, Harvard University, Cambridge, MA

1 Non-Dominated Designs for Adaptive Clinical Trials

Eric Laber, Duke University, Durham, NC

Sequential experiments are often designed to ensure a balance between exper-iments that efficiently generate information and experiments that generate utility.A sequential experimental design that maximizes long-term cumulative utility mustexplore, i.e., forgo immediate utility in favor of information, only if and when thevalue of information generated by exploration outweighs the short-term loss in utility. Unfortunately, it is not possible to construct such designs in general. Instead,researchers must rely on heuristics that force exploration through randomization orby adding an exploration `bonus' to the utility function. We show that experimentsselected by commonly used heuristics frequently generate less information and lessutility than alternatives. Such experiments are said to be dominated in terms of utilityand information. We show that if one removes from consideration experiments thatare estimated to be dominated at each time point and then applies standard heuris-tics for forced exploration it is still possible to obtain consistency and asymptoticnormality. Furthermore, in a suite of simulation experiments, these non-dominatedheuristics generate more utility and more information (i.e., are more efficient) thantheir standard counterparts.

2 Adaptive Sequential Design For Long Time-series

Ivana Malenica, Harvard University, Cambridge, MA

This work is motivated by the need for robust personalized medicine, introducing a sequential, adaptive design for a single individual in a nonparametric model. We aim to learn an optimal choice of the controlled components of the design and continue to adapt randomization for future experiments. First, we define a class of conditional causal parameters suited for time-series data. We present a study of the data-adaptive inference for the mean under the optimal policy, where the target parameter adapts over time in response to the observed context. Out proposed estimator is double-robust, with favorable statistical properties for the mean under both true and estimated optimal rule. Secondly, we explore a setting where short-term rewards are not available, and the experimenter only has access to the final outcome at the end of a long time-series.

3 Identifying Synthetic Lethality Pairs with Recursive Feature Machines

Adityanarayanan Radhakrishnan, Cathy Cai, Caroline Uhler, MIT, Cambridge, MA, Contact: aradha@mit.edu

Synthetic lethality, i.e., the idea that simultaneous inactivation of pairs of genes can lead to cell death but individual inactivation does not, provides an avenue for identifying drug targets for cancer. The recent rise of large scale gene perturbation screens offers the opportunity to identify such pairs automatically using machine learning. In this work, we present a pipeline for unsupervised synthetic lethality screening based on feature learning kernel machines known as Recursive Feature Machines (RFMs). We demonstrate that RFMs more accurately recover synthetic lethality pairs and are orders of magnitude faster than prior methods for screening based on random forests or univariate statistical methodology. Moreover, we show that feature matrices from RFMs are useful for characterizing candidate pathways for treatment.

4 Tell Me Something Interesting: Clinical Utility of Machine Learning Prediction Models in the Icu

Bar Eini, Danny Eytan, Ofra Amir, Uri Shalit, Technion, Haifa, Israel. Contact: beini@campus.technion.ac.il

Machine learning (ML) prediction models for the intensive care unit (ICU) often prioritize overall precision, but is that aligned with clinicians' priorities? We believe that patient care is at its core a joint human-AI task, and that models should be optimized for this collaboration. In this talk, I will present our work aiming to understand and address clinicians' needs when designing ML models predicting vital signs for patients in the ICU. This includes prediction targets and timescales stemming from actionability requirements, and concerns regarding evaluation and trust in prediction algorithms. Based on our findings, we suggest new ways to measure model performance that go beyond the usual mean squared error. We show how these new utility functions can in turn be used as loss functions for training models that focus their predictive power on these more useful measures.

Analytics for Risk, Resilience and Safety in Supply Chains

Community Committee Choice Session

Session Chair: Retsef Levi, MIT, Cambridge, MA

1 A Discretization Framework for Robust Contextual Stochastic Optimization

Rares Cristian[1], Georgia Perakis[2], [1]Massachusetts Institute of Technology, Cambridge, GA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: raresc@mit.edu

Many real-world optimization problems depend on uncertain parameters that must be predicted from historical data. For example, in inventory allocation problems, demand distributions can vary based on observed features like location or season. We consider the class of contextual stochastic optimization problems and present a novel method to combine the learning and optimization steps in order to produce decisions that can minimize cost but also be robust and safeguard against worst-case scenarios. Our experimental results demonstrate that our approach is competitive in terms of average regret and yields more robust solutions than other methods proposed in the literature. Specifically, when the objective function is nonlinear, our method outperforms other methods by up to 50% in terms of 95th quantile costs.

2 Digital Supply Chain Analytics to Predict Cyber Risk

Kevin Hu, Retsef Levi, Raphael (Rafi) Yahalom, El Ghali Zerhouni, MIT, Cambridge, MA

The presentation provides the first empirical evidence that certain supply-chain attributes are significant predictors of cyber risk for enterprises, in addition to their internal characteristics and level of cybersecurity management. It leverages outside-in cyber risk scores that represent quality of cyber security management, and augment these with supply chain features that are inspired by network science research, to develop a more comprehensive risk assessment. The main result is to develop a model that shows that supply chain network features add significant detection power relative to merely internal enterprise attributes in predicting risk of cyber data breach incidents. Additionally, the model highlights several cybersecurity risk insights related to third party data breach mechanisms that have seen significant increase over the last several years.

3 Transmission Interaction Persistence (TIP): A Supply Chain and Epidemiological Model for Zoonotic Diseases Outbreaks

El Ghali Zerhouni[1], Retsef Levi[2], [1]MIT, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: egaz@mit.edu

Zoonotic diseases that jump from animals to humans, such as avian influenza, swine flu, or SARS, have been responsible for major pandemics in the last several decades. Meanwhile farms could be a source of such diseases, most of the outbreaks have been linked to live animal markets in China. This talk presents a supply chain motivated transmission, interaction, and persistence (TIP) stochastic epidemiology model that seeks to explain the mechanism of disease amplification in markets, with a case study on avian influenza. It shows how even low infection rates among animals flowing from farms to markets and staying there less than one day can lead to large outbreaks. The study identifies the environment as a critical transmission host and vector of the disease. The results also stress and quantify the importance of sanitation practices to mitigate the risk of future pandemics.

4 Surveillance of Adverse Event Variability Across the Manufacturing Supply Chain of Biologic Drugs

Josh Wilde, Jacqueline Wolfrum, Stacy Springs, Retsef Levi, MIT, Cambridge, MA

In this talk we describe an innovative data-driven methodology to detect post marketing safety signal in biologic drugs that potentially emerge from variability in the manufacturing and supply chain conditions. Hidden Markov Chain modeling is used to detect safety signals based on the adverse reporting rate per lot.Real data is used to illustrate the applicability of the approach.

Digital Platforms

Community Committee Choice Session

Session Chair: Dmitry Mitrofanov, Boston College, Chestnut Hill, MA

1 Deep Learning for Policy Targeting with Continuous Treatment

Zhiqi Zhang[1], Zhiyu Zeng[2], Ruohan Zhan[3], Dennis Zhang[4], [1]Washington University in St. Louis, St. Louis, MO, [2]Tsinghua University, Beijing, China; [3]Hong Kong University of Science and Technology, Clear Water Bay, China; [4]Washington University in St Louis, ST LOUIS, MO, Contact: z.zhiqi@wustl.edu

Optimizing continuous monetary treatments in marketing and operations, including wages, pricing, incentives, and discounts, is a complex task. Current approaches utilize discrete experiments to assess people's responses and return on investment (ROI) at specific treatment levels. We propose a double-machine-learning framework that leverages personal characteristics to determine the optimal treatment level for each customer. Unlike traditional discrete experiments, our approach provides theoretical guarantees on revenue and enables the identification of the optimal treatment level without relying on discrete levels. We validate our approach using a random field experiment on a large-scale video-sharing platform.

2 Optimal Mix of Dedicated and Flexible Supply in Digital Marketplaces

Chiara Farronato[1], Yejia Xu[2], [1]Harvard Business School, Brookline, MA, [2]Harvard Business School, Boston, MA, Contact: rxu@hbs.edu

We study the optimal mix of dedicated and flexible supply in digital marketplaces. We define dedicated supply as the set of service providers who are expected to be working with a planned schedule ex ante, while flexible supply as those who freely decide when and where to operate. Using data from a food-delivery platform operating in South America, we explore how the optimal supply mix changes across different geographic locations and hours of the day, and examine how it has changed over time as the platform has grown. Our results have implications on driver scheduling for both nascent and established platforms.

3 Disclosing Low Product Availability: An Online Retailer's Strategy for Mitigating Stockout Risk

Dmitry Mitrofanov[1], Benjamin Knight[2], [1]Boston College, Chestnut Hill, MA, [2]Instacart, San Francisco, CA

Ensuring product availability and the successful fulfillment of orders are key priorities for any company operating in the retail industry. In this paper, we investigate the impact of sharing information about low item availability on customer purchase decisions in the retail industry. It is hard to predict the net impact of sharing item availability information on business metrics ex-ante because there are multiple effects that might act in opposite directions. Through a field experiment with over 840K customers on Instacart, the study reveals that customers are 25% less likely to purchase low-stock items when informed about their availability. In addition, this disclosure also leads to higher customer satisfaction and positively affects revenue and order frequency, with a 5.33% increase in revenue per customer and a 4.9% increase in order frequency.

4 Customers' Multihoming Behavior in Ride-Hailing: Empirical Evidence Using a Structural Model

Sandeep Chitla[1], Maxime Cohen[2], Srikanth Jagabathula[1], Dmitry Mitrofanov[3], [1]NYU Stern School of Business, New York, NY, [2]McGill University, Kirkland, QC, Canada; [3]Boston College, Chestnut Hill, MA, Contact: chitlasandeep@gmail.com

We examine customer multihoming using a large ride-hailing panel dataset that observes repeated Uber and Lyft choices of 1.4 million rides completed by 160k NYC riders in NYC in 2018. To explain riders' choices, we develop a structural model that incorporates customers' search behavior and consideration set formation. We find that operational factors do not fully explain riders' choices, suggesting customers view platforms as differentiated service providers. In 2018, 45% of users used only Uber and 20% only Lyft, and only

43% of the remaining 35% of Uber and Lyft users considered both platforms. Targeting customers earlier in their lifecycle increases the platform's market share by 77.56% more than their current promotional strategy. Targeting customers with low search friction increases market share by 24.78% more than targeting customers with high search friction.

Health IT and Analytics

Community Committee Choice Session

Session Chair: Tan (Suparerk) Lekwijit, W. P. Carey School of Business, Arizona State University, Tempe, AZ

1 Impact of Telehealth on Appointment Adherence in Ambulatory Care

Masoud Kamalahmadi, Christos Zacharias, Howard Gitlow, University of Miami, Coral Gables, FL, Contact: mkamalahmadi@miami.edu

We study the effect of telehealth on patients' adherence to medical appointments. Using data from a large medical system, we find that no-show and late-arrival probabilities decrease over telehealth. We discuss the underlying mechanisms of these improvements and their implications for managers and policy makers.

2 People Talking and AI Listening: How Stigmatizing Language in EHR Notes Affects AI Fairness

Yizhi Liu[1], Weiguang Wang[2], Gordon Gao[3], Ritu Agarwal[4], [1]University of Maryland, College Park, College Park, MD, [2]University of Rochester, Rochester, NY, [3]Johns Hopkins University, Baltimore, MD, [4]Johns Hopkins Carey Business School, Baltimore, MD, Contact: yizhiliu@umd.edu

Electronic healthcare records (EHRs) are a critical data source for the artificial intelligence (AI)-driven transformation in healthcare. However, clinician biases reflected in EHR notes can lead to AI models inheriting these biases and perpetuating health disparities. This study focuses on the impact of stigmatizing language (SL) in EHR notes on mortality prediction using a deep learning model. We find that SL written by clinicians impedes AI performance, especially for black patients, highlighting SL as a source of racial disparity in AI development. Further, we investigate the generation of SL and find that removing SL written by central clinicians in their collaborative network is an efficient bias reduction strategy. This study provides actionable insights for responsible AI development and contributes to understanding clinician behavior in EHR note writing.

3 Toward Equitable Care Access: The Impact of Telehealth Adoption in Safety-Net Health Centers

Kyuyeon (Jenny) Rhee[1], Xiao Liu[2], Tan Lekwijit[1], Pei-yu Chen[2], [1]W. P. Carey School of Business, Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: krhee1@asu.edu

This research examines the effectiveness of telehealth in safety-net community health centers (CHCs) in the U.S., specifically targeting underserved populations and mental health services. Focusing on barriers like specialist access and distance to care, it analyzes how mental telehealth implementation varies across locations and delivery models. Key findings indicate an increase in mental health patients and visits, particularly in lower-income areas. The study also differentiates between specialist-facilitated and remote telehealth models, highlighting the nuanced implications for quality and access. The research emphasizes that telehealth's deployment must consider various socioeconomic factors and calls for context-specific strategies, offering critical insights into healthcare disparities.

4 Impact Of Health Information Exchanges On Continuity Of Care

Saeede Eftekhari[1], Ramaswamy Ramesh[2], [1]Tulane University, NEW ORLEANS, LA, [2]SUNY Buffalo, East Amherst, NY

Patient movement between service providers is an important phenomenon in the continuum of healthcare. In this research, we focus on primary care settings, and we investigate how Health Information Exchanges (HIEs) affect patients' return to the primary care physicians (PCPs) for follow-up care. More specifically, we study whether HIEs can speed up the return of patients to the primary care physicians after specialist care is given. Our findings have important managerial and policy implications for both healthcare markets and HIE platforms.

FinTech and Blockchain

Community Committee Choice Session

Session Chair: Fasheng Xu, Syracuse University, Long

Island City, NY

1 The Paradox of Just-In-Time Liquidity in Decentralized Exchanges: More Can Sometimes Mean Less

RUIZHE Jia, Agostino Capponi, Brian Zhu, Columbia University, New York, NY, Contact: rj2536@columbia.edu

This study scrutinizes the intricacies of Just-in-Time (JIT) liquidity in blockchain-based decentralized exchanges. While JIT liquidity providers, acting as high-frequency market makers, ostensibly enhance the liquidity pool, our findings reveal they inadvertently crowd out passive liquidity providers. This surprising paradox, where 'more leads to less', occurs due to the unchanged adverse selection costs and reduced fee earnings for passive providers. This can diminish overall equilibrium liquidity and increase execution risk for traders, since JIT liquidity, unlike passive liquidity, is unobservable pre-trade.

2 What Drives the (In)stability of a Stablecoin?

Yujin Kwon[1], Kornrapat Pongmala[1], Kaihua Qin[2], Ariah Klages-Mundt[3], Philipp Jovanovic[4], Christine Parlour[5], Arthur Gervais[4], Dawn Song[1], [1]UC Berkeley, Berkeley, CA, [2]Imperial College London, London, United Kingdom; [3]Cornell University, Winona, MN, [4]UCL, London, United Kingdom; [5]University of California - Berkeley, Berkeley, CA, Contact: yujinyujin9393@berkeley.edu

In May 2022, an apparent speculative attack, followed by market panic, led to the precipitous downfall of UST, one of the most popular stablecoins at that time. However, UST is not the only stablecoin to have been depegged in the past. Designing resilient and long-term stable coins, thus, appears to present a hard challenge.
To further scrutinize existing stablecoin designs and ultimately lead to more robust systems, we need to understand where volatility emerges. Our work provides a game-theoretical model aiming to help identify why stablecoins suffer from a depeg. This game-theoretical model reveals that stablecoins have different price equilibria depending on the coin's architecture and mechanism to minimize volatility. Moreover, our theory is supported by extensive empirical data consisting of daily prices for 22 stablecoins and on-chain data from five blockchains.

3 Web3 Reputation: Introducing Dynamic Incentives into Distributed Networks

Lin William Cong[1], Luofeng Zhou[2], [1]Cornell University, Ithaca, NY, [2]NYU Stern School of Business, New York, NY, Contact: lz2198@nyu.edu

In this paper, we introduce dynamic incentives to distributed systems via incorporating suppliers' reputation. Reputation aligns suppliers' incentive to platform welfare and allows myopic suppliers to consider long-term interests. Using Proof-of-Stake (PoS) protocol as an example, we show that the platform can support more throughput with same amount of staking, and the transaction fee is immune to shocks to suppliers. Furthermore, we analyze how dynamic incentives mitigate moral hazard in decentralized reporting game, and how decentralization solves wealth concentration caused by dynamic incentives. These analyses propose adding reputation to Web3 applications in support of sustainable and robust long-run prospect.

4 The Value of Information on Trade Credit Platforms

Jiding Zhang[1], Song Yang[2], Xiangfeng Chen[3], Xinyue Cheng[4], [1]Arizona State University, Tempe, AZ, [2]London Business School, London, United Kingdom; [3]Fudan University, Shanghai, China; [4]Shanghai Jiao Tong University, Shanghai, China

We examine the role of information transparency on a trade credit platform. We first build a structural model to study the cost and benefit associated with different actions upon receivcing bills (account receivables) for each agent on the supply chain. We then run counterfactual experiments to examine how different levels of information transparency affect the efficiency of the supply chain finance.

Digital Marketplace: Operational Challenges and Opportunities

Community Committee Choice Session

Session Chair: Guangwen (Crystal) Kong, Temple University, Philadelphia, PA
Session Chair: Hao Jiang, temple university, PHILADELPHIA, PA

1 Food-Delivery Platforms: Near-Optimal Policies for Capacity Sizing, Order-Batching and Routing

Yang Bo[1], Milind Dawande[2], Ganesh Janakiraman[3], [1]The Chinese University of Hong Kong, Shatin, N.T., Hong Kong; [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas- Dallas, Richardson, TX, Contact: yangbo@cuhk.edu.hk

We study the one-time capacity sizing and infinite-horizon real-time orders' batching and routing problem for a food delivery platform. The objective is to minimize the long-run average cost incurred per unit time, where the cost includes wages to servers plus the delay penalty cost. We characterize the fundamental trade-off between spatial economies of scale and orders' waiting time before entering delivery service in this setting through a lower bound on the cost under any policy within a general class of policies. We then identify a simple, near optimal algorithm whose performance gap with respect to this lower bound vanishes in a meaningful asymptotic regime.

2 Wage Fairness in Two-Sided Markets

Jingyuan Wan, University of Minnesota, Minneapolis, MN

Wage discrimination is a pervasive issue in labor markets. But will imposing wage fairness regulation be the solution? In this work, we develop a model of a two-sided market to study the impact of fairness constraint on outcomes for workers, consumers, and the firm. The model captures the heterogeneity of workers by dividing them into distinct groups based on their salient characteristics. We show that conditions exist under which imposing fairness constraints may not lead to better outcomes, including for the target group.

3 Strategic Delay In Grocery Delivery Platform

Hao Jiang[1], Guangwen (Crystal) Kong[2], [1]temple university, PHILADELPHIA, PA, [2]Temple University, Philadelphia, PA, Contact: tul13843@temple.edu

Inspired by the interactions between customer's online shopping experience and the grocery delivery platform's service strategies, we study whether the platform should strategically delay the service when considering the store's inventory. We find the platform's strategic delay may be higher than the delay determined by the queueing system.

4 The Impact of Automation on Workers when Workers are Strategic: The Case of Ride-Hailing

Zicheng Wang, University of Minnesota, Minneapolis, MN

Technological advances in robotics, machine learning, and artificial intelligence have raised concerns about the displacement of human workers by automation. We study the impact of automation on worker welfare when workers have discretion in how they carry out the work and may act strategically. We ground our analysis in the setting of a ride-hailing service that operates a mixed fleet with human drivers and autonomous vehicles (AVs). We show that the introduction of AVs, by inducing a more favorable equilibrium, can lead to outcomes that improve both efficiency and worker welfare.

Procurement and Market Design

Community Committee Choice Session

Session Chair: Mehdi Farahani, University of Miami, Miami, FL

1 Asymmetric Cost of Quality, Sourcing, and Vertical Differentiation

Jie Ning[1], Zhibin (Ben) Yang[2], [1]Case Western Reserve University, Cleveland, OH, [2]Universtiy of Oregon, Eugene, OR, Contact: zyang@uoregon.edu

Should firms differentiate quality to soften competition, or equalize it by sourcing? We study sourcing by inefficient firm 2 from efficient firm 1. We show firm 2 prefers sourcing, if it well improves quality. Otherwise, firm 2 may not source even for free. Firm 1 averts sourcing if it enjoys large quality leadership under no-sourcing and low horizontal product differentiation. While sourcing pools resource for innovation to firm 1, it may lead to lower quality than no-sourcing if firm 1 has small efficiency advantage.

2 Price Subsidies with or Without Physical Procurement: Impact on Quality, Profits, and Welfare

Omkar D. Palsule-Desai[1], Aysajan Eziz[2], Srinagesh Gavirneni[3], [1]IIM Indore, Indore, India; [2]Ivey Business School, Western University, London, ON, Canada; [3]Cornell University, Montreal, Canada. Contact: omkardpd@iimidr.ac.in

Newly introduced price subsidy programs without physical procurement have resulted in an increased (vis-\`{a}-vis the subsidy programs with physical procurement) preponderance of deliberate quality degradation for certain crops by Indian farmers. The physical procurement of the crop from farmers provides an alternate sales channel to farmers. The farmers' deliberate quality degradation may moderate the benefits of the altered competitive structure. Using a multi-stage incomplete information-based (Bayesian) game-theoretic model, we characterize the farmers' strategic production and selling decisions. We demonstrate that to eliminate farmers' deliberate crop quality degradation, when MSP is moderate, if not lower, the government should (should not) procure the crop physically if the high-quality crop price premium in the open market is higher (lower).

3 A Prior-Free Asymptotically Efficient Mechanism for Two-Sided Platforms with Dynamic Arrivals

Arun Kumar Rout[1], Milind Dawande[1], Ganesh Janakiraman[2], [1]The University of Texas at Dallas, Richardson, TX, [2]University of Texas- Dallas, Richardson, TX, Contact: arun.rout@utdallas.edu

We consider a platform that operates a two-sided market in which unit-demand buyers with private valuations and unit-supply sellers with private costs arrive dynamically over time — the arrival processes of these agents and their value/cost distributions are Markov-modulated. The platform incurs a waiting cost per agent per unit time for agents waiting in the market. The platform seeks to design a mechanism that maximizes its efficiency, which is the difference of the aggregate valuation of the matched buyers and the aggregate cost of the matched sellers, less the waiting cost. For this problem, we develop a prior-free asymptotically efficient mechanism. More generally, we provide a framework that takes as input a static mechanism with some desirable properties and outputs a dynamic mechanism that retains these properties and is prior-free and asymptotically efficient.

4 Pay with Your Data: Designing Optimal Data-Sharing Mechanisms for Artificial Intelligence Services

Chandrasekhar Manchiraju[1], Sameer Mehta[2], Milind Dawande[3], Ganesh Janakiraman[4], [1]Michigan State University, East Lansing, MI, [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]The University of Texas at Dallas, Richardson, TX, [4]University of Texas- Dallas, Richardson, TX, Contact: chandumanchi@gmail.com

The rapid advances in the field of Machine Learning (ML) have led to the proliferation of Artificial Intelligence (AI) services offered by firms. To develop a valuable AI service, a firm must build an accurate ML model which requires a large amount of training data. Present-day firms usually obtain this data by offering incentives to consumers to share their data during the initial development phase of the AI service, and then use that data to re-train the ML models to improve the quality of the AI service. In this paper, we analyze two popular data-sharing mechanisms employed by firms: manual data-sharing and algorithmic data-sharing. For both approaches, we obtain revenue-maximizing mechanisms for the firm and analyze the fundamental differences between the two approaches in terms of the revenue accrued by the firm, the consumer surplus, and the volume of data collected.

Optimizing Supply Chain Operations

Community Committee Choice Session

Session Chair: Shivam Gupta, University of Nebraska Lincoln, Lincoln, NE

1 Cloud Cost Optimization: Model, Bounds, and Asymptotics

Zihao Qu[1], Milind Dawande[1], Ganesh Janakiraman[2], [1]The University of Texas at Dallas, Richardson, TX, [2]University of Texas- Dallas, Richardson, TX, Contact: zihao.qu@utdallas.edu

Motivated by the rapid growth of the cloud computing industry, we study an infinite-horizon, stochastic optimization problem from the viewpoint of a firm that employs cloud resources to process incoming orders (or jobs) over time. There are several types of resources that differ in their costs, performance attributes, reserved prices and on-demand prices. Orders of several types arrive stochastically through time -- orders differ in their deadlines and in their resource-specific processing-time distributions. The firm's goal is to minimize the long-run average expected cost per period, considering reserved-capacity costs, on-demand capacity costs, and order-delay costs. We show that our proposed policy is asymptotically optimal. We also report results of a comprehensive numerical study -- on a testbed informed by capacity and pricing data from Amazon Web Services.

2 Ordering of Perishable Products Where Order Value is Constrained by Revenue

Jyotishka Ray, Miami University, Oxford, OH

We consider a spare-parts dealer who is authorized by a firm to purchase OEM parts and sell it in the local market at regulated price. The parts are purchased on credit and needs to be paid at the beginning of the next period when the order arrives. The unsold parts are carried forward in the next period and perceived to be perishable after the arrival of the new parts. We consider the dealer's problem of finding optimum order policy so that the revenue generated in a period is sufficient enough to repay the credit for the next period order after incurring holding and maintenance costs. We use uniform demand distributions of a single old-and new parts to find a simple steady state ordering policy. We formulate a multi-part finite horizon dynamic program which is separable in parts. A fast converging, efficient, and scalable heuristic is developed which is free of any optimization steps.

3 Procurement for Assembly Systems Under Disruption Risk: Optimal Mechanisms

Like Bu, Milind Dawande, Ganesh Janakiraman, The University of Texas at Dallas, Richardson, TX, Contact: lxb190003@utdallas.edu

Motivated by the recent surge in supply chain disruptions, we study a mechanism design problem faced by a firm assembling a product from multiple components. For each component, the firm has access to an unreliable supplier whose production cost information is private and whose production could be disrupted with some publicly known probability. In addition, for each component, the firm has access to a more expensive but reliable supply source upon whom it can fall back in the event of a disruption. The goal is to design a procurement mechanism for the firm. Our research presents a practically appealing optimal mechanism, and we provide optimal mechanisms for two extensions in which supply uncertainty is modeled as general discrete random variables and continuous random variables. With an eye on practice, we offer screening implementations of all our mechanisms.

4 Data-Driven Condition-Based Maintenance for Perpetual Systems

Sandun Perera, College of Business, University of Nevada, Reno, NV

We consider an IOT-based smart system where the past performance of the system is monitored in real-time and is used to derive the operational control bands to optimize its performance over time. In particular, we show that the optimal maintenance policy for this smart system is to follow a "two-band control" on the current performance level. The smart system autonomously switches to a prearranged backup system when its performance is detected to be unacceptable (not in control) and immediately transmits an IoT-enabled Kanban signal to the maintenance crew. When the maintenance order is completed, the backup system switches back to the original system. This paper not only proves the optimal policy is a two-band control policy but also provides efficient ways to approximate the optimal policy as well as the underlying performance of the system.

5 Product Line Design in Distribution Channels with Demand-Learning Considerations

Yulia Vorotyntseva, Saint Louis University, St Louis, MO, Contact: yulia.vorotyntseva@slu.edu

This paper proposes an analytical framework for optimizing the product line of a distributor who sells to small retailers. The distributor has better information about consumer demand but does not share it with the retailer, who uses her own sales data to decide which, if any, product to pick from the distributor's assortment. Upon offering a product, the retailer receives a noisy signal about its performance and updates her beliefs about the market demand in a Bayesian fashion. The proposed model captures the distributor's tradeoff between the risk of losing a retailer to another distributor if none of the products in the assortment appeal to her and the risk of the retailer substituting a higher margin product for a lower margin one.

1 Learning by Failing: The (Unintended) Consequence of Test Reporting on Autonomous Vehicle Training

Zhi Chen[1], Wenjie Xue[2], [1]National University of Singapore, Singapore, Singapore; [2]Cornerstone Research, Inc., Menlo Park, CA, Contact: zhi.chen@nus.edu.sg

Autonomous vehicles (AVs) have great potentials to revolutionize the transportation industry. The success of AVs depends on its access to various real-world driving scenarios. To improve AVs' algorithms, firms send testing vehicles onto public roads to discover those rare complex driving scenarios ("edge cases"). While these edge cases are valuable for AVs' future improvements, they trigger failure of testing vehicles (called disengagement) each time an edge case is discovered. Using a game-theoretic model, we study how disengagement reporting requirements by regulators affects the testing strategies of AV firms.

2 Advising Entrepreneurs: Optimal Recommendation of Alternatives

Zeya Wang[1], Morvarid Rahmani[2], Karthik Ramachandran[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA

Facing emergent business challenges, entrepreneurs often seek guidance from experienced advisors. When multiple alternatives could potentially solve the entrepreneur's problem, advisors can lead the entrepreneur's exploration by choosing which alternative(s) to suggest and in what sequence. We develop a dynamic game-theoretic model that captures the sequential interaction between an advisor and an entrepreneur. Our analysis reveals that, following a failed trial, the advisor should readily offer a new alternative if the entrepreneur's capability is either very high or low. Otherwise, the advisor should encourage the entrepreneur to try the same solution multiple times. In situations where alternative solutions are interdependent, our analysis reveals that the advisor might find it optimal to present them simultaneously and early in the horizon.

3 Access to Science in the Town Square:Social Media Democratize Science Communication

Yang Yang[1], Tanya Tian[2], Brian Uzzi[3], Benjamin Jones[3], [1]University of Notre Dame, Notre Dame, IN, [2]New York University, New York, NY, [3]Northwestern University, Evanston, IL

Science is increasingly communicated to the public through social media, raising significant questions about the role that social media serve in how scientific knowledge is consumed in public domains. Here, we engage in systematic investigation combining several large-scale datasets. There are several important findings. First, our results demonstrate that social media use high-quality science consistent with what is impactful within science. Second, while mainstream media coverage is concentrated in a handful of fields, social media usage of science draws broadly and equitably from different fields. Further, while eminent institutions tend to dominate mainstream media coverage, social media gives voice more equally. Finally, our analyses on scientists active on social media reveal a remarkable alignment between social media impact and eminence in science.

4 Slow Hunch to Vision. the Interaction Between Entrepreneurial Vision Making and Pivoting

Monique Boddington, Stylianos Kavadias, University of Cambridge, Cambridge, United Kingdom. Contact: mib25@cam.ac.uk

This paper focusses on the micro-foundations of strategy, explaining how entrepreneurial vision making influences pivoting and persevering, in early stage ventures. The success of a venture is dependent both on the quality of the idea and strategy. What is less clear is how entrepreneurs balance their own vision of an entrepreneurial opportunity, with external feedback gained through a 'scientific' approach to entrepreneurship. This paper proposes that entrepreneurs engage in an interplay, between vision making and learning, through experimentation and external feedback. We document, how vision, rather than being a single epiphany, comes into being as a 'slow hunch' that develops over time, influenced by multiple events. Through testing and iteration, entrepreneurs strengthen their own vision, which increasingly acts as a guiding light for future decisions.

1 Supercharged by Advanced Analytics, JD.com attains Agility, Resilience, and Shared Value Across its Supply Chain

Yongzhi Qi, JD.com, Beijing, China

Despite challenges in the sophisticated retail supply chain, JD.com has strengthened its supply chain agility, and attained shared value by focusing on supply chain efficiency, supply chain resilience, and customer-demand intelligence. Specifically, JD.com implemented an end-to-end inventory management system based on a dynamic programming model and a neural network model, leading to a reduction in costs and enhancements in operational efficiency. To be able to provide guaranteed service levels for consumers during supply chain disruptions, JD.com utilized intelligent techniques, including an emergency classification mechanism and a simulation model, to strengthen critical partnership collaboration, to attain resilience, and to benefit the society as a whole. For the upstream manufacturers, JD.com implemented the consumer-to-manufacturer (C2M) system by incorporating state-of-the-art artificial intelligence algorithms, and enabled manufacturers to accurately sense customer demand and produce more popular products, hence creating value for the entire ecosystem. Billions of dollars in increased revenue and tens of millions of dollars in cost savings have been achieved since the implementation of aforementioned techniques to date, and customer welfare and partner manufacturers' benefits have been significantly enhanced.

2 A Better Match for Everyone, Reinforcement Learning at Lyft

Sebastien Martin[1], Tony Qin[2], [1]Kellogg School of Management, Northwestern University, Evanston, IL, [2]Lyft, San Francisco, CA

To better match drivers to riders in our ridesharing application, we revised Lyft's core matching algorithm using a novel reinforcement learning approach. This innovation enabled our drivers to serve millions of additional rides each year, leading to more than $30 million per year in incremental revenue.This change was the first documented real-world implementation of a ridesharing matching algorithm that can learn and improve in real time. Our experiments showed that this approach benefits drivers, riders, and the platform.

3 Innovative Integer Programming Software and Methods for Large-Scale Routing at DHL Supply Chain

Jon Cox[1], Manjeet Singh[1], Yibo Dang[2], Theodore Allen[2], [1]DHL Supply Chain, Westerville, OH, [2]Ohio State University, Columbus, OH

We utilize innovative integer programming approaches in the TNO software, including a new type of two-color ant colony search, leading to over $117 million in estimated savings to DHL Supply Chain and its customers and increasing the win rate from approximately 15% to approximately 60%.

Convex Relaxations for Polynomial Optimization

Community Committee Choice Session

Session Chair: Jie Wang, Chinese Academy of Sciences, China

1 A Correlative Sparse Lagrange Multiplier Expression Relaxation for Polynomial Optimization

Zheng Qu[1], Xindong Tang[2], [1]The University of Hong Kong, Pokfulam, Hong Kong; [2]The Hong Kong Polytechnic University, Hung Hom, Hong Kong

We consider polynomial optimization with correlative sparsity. We construct correlative sparse Lagrange multiplier expressions (CS-LMEs) and propose CS-LME reformulations for polynomial optimization using the KKT optimality conditions, and solve these reformulations by correlative sparse sum-of-squares (CS-SOS) relaxations. We show that the CS-LME reformulation inherits the original correlative sparsity pattern, and the CS-SOS relaxation provides sharper lower bounds when applied to the CS-LME reformulation, compared with when it is applied to the original problem. The convergence is guaranteed under mild conditions. In numerical experiments, our new approach usually finds the global optimum with a low relaxation order. Also, by exploiting the correlative sparsity, our CS-LME approach requires less computational time than the original LME approach.

2 Sum-Of-Squares Chordal Decomposition of Polynomial Matrix Inequalities

Yang Zheng[1], Giovanni Fantuzzi[2], [1]University of California San Diego, San Diego, CA, [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen, Germany. Contact: zhengy@eng.ucsd.edu

Sum-of-squares (SOS) optimization has found many applications in control theory, fluid dynamics, and power systems. In theory, SOS optimization can be solved in polynomial time using interior-point methods, but these methods are only practical for small- to medium-sized problems. In this work, we introduce decomposition methods for SOS optimization with chordal sparsity, which scale more favorably to large-scale instances. Chordal decomposition allows one to decompose a positive semidefinite cone into a set of smaller and coupled cones. This work extends the classical chordal decomposition to the case of sparse polynomial matrices that are positive (semi)definite globally or locally on a semi-algebraic set. The extended results can be viewed as sparsity-exploiting versions of the Hilbert-Artin, Reznick, Putinar, and Putinar-Vasilescu Positivstellensätze.

3 Community/Committee'S Choice Submission

Ngoc Hoang Anh Mai, Konstanz, Denmark

4 Risk Analysis for Stochastic Processes Using Polynomial Optimization

Jared F. Miller, Northeastern University, Boston, MA

This work formulates algorithms to upper-bound the maximum Value-at-Risk (VaR) of a state function along trajectories of stochastic processes. The VaR is upper bounded by concentration tail-bounds (Cantelli, Vysochanskij-Petunin). Concentration bounds lead to a infinite-dimensional Second Order Cone Program (SOCP) in occupation measures. Under compactness and regularity conditions, there is no relaxation gap between the infinite-dimensional convex program and their nonconvex optimal-stopping stochastic problems. Upper-bounds on the SOCP are obtained by a sequence of semidefinite programs through the moment-Sum-of-Squares hierarchy. The VaR-upper-bounds are demonstrated on example polynomial Stochastic Differential Equations.

Algorithms for Discrete Optimization

Community Committee Choice Session

Session Chair: Swati Gupta, ISyE Georgia Tech, Atlanta, GA

Session Chair: Jai Moondra, Georgia Institute of Technology, Atlanta, GA

1 Online Demand Scheduling with Failovers

Rudy Zhou[1], Konstantina Mellou[2], Marco Molinaro[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Microsoft Research, Redmond, WA

Motivated by cloud computing applications, we study the problem of how to deploy new hardware subject to power and robustness constraints. We have identical devices with capacity constraints. Demands come one-by-one and, to be robust against a device failure, need to be assigned to a pair of devices. When a device fails (in a failover scenario), each demand assigned to it is rerouted to its paired device (which may now run at increased capacity). The goal is to assign demands to the devices to maximize the total utilization subject to both the normal capacity constraints as well as these novel failover constraints. These latter constraints introduce new decision tradeoffs not present in classic assignment problems such as Multiple Knapsack and AdWords. We present algorithms for both the worst case and stochastic model, where demands come i.i.d. from an unknown distribution.

2 Determinant Maximization via Matroid Intersection

Adam Brown[1], Aditi Laddha[1], Madhusudhan Pittu[2], Mohit Singh[1], Prasad Tetali[2], [1]Georgia Tech, Atlanta, GA, [2]Carnegie Mellon University, Pittsburgh, PA

Determinant maximization provides a general framework for problems from statistics, convex geometry, fair allocation and network design. In an instance of the determinant maximization problem we are given a collection of vectors and the goal is to select a small subset where the sum of the rank-1 matrices formed by the chosen vectors has large determinant. In general we may have additional combinatorial constraints on which subsets can be selected, such as a matroid base constraint. In this work, we adapt the classical weighted matroid intersection algorithm and apply it to approximate determinant maximization. Instead of the traditional vertex weights, we use edge weights which measure the change in determinant after an individual swap, and iteratively search for improving cycles. Joint work with Aditi Laddha, Madhusudhan Pittu, Mohit Singh, and Prasad Tetali.

3 Online Covering in Stochastic and Random-Order Settings

Anupam Gupta[1], Gregory Kehne[2], Roie Levin[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Harvard University, Cambridge, MA, [3]Tel Aviv University, Tel Aviv, Israel

We present a framework for solving a broad class of online integer covering problems---including set cover, covering integer programs, and non-metric facility location---in a number of beyond-worst-case settings. We obtain simple and efficient O(log mn)-competitve algorithms for these {problems}×{settings} which are asymptotically optimal and essentially match offline complexity-theoretic lower bounds. We address models when constraints arrive (1) in random order, (2) from a partially observed adversarial input sequence, (3) drawn from distinct prior distributions, and (4) in a hybrid two-stage/online stochastic model. We derive algorithms for (2)-(4) via simple black-box reductions to the random-order setting (1).

4 Maintaining Matroid Intersections Online

Sherry Sarkar[1], Daniel Hathcock[1], Anupam Gupta[1], Niv Buchbinder[2], Anna Karlin[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Tel Aviv University, Tel Aviv, Israel; [3]University of Washington, Seattle, WA, Contact: sherrys@andrew.cmu.edu

Maintaining a maximum bipartite matching online while minimizing recourse/augmentations is a well studied problem, motivated by content delivery, job scheduling, and hashing. A breakthrough result of Bernstein, Holm, and Rotenberg resolved this problem up to a logarithmic factors. However, we may need a richer class of combinatorial constraints (e.g., matroid constraints) to model other problems in scheduling and resource allocation. We consider the problem of maintaining a maximum independent set of an arbitrary matroid M and a partition matroid P in the online setting. Our main result is an O(n log ^2 n)-competitive algorithm, where n is the rank of the largest common base. A key contribution of our work is to make connections to market equilibria and prices, and our use of properties of these equilibria in submodular utility allocation markets.

Network Design and Optimization

Community Committee Choice Session

Session Chair: Zeyad Kassem, Arizona State University, Tempe, AZ

1 Using Hexagonal Grid Topology for Wireless Sensor Networks Optimization

Ceca Mijatovic, The George Washington University, Washington, D.C., DC, Contact: cecamijatovic@gwmail.gwu.edu

Distribution of Internet-of-Things sensors often leads to transmission conflicts and inefficiency of energy utilization, resulting in decreased sensor communication and incomplete data for decision making. Even 5% to 20% of missing data makes the performance of recognition sensors decrease to 84% and 45% respectively, rendering the data unusable. In common deployments, sensors are placed randomly, causing limited coverage and poor monitoring quality. The use of hexagonal grid topology in broad wireless sensor networks deployments (for monitoring of wind power plants, water surface pollution, and deep space) can optimize network coverage, reduce energy consumption, and enhance network reliability. Optimization objective is to maximize sensor spacing while minimizing the total energy consumption of the network by leveraging unique hexagonal grid properties.

2 Where to Invest in Resilience in a Facility Network?

Kedong Chen[1], Ankur Mani[2], Kevin W. Linderman[3], [1]Old Dominion University, Norfolk, VA, [2]University of Minnesota - Twin Cities, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN, Contact: kchen@odu.edu

This study examines an underexplored question of where to invest in resilience in a facility network. Prior studies offered insights into this issue, with some scholars recommending a focus on critical nodes, while others emphasize the importance of critical paths. Yet the node and path perspectives have not been fully integrated and optimized for facility networks. This study reconciles the debate over node vs. path and proposes the optimal strategy of resilience investment that maximizes expected max-flow through the network. The analysis reveals that investing in high-capacity nodes is optimal under rare disruptions, whereas investing in entire paths is best under frequent disruptions. The problem is generally NP-hard, but we propose greedy algorithms inspired by both the node and path perspectives to provide approximate solutions with performance guarantees.

3 Minimum Feedback Arc Set over Bidirectional Graphs with an Application to Faculty Hiring Network

Adolfo Raphael Escobedo, Sina Akbari, Arizona State University, Tempe, AZ

This work introduces a novel graph theory problem that includes the minimum feedback arc set as a special case, specifically, it expands from this classic problem by allowing bidirectional arcs in the input graph and output arc set. Multiple integer programming formulations for solving it are derived and compared. The proposed framework is implemented to study faculty hiring networks to identify the prestige (rank) of different departments within specific disciplines.

4 The Edge-Based Contiguous P-Median Problem with Connections to Territorial Districting

Zeyad Kassem, Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ, Contact: zekassem@asu.edu

We introduce the edge-based contiguous p-median (ECpM) problem to partition a road network into a given number of compact and contiguous territories. Two binary programming models are introduced. The first model requires an exponential number of cut set-based constraints to model contiguity; it is paired with an iterative branch and bound algorithm with a cut generation scheme (B&B&Cut). The second model utilizes a polynomial number of shortest-path constraints to model contiguity and can be solved with off-the-shelf solvers. The two solution approaches associated with the proposed models are tested on road networks with up to 2,018 nodes and 2,655 edges. The shortest path-based formulation attains speed ups in computational time up to almost 4x relative to the computational time of solving the first optimization model via B&B&Cut.

The Interplay between Learning, Optimization, and Statistics

Community Committee Choice Session

Session Chair: Lijun Ding, University of Wisconsin -- Madison, Seattle, WA

Session Chair: Alex L. Wang, [1</sup]

1 Self-Calibration and Biconvex Compressed Sensing with Applications in MRI

Yuan Ni[1], Thomas Strohmer[1,2], [1]University of California Davis, Davis, CA, [2]Center for Data Science and Artificial Intelligence Research (CeDAR), Davis, CA, Contact: yuani@ucdavis.edu

Self-calibrated parallel imaging strategies provide a robust mechanism for accelerating MRI acquisitions. However, most such strategies result in reconstruction that corresponds to solving a challenging biconvex optimization problem. In this work, we bring together the concepts of Self-Calibration, Compressive Sensing, and Biconvex Optimization. We show how self-calibrated parallel imaging can be treated as a convex optimization problem using the idea of 'Lifting'. By exploiting block sparsity in the signal model, we derive explicit theoretical guarantees for robust and stable recovery.

2 Score Approximation, Estimation and Distribution Recovery of Diffusion Models on Low-Dimensional Data

Minshuo Chen[1], Mengdi Wang[2], [1]Princeton University, Princeton, NJ, [2]Princeton University, Princeton, NJ

Diffusion models achieve state-of-the-art performance in various generation tasks. However, their theoretical foundations fall far behind. This paper studies score approximation, estimation, and distribution recovery of diffusion models. Our result provides sample complexity bounds for distribution estimation using diffusion models. We show that with a properly chosen neural network architecture, the score function can be both accurately approximated and efficiently estimated. Furthermore, the generated distribution based on the estimated score function captures the data geometric structures and converges to a close vicinity of the data distribution. The convergence rate depends on the data intrinsic dimension, indicating that diffusion models can circumvent the curse of data ambient dimensionality.

3 Sharp Exact Penalty Formulations in Signal Recovery

Lijun Ding[1], Alex L. Wang[2], [1]University of Wisconsin -- Madison, Seattle, WA, [2]Purdue University, West Lafayette, IN, Contact: wang5984@purdue.edu

 We study a sample complexity vs. conditioning tradeoff in modern signal recovery problems where convex optimization problems are built from sampled observations. We begin by introducing a set of condition numbers related to sharpness for a general class of convex optimization problems covering sparse recovery, low-rank matrix sensing, and (abstract) phase retrieval. Then, we show that these condition numbers improve with the number of samples in each of the three signal recovery problems. Finally, we introduce a new first-order method based on mirror descent that is able to converge linearly on these problems. This new algorithm has a convergence rate explicitly depending on our condition numbers.

4 Benign Overfitting And Grokking In Two-layer Neural Networks

Zhiwei Xu[1], Yutong Wang[1], Spencer Frei[2], Gal Vardi[3], Wei Hu[1], [1]University of Michigan, Ann Arbor, MI, [2]UC Davis, Davis, CA, [3]TTI-Chicago, Chicago, IL, Contact: yutongw@umich.edu

Grokking refers to the phenomenon in which a model near-perfectly fits the training data, while the test accuracy stagnates before eventually rising. For non-linearly separable data generated by a noisy XOR function, we prove that two-layer neural networks trained by gradient descent exhibit a grokking-like behavior under suitable assumptions. More precisely, we show that after one training iteration, the model perfectly fits the training data, while the expected test accuracy is close to 1/2. Moreover, after two training iterations, the model generalizes to the test data.

Special Topics in Derivative-free Optimization

Community Committee Choice Session

Session Chair: Sara Shashaani, North Carolina State University, Raleigh, NC

Session Chair: Yunsoo Ha, NC State, Raleigh, NC

1 Consistency and Complexity of Adaptive Sampling Based Trust-Region Optimization

Yunsoo Ha[1], Sara Shashaani[2], [1]NC State, Raleigh, NC, [2]North Carolina State University, Raleigh, NC

We present complexity results of a class of stochastic noncovex optimization problems with trust-region methods and adaptive sampling schemes devised for zeroth order (ASTRO-DF) and first order (ASTRO) stochastic oracles. We present two metrics for measuring efficiency; the classical iteration complexity and work or sampling complexity. The latter is more appropriate for adaptive sampling procedures where the total number of queries to the stochastic oracle varies per iteration.

2 Deepzero: Scaling up Zeroth-Order Optimization for Deep Model Training

Aochuan Chen[1], Yimeng Zhang[1], James Diffenderfer[2], Bhavya Kailkhura[2], Sijia Liu[1], [1]Michigan State University, East Lansing, MI, [2]Lawrence Livermore National Laboratory, Livermore, CA

Zeroth-order (ZO) optimization has become a popular technique for solving machine learning (ML) problems when first-order (FO) information is difficult or impossible to obtain. However, the scalability of ZO optimization remains an open problem: its use has primarily been limited to relatively small-scale ML problems. To overcome this roadblock, this paper proposes DeepZero, a principled and practical ZO deep learning (DL) framework that scales ZO optimization to DNN training through three primary innovations. We show that DeepZero achieves state-of-the-art (SOTA) accuracy on ResNet-20 trained on CIFAR-10, approaching FO training performance for the first time. Furthermore, we demonstrate the practical utility of DeepZero in two real-world use cases, certified adversarial defense and physics-coupled DL.

3 Sample Sizing for Function Estimation in Stochastic Derivative-Free Optimization

Luis Nunes Vicente, Lehigh University, Bethlehem, PA

We introduce a new tail bound condition for function estimation which allows for an improvement in the required sample sizing for derivative-free optimization of the order delta^{-2q} (non-correlated errors) and delta^{2-2q} (correlated errors), where delta is the step size or trust-region radius and the error is assumed to have a momentum of order q/(1-q). We also introduce simple stochastic non-smooth direct-search and trust-region methods, sharing the following principles: generate a direction; generate the new iterate by either search along the direction or by solving a trust-region subproblem (where the linear term is the direction); use a sufficient decrease acceptance test to decide if the trial point can be accepted or not. The methods are shown to globally converge almost surely under the new tail bound condition. Joint work with F. Rinaldi and D. Zeffiro.

4 The Limitation of Neural Nets for Approximation and Optimization

Tommaso Giovannelli, Griffin Kent, Luis Nunes Vicente, Lehigh University, Bethlehem, PA, Contact: tog220@lehigh.edu

We are interested in assessing the use of neural networks to approximate and minimize objective functions in optimization problems. While neural networks are widely used for machine learning tasks such as classification and regression, their application in solving optimization problems has been limited. Our study begins by determining the best activation function for approximating objective functions of popular nonlinear optimization test problems. We then show that the composition of an activation function with the natural basis can lead to benefits for polynomial interpolation or regression. Lastly, we provide insights into the limitation of using neural networks to enhance the performance of optimization methods that do not use derivatives.

Recent Theory and Applications in DRO 2

Community Committee Choice Session

Session Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN

Session Chair: Eojin Han, Southern Methodist University, Dallas, TX

1 Robust Satisficing MDPs

Haolin Ruan[1], Siyu Zhou[2], Zhi Chen[3], Chin Pang Ho[1], [1]School of Data Science, City University of Hong Kong, Hong Kong, China; [2]The City University of Hong Kong Shenzhen Research Institute, Shenzhen, China; [3]CUHK Business School, The Chinese University of Hong Kong, Hong Kong, China. Contact: haolin.ruan@my.cityu.edu.hk

Robust MDPs are proposed to overcome parameter ambiguity in MDPs by optimizing the worst-case performance under ambiguity. While robust MDPs can provide reliable policies with limited data, their worst-case performances are often overly conservative. This paper proposes robust satisficing MDPs (RSMDPs), where the expected returns of feasible policies are softly-constrained to achieve a user-specified target under ambiguity. We derive a tractable reformulation for RSMDPs and develop a first-order method for solving large instances. Experimental results showcase the strong target-oriented feature of RSMDPs. Moreover, the average and percentile performances of our model are competitive among other models. We also demonstrate the scalability of the proposed algorithm compared with a state-of-the-art commercial solver.

2 A General Approach to Solve Shape-Constrained Distributional Optimization via Importance-Weighted Sample Average Approximation

Zhenyuan Liu[1], Henry Lam[1], Devaushi Singham[2], [1]Columbia University, New York, NY, [2]Naval Postgraduate School, Monterey, CA

Shape-constrained optimization arises in a wide range of problems including distributionally robust optimization (DRO) that has surging popularity recently. In the DRO literature, these problems are usually solved via reduction into moment-constrained problems using the Choquet representation or its variants, whose tractability is determined case by case. In this work, we develop a general method to solve shape-constrained DRO by integrating sample average approximation with importance sampling, which reduces these infinite-dimensional problems into linear programs. Our approach handles shape-constrained DRO that are beyond the reach of previous Choquet-based reformulation. Our theoretical underpinning builds on empirical process theory and reveals how shape constraints play an important role to guarantee desirable consistency and convergence rates.

3 A Distributionally Robust Stochastic Clearing Policy

Sila Cetinkaya[1], Eojin Han[2], [1]SMU, Dallas, TX, [2]Southern Methodist University, Dallas, TX

We propose a distributionally robust optimization framework for operating of a stochastic clearing system consisting of an input process (orders) and a clearing mechanism that instantaneously serves them. We show that distributionally robust optimal clearing cycles can be found efficiently when distributional ambiguity is described with mean, support and mean-absolute deviation. The proposed method allows analytical solutions in special cases which offer multiple managerial insights. Our framework is general, and, thus, can incorporate temporally correlated arrivals and convex cost structure. Extensive simulation results are provided to obtain additional practical insights on the proposed method.

4 Distributionally Robust Discrete Choice Model and Assortment Optimization

Bin Hu[1], Qingwei Jin[2], Daniel Zhuoyu Long[1], Yu Sun[1], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Zhejiang University, Hangzhou, China. Contact: sun-yu@link.cuhk.edu.hk

We introduce two distributionally robust assortment formulations, robust assortment revenue optimization and robust assortment revenue satisficing. By using the multinomial logit model as the reference choice model for both formulations, we show that the optimal assortments exhibit a revenue-ordered property, derive the closed-form worst-case distribution, construct a discrete choice model based on the worst-case distribution and conduct corresponding analysis. Moreover, we generalize the analysis to the distributionally robust assortment under the nested logit model. We next compare the two approaches and find that the revenue satisficing approach can achieve the target revenue with a higher probability and a lower computational complexity. In computational studies, we show that our approaches outperform both robust and stochastic approaches.

Stochastic Programming with Discrete Decisions and/or Decision-Dependent Uncertainty

Community Committee Choice Session

Session Chair: Zhichao Ma, University of Wisconsin Madison, Madison, WI

1 Data-Driven Facility Location Problem with Multimodal Decision-Dependent Demand Ambiguity

Beste Basciftci, University of Iowa, Iowa City, IA

We propose a distributionally robust facility location problem under demand uncertainty where customer demand is multimodal and its distribution depends on the location decisions. We present a moment-based ambiguity set, where the first and second moment information of multimodal demand distribution depend on the open facilities. We derive a monolithic reformulation of the proposed problem under this set, which can be a mixed-integer linear program depending on the form of decision-dependency. We propose a cutting-plane based solution algorithm that leverages separation problems and derive valid inequalities to strengthen the formulation. Our computational studies demonstrate the value of integrating multimodality and decision dependency into this problem by having better performance in terms of profit and quality of service, compared to existing approaches.

2 Scaled Cuts for Stochastic Mixed-Integer Programming

Ward Romeijnders, Niels van der Laan, University of Groningen, Groningen, Netherlands. Contact: w.romeijnders@rug.nl

We develop a new type of Benders' decomposition for two-stage stochastic mixed-integer programs with general mixed-integer variables in both time stages. In this algorithm we iteratively construct tighter lower bounds of the expected second-stage cost function using a new family of so-called scaled optimality cuts. We derive these cuts by parametrically solving extended formulations of the second-stage problems using deterministic mixed-integer programming techniques. The advantage of these scaled cuts is that they allow for parametric non-linear feasibility cuts in the second stage, but that the optimality cuts in the master problem remain linear. We establish convergence by proving that the optimality cuts recover the convex envelope of the expected second-stage cost function.

3 A Risk-Averse Multistage Stochastic Model Utilizing Scenario Dominance Cuts for Optimal Control of a Forest Invasive Insect

Sabah Bushaj[1], Esra Buyuktahtakin Toy[2], Robert G. Haight[3], [1]State University of New York at Plattsburgh, Plattsburgh, NY, [2]Virginia Tech, Blacksburgh, VA, [3]USDA Forest Service, Saint Paul, MN, Contact: sbush010@plattsburgh.edu

In this study, we formulate a risk-averse multistage, stochastic, mixed-integer programming (RA-MSS-MIP) model. We then present a cutting plane algorithm based on scenario ordering to tackle decision-dependent uncertainty for an invasive species management problem. We aim to assist decision-makers in allocating resources for the surveillance of the ash population for Emerald Ash Borer (EAB) infestation and subsequent treatment and removal of infested trees over space and time in the State of New Jersey.

4 A Model and Method for Optimization Problems with Decision-Dependent Uncertainty

Zhichao Ma[1], Jeffrey T. Linderoth[2], Jim R. Luedtke[2], [1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, Contact: zma59@wisc.edu

Traditional stochastic programming models assume exogenous uncertainties, where decision-makers have no control over the realization of uncertain parameters. However, in many real-world situations, uncertainties are endogenous, influenced by the decision-maker's actions or policies. We focus on stochastic programs with endogenous uncertainty in which decisions can affect the time of realization of uncertainty. We provide a three-stage stochastic program with binary decision variables in the first stage that can determine the realization time of uncertainty, whether in the second stage or in the third stage. We develop methods to estimate the upper and lower bounds of this problem. Additionally, we present a branch and bound algorithm to efficiently solve the problem, which can significantly reduce computation time compared to the extensive form.

Facility Location and Logistics for Disaster Operations Management

Community Committee Choice Session

Session Chair: Vedat Bayram, Kent, United Kingdom
Session Chair: Ali Kemal Dogru, University of Southern Mississippi, Hattiesburg, MS

1 Multimodal Social Aid Distribution in Urban Areas

Baris Yildiz[1], Vedat Bayram[2], Vahid Akbarighadikolaei[3], Ali Kemal Dogru[4], Pinar Keskinocak[5], [1]Koc University, Sariyer, Turkey; [2]University of Kent, Kent Business School, Canterbury, United Kingdom; [3]University of Nottingham, Nottingham, United Kingdom; [4]University of Southern Mississippi, Hattiesburg, MS, [5]ISyE Georgia Tech, Atlanta, GA

The lack of an infrastructure to facilitate the fast and economical distribution of social aid is one of the main obstacles to enhancing the scope and the quality of social aid efforts. Difficulties related to last-mile delivery operations result in spending a significant part of the aid resources on delivery expenditures or blocking a substantial in-kind donation potential. To address this issue, for the first time in the literature, we propose to use existing public transit (PT) systems to constitute a backbone network to transfer in-kind donations in an urban area and place collection/transshipment centers in the selected PT stations to facilitate transportation of goods between origins/destination points of the donations and the public transit system by the volunteer couriers.

2 Mixed-Integer Programming for Team Sizing and Vehicle Assignment in Unstructured Off-Road Environments

Sachet Khatiwada[1], Pamela Murray-Tuite[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: sachetk@g.clemson.edu

Off-road vehicle operations are common in post-disaster relief and evacuation scenarios. Moving in an unstructured off-road environment requires consideration of many variables, for mission completion and safety. This presentation proposes a mixed integer linear programming-based approach to assign vehicles from a heterogeneous vehicle fleet into different teams along different paths while considering vehicle properties and path characteristics. Preliminary results from experiments for team assignment along two different paths in unstructured environments, from a 17-vehicle fleet of 3 different vehicle types show that this approach successfully assigns teams along the planned paths. OPSEC #7490 DISTRIBUTION A. Approved for public release; distribution unlimited.

3 Capacity Pre-Allocation for Multi-Period Mobile Facility Location with Spatial Coverage

Jessa Rhea, University of Iowa, Iowa City, IA

In covering mobile facility location, the task is to route a fleet of *M* mobile facilities with capacity *Q* over *T* discrete time periods to maximize the difference between the total demand served of customers within the mobile facilities' coverage radii and the transportation costs of the mobile facilities. Our model captures the situation where customers ultimately decide when and which mobile facility to visit and treats the resource provided by the mobile facility as a fixed amount rather than a rate per unit time. We focus on the behavior of the model as various capacity pre-allocation strategies are considered with the goal of providing equitable service to customers in each period while still maximizing served demand.

4 Preparedness Network Design for Relief Supplies in Response to Foreseen Disasters

Vala Rahmati, Halit Uster, Southern Methodist University (SMU), Dallas, TX, Contact: vrahmati@smu.edu

A well-designed relief network can be crucial in saving lives and helping people recover after a disaster. However, designing such a network involves considering various factors such as cost and time constraints. To address this, we proposed a mixed integer model that minimizes costs and satisfies evacuee demand by determining the supply locations and delivery in a time-efficient manner. For the model solution, we examine several enhancement techniques within a Benders Decomposition framework. We report results based on randomly generated instances for the algorithmic efficiencies and also results of a real case study with real data from the state of Texas using GIS.

Large-scale Data Analytics for Transportation Systems - Session II

Community Committee Choice Session

Session Chair: Sean Z. Qian, Carnegie Mellon University, Pittsburgh, PA

1 Pathways for Harnessing Open-Specification and Multi-Resolution Network Analysis Tools for Advanced Transportation Systems Analysis

Mustafa Gadah[1], Xuesong Zhou[2], [1]Arizona State University, tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: mgadah1@asu.edu

Expanding the open-specification GMNS-based ecosystem and harnessing the power of Geographic Information Systems (GIS) and Python are the primary objectives in enhancing transportation systems analysis. This talk presents the extensive use of these tools for large-scale data analytics in smart city transportation planning. Topics covered include fundamental aspects of GIS, advanced network modeling techniques, and the mapping of linear reference systems. Additionally, a case study conducted in the Town of Gilbert showcases a streamlined workflow for transportation analysis modeling and simulation, demonstrating the practicality of utilizing open-source and multi-resolution network analysis tools.

2 A-Team: Advanced Traffic Event Analysis and Management Platform for Enhanced Transportation Decision-Making

Zilin Bian, New York University, New York, NY, Contact: zb536@nyu.edu

With the surge in transportation data availability, integrating emerging AI/ML methods into decision support systems is both promising and challenging. A full-fledged decision support system requires not only well developed and calibrated models, but also efficient connections with back-end infrastructure and front-end utilities. This paper introduces the A-TEAM, a large-scale data analytics platform designed to streamline the decision-making process. It can incorporate user-defined AI/ML models, providing versatile visualization and interactive front-end functionalities to generate various case scenario results. The A-TEAM demonstrated three real-world applications tested on NY City datasets: work zone management, traffic forecasting, and crash analysis, providing valuable decision-making support to both traffic researchers and practitioners.

3 Applying Data-Driven Research to Real-World Traffic Operations Issues

Yao-Jan Wu, Pramesh Pudasaini, University of Arizona, Tuscon, AZ

Transportation agencies have invested a great deal amount of funding in intelligent transportation systems, especially traffic sensor technologies, to better manage traffic and reduce congestion. However, not all agencies have fully utilized the capacities of advanced technologies. This presentation aims at providing data-driven solutions to enhancing traffic data usability for performance measurement for responsive traffic management and operations.

4 Optimizing Universal Basic Mobility Programs in Multimodal Networks

Lindsay Graff, Carnegie Mellon University, PITTSBURGH, PA, Contact: lgraff@andrew.cmu.edu

Several American cities have recently piloted Universal Basic Mobility (UBM) programs aimed at removing transportation barriers. UBM programs offer community members a fixed monthly credit to be used on shared mobility services, such as public transit, car share, e-scooter, and bike share. However, the relationship between UBM's social impact and the monetary value of the fixed credit in multimodal systems is unclear. Owing to open data policies that have made new types of transportation-related data available, this analysis is now possible. Building upon previous work where we design a routable multimodal network model, we propose a method that uses this model to optimize the value of the fixed credit to maximize social benefit. Social benefit in this context is defined in terms of accessibility to opportunities.

Data Intelligence and Travel Behaviors

Community Committee Choice Session

Session Chair: Yili Tang, University of Regina, Regina, SK, Canada

1 Evaluating Impacts of the Joint Price-Resource Strategy in Transport Markets Under Equity Constraints Using Hong Kong Travel Data

Yanyan Ding, Xiaoshu Ding, Sisi Jian, Liu Jianing, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong

Recent advances in information technology have enriched the data that mobility service providers (MSPs) can collect from travelers, such as trip records and individual characteristics. MSPs can adopt a discriminatory mobility resource allocation and pricing strategy to maximize their profits according to traveler clusters derived from customer data. Nonetheless, such inequitable treatment of travelers has sparked widespread social concerns. To ensure that mobility services are accessible and affordable to all social groups, we develop a framework to investigate MSPs' joint pricing and mobility resource allocation strategies under equity constraints and use Hong Kong travel data to quantify the corresponding impacts. Results show that there exists an equity level threshold, above which the MSP will cease operation to avoid a deficit.

2 Spatial-Queue Based Mesoscopic Traffic Model and Its Application in Wildfire Evacuation Simulations

Pengshun Li[1], Bingyu Zhao[2], Kenichi Soga[1], [1]University of California, Berkeley, Berkeley, CA, [2]Vienna University of Technology, Vienna, Austria. Contact: pengshun@berkeley.edu

To capture highly dynamic traffic situations, efficient mesoscopic models can deliver comprehensive yet fast results. This paper presents a spatial-queue based mesoscopic simulation model, with each vehicle represented as an autonomous agent with origin, destination, route choice, and other properties. Vehicles on a road are assumed to run at free-flow speed until joining a queue of vehicles at the downstream end. The length of the queue increases until no more vehicles can enter, creating the spillback effect often seen in congestion and disaster evacuation situations. Case studies are presented to demonstrate the applications in wildfire evacuations. The detailed disaggregated results are used to quantitatively evaluate intervention options and understand the challenges for evacuees in reaching safe destinations due to traffic bottlenecks and congestion.

3 A Framework for Enhanced EV Adoption: Optimizing Long-Distance Electric Vehicle Infrastructure in Canadian Sparsely Populated Areas

Majid Emami Javanmard, Yili Tang, University of Regina, Regina, SK, Canada. Contact: emami@uregina.ca

The research offers a novel approach for locating crucial route segments and tailoring long-distance EV infrastructure in order to increase the comfort of EV travel. It investigates current vehicle traffic patterns, including origins, destinations, trip lengths, and seasonal fluctuations, by analyzing intercity highway records, traffic statistics from Regina, and the provincial traffic database of Saskatchewan. Sensitivity studies examine the viability of transforming petrol stations into EV charging stations, taking into account variables like station number, locations, and vehicle types. The study gives helpful suggestions for enhancing long-distance EV travel in sparsely populated Canadian locations, improving EV charging infrastructure, and resolving concerns about limited range.

4 Users' Charging Behavior and Power Level Preferences of Electric Vehicle on Urban Areas

Jesús Adrián Martínez Hernández, University of Regina, Regina, SK, Canada

In 2020 road transportation accounted for around 19% of total greenhouse gas emissions in Canada. According to estimates, by 2030 at least 95% of light duty vehicles sales should be EVs to meet decarbonisation goals and keep global average temperature increase below 1.5 °C. Yet many challenges remain for the in-mass adoption, being the absence of a fully deployed charging infrastructure one of the main concerns for prospect users. This research seeks to employ discrete choice modelling based on revealed preference data to analyze users' charging behavior and power level preferences. The proposed approach can help to develop an integrated framework with the purpose to optimally deploy infrastructure according to actual EV users' behavior and needs, achieving a better allocation of resources in the short term, and a more efficient and reliable infrastructure for users.

5 Spatial-Temporal Impacts of On-Demand Transit Service on Neighborhood Ridership and Economic Growth

Yili Tang, Zaima Tasneem, University of Regina, Regina, SK, Canada. Contact: ytangap@gmail.com

On-demand transit (ODT) services is being rapidly adopted by many transit agencies given its advantages in flexibility and potential cost reduction. This paper analyzed and evaluated the impacts of on-demand transit services on neighbourhood with a case study in the City of Regina, Canada. The analysis suggests a growth in the ridership for each individual neighborhood that implemented the ODT service. The study also specifically investigates the effects of location endowment characteristics of a neighborhood (evaluated by accessibility and connectivity) to understand these impacts. Results indicated the potential of on-demand transit services not only improve ridership but also the economy of a neighborhood. Moreover, the accessibility and connectivity of neighboring areas also impact the economic growth of one another.

Advanced Control, Command and Optimization for Transportation Networks

Community Committee Choice Session

Session Chair: Xuewu Dai, 1</sup

Session Chair: Meng Zhao, 1</sup

1 Pricing for Shared Charging Parking Spaces in Urban Mixed Parking Lots

Yi Zhang, Minfang Huang, North China Electric Power University, Beijing, China. Contact: yizoe@foxmail.com

In view of the increasing market penetration of electric vehicles, mixed parking has emerged as an operational paradigm that allows for shared parking and charging spaces for both fuel-powered and electric vehicles. However, in urban areas where parking spaces are generally limited, conflicts arise between user demands, such as fuel-powered or fully charged vehicles occupying charging spaces. This study examines the coordinated management of mixed parking lots, and develops a two-tier game model that produces the Pareto-Nash equilibrium that maximizes social welfare. The proposed theoretical methods of pricing for shared charging and parking spaces may contribute to optimizing urban static traffic environment, increasing the efficiency of charging and parking resources, and promoting sustainable development in the electric vehicle industry.

2 Integrated Optimization of Rolling Stock Allocation and Train Timetables for Urban Rail Transit Networks: A Benders Decomposition Approach

Fan Pu, Texas A&M University, College Station, TX

We investigate integrated optimization of rolling stock allocation and train timetables (RATT) in an urban rail transit network with multiple lines and depots. Our model aims to optimize investment cost and passenger service quality by generating rolling stock allocation plans and train schedules. To handle computational complexity, we develop a Benders decomposition-based solution algorithm, decomposing the problem into a rolling stock assignment problem and train scheduling subproblems. We test our approach on real-world instances from the Beijing rail transit network, showing significant improvements in service quality compared to existing plans. Our RATT approach achieves a 17.6% average improvement in service quality using the same fleet size.

Forecasts and Machine Learning in Air Transportation

Community Committee Choice Session

Session Chair: Xufang Zheng, American Airlines,

Fort Worth, TX
Session Chair: shulu Chen, George Washington University, Arlington, VA

1 Integrated Conflict Management for Uam with Strategic Demand Capacity Balancing and Learning-Based Tactical Deconfliction

Shulu Chen[1], Antony Evans[2], Marc Brittain[3], Peng Wei[1], [1]George Washington University, Washington, DC, [2]Airbus UTM at Acubed, Sunnyvale, CA, [3]MIT Lincoln Laboratory, Lexington, MA, Contact: shulu@gwu.edu

Before the commercialization and adoption of Urban air mobility (UAM), aviation safety must be guaranteed. Reinforcement learning has demonstrated effectiveness in the tactical deconfliction of en route commercial air traffic in simulation. However, its performance is found to be dependent on the traffic density. In this project, we propose a novel framework that combines demand capacity balancing (DCB) for strategic conflict management and reinforcement learning for tactical separation. By using DCB to precondition traffic to proper density levels, we show that reinforcement learning can achieve much better performance for tactical safety separation. In addition, combining strategic DCB with reinforcement learning for tactical separation can meet these safety levels while achieving greater operational efficiency than alternative solutions.

2 Air Transportation Local Share Analysis and Forecast

Xufang Zheng, American Airlines, Fort Worth, TX

Air transportation local share is a crucial metric that quantifies the disparity between original passengers and connecting passengers at airports. It serves as an indicator of an airport's role within the intricate air transportation network system, reflecting the network strategies employed by competing airlines at that airport. In the wake of the pandemic, airports are undergoing significant transformations due to changes in demand and network dynamics. Understanding which airports will regain their pre-pandemic status and which will assume new roles is a compelling research topic for the Federal Aviation Administration (FAA). This study focuses on analyzing and forecasting the local share at domestic airports across the United States to identify distinct changes and future behaviors of local share .

3 Identifying Similar Thunderstorms via the Optimal Transport Theory

Binshuai Wang, The George Washington University, Washington, DC, Contact: derekwang@gwu.edu

Thunderstorms are one of the important uncertainties in air traffic control. We propose a new approach to identify temporal-spatial similar thunderstorms with respect to aviation operational considerations via the optimal transport theory. Different from existing geometric methods, we represent each thunderstorm with a probability distribution, and similarity is measured by the Wasserstein distance of their distributions. By setting different kernel functions, we can also redefine the similarity of thunderstorms, so that multiple factors can be expressed in the same framework. In addition, we also develop an unsupervised learning method to cluster thunderstorms and generate similar thunderstorm data based on clustering. Experimental results show our approach is robust and efficient.

4 Machine Learning-Based Approach Towards Dynamic Airspace Network Generation for Regional Air Mobility Operations in South Korea

Junghyun Kim[1], Seulki Kim[2], [1]Handong Global University, Pohang, Korea, Democratic People's Republic of; [2]Georgia Institute of Technology, Atlanta, GA

This research focuses on establishing airspace infrastructure for upcoming Regional Air Mobility (RAM) operations in South Korea. The proposed methodology leverages three different algorithms: 1) a partitioning-based clustering algorithm for placing vertiport locations, 2) a density-based clustering algorithm for predicting areas of convective weather, and 3) the Latin Hypercube Sampling-based Probabilistic Roadmap (LHS-based PRM) algorithm for generating an adaptive airspace network. The resulting airspace takes into account airspace restriction areas such as prohibited areas or military operation areas. The main contribution of this research is to employ a data-driven approach using machine learning and LHS-based PRM algorithms to dynamically establish airspace infrastructure potentially utilized for upcoming RAM operations in South Korea.

5 Machine Learning for Anomaly Detection and Precursor Identification in Commercial Aviation

Nikunj C. Oza, NASA, Moffett Field, CA

The National Airspace is a very safe system. We must keep it safe through expected changes such as increasing variety of traffic (e.g., UAVs). The system is currently monitored using exceedances---rules describing known safety issues. By definition, these rules cannot identify previously unknown safety issues. Also, they do not identify precursors to safety issues—states that may not represent safety issues themselves, but are conditions under which safety issues are more likely to occur. In this talk, I describe machine learning-based methods that we have developed for anomaly detection and precursor identification and the aviation safety results that we have obtained. I also describe the active learning algorithm that we have developed to mitigate the false alarm problem that is common to data-driven anomaly detection methods.

Adaptive Learning for Platform Operations

Community Committee Choice Session

Session Chair: Ruohan Zhan, Hong Kong University of Science and Technology, Clear Water Bay

Session Chair: Zhengyuan Zhou, Stern School of Business, New York University

1 Treatment Effects in Market Equilibrium

Evan Munro[1], Stefan Wager[2], Kuang Xu[3], [1]Stanford University, Stanford, CA, [2]Stanford GSB, Stanford, CA, [3]Stanford Graduate School of Business, Stanford, CA, Contact: munro@stanford.edu

When randomized trials are run in a marketplace equilibriated by prices, interference arises. To analyze this, we build a stochastic model of treatment effects in equilibrium. We characterize the average direct (ADE) and indirect treatment effect (AIE) asymptotically. A standard RCT can consistently estimate the ADE, but confidence intervals and AIE estimation require price elasticity estimates, which we provide using a novel experimental design. We define heterogeneous treatment effects and derive an optimal targeting rule that meets an equilibrium stability condition. We illustrate our results using a freelance labor market simulation and data from a cash transfer experiment.

2 Adaptively Learning to Rank Unstructured Items in Online Platforms

Ying Jin, Department of Statistics, Stanford University, Stanford, CA

We study learning to adaptively rank a list of unstructured items to optimize cumulative user engagement in online platforms. We formulate this problem via a contextual-bandit approach, with actions being rankings that account for user characteristics and position effects. For each item ranked at any position, we construct an upper confidence bound for the engagement score to balance exploration and exploitation. Our algorithm then chooses the ranking action by solving a maximum weight matching problem. Our algorithm achieves the regret of O(Kd\sqrt{T}) when ranking K items in a d-dimensional feature space over T rounds, under the generalized linear model assumption on user engagement scores. This regret relieves the dependence on the total action space of K! different rankings. Experiments demonstrate improved user engagement of our algorithm compared to baselines.

3 Synthetic Combinations: A Causal Framework for Combinatorial Interventions

Abhineet Agarwal, University of California, Berkeley, Berkeley, CA, Contact: aa3797@berkeley.edu

Consider the problem of learning unit-specific potential outcomes for N heterogenous units under any combination of p interventions. Running N x 2^p experiments to estimate all parameters is infeasible. Further, with observational data there is confounding. We study this problem under a novel model that imposes latent structure across both units and combinations. That is, we assume the matrix of potential outcomes, and the coefficients in the Fourier expansion of potential outcomes have rank r, and sparsity s respectively. We establish identification, and propose a estimation procedure, Synthetic Combinations, for all parameters despite unobserved confounding. Our approach requires far fewer observations to achieve consistency as compared to previous methods. We use Synthetic Combination to propose a experimental design mechanism for combinatorial inference.

4 Risk-Sensitive Reinforcement Learning

Zhengqi Wu, Renyuan Xu, University of Southern California, Los Angeles, CA, Contact: zhengqiw@usc.edu

Reinforcement learning (RL) methods have garnered significant attention in Operations Research, particularly in applications such as portfolio management, traffic planning, and clinical trial recommendations. There is a pressing need to mitigate the risk of the decision maker (DM). Problem-dependent criteria have been proposed, such as safety constraints and exponential utility functions. However, Risk-sensitive RL with general utility functions remains an open question.

In this talk, we consider a scenario where the DM optimizes a general utility function of the cumulative reward. We extend the state space with an extra dimension for the cumulative reward. We then propose a modified value iteration algorithm that employs an epsilon-covering over the extended state space. Under mild assumptions, our algorithm efficiently identifies the near-optimal policy.

5 Revisiting the Role of Competitor Information in Airline Pricing: Insights from a Field Experiment

Gang Guo, Changchun Liu, Chung Piaw Teo, National

University of Singapore, Singapre, Singapore. Contact: gangg@u.nus.edu

The determination of airfares is a crucial aspect of revenue management in the airline industry. While it is common for airlines to consider competitors' price ladders when designing their own, we argue that this approach may be suboptimal in volatile and uncertain competitive environments. We propose the integration of demand prediction into ladder pricing. We test our hypothesis by partnering with a leading airline company, consisting of 16 routes over two months. Our results show that embedding demand prediction into ladder pricing leads to increased revenue. Our findings suggest that in volatile competitive environments, greater weight should be given to self-demand when setting prices, and less weight should be allocated to competitors' information.

Learning in Games

Community Committee Choice Session

Session Chair: Christian Kroer, Columbia University, New York, NY

Session Chair: Gabriele Farina, 1</sup

1 Near-Optimal Learning of Extensive-Form Games with Imperfect Information

Yu Bai, Salesforce AI Research, Palo Alto, CA, Contact: yu.bai@salesforce.com

Imperfect Information Games, where players can only make decisions based on partial information about the true underlying state of the game, constitute an important challenge for modern artificial intelligence. This talk presents several recent advances on learning Imperfect-Information Extensive-Form Games (EFGs) from bandit feedback. We present the first line of near-optimal algorithms for learning various equilibria, such as Nash Equilibria in two-player zero-sum games, Coarse Correlated Equilibria in multi-player zero-sum games, and various notions Correlated Equilibria such as the Extensive-Form Correlated Equilibria and its several generalizations. The number of episodes scale only linearly in the number of information sets in the game tree, building on new *balancing* techniques.

2 Zero-sum Polymatrix Markov Games: Equilibrium Collapse and Efficient Computation of Nash Equilibria

Ioannis Panageas, Fivos Kalogiannis, UC Irvine, Irvine, CA

The works of (Daskalakis et al., 2009, 2022; Jin et al., 2022; Deng et al., 2023) indicate that computing Nash equilibria in Markov games is a computationally hard task. This fact raises the question of whether or not computational intractability can be circumvented if one focuses on specific classes of Markov games. Inspired by zero-sum polymatrix normal-form games (Cai et al., 2016), we define a class of zero-sum multi-agent Markov games in which there are only pairwise interactions described by a graph. For this class of Markov games, we show that an □-approximate Nash equilibrium can be found efficiently. To do so, we show that the set of coarse-correlated equilibria collapses to the set of Nash equilibria. Afterwards, it is possible to use any algorithm that computes approximate Markovian coarse-correlated equilibria policies to get an approximate Nash equilibrium.

3 Block-Coordinate Methods and Restarting for Solving Extensive-Form Games

Darshan Chakrabarti, Columbia University

Coordinate methods are popular for their simple updates and excellent practical performance. Extending them to sequential games is difficult because the strategy spaces do not satisfy the separable block structure exploited by these methods. We present the first cyclic coordinate-descent-like method for computing a Nash equilibrium in two-player zero-sum extensive-form games. We show our method enjoys a O(1/T) convergence rate, while avoiding polynomial scaling in the number of blocks. Our method exploits the recursive structure of the proximal update induced by dilated regularizers in order to perform pseudo-block updates. Empirically, our algorithm usually performs better than mirror prox and sometimes beats CFR+. We also introduce a restarting heuristic for EFG solving that can often lead to speedups for our cyclic method and existing methods.

4 Learning to Bid in Adversarial First-Price Auctions

Zhengyuan Zhou, NYU Stern, New York, NY

First-price auctions have very recently swept the online advertising industry, replacing second-price auctions as the predominant auction mechanism on many platforms. This shift has brought forth important challenges for a bidder: how should one bid in a first-price auction, where unlike in second-price auctions, it is no longer optimal to bid one's private value truthfully and hard to know the others' bidding behaviors? In this paper, we take an online learning angle and address the fundamental problem of learning to bid in repeated first-price auctions, where both the bidder's private valuations and other bidders' bids can be arbitrary.

Modeling for Equity and Sustainability

Community Committee Choice Session

Session Chair: Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA

Session Chair: Zana Cranmer, Bentley University, Waltham, MA

1 Municipal Climate Action Planning

Zana Cranmer, Bentley University, Waltham, MA

National climate targets are made up of climate actions taken at a local level. Larger and more well-resourced municipalities can draw on expertise to craft and implement plans. Smaller and under-resourced municipalities have greater difficulty in accessing the same opportunities. This work develops an open-source tool to support local stakeholders with varying levels of expertise to tap into data and modeling resources.

2 The Role of Carbon Capture in a Power System's Just Decarbonization

Paola Furlanetto[1], Erin Baker[2], [1]UMass Amherst, Amherst, MA, [2]Univ of Massachusetts-Amherst, Amherst, MA, Contact: ppimentelfur@umass.edu

We evaluate how adding Carbon Capture to fossil fuel power plants influences the stock and distribution of heath-harming airborne pollutants (local pollutants) considering technological uncertainties and policy design. The objective of this exercise is to identify scenarios where a climate policy - one that focuses on CO2 limits - leads to more local pollution or to an unequal pollution burden to vulnerable communities. Our results indicate Carbon Capture leads to higher local pollution when the corresponding emission controls are not enforced. Including additional air pollution controls translates into more costs for an already expensive technology. In short, for Carbon Capture to be part of a route to net zero that is also equitable, baseline costs and emission requirements must go beyond greenhouse gases.

3 Exploring Equity of Ridehailing for Essential Travel During Disrupting Weather Conditions

Carlos Mateo Samudio Lezcano, Destenie Nock, Corey Harper, Jeremy Michalek, Gregory Lowry, Carnegie Mellon University, Pittsburgh, PA, Contact: csamudio@andrew.cmu.edu

The dependence on ridehailing as a widespread means of transportation has increased significantly in recent years. As a result, the shifts in market prices can significantly impact the population of essential riders who rely solely on ridehailing for their transportation needs. This study aims to estimate the effects of disruptive weather events, such as rain, snow, and heat waves, on ridehailing market prices. Using this estimation, we analyze the impact of these weather events on the essential rider population. The study provides insights into the challenges faced by essential riders and highlights the need for policies to ensure equitable access to affordable ridehailing services during disruptive weather events.

4 Comparing Electric Vehicle Charging Station Long-Distance Coverage

Lily Hanig[1], Catherine Ledna[2], Destenie S. Nock[3], Corey D. Harper[4], Arthur Yip[2], Eric Wood[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]National Renewable Energy Laboratory, Golden, CO, [3]Carnegie Mellon University, Pittsburgh, PA, [4]Carnegie Mellon University, Pittsburgh, PA, Contact: lhanig@andrew.cmu.edu

Passenger vehicles are the largest sector of greenhouse gas emissions in the US. Electric vehicles (EVs) present a lower-emissions option; however, many consumers hesitate to purchase an EV because of 'range anxiety'. The Bipartisan Infrastructure Law (BIL) allocates $5 billion for fast chargers along interstates to spur EV adoption and the National Electric Vehicle Infrastructure (NEVI) Program designated highway corridors to place fast chargers on first. We use a breadth-first search to compute a novel consecutive coverage metric to find: 1) What is the consecutive EV charging coverage from each county? 2) What is the increase in coverage by state from the NEVI program? In 2023, only 10% of counties have minimum viable coverage above 75%. The NEVI-program will improve fast charger coverage the least for California (21% increase) and the most for Maine (94% increase).

High-Dimensional Data Analytics for Manufacturing

Community Committee Choice Session

Session Chair: Fenglian Pan, University of Arizona, Tucson, AZ
Session Chair: Jian Liu, University of Arizona, Tucson, AZ

1 Layer-Wise Process Parameters Optimization for Metal Additive Manufacturing

Chaoran Dou, Rongxuan Wang, Zhenyu James Kong, Virginia Tech, Blacksburg, VA

Metal parts produced by Additive Manufacturing (AM) suffer from many quality issues due to suboptimal process parameters setting. Traditional approaches used fixed process parameters for the entire part. Such methods do not consider the layer-wise difference during printing. Nevertheless, if considering the layer-wise effect, the number of process parameters to be optimized brings tremendous challenges for process optimization. Therefore, we proposed a novel methodology, which formulates process parameters along the layer-wise direction as a parametric function. Such a function is a linear combination of several pre-determined base functions. Then, the weights of each base function can be optimized to achieve the best final quality. In case studies, the proposed method significantly improved the overall printing quality compared to traditional approaches.

2 Multimodal Probabilistic Modeling and Characterization of Melt Pools

Runsang Liu, Hui Yang, Penn State University, State College, PA, Contact: rzl275@psu.edu

The variations of melt pool geometry are closely pertinent to mechanical and functional properties of final AM builds. Most of previous works are concerned about the extraction of melt pool features (e.g., geometric statistics, size, shape descriptors) for AM process monitoring. However, very little has been done to investigate the emission physics of photons that leads to the generation of melt pool images. This work presents a novel approach to simulate the emission of photons for statistical estimation and modeling of the multimodal probability distribution function (PDF) of a melt pool. In addition, we investigate how process conditions influence the geometric variations of melt pools. Experimental results show that the proposed methodology effectively builds the multimodal distribution model of melt pool geometric variations.

3 Adaptive Sampling and Monitoring for Image Data

Jinwei Yao[1], Chao Wang[2], [1]The University of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, IA, Contact: jinwei-yao@uiowa.edu

Image-based monitoring techniques have achieved great success in many engineering applications. However, most existing image monitoring methods require fully observed images to implement modeling/monitoring. This requirement limits the application of these techniques for images with large sizes and/or cameras with limited scanning area. In this paper, we propose to solve this issue by splitting the large image into multiple sub-images and using partially observed sub-images to implement monitoring of the whole large image. More specifically, the two-dimensional multivariate functional principal analysis (2D-MFPCA) is proposed to model the cross-and-within correlation among sub-images, which facilitates the information augmentation from partially observed sub-images.

4 Probabilistic Framework for Modeling Internal Defects in Additive Manufacturing

Shehzaib Irfan, Jia Liu, Auburn University, Auburn, AL, Contact: szi0016@auburn.edu

Additive manufacturing (AM) offers many advantages, but AM parts are prone to forming internal defects that adversely affect the fatigue life of these parts. These defects are of different types, each impacting the fatigue differently due to its distinct geometry. Also, the spatial distribution of these defects in the manufactured part plays a key role in the fatigue behavior of that part. Therefore, accurate spatial modeling of these defects is paramount and can contribute to a better understanding of the fatigue behavior of additively manufactured parts. We will develop a probabilistic framework using spatial statistics to model the distribution of different defects inside the part. This will provide insights into process physics beyond the mere parameters and enable researchers to incorporate the impact of defects' location in modeling AM parts' fatigue behavior.

High-dimensional Data Modeling for Quality and Reliability Improvements

Community Committee Choice Session

Session Chair: Meng Zhao, University OF Florida, Gainesville, FL
Session Chair: Mostafa Reisi, University of Florida, Gainesville, FL

1 Personalized Tucker Decomposition: Modelling Commonality and Peculiarity on Tensor Data

Jiuyun Hu[1], Naichen Shi[2], Raed Al Kontar[2], Hao Yan[1], [1]Arizona State University, Tempe, AZ, [2]University of Michigan, Ann Arbor, MI, Contact: jiuyunhu@asu.edu

We propose a personalized Tucker decomposition (perTucker) to address the limitations of traditional tensor decomposition methods in capturing the heterogeneity in distributed systems. PerTucker decomposes tensor data into shared global components and personalized local components. We introduce a mode orthogonality assumption and develop a proximal gradient regularized Block Coordinate Descent algorithm, guaranteed to converge to a stationary point. PerTucker enables efficient data representation for multiple clients and demonstrates effectiveness in anomaly detection, client classification, and clustering through a simulation study and two case studies: solar flare detection and tonnage signal classification.

2 E^{Rpca}: Robust Principal Component Analysis for Exponential Family Distributions

Xiaojun Zheng, Duke University, Durham, NC

Robust Principal Component Analysis (RPCA) is a widely-used method for recovering low-rank matrices corrupted by significant and sparse outliers. The joint identification of the corruptions with its low-rank background is fundamental for process diagnosis and quality control. However, existing RPCA methods do not account for non-Gaussian noise, which arises in a variety of process imaging and monitoring applications. We thus propose a new method called Robust Principal Component Analysis for Exponential Family distributions e^{RPCA}, which can perform the desired decomposition into low-rank and sparse matrices under exponential family noise. We present a novel alternating direction method of multiplier optimization algorithm, and demonstrate the effectiveness of e^{RPCA} in two applications for steel defect detection, and for Atlanta crime activity monitoring.

3 Multi-Sensor Prognostics Modeling for Failure Mode Identification of Systems with Two Failure Modes

Linfeng Song, North Carolina State University, Raleigh, NC, Contact: lsong5@ncsu.edu

The failure of complex engineering systems often can result from one of its multiple components, which yields multiple failure modes. However, it is usually challenging to identify the failure mode of an in-situ system using condition monitoring signals. In this work, we propose a supervised dimension reduction-based failure classification method that can fuse the degradation signals from multi-sensors to identify the failure mode of a partially degraded system. A computationally efficient optimization algorithm is proposed for parameter estimation. The effectiveness of the proposed method is validated using numerical studies.

4 An Adaptive Approach for Online Monitoring of Large Scale Data Streams

Shuchen Cao[1], Ruizhi Zhang[2], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]UGA, Athens, GA, Contact: Ruizhi.Zhang@uga.edu

In this paper, we propose an adaptive top-r method to monitor large-scale data streams where the change may affect a set of unknown data streams at some unknown time. Our proposed method combines the Benjamin-Hochberg (BH) false discovery rate (FDR) control procedure and the CUSUM procedure to construct a global monitoring statistic that can estimate the number of changed data streams adaptively and can detect the change quickly. Theoretically, we show that our proposed method can estimate the number of changed data streams for both the pre-change and post-change status. Moreover, we perform simulations and two case studies to show its detection efficiency.

High-dimensional Data Analysis: Modeling, Monitoring and Control

Community Committee Choice Session

Session Chair: Kamran Paynabar, ISyE Georgia Tech, Atlanta, GA

Session Chair: Mohammad Bisheh, Georgia Institute of Technology, Atlanta, GA

1 Umap for Degradation Modeling and Prognostic Analysis Under Multiple Failure Modes and Working Conditions

Ying Fu, Kaibo Liu, University of Wisconsin-Madison, Madison, WI, Contact: ying.fu@wisc.edu

Complex systems often face multiple failure modes, necessitating diagnostic measures. Using a single prognostic model for RUL prediction often underperforms. Current methods, which require failure mode labels and employ high-dimensional classification, face interpretability, and practicality issues.

To counter this, we adapted UMAP to identify failure modes and trace each unit's degradation. A time-series trajectory-based clustering method was used to determine failure mode labels. For new data, a low-dimensional classification model calculates the probability of each failure mode. RUL prediction is handled by a deep-branched LSTM network with partitioned inputs. The final output, a combination of the LSTM units' outputs weighted by the failure mode probability, has proven effective in assessing multiple failure modes in aircraft gas turbine engines.

2 Latent State Behavior Estimation Through A Variational Autoencoder Structure With Application To Utility Analytics

Afshin Asadi, Ramin Moghaddass, University of Miami, Coral Gables, FL

Identifying factors that derive the consumption behavior of industrial equipment, like compressors and chillers, is a known challenge that requires a comprehensive understanding of the equipment's dynamic behavior as well as hidden variables, such as efficiency and degradation status. Leveraging the power of Variational Autoencoders (VAEs), our model aims to extract undercover latent patterns hidden in power consumption. The VAE's structure captures essential features and generates new data instances. By fusing real-time measurements of known variables with VAE-generated samples, we enable dynamic predictions of the power consumption over time. Through this approach, our model harnesses both VAE capabilities and Seq2Seq architecture to deliver real-time predictions for power consumption, while optimizing data logging in industrial efficiency projects.

3 Image-Based Characterization of Laser Scribing Quality Using Transfer Learning

Mohammad N. Bisheh, Georgia Institute of Technology, Atlanta, GA

This research explores the use of ultrafast laser scribing for microscale materials processing. The study focuses on real-time quality monitoring during the scribing process. A deep transfer learning model is proposed, which leverages a pre-trained CNN model for basic geometric features. The transfer learning model successfully characterizes scribing quality, including debris, scribe width, and straightness, with 96% accuracy using both small and large datasets. The model's performance remains consistent even when applied to a different scribing application with additional training. This approach enables effective measurement of quality characteristics using a smaller image dataset and reduce number of trainable parameters to a third compared to regular CNN models.

4 Reliability Analysis of Multivariate Degradation Processes Considering Long Range Dependence

Ali Asgari, Wujun Si, Wichita State University, Wichita, KS

Multivariate degradation modeling has been widely used to obtain the reliability information of products using degradation data of multiple Performance Characteristics (PCs). Recently, a Long-Term Memory (LTM) effect has been observed in the degradation process of various PCs, which implies that the future degradation process highly depends on both the present degradation state and the past degradation trajectory. However, the LTM effect has not been considered in the current multivariate degradation modeling. In this talk, we will present a new multivariate degradation model that captures the LTM effect, based on which reliability analysis is developed. Simulation and real case studies are proposed to validate the proposed model.

ENRE Energy and Climate Session

Community Committee Choice Session

Session Chair: Max Vanatta, University of Michigan, Ann Arbor, MI

1 A Targeted Approach to Energy Burden Reduction Measures: Comparing the Effects of Energy Storage, Rooftop Solar, Weatherization, and Energy Efficiency Upgrades

Bethel Tarekegne, Jessica Kerby, PNNL, Richland, WA, Contact: bethel.tarekegne@pnnl.gov

As energy prices rise and climate change brings more extreme and frequent days of heating and cooling, households must allocate more of their income to energy bills, increasing their energy burden. Many strategies are employed to alleviate high energy burden, such as weatherization, energy efficiency, and energy storage and rooftop solar, though the benefits of each scale based on factors such as climate, housing characteristics, and energy behaviors. This study used variation in these factors across the United States to create a set of representative houses to investigate the variable responses to different energy burden reduction measures in the simulation environment GridLABD.

2 Energy Planning for Decarbonization in Neighborhoods and Districts

Ben Polly, National Renewable Energy Laboratory
Approaching energy planning for decarbonization at a community scale, such as in urban districts and neighborhoods, can unlock unique opportunities for advanced solutions that deliver deep savings and enhanced benefits. This can include technologies and strategies such as electrified, efficient and energy-flexible buildings; shared energy systems; heat recovery and heat pump-based district thermal systems; integrated distributed energy resources and coordinated controls. However, robust methods and tools are needed to analyze and optimize community-scale decarbonization solutions in conjunction with electricity grid infrastructure, including understanding how demand-side investments can be optimized in conjunction with grid upgrades and controls. This presentation will describe efforts to develop the open-source URBANopt modeling platform to help address these needs, including efforts to make capabilities accessible and highly customizable for practitioners to work with communities to develop equitable and tailored solutions.

3 Opportunities and Challenges for Community Solar: A Case Study on Community Solar to Increase Renewable Energy Deployment in the City of Los Angeles

Ashreeta Prasanna, Jane Lockshin, National Renewable Energy Laboratory, Golden, CO, Contact: ashreeta.prasanna@nrel.gov
Community solar enables access to electricity savings from solar for customers unable to install rooftop solar. The goal of the analysis presented in this paper is to identify potential community solar sites that encourage equitable access to solar in the city of Los Angeles (LA). We find that despite significant technical potential on government owned and other public-use land parcels, only a small proportion of sites (25%) would be economically viable to develop. Additional market factors and other challenges in deployment are likely to reduce this economic potential further resulting in lower deployment. Without targeted incentives and modifications to the current program structure, community solar is unlikely to be deployed at the required scale and provide the benefits of solar deployment, investment, and alleviation of electricity burden for communities in need.

Resilience and Sustainability Considerations in Power Grid Planning and Operations

Community Committee Choice Session

Session Chair: Brent Austgen, The University of Texas at Austin, Lowell, IN

1 Scenario-based Optimization Models For Power Grid Resilience Decision-making For Extreme Flood Events

Ashutosh Shukla, Erhan Kutanoglu, John Hasenbein, University of Texas at Austin, Austin, TX, Contact: ashutosh.shukla@utexas.edu
Extreme weather events such as hurricanes cause significant damage to the power grid. Consequently, stakeholders must evaluate and adopt mitigation measures to enhance its resilience. To help address this challenge, we present scenario-based optimization models for power grid resilience decision-making, using flooding as a motivating example. We integrate flood forecasts from a physics-based storm-surge model with a power flow model to decide an optimal substation hardening strategy. We account for uncertainties associated with the flood forecasts using robust and stochastic formulations. Finally, we propose a method to suggest near-optimal value of budget that should be allocated for substation hardening to minimize the total disaster cost. We develop our results using a case-study for the Texas coastal region using storm surge scenarios developed by NOAA.

2 Integrated Planning Of Hydrogen Supply Chain Network And Power System

Siqiang Guo[1], Erhan Kutanoglu[2], Shadi Goodarzi[3], [1]University of Texas at Austin, Austin, TX, [2]University of Texas-Austin, Austin, TX, [3]University of Texas Austin, Austin, TX, Contact: siqianggeorgeguo@gmail.com
Hydrogen is an important solution to decarbonize sectors such as heavy-duty transportation, industry, and utility. A comprehensive design of hydrogen supply chains (HSC) makes decisions for the production, distribution, and storage of hydrogen based on its application. Due to high diversity of choices in each of these stages, optimal HSC planning remains challenging. Moreover, renewable hydrogen, which is mainly produced through electrolysis, inherently relates to the power system. It is intuitively right to plan HSC and power system integratedly.
We formulate a model that combines capacity expansion modeling of power system and planning of HSC. We answer questions like: What does the optimal HSC look like? Does

integrated planning differ much from separate planning? We also explore aspects such as carbon tax, different ways of incentives, and their effectiveness.

3 Exploring American Residential Community Distributed Energy Resource Adoption Potential by Energyshed

Eric Scheier, Emergi Foundation, SF Bay Area, CA

Energy equity and distributed resource integration have the potential to interact positively and negatively throughout the energy transition. Here, we estimate the impact of deploying community co-located DERs within each United States electric distribution grid as measured by a number sustainability and resilience metrics alongside market values. We show which cohorts are expected to contribute to and benefit most from different energy transition pathways and demonstrate future scenarios that meet 24/7 energy needs with affordable, clean energy.

4 Accelerating Grid Orchestration And Digital Transformation: Cloud Migration For A Carbon-Neutral Power Grid

Joe Nyangon, PhD, SAS Institute, Cary, NC

Accelerating grid orchestration and decarbonization is pivotal for digital transformation and modernization of power systems, and cloud migration has emerged as the catalyst for this change. This presentation delves into how strategic cloud migration, sustainable software engineering, and optimization can foster this acceleration. Attendees will learn about cloud computing service models, industry analysis, and the benefits of migration. Sustainable and financial gains depend on the provider's renewable power mix, hardware efficiency, and circular value chains. The session will conclude with a discussion on the future of cloud migration, technological innovation, and the utility industry's imperative to orchestrate a clean energy grid.

Wildfire Risk Management for Electric Power Systems

Community Committee Choice Session

Session Chair: Line Roald, University of Wisconsin - Madison, Los Alamos, NM

Session Chair: Noah Rhodes, Greenville

1 A Data-Driven Automated Mitigation Approach for Resilient Wildfire Response in Power Systems

Amarachi Umunnakwe, Texas A&M University, College Station, TX, Contact: amarachi@tamu.edu

Wildfires lead to colossal losses on territory, state, and federal levels affecting critical infrastructure, the economy, decarbonization and social sustainability, hence highlighting the need to improve critical infrastructure wildfire-resilience. Existing wildfire mitigation methods are usually compartmentalized, focusing on already progressing wildfires. We present a data-driven, spatiotemporal, low-cost, and resilience-comprehensive model, SL-PWR, that automates wildfire mitigation by optimizing and providing real-time information from processed quantitative, qualitative, and visual data to appropriate emergency response teams. The SL-PWR de-compartmentalizes wildfire response, improving situational awareness and rapidity before, during, and after wildfire incidents, from proactive wildfire detection through to system restoration.

2 Optimal Power System Decision-Making in Presence of Active Wildfires

Anamitra Pal, Arizona State University, Tempe, AZ, Contact: anamitra.pal@asu.edu

In this session, I will talk about a decision-making framework for secure, economical, and resilient power system operation during active wildfires that leverages synchrophasor measurement-based enhanced situational awareness. The methodology involves solving the optimal power flow (OPF) problem iteratively, while incorporating security and stability constraints identified through steady-state and transient stability analyses. Specifically, we formulate a static security-constrained OPF for mitigating branch overloads and cut-set saturation and show the feasibility of transient stability-constrained OPF using machine learning. We also address the challenges of evaluating these constraints under diverse wildfire impacts and time limitations.

3 Risk-Averse Stochastic Programming for Wildfire Fuel Treatment Planning

Lina M. Villa-Zapata, Texas A&M University, College Station, TX, Contact: lina.villa@tamu.edu

Fuel treatment involves removing all or some of the vegetation from a landscape to reduce the potential for fires and their severity. Given the current state of the vegetation and a set of areas, fire managers must first decide on treatment options before fires occur. Then after the fire locations are known, the fire managers need to contain the fires to minimize damage. We model this problem using a rolling horizon framework that captures uncertainties in vegetation growth, weather, and wildfire risk. We parameterize our model through different fuel treatment options, vegetation growth, and wildfire behavior using standard wildfire simulation software. We apply this model to a case study based on historical data for West Texas.

4 Security Constrained Optimal Power Shutoff
Noah Rhodes[1], Carleton Coffrin[2], Line Roald[3], [1]University of Wisconsin-Madison, Madison, WI, [2]Los Alamos National Laboratory, Los Alamos, NM, [3]University of Wisconsin - Madison, Los Alamos, NM, Contact: nrhodes@wisc.edu
Electric grid faults are increasingly the source of ignition for major wildfires. To reduce the likelihood of such ignitions in high-risk situations, utilities use pre-emptive deenergization of power lines, commonly referred to as Public Safety Power Shut-offs (PSPS). This may leave the network particularly vulnerable to unexpected line faults that may occur while the PSPS is in place. Previous works have not explicitly considered the impacts of such outages. To address this gap, we propose the *Security-Constrained Optimal Power Shutoff* (SC-OPS) problem which uses post-contingency security constraints to model the impact of unexpected line faults when planning a PSPS. This SC-OPS model enables the exploration of trade-offs while designing PSPS plans, providing useful insights for utilities and policy makers considering different approaches to PSPS.

Monday, October 16, 8:00 AM - 9:15 AM

CC-North 231A
Elements of Electricity Market Design
Community Committee Choice Session
Session Chair: Harsha Gangammanavar, Southern Methodist University, Dallas, TX

1 Market Power Mitigation in a Two-Stage Electricity Market
Rajni Kant Bansal[1], Yue Chen[2], Pengcheng You[3], Enrique Mallada[4], [1]Johns Hopkins University, Baltimore, MD, [2]The Chinese University of Hong Kong, Sha Tin, Hong Kong; [3]College of Engineering, Peking University, Beijing, China; [4]Johns Hopkins University, Baltimore, MD, Contact: rbansal3@jhu.edu
Despite an efficient two-stage electricity market design, lack of market competition introduces price manipulation opportunities. To this end, operators are planning system-level market power mitigation (MPM) policies that replace noncompetitive bids. However, policy implementation with a limited understanding of participant incentives may lead to unintended losses. We model interactions of generators and loads in a two-stage settlement market with an MPM policy. For a real-time MPM policy, Nash equilibrium leads to a complete shift in demand allocation to real-time; a scenario highly undesired. The day-ahead MPM policy results in a generalized Stackelberg-Nash game where load makes decisions (leaders) in day-ahead, and generators make decisions (followers) in real-time. Equilibrium analysis leads to a closed-form solution that unveils several insights.

2 Power Sector Reliability Under Decarbonization and Energy Demand Pressures in Hydro-Dominated Regions of China
Michael R. Davidson[1], Ming Wei[2], [1]University of California, San Diego, San Diego, CA, [2]University of California San Diego, San Diego, CA, Contact: m2wei@ucsd.edu
China's electricity sector is key to addressing many of the country's most pressing public policy challenges. Partly as a result of the incomplete transition away from central planning, the sector now faces the paradoxical dilemma of generator overcapacity and seasonal power shortages across many regions. Based on newly collected open-source data, we explore these challenges in southern China, home to hydro-dominated Yunnan province with 100 GW of exploitable capacity. Firstly, we utilize monthly market data from 2016-2022 to analyze the effects of implementing a pay-for-performance capacity market coupled with other market and administrative measures. Secondly, we develop a unit commitment and economic dispatch model to assess historical periods of power tightness and future seasonal supply and demand reliability under different extremes conditions.

3 Spatial Arbitrage Through Bidirectional Electric Vehicle Charging with Delivery Fleets
Mostafa Mohammadian[1], Kyri Baker[1], Constance Crozier[2], [1]University of Colorado Boulder, Boulder, CO, [2]University of Colorado, Boulder, CO, Contact: mostafa.mohammadian@colorado.edu
The adoption of electric vehicles (EVs), including electric taxis and buses, as a mode of transportation, is rapidly increasing in cities.In addition to providing economic and environmental benefits, these fleets can potentially participate in the energy arbitrage market by leveraging their mobile energy storage capabilities. This presents an opportunity for EV owners to contribute to a more sustainable and efficient energy system while also reducing their operational costs. The study introduces deterministic and single-stage stochastic optimization frameworks that aim to maximize revenue by

optimizing the charging, discharging, and travel of a fleet of electric vehicles in the context of uncertainty surrounding both spatial and temporal energy prices.

CC-North 231B

Optimization Meets Machine Learning

Community Committee Choice Session

Session Chair: Carlos Henrique Cardonha, University of Connecticut, Storrs, CT

1 The Madness of Multiple Entries in March Madness

Jeff Sylvestre-Decary[1], David Bergman[2], Carlos Henrique Cardonha[2], Jason P. Imbrogno[3], Andrea Lodi[4], [1]University of Connecticut, Storrs, CT, [2]University of Connecticut, Storrs, CT, [3]University of North Alabama, Florence, AL, [4]Cornell Tech, New York, NY, Contact: jeff.sylvestre-decary@uconn.edu

This paper presents multi-entry betting strategies for single-elimination tournaments with top-heavy payoff structures. In these betting pools, participants select a winner for each game in the competition, and the number of correct guesses determines their score. A good strategy for bettors is to aim for a set of entries that maximizes the expected result of their best-performing entry. There is no known closed-form expression that computes this expectation for two or more entries, so we present a simulation algorithm and a Neural Network to estimate it. We then embed these methods within optimization procedures tailored to the problem. We tested our algorithms on every March Madness tournament played since 2017, and our results show that our best entries would have won $1 million against some of the best sports bettors in the world in a contest organized by DraftKings.

2 Optimizing over an Ensemble of Trained Neural Networks

Keliang Wang[1], Leonardo Lozano[2], Carlos Henrique Cardonha[3], David Bergman[3], [1]University of Connecticut, School of Business, Storrs, CT, [2]University of Cincinnati, Cincinnati, OH, [3]University of Connecticut, Storrs, CT

Recent literature has explored the use of a single neural network to model either uncertain or complex elements in an objective function. It is well known that ensemble of neural networks produce more stable predictions and have better generalizability than single neural networks. We study how to incorporate a neural network ensemble as the objective function. We develop a two-phase approach for our model that combines preprocessing procedures to tighten bounds for critical neurons in the neural networks with a Lagrangian relaxation-based branch-and-bound approach. Experimental evaluations suggest that using ensembles of neural networks yields more stable and higher quality solutions, compared with single neural networks, and that our optimization algorithm outperforms the state-of-the-art approach in terms of computational time and optimality gaps.

3 Constraint Learning to Define Trust Regions in Predictive-Model Embedded Optimization

Chenbo Shi[1], Mohsen Emadikhiav[2], Leonardo Lozano[3], David Bergman[1], [1]University of Connecticut, Storrs, CT, [2]Florida Atlantic University, Boca Raton, FL, [3]University of Cincinnati, Cincinnati, OH

There is a recent proliferation of research on the integration of machine learning and optimization. One expansive area within this research stream is predictive-model embedded optimization. In this setting, features of the predictive models become decision variables in the optimization problem. Despite a recent surge in publications in this area, only a few papers note the importance of incorporating trust region considerations in this decision-making pipeline. In this paper, we provide an overview of the approaches appearing in the literature to construct a trust region, and propose three alternative approaches. Our numerical evaluation highlights that trust-region constraints learned through isolation forests, one of the newly proposed approaches, outperform all previously suggested approaches, both in terms of solution quality and computational time.

4 Learning Decisions Offline from Censored Observations with □-Insensitive Operational Costs

Minxia Chen[1], Ke Fu[2], Teng Huang[2], [1]Sun Yat-sen University, Guangzhou, China; [2]Sun Yat-sen University, Guangzhou, China. Contact: huangt258@mail.sysu.edu.cn

We investigate the data-driven decision-making problem with an offline dataset that contains the feature data and the censored historical data of the variable of interest, but without the censoring indicators. We propose a novel offline framework to prescribe decisions based on the censored offline dataset via one-step machine-learning algorithms. Specifically, we design and leverage □-insensitive operational costs to deal with the unobserved censoring in an offline data-driven fashion. We derive a tight generalization bound for the custom LR model (LR-□NVC) and a high-probability generalization bound for the custom NN (NN-□NVC) trained by stochastic gradient descent. The numerical

results show that LR-NVC and NN-NVC outperform two benchmarks, with maximum cost savings up to 14.40% and 12.21% compared to the lowest cost generated by the two existing approaches.

Digital Freight Marketplaces

Community Committee Choice Session

Session Chair: Klaas Fiete Krutein, Convoy, Inc., Seattle, WA

1 Routing Synchronization Toward Sustainable Logistics

Alexandre Jacquillat[1], Sean Lo[2], Alexandria Schmid[2], [1]MIT Sloan School of Management, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: alexjacq@mit.edu

Advances in vehicle technologies and freight marketplaces offer opportunities to mitigate the environmental footprint of the logistics sector. Yet, emerging operating models require extensive coordination across logistics networks. This talk presents synchronized routing problems to support this transition, including: (i) a relay logistics problem in which long-haul shipments into short segments traveled by separate drivers; and (ii) an electric routing problem in which routing and charging decisions need to be optimized simultaneously. We propose extended formulations in time-space networks along with column generation algorithms to solve them at scale. Results show the scalability of the methodologies, and the impact of synchronization toward more efficient, reliable and sustainable supply chains. We conclude with emerging research directions.

2 Overcoming Spatial Frictions in Freight Platforms: Novel Contract Designs

Ozan Candogan[1], Klaas Fiete Krutein[2], [1]University of Chicago, Chicago, IL, [2]Convoy, Inc., Seattle, WA

Freight marketplaces connect shippers with carriers. However, spatial frictions can lead to inefficiencies such as carriers struggling to find a backhaul, which may disincentivize some carriers from participating in the marketplace. To address this challenge, we propose innovative contract designs in which carriers commit to the platform, and the platform selects shipments for contract carriers in both the short run and for the backhaul. We develop a model to analyze these contracts, create algorithms to optimize their performance, and highlight their practical implications using real-world data. Our findings shed light on the value of these contract designs in overcoming spatial frictions and improving efficiency in freight marketplaces.

3 Predictions and Demand Optimization in a Digital Freight Network

Felix Cheng, Convoy, Seattle

This abstract explores a pioneering industry initiative that seeks to establish a digital freight network. By leveraging Machine Learning and Optimization, it capitalizes on the extensive knowledge of experienced freight industry veterans across diverse local networks. The application of a TabTranform Deep Learning architecture enables a flexible freight cost prediction framework. Furthermore, it tackles the complex revenue optimization challenge by effectively balancing margin and win rate trade-offs through exploration and exploitation. The overall fundamental cornerstone of success lies in the implementation of a “human in the loop” strategy.

4 Routing for Dedicated-Like Trucking Services in a Digital Freight Marketplace

Klaas Fiete Krutein, Convoy, Inc., Seattle, WA, Contact: fietekrutein@gmail.com

The emergence of digital freight marketplaces has sparked new dynamics in the freight market. With increasing market density, digital marketplaces allow to leverage large amounts of data to increase the efficiency of the freight network through advanced truck routing solutions in dense market environments. There, trucking capacity can be sourced by time spans instead of by shipment, giving the marketplace operator more flexibility in assigning schedules. This presentation will introduce an approach to truck routing that considers the unique circumstances and dynamics of digital freight marketplaces.

Monday, October 16, 8:00 AM - 9:15 AM

Convexification: Theory and Applications

Community Committee Choice Session

Session Chair: Chen Chen, The Ohio State University, Columbus, OH

1 Rank Pump for Polynomial Optimization

Daniel Bienstock[1], Chen Chen[2], Gonzalo Munoz[3],

[1]Columbia University, New York, NY, [2]The Ohio State University, Columbus, OH, [3]Universidad De O'Higgins, Rancagua, Chile. Contact: chen.8018@osu.edu

The feasibility pump is a well-known primal heuristic for integer programming that involves two alternating sequences of projections. The original pump was designed for binary problems, and found such projections using linear programming and simple rounding. Unfortunately, the elegance of the pump may be lost in other settings. For instance, a natural extension of the pump to nonconvex MINLP involves NP-hard projection problems. We present the latest results on our adaptation of the feasibility pump to polynomial optimization, called the rank pump. The rank pump has polynomial-time iterations, as its projection problems can be solved in polynomial time.

2 Sparsity-Exploiting Distributed Projections onto a Simplex

Yongzheng Dai, Chen Chen, The Ohio State University, Columbus, OH, Contact: dai.651@osu.edu

Projecting a vector onto a simplex is a well-studied problem that arises in a wide range of optimization problems. Numerous algorithms have been proposed for determining the projection; however, the primary focus of the literature has been on serial algorithms. We present a parallel method that decomposes the input vector and distributes it across multiple processors for local projection. Moreover, the method can be adapted to parallelize a broad range of serial algorithms from the literature. We fill in theoretical gaps in serial algorithm analysis, and develop similar results for our parallel analogues. Numerical experiments conducted on a wide range of large-scale instances, both real-world and simulated, demonstrate the practical effectiveness of the method.

3 A Slightly Lifted Convex Relaxation for Nonconvex Quadratic Programming with Ball Constraints

Samuel Burer, University of Iowa, Iowa City, IA

Globally optimizing a nonconvex quadratic over the intersection of m Euclidean balls is known to be polynomial-time solvable for fixed m. However, there is no known explicit, tractable, exact convex representation for $m > 2$. In this talk, we construct a new, polynomially sized semidefinite relaxation for this problem, and we demonstrate empirically that it is quite strong and quick compared to existing relaxations. The key idea is a simple lifting of the original problem into one higher dimension.

4 Mixed-Integer Conic Optimization for Reliability Enhancement of Distribution Systems

Milad Dehghani Filabadi, The Ohio State University, Columbus, OH

This paper provides a tractable optimization model for determining the placement of switches, tie lines, and underground cables in order to maximize the reliability of a distribution system. A central novelty in the model is the inclusion of nodal reliability constraints, which consider network topology. The resulting placement problem can be formulated either as a mixed-integer conic optimization problem or as a mixed-integer linear program. We demonstrate both theoretically and empirically that the judicious application of partial linearization is key to rendering a practically tractable formulation. Computational studies indicate that realistic instances can indeed be solved in a practical amount of time on standard hardware.

Perspectives on Novel Business Models and Emerging Technologies

Flash Session

Session Chair: Sara Saberi, Worcester Polytechnic Institute, Worcester, MA

1 A Business Model Approach to the Current State of Microsaas

Isa Mostachetti, Portland State University, Portland, OR

As platforms grow, so do their plugin offerings. Plugins, low code software, mobile applications, and Steam games are all instances of MicroSaaS. However, there is no agreed upon definition of MicroSaaS. This paper attempts to define the MicroSaaS business model based on existing literature. The findings suggest there are two defining features for MicroSaaS. The paper also lists the advantages and disadvantages of choosing the MicroSaaS business model for today's digital entrepreneur.

2 Explainability and Preference Manipulation of Algorithmic Nudge

Yuxiao Luo, Baruch Colege (CUNY), New York, NY, Contact: yuxiaoluo@hotmail.com

This paper investigates the impacts of digital nudging on customer purchase decisions. Drawing on literature of nudge and anchoring effect, this study proposes two types of nudges based on the transparency level: ambiguous badge (ex., *Amazon's Choice*) and specific badge (ex., *Best Seller*).

We further hypothesize that that specific badge will be less likely to manipulate user's preferences than ambiguous badge under the condition of preference mismatch. This study will contribute to the nudge literature, recommendation system and dark side in IS and bring ethical implication to the use of AI/ML model and algorithmic nudging.. The empirical result can be applied to user interface design for lowering the e-commerce product return rate.

3 Closed-Loop Supply Chain Model for Electronic Products: Examiningthe Impact of Blockchain Implementation

Sahar Bajgani[1], Sara Saberi[1], Fuminori Toyasaki[2], [1]Worcester Polytechnic Institute, Worcester, MA, [2]York University, Toronto, ON, Canada. Contact: ssaberi@wpi.edu

The COVID-19 pandemic has caused major supply chain disruptions and a chip shortage, affecting the semiconductor industry. Reverse logistics can optimize supply chains, reduce waste, and increase production capacity, but poses challenges such as e-waste quality, fraud prevention, and secure disposal of sensitive information. Blockchain technology can prevent counterfeit electronic parts and enhance traceability, but implementation requires significant investment and raises security concerns. We propose a closed-loop supply chain model for electronic products to examine the impact of blockchain implementation on outcomes.

Digital Twins and AI Applications

Contributed Session

Session Chair: Shankar Prawesh, Indian Institute of Technology (IIT Kanpur), Kanpur, India

1 Machine Learning-Based Vision for Additive Manufacturing Process

Iida Haghnegahdar, Texas University, Denton, TX

Manufacturing systems are increasingly faced with intrusions not only by traditional malicious actors such as hackers and cyber-criminals but also by some competitors and nations engaged in corporate espionage. Artificial intelligence (AI) is one of the novel approaches that has emerged to overcome the increasing complexity and sophistication of cybersecurity intrusions in manufacturing. These defensive and control-based AI method implements various machine learning algorithms for diverse types of controls, such as intrusion detection and malware detection. In this paper, the authors propose an action for AI-based intrusion and anomaly controls in research and practice for additive manufacturing. This paper proposes a deep convolutional neural network that is the most common type of neural network that use to recognize patterns in AM images through 3D printing.

2 Simulation and Digital Twin: Bridging the Gap

Ana C. Wooley[1], Daniel F. Silva[2], [1]University of Alabama in Huntsville (UAH), Huntsville, AL, [2]Auburn University, Auburn, AL, Contact: anacwooley@gmail.com

Modern industrial processes are being transformed by data-driven decision support tools like simulation, advanced data analytics, and Artificial Intelligence (AI). While Discrete Event Simulation (DES) accurately models manufacturing systems, it can be time-consuming and data-intensive. Integrating methods from big data analytics and AI, a Digital Twin (DT) can provide real-time insights and faithfully represent the system. This research aims to bridge the gap between DES and DT by demonstrating the steps to transform a fully capable DES model to a DT through a case study. Key transformation steps, challenges, and solutions are identified, showcasing the potential benefits of bridging DES and DT. The research concludes with lessons learned, critical success factors, and recommendations for future studies.

3 A Scheduling Framework for Real-Time Large-Scale Job Shop Scheduling

Shankar Prawesh[1], Avijit Khanra[1], Neha Kadu[1], Yuichi Koga[2], Yosuke Watanabe[2], Naoyuki Fujiwara[3], [1]Indian Institute of Technology (IIT) Kanpur, Kanpur, India; [2]Mitsubishi Heavy Industries, Ltd., Tokyo, Japan; [3]Mitsubishi Heavy Industries, Ltd., Tokyo, Japan. Contact: sprawesh@iitk.ac.in

The digital transformation of the manufacturing ecosystem enabled by data generated from disparate sources has created many opportunities for the adoption of lean manufacturing practices. However, there is scant research on using these data for large-scale production scheduling. We present a real-time large-scale job shop scheduling framework that could generate a good just-in-time schedule for operations in the order of millions honoring resource constraints, working shifts, and precedence relations. In this presentation, we will discuss the specifics of real-life job-shop problems that call for a careful design of algorithms and data structure. We will present our approach to solving this problem in detail and discuss how our scheduling framework can be leveraged for developing machine learning algorithms to achieve the just-in-time scheduling objectives.

MCGDM: MultiCriteria Group Decision Making Models

Community Committee Choice Session

Session Chair: Danielle C. Costa Morais, Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil
Session Chair: Eduarda Asfora Frej, Universidade Federal de Pernambuco, Recife, Brazil

1 Designing Cybersecurity Readiness Assessment Tool (CRAT): Navigating the Dilemma of Selecting the Right MCDM Method and Mapping It to User Interfaces

Abhishek Sharma, Rangaraja P. Sundarraj, Indian Institute of Technology Madras, Chennai, India. Contact: abhisheksharma.27ju@gmail.com

This study gives a design journey of a Cybersecurity Readiness Assessment Tool (CRAT) prototype through the lens of a mixed-mode study entailing four stages. This study's key contribution is the process we followed in developing the prototype tool and evaluating the tool at each stage. Overall the stages of the prototype development include mapping readiness factors and countermeasures and checking its feasibility for application to MCDM methods. We surveyed various MCDM and weighting methods in order to understand the feasibility of the initial design. This led us to test the concept of digital nudging, with respect to the User Interface (UI). We examine how different UIs perform in terms of cognitive effort and time performance and change in decision outcomes by using PL-TOPSIS as a base.

2 Multicriteria Group Decision Model for Ranking Beneficiaries of the Brazilian Agrarian Reform Program

João Batista Sarmento dos Santos-Neto, Carolina Lino Martins, Saulo Gomes Moreira, Nadya Kalache, Federal University of Mato Grosso do Sul, Campo Grande, Brazil. Contact: joao.sarmento@ufms.br

The agrarian reform began to be discussed by the government in Brazil in the late 1950s. Currently, the National Agrarian Reform Program (PNRA) seeks to enable access to land by small farmers by distributing public lands divided into areas. In this context, it is necessary within the scope of public policies for territorial and land governance to use models to define priorities in the occupation of the land in the country. Therefore, this study proposes a multicriteria group decision model to rank the candidate families interested in joining the PNRA to select beneficiaries for public policies aligned with the federal government's strategic social, environmental, and economic goals.

3 Group Decision Model for Sorting Flood Risks in Urban Areas

Danielle C. Costa Morais[1], Lucas da Silva[2], Marcelo Hazin Alencar[3], Rodrigo Ferreira[3], Adiel Teixeira De Almeida[4], [1]Universidade Federal de Pernambuco - UFPE, Recife - PE, Brazil; [2]Universidade Federal do Rio Grande do Norte (UFRN), Natal, Brazil; [3]Universidade Federal de Pernambuco, Recife, Brazil; [4]Universidade Federal de Pernambuco, Recife PE, Brazil. Contact: dcmorais@insid.org.br

Floods in urban areas have caused troubles in several dimensions such as social, economic, and environmental. This kind of problem deals with public decisions characterizing a group decision approach. This study proposes a multicriteria group decision model for sorting flood risks in urban areas, based on different DMs' perspectives regarding risks, using the ALARP (As Low As Reasonably Possible) principle with Utility Theory with the aid of a majority-oriented aggregation rule for establishing the initial preferences. Afterward, using FITradeoff for sorting method to recommend the flood risk categorization of urban areas (Intolerable, Manageable, Tolerable, and Broadly acceptable), to support the implementation of emergency mitigating disaster actions.

Locational Analysis for Supply Chain Design

Contributed Session

Session Chair: Youssef Boulaksil, UAE University, Al Ain, United Arab Emirates

1 Capacitated Facility Location and Inventory Management Problem Under Stochastic Demand: Multi-Period Closed-Loop Supply Chain Network Design
Sungjune Lee[1], Daeki Kim[2], [1]Korea University Business School, Seoul, Korea, Republic of; [2]Korea University Business School, Seoul, Korea, Republic of. Contact: junandhun@korea.ac.kr
A closed-loop supply chain is a supply chain that seeks to reduce costs and environmental impact by reusing products, and a pallet pooling system is selected as an example in this study. The proposed multi-period closed-loop supply chain optimization problem simultaneously considers the distribution center location decision and the inventory management problem to meet the stochastic customer demand. The non-linear objective function is linearized and CPLEX is adopted to solve conic quadratic mixed-integer programming. The additional constraint and row generation technique are adopted to boost the optimization.

2 Facility Location Optimization Model for Covid-19 in Oklahoma
Hamidreza Samadi[1], Shivakumar Raman[2], [1]The University of Oklahoma, Norman, OK, [2]The University of Oklahoma, Norman, OK, Contact: hamidreza.samadi@ou.edu
This paper implements a facility location-based approach to locate the COVID-19 test centers in the major counties of Oklahoma. The main goal is to minimize the total traveling distance to get tested and pursue a county-based demand approach. The model guarantees that the demand of people in each county will be satisfied. Parameters are assigned based on the released COVID-19 statistics. In the implementation process, two alternative scenarios are applied to the main model and further analysis is conducted. This project suggests a plan to choose the best locations among potential sites in terms of optimal travel distance. It also mentions about proposed model's limitations and possible research extensions.

3 Enhancing Instore Picking Efficiency: A Comprehensive Analysis of Backroom Assignments
Sebastian Köhler, Felicia Theilacker, Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany. Contact: sebastian.koehler@kit.edu
Omnichannel services have increased the complexity of instore logistics processes. In today's retail environment, the backroom is typically used only to buffer deliveries. Using the backroom for picking has been shown to improve efficiency, but a comprehensive analytical approach and optimized allocation strategy is lacking. This study presents a model that examines the impact of allocating additional item stock in the backroom on instore logistics and discusses how it differs from warehouse allocation problems. An optimization model is proposed that determines the items and quantities to be assigned to the backroom with the goal of minimizing instore logistical costs. The results contribute to improving instore operations for omnichannel services.

4 Optimizing Modern Retailers' Location in Emerging Markets' Megacities
Youssef Boulaksil, UAE University, Al Ain, United Arab Emirates. Contact: youssef.boulaksil@gmail.com
In this paper, we study the location problem for modern retail stores in a densely populated megacity in an emerging market. A trade-off is made between a higher population density (and hence demand) when getting closer to the city center, and higher opening and logistics cost. We extend Hotelling's line model to an analytical framework that incorporates the specific characteristics of traditional and modern retailers. We analyze the single-store model

analytically and determine the optimal location for a hypermarket. Our numerical study shows how customers' travel cost, appreciation, and price setting influence the optimal locations and profits. Given the complexity of the model, analysis becomes intractable when multiple stores are opened. Therefore, we devise an approximation and show that it can yield accurate results.

Enhancing Community Resilience and Sustainability

Community Committee Choice Session

Session Chair: Andres David Gonzalez, University of Oklahoma, Norman, OK

1 Bi-Level Optimization in Community- and Building-Level Mitigation for Flooding Hazards

Himadri Sen Gupta[1], Omar M. Nofal[2], Andres D. Gonzalez[1], Charles D. Nicholson[1], John W. van de Lindt[3], [1]University of Oklahoma, Norman, OK, [2]Florida International University, Miami, FL, [3]Colorado State University, Fort Collins, CO, Contact: hgupta@ou.edu

This research proposes a bi-level optimization model to minimize direct economic loss and population dislocation in a community due to flood-related building damage. The model considers pre-event short- and long-term mitigation strategies and trade-offs, and integrates information on cost, type of mitigation strategy, and expected losses and population dislocation for each building at different levels of mitigation.

2 A Behavioral Science Centric Understanding of Energy Limiting Behavior

Sheng Lun (Christine) Cao, Destenie S. Nock, Carnegie Mellon University, Pittsburgh, PA, Contact: shenglun@andrew.cmu.edu

Energy limiting behavior arises from a household's inability or unwillingness to consume a safe and healthy level of energy. The Low-Income Home Energy Assistance Program (LIHEAP) is designed to financially assist energy-poor households, but there exist gaps in understanding the effectiveness of LIHEAP as an intervention mechanism. We propose a behavioral science-centric study to understand people's energy use preferences in energy limiting conditions and examine whether LIHEAP is effective. Using a regression model and household energy use data, individual priorities for energy use in energy limiting conditions are revealed. In contrast, stated preferences of LIHEAP participants shows how much extra household energy could be used if they had expanded budgets. These two joint methods provide a holistic view of energy limiting behavior and LIHEAP effectiveness.

3 Two-Stage Stochastic Program for Environmental Relocation Decision-Making

Buket Cilali[1], Kash Barker[1], Andrés David González[1], Ahti Salo[2], [1]University of Oklahoma, Norman, OK, [2]Aalto University, Aalto SCI, Finland. Contact: buket.cilali@ou.edu

Slow-onset climate change impacts have been turning many settlements around the world into uninhabitable regions and the situation is expected to become worse in the upcoming decades. In order to handle the resulting need for a mass movement, we focus on the long-term displacement problem, especially in climate-driven cases in which people will be forced to leave uninhabitable regions to escape unlivable conditions, water stress, crop failure, and sea level rise. We develop a mathematical model where uncertainty in demand is represented with various demand scenarios, demand and capacity are managed dynamically, and integration outcomes and related costs are optimized. In this study, we propose a two-stage stochastic model under three different demand scenarios and analyze the societal impacts of the suggested movements on the host regions.

Data Analysis and Optimization in Communication and Social Networks

Community Committee Choice Session

Session Chair: Alexander Semenov, University of Florida, Shalimar, FL

1 Optimal Target Selection in Social Networks with Tiered Influence and Activation Thresholds
Qipeng Phil Zheng, University of Central Florida, Orlando, FL
In this study, we address the problem locating those influential users in social media through solving the tiered influence and activation thresholds target set selection problem, which is to find the seed nodes that can influence the most users within a limited time frame. Both the minimum influential seeds and maximum influence within budget problems are considered in this study. Besides, this study proposes several models exploiting different requirements on seed nodes selection, such as maximum activation, early activation and dynamic threshold. To address the computational challenges, this study designs and leverages several efficient algorithms, i.e., Graph Partition, Nodes Selection, Greedy Algorithm, Recursive Threshold Back Algorithm and Two-stage Approach in Time, especially for large-scale networks.

2 Double-Threshold Models for Network Influence Propagation
Vladimir Boginski, University of Central Florida, Orlando, FL
We consider new models of activation/influence propagation in networks based on the concept of double thresholds: a node will "activate" if at least a certain minimum fraction of its neighbors are active and no more than a certain maximum fraction of neighbors are active. These models are more flexible than standard threshold models as they allow to incorporate more complex dynamics of diffusion processes when nodes can activate and deactivate. In a social network, consistently with the hypothesis originally proposed by Granovetter (1978) , a person may "activate'' (e.g., adopt and/or repost an opinion) if *sufficiently many* but *not too many* of their friends (i.e., neighbors in a network) have adopted this opinion. We study several versions of this problem setup under different assumptions on activation/ deactivation mechanisms and initial choices of seed nodes.

3 Reducing Encryption Complexity of Maximum Key Assignments in Sensor Networks Using Spanning Trees
Maciej Rysz[1], Alexander Semenov[2], [1]Miami University, Oxford, OH, [2]University of Florida, Shalimar, FL
We propose an efficient q-composite encryption scheme for large-scale sensor networks. By leveraging spanning trees, we determine the maximum number of non-redundant keys that can be assigned to sensors with limited memory capacities. Our method reduces encryption complexity by finding a spanning tree with known characteristics using a polynomial time algorithm. Our approach demonstrates that network-based algorithms can solve the key cases of the management problem. Numerical experiments confirm the effectiveness and scalability of our approach, enabling secure information exchange in sensor networks.

4 Chance-Constrained Set K-Covering Problem
Shunyu Yao, Neng Fan, University of Arizona, Tucson, AZ, Contact: shunyuyao@arizona.edu
We consider a variant of the set covering problems with uncertain data, which we refer to as the chance-constrained set k-covering problem. In this problem, we assume that there is uncertainty regarding whether a selected set can cover an item, and the objective is to determine a minimum-cost combination of sets that covers each item i at least k_i times with a prescribed probability. We formulate deterministic integer programs and propose solution approaches for this problem using some combinatorial methods.

Frontline Innovation and Sustainability

Community Committee Choice Session

Session Chair: Bilal Gokpinar, UCL School of Management, London, United Kingdom

Session Chair: Leonardo P. Santiago, Copenhagen Business School, Frederiksberg, Denmark

1 Networks of Design Rules - Developing Pharmaceutical Process Innovations Across Dissimilar Networks

Tomas Harrington[1], Nitin R. Joglekar[2], Sriram Narayanan[3], Jagjit Srai[4], [1]University of East Anglia, Norwich, United Kingdom; [2]Boston University Questrom School of Business, Boston, MA, [3]Michigan State University, East Lansing, MI, [4]University of Cambridge, Cambridge, United Kingdom

We address a trans-specialist learning and coordination question: how do structurally dissimilar sub-networks work together to generate, track, and share knowhow while undertaking rapid development to promote process innovation? Using a 10-year micro dataset on the evolution of collaboration networks in pharmaceutical continuous manufacturing (CM) development consortia, we posit that a "network of design rules" as the key mechanism that enables heterogeneous specialist stakeholders to exchange knowledge among one another, create new processes, through trans-specialist understanding. We discuss the implications of the finding for both process and product development beyond pharmaceutical industry.

2 How Do Robots Affect Firms' Innovation Performance? Evidence from Spanish Manufacturers

Yiyao Zhou, Bilal Gokpinar, UCL School of Management, London, United Kingdom. Contact: uceihog@ucl.ac.uk

This paper examines the impact brought by robot use on manufacturing firms' innovation performance. The analysis uses a rich panel dataset of Spanish manufacturing firms over 27 years (1990-2016). Our findings suggest that robot use has a negative effect on firms' process innovation. However, we do not observe a similar effect on firms' product innovation. We also explore mechanisms by which robot use may affect process innovation. We find that the negative effect of robot use on process innovation is only salient for complex manufacturing, rather than light manufacturing or heavy manufacturing. In addition, we find that the negative effects brought by robots on process innovation are smaller for older firms. These results point to a potential mechanism whereby robots may impede process innovation through reducing human involvement.

3 Happy Hour: Markdown Pricing to Reduce Food Waste

Xabier Barriola[1], Lauri Saarinen[2], Lauri Loikkanen[2], Jan Holmström[2], [1]INSEAD, Fontainebleau, France; [2]Aalto University, Helsinki, Finland. Contact: lauri.3.saarinen@aalto.fi

Product expiration in grocery stores contributes significantly to food waste. Retailers use end-of-day markdowns to boost sales and reduce waste, but this method is operationally expensive and lacks accurate inventory info. We analyze the impact of a simple automated markdown pricing on food waste. Our findings reveal that automated markdown pricing benefits the triple bottom line, by reducing food waste, increasing gross margins, and lowering prices through higher discounts. We discuss challenges and opportunities for online and physical retailers adopting automated markdown pricing and provide a qualitative evaluation of available solutions. We highlight the technology and policy impact potential for enabling solutions.

4 The Impact of Demand and Regulatory Uncertainties on Shipowner Investment Decision

Leonardo P. Santiago[1], Franz Maximilian Buchmann[2], [1]Copenhagen Business School, Frederiksberg, Denmark; [2]Copenhagen Business School, Frederiksberg c, Denmark

This paper investigates a design of an emission trading scheme that aims at reaching an industry-wide emission targets on a ship owner's investment decisions. We show that increased uncertainty in the demand for pollution and regulatory risks has a substantial impact on a ship owner's costs of regulation and the value of managerial flexibility. We discuss the implications for regulatory authorities aspiring to incentivize the adoption of clean technologies to decarbonize the maritime industry.

Collaborative Problem-Solving

Community Committee Choice Session

Session Chair: Tian Chan, Emory University, Atlanta, GA

1 Human-AI Collaborative Problem Solving

Binyang Song[1], Qihao Zhu[2], Jianxi Luo[2], [1]MIT, Cambridge, MA, [2]Singapore Univ of Technology & Design, Singapore, Singapore. Contact: binyangs@mit.edu

AI is rapidly advancing, unlocking unprecedented capabilities for generative tasks, creative endeavors, and complex problem-solving. Given these capabilities, it is anticipated that AI will assume diverse collaborative roles in future problem-solving and innovation processes. These roles will facilitate varying modes of human-AI interaction and collaboration, each tailored to specific problem-solving tasks. However, human-AI teams must be meticulously designed to foster value-creating dynamics and mitigate potential risks in diverse contexts. This presentation will explore various designs of human-AI teams for collaborative problem-solving, providing a roadmap for the future.

2 More Investment Less Profit? An R&D Investment Conundrum of a Financially Constrained Firm in a Supply Chain

Junghee Lee[1], Jingqi Wang[2], [1]University of Notre Dame, Notre Dame, IN, [2]Chinese University of Hong Kong (Shenzhen), Shenzhen, China

Firms, especially small and medium enterprises (SMEs), suffer from financial constraints and cannot invest enough in R&D. The issue becomes even more intricate in a supply chain setting, where one firm's R&D investment influences another firm's profit and decisions. To study the impact of a firm's financial constraint for R&D investment on the focal firm and the supply chain, we analyze a supply chain consisting of one supplier and one manufacturer, where the manufacturer has a cost-reduction R&D opportunity with limited resources. Our analysis reveals that the manufacturer's profit may decrease, even if it can afford more investment, which we refer to as the "R&D conundrum" in a supply chain. We also investigate operations and information strategies that the manufacturer can take.

3 Design Thinking in Operations Management

Sebastian Fixson, Babson College, Babson Park, MA

Even substantial interest and efforts in both practice and academia over the past 20 years have so far not produced in the operations management literature a reliable method on how to operationally manage design thinking successfully. In response, I expand the operations management lens by unpacking the definitions of two critical process dimensions in greater detail: the outcomes of an operation, and its transformation function. Applying these dimensions of the expanded framework to a set of over 140 references identifies contributions from other disciplines to explain the conditions under which design thinking operations can be managed successfully, and pinpoints areas for future research.

4 Traversing the Problem-Solution Space: An Investigation of the Creative Problem-Solving Journey in Ikea Hacks

Shi-Ying Lim[1], Tian Chan[2], [1]National University of Singapore, Singapore, Singapore; [2]Emory University, Atlanta, GA, Contact: tian.chan@emory.edu

We theorize and empirically investigate how individual user-innovators navigate between search in the problem space versus the solution space. Using a dataset of user-innovations in IKEA hacks, we characterize the kind of problem-solving journey that would lead to more novel creative problem-solving outcomes. Specifically, starting the journey with a concrete (as opposed to an abstract) problem would lead to more novel outcomes. During the journey, we show that having (1) an abstract search of the solution space, and (2) frequent traversal from problem to solution space and back, are also associated with more novel outcomes.

Exploring the Potential of Data Mining in Higher Education: Strategies and Best Practices

Community Committee Choice Session

Session Chair: Youqin Pan, Salem State University, Salem, MA

1 Digital Divide In Higher Education: A Text-mining Approach

Youqin Pan, Salem State University, Salem, MA

This study examines the development of the digital divide, which refers to the disparities in access, usage, and outcome of information and communication technology. Higher education has experienced faster digitalization and online learning due to the COVID-19 pandemic. Digital divide has attracted a lot of attention since the covid-19 pandemic has further widened the gap. As technology continues to expand and integrate with society, the digital divide may continue to grow. However, there is a lack of research about the process of digital divide and how it can be managed to facilitate the digital transformation in higher education. The results of this study on the digital divide in higher education will provide insights on necessary steps to be taken to bridge the gap.

2 Analyzing Multidimensional Data in an Interactive No Code Environment

Kevin Potcner, JMP Statistical Discovery, San Francisco, CA, Contact: Kevin.Potcner@jmp.com

Fully analyzing data requires an analyst to generate a wide variety of visualizations, analyses, and models. The insights gleaned from each step leads the analyst to a next set of analyses to try, and so on. This exploratory approach can become very cumbersome in a coding environment.Without strong proficiency in programming, students often get frustrated finding themselves unable to run many different analyses and visualization quickly. In this presentation, a statistical scientist from JMP will illustrate how easy it can be to explore multi-dimensional data through interactive visualizations, analyses, and models in a "no code" environment. The audience will see how this approach not only greatly expedites data analysis efforts, but provides students with a much richer and more engaging experience to learning analytics.

3 Calibrating a Car-Following Model to Capture Impacts of Vehicle Driving Automation System on Human-Driven Vehicles

Zhitong Huang[1], John Hourdos[2], Qinzheng Wang[1], Saeid Soleimaniamiri[1], [1]Leidos, McLean, VA, [2]FHWA, McLean, VA

Different levels of vehicle automation systems (VAS) have already started to travel on public roads. The impacts of automation on transportation operations must be accurately assessed to support different transportation agencies in preparing for the deployment and adoption of CAV technology. However, there is a lack of research on human driver behavior when interacting with VAS. To cover this gap, we calibrate the Intelligent Driver Model (IDM) using field data from a data collection project, which involved SAE level 1 and 2 VAS-equipped vehicles. Statistical testing confirms significant behavioral differences between human drivers interacting with VAS and those driving conventional vehicles. We also employ a machine learning-based methodology to refine the IDM model calibration to investigate changes in human driver behavior when interacting with VAS.

4 Intelligent Prevention of Ddos Attacks Using Reinforcement Learning and Smart Contracts

Erotokritos Skordilis, Maikel Leon Espinosa, Avner Yeshurun, Emily Struble, University of Miami, Herbert Business School, Miami, FL

Contemporary computer networks face constant cyber threats, especially in critical areas like finance, power grids, and education. To address this issue, advanced cyber-defense tools using either Blockchain and/or Artificial Intelligence (AI) frameworks have been developed. Smart contracts in Blockchain can isolate nodes at risk of attack, while AI tools can predict attack patterns in advance. This work proposes a novel cyber-defense approach that uses smart contracts and collaborative multi-agent reinforcement learning. Each agent represents a node on the blockchain network, where a smart contract isolates that node from the network when an agent predicts an imminent attack, thus minimizing the impact and costs of the attack. Numerical experiments show the method's ability to predict imminent attacks, reducing the risk of service disruption.

5 Visual Programming for Predicting and Mitigating College Students Attrition

Dursun Delen[1], Behrooz Davazdahemami[2], [1]Oklahoma State University, Tulsa, OK, [2]University of Wisconsin-Whitewater, Whitewater, WI, Contact: dursun.delen@okstate.edu

With the emergence of novel methods for improving machine learning (ML) transparency, traditional decision support systems need an upgrade in their approach toward providing more actionable insights for practitioners. Particularly, given the complex decision-making process of humans, using insights obtained from population-level interpretation of ML models for designing individual interventions may lead to less-than-optimal outcomes. Using a visual programming tool (i.e., KNIME Analytics Platform) along with a large data set of demographics, educational, financial, and socio-economic factors, we developed explainable ML models to provide actionable insights for designing personalized interventions for students who are at risk of drop out.

Novel Data Mining Approaches in the Era of Emerging Technologies and Simulation

Community Committee Choice Session

Session Chair: Md Tariqul Islam, 1</sup

1 Neural Network-Based Intention Recognition for Human-Robot Interaction in Manufacturing: A Virtual Reality Driven Approach

Ali Kamali Mohammadzadeh, Sara Masoud, Wayne State University, Detroit, MI

Intention recognition is an important aspect of human-robot interaction in manufacturing. With the increasing use of virtual reality (VR) in manufacturing, there is a growing need for intention recognition in VR to ensure safe and efficient collaboration between humans and robots. Neural networks, as a branch of machine learning, have shown great potential in recognizing human intentions in various environments. This study uses neural networks for intention recognition in manufacturing. The goal is to investigate the feasibility of using neural networks to recognize human intentions in VR and evaluate its performance in human-robot interaction in manufacturing. The introduction of intention recognition in VR environments will enable more efficient collaboration between humans and robots, thus improving the overall performance of manufacturing systems.

2 Digital Twins Integrated with Dynamic Data Driven Application Systems for Healthcare Systems: Time-Sensitive Simulation and Prediction

Yijie Chen[1], Md Tariqul Islam[2], Young-Jun Son[3], [1]University of Arizona, Tucson, AZ, [2]Purdue University, Lafayette, IN, [3]Purdue University, West Lafayette, IN, Contact: yijiechen@arizona.edu

In this work, we discuss real-time digital twin in two applications: (1) a wearable device-based individual respiration and physiological status monitoring and (2) a Wi-Fi and App-based university infectious disease simulation. Models are developed with two-way data integration and interaction under differenttime frameworks for nowcasting and forecasting to support decision/policy making. The complex data inputs via wearable sensors and discrete event/subjective reports necessitate a more flexible structure for the system and novel model validation and verification approaches with data and model dynamics. We employ agent-based modeling methods for data fusion and integrate it with time convolutional networks for model iteration and prediction updates.

3 A Multivariate, Spatiotemporal, Deep-Learning Model to Predict Covid-19 Infections Based on Historical Cases and Changes in State Policy

MD TARIQUL ISLAM[1], Young-Jun Son[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: islam70@purdue.edu

Epidemiological processes that change quickly and are spatially heterogeneous are challenging to capture using commonly utilized compartmental models. Machine learning models such as deep neural networks can learn complex mappings from inputs to outputs, but the unnoticed geographic dependence between states limits their applicability. The proposed research will develop a deep-learning model framework to forecast COVID-19 infections. A multivariate graph neural network-based long short-term (GCN-LSTM) network will be trained and validated using publicly available multivariate COVID-19 datasets. In addition to temporal dependencies learned through the LSTM structure, the GCN will aid the model in learning spatial dependencies between states.

4 Approach to Data Mining in Healthcare System Process Improvement

Faujia Islam, Inova Health System, VA

Inova Health System is a large, non-profit healthcare provider in Northern Virginia. The system is using data analysis and process improvement tools to improve its performance.
The use of data analysis and process improvement tools has helped Inova to improve its performance in a number of ways. The system has seen reductions in readmission rates, mortality rates, and patient wait times as well as efficiency of its operations.
The use of data analysis and process improvement tools is an important part of Inova's strategy for improving its performance. The system is committed to using these tools to identify areas for improvement, develop and implement interventions, and measure the impact of those interventions.

Towards Data-driven Healthcare: Improving Patient Outcomes through Advanced Analytics

Community Committee Choice Session

Session Chair: Chenxi Yuan, 1</sup

1 Generative Model for Fair Synthetic EHRs

Huan He, Harvard Medical School

Synthetic electronic health records (EHRs) are artificially generated patient records that mimic real-world medical data. They play a crucial role in healthcare research, development, and testing, as well as in training healthcare professionals and improving patient care. However, creating and utilizing synthetic EHRs comes with several challenges including privacy leakage, attribute fairness, and quality. In this, we present a novel diffusion based generative model that can generate fair, and high quality EHRs with minimal privacy leakage issue.

2 Accounting for Network Noise in Graph-Guided Bayesian Modeling of Structured High-Dimensional Data

Wenrui Li, University of Pennsylvania, Philadelphia, PA, Contact: wenrui.li@pennmedicine.upenn.edu

There is a growing body of literature on graph-guided statistical learning methods for analysis of structured high-dimensional data (such as genomic and transcriptomic data) that can incorporate knowledge of underlying networks derived from functional genomics and functional proteomics. However, these methods typically use graphs extracted from existing databases or rely on subject matter expertise which are known to be incomplete and may contain false edges. To address this gap, we propose a graph-guided Bayesian modeling framework to account for network noise in regression models involving structured high-dimensional predictors. We develop an efficient Markov chain Monte Carlo algorithm for posterior sampling. We demonstrate the advantages of our method over existing methods in simulations, and through analyses of omics datasets for Alzheimer's disease.

3 Capturing Uncertainty by Neural Network-Based Prediction Interval Approach for Pain Intensity Estimation

Burcu Ozek, Northeastern University, Boston, MA, Contact: ozek.b@northeastern.edu

Accurately assessing pain severity is imperative for determining the appropriate intervention, but it can be challenging due to its subjective nature in individual experiences. To address this challenge, researchers have employed machine learning models to evaluate pain objectively. However, these models have mainly focused on point estimation, failing to consider uncertainty in the data and model and resulting in overconfident predictions that can be hazardous in clinical settings. To overcome these limitations, this study proposes a neural network-based prediction interval method that estimates ranges for pain severity. This approach establishes a crucial capability that enhances the effectiveness of pain management and reduces the risks associated with improper treatment.

4 Nonparametric Bayesian Functional Modeling for Breast Cancer Racial Disparities

Wenyu Gao, Harvard School of Public Health, Boston, MA, Contact: wgao@hsph.harvard.edu

Different incidence and mortality rates for breast cancer exist among various racial populations. To study these disparities, surface-enhanced Raman spectroscopy (SERS) has been conducted to provide biomolecular fingerprint information. Large intra-class variations exist due to cellular and additional cancerous heterogeneity. To study the differences between two types of triple-negative breast cancer cell lines at the molecular level, we proposed a nonparametric Bayesian functional clustering (via weighted Dirichlet process mixture (WDPM) modeling) and peak point selection method. The proposed method is named WDPM-VS, and it will greatly outperform its comparison methods in root mean squared errors. Based on this proposed method, we identified essential wavenumbers that can explain the racial disparities.

5 Diffusion Models for Longitudinal 3D Structural MRI Imputation in Alzheimer's Disease

Chenxi Yuan, University of Pennsylvania, Philadelphia, PA, Contact: chenxi.yuan@pennmedicine.upenn.edu

Missing data is a significant challenge in medical research. Missing data hinders accurate disease diagnosis, monitoring, and management in individual patients and may bias inference about patient populations using statistical models. To address the problem of missing magnetic resonance imaging (MRI) data in Alzheimer's disease (AD) applications, we propose a Diffusion model-based longitudinal structural MRI Imputation framework (DMRI) which relies on conditional generation of a missing image at a single designated visit. Specifically, the DMRI model imputes a missing 3D MRI image by taking the past visit or both past and future visits as conditions during the image generation. Experimental results show that our method can generate high-quality individual 3D structural MRI with high similarity to the missing visit's observed image.

Frontiers in the Digital Economy

Community Committee Choice Session

Session Chair: Grace Gu, Los Angeles, CA

1 Artificial Intelligence, Lean Start-Up Method and Product Innovations

Gavin Wang, University of Texas at Dallas, Dallas, TX

Despite the transformative potential AI has on business and innovation, many firms fail to reap any benefits from AI. We investigate the organizational support required to make AI perform well. Specifically, we examine the role of the lean startup method (LSM) in explaining the impact of AI capability on product innovations at startups. Using a dataset of 2,000 startups in China from 2011 to 2020, we find that companies that adopt general AI capability create more innovative products every year. Next, we find that AI investments complement LSM in product innovations, and the complementarities depend on the type of product innovations and the type of AI used. Our research shows the importance of treating AI as a heterogeneous construct because different AI capabilities depend upon different organizational processes to succeed.

2 Optimal Design for Revenue-Based Financing
Eryn Juan He, University of Utah, Salt Lake City, UT
VC funding has grown massively recently. However, less than 1% of the new companies ever raise VC funding. Revenue-based financing has emerged as an alternative, which is repaid based on a percentage of future revenues. We aim to develop insights into the value of RB financing, compared with traditional modes.

3 The Impact of Platform Commission Rates on Content Creation and Consumption
Pu Zhao[1], Georgios Zervas[2], Xintong Han[3], [1]Boston University Questrom School of Business, Boston, MA, [2]Questrom School of Business, Boston, MA, [3]Concordia University, Montreal, QC, Canada. Contact: puzhao@bu.edu
Digital marketplaces allow independent creators to flourish by connecting them to larger audiences in exchange for charging them a sales commission. However, these rates are sometimes perceived as controversially high. Using a unique dataset from a leading Chinese creator platform, we study how commission rate changes affect creators' pricing strategies, content production, and consumer welfare. We show that when the platform significantly reduced its commission rate for certain eligible creators, content prices on average went up. We then show that creators who were not eligible for the reduced commission rate exited the platform, reducing competition and resulting in increased prices. We show that these effects were more pronounced in content categories that had fewer creators that were eligible for the reduced rate.

4 Disintermediation Governance and Complementor Innovation: An Empirical Look at Amazon.Com
Gaoyang Cai[1], Xia Han[2], Grace Gu[3], [1]Northwestern University, Evanston, IL, [2]Soochow University, Suzhou, China; [3]University of Southern California, Los Angeles, CA
This study investigates how the disintermediation governance policy, i.e., restricting communication channels through which complementors can persuade buyers to circumvent the platform and transact directly, affects complementors' innovation behavior. Leveraging a governance policy change on Amazon.com that prohibits external website links during buyer-seller communications, based on a coarsened exact matching and a difference-in-differences approach, we find that complementors significantly reduce their number of new products launched on the focal platform after the policy change. Such an effect is mitigated by complementor reputation and strengthened by the capacity constraint. Our results provide implications for platform governance policies against disintermediation and its impact on complementor product innovation both on and off the platform.

1 Live-Stream Selling as a New Channel for Brands
Yichao Yuan[1], Amit Mehra[2], Zhe Zhang[3], [1]Nanjing University, Nanjing, China; [2]University of Texas at Dallas, Richardson, TX, [3]University of Texas Dallas, Richardson, TX, Contact: dg1915012@smail.nju.edu.cn
Live-stream selling adds a great selling channel for brands. Even though selling via an influencer can be costly, the time allocated by an influencer to the brand can reduce consumers' price sensitivity to the product. We develop a game-theoretic model in which two brands engage in price competition in a new market according to the time allocated by an influencer. We find some interesting insights about how the live-stream channel affects the brands' prices and profits, as well as the consumer surplus under competition.

2 The Role of Data Sharing and Analytics Capabilities in Interoperable Healthcare Services
Yeongin Kim[1], Geng Sun[2], Byung Cho Kim[3], [1]Virginia Commonwealth University, Glen Allen, VA, [2]University of Texas Rio Grande Valley, Edinburg, TX, [3]Korea University, Seoul, Korea, Republic of. Contact: ykim3@vcu.edu
Effective data sharing is crucial in delivering high-quality healthcare. This study presents a game-theoretical model of a two-tiered healthcare system. In this system, a general care provider offers initial care with varying data quality, while two specialty care providers offer specialized care based on the data shared by the general care provider. The findings emphasize the significance of market power and analytic capability of the specialists in determining the data quality provided by the general care provider. This research contributes to the existing knowledge on data sharing

in interoperable healthcare and underscores the need to comprehend the dynamics between general care providers and specialists to optimize patient outcomes.

3 Consumer Aversion to Algorithm-Driven Price Volatility: Empirical Investigation of Airbnb

Jiaqi Shi[1], Jinan Lin[1], Tingting Nian[2], Mingyu Joo[3], [1]UC Irvine, Irvine, CA, [2]University of California, New York, NY, [3]University of California-Riverside, Irvine, CA, Contact: jiaqis@uci.edu

Dynamic-pricing algorithms facilitate frequent price adjustments to optimize sales. Yet, overly frequent price fluctuations may complicate consumers' purchase decisions. This paper empirically investigates how algorithm-driven price volatility influences the occupancy rates of rental properties in New York City listed on Airbnb. Because properties on Airbnb can be booked up to 12 months in advance, we compile two price-volatility measures: a property's frequency of price changes across travel dates on a given booking date and a property's frequency of price changes across booking dates on a given travel date. For both measures, the occupancy rates increase from flat pricing to a certain degree of dynamic pricing. However, the occupancy rates start to decrease when prices become too volatile, controlling for the magnitudes of price-level variation.

4 Social Media Platform Policies for User-Shared External Shopping Links

Yan Zhu[1], Jianqing Chen[2], Srinivasan Raghunathan[3], [1]The University of Texas at Dallas, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas-Dallas, Richardson, TX, Contact: yan.zhu@utdallas.edu

Advertising has been the primary source of revenue for social media platforms. However, the rise of influencer marketing poses challenges for these platforms because influencers and platforms compete for advertising revenue. As a response, some platforms prohibit clickable links, while others allow them but charge a service fee for links directing to shopping sites. This research studies the heterogeneous policies of these platforms regarding shopping links from an economic perspective.

Emerging Concepts, Practices, and Analytics Applications to Democratize Data and Leverage AI

Community Committee Choice Session

Session Chair: Darshan Desai, Berkeley College, New Providence, NJ

1 What Can a Person Change to Obtain a Desired Prediction? an Interpretability Approach

XUEFEI LU[1], Emanuele Borgonovo[2], [1]SKEMA Business School - Université Côte d'Azur, Suresnes, France; [2]Bocconi University, Milano, Italy. Contact: xuefei.lu@skema.edu

Machine learning plays an important role in many deployed decision systems and often appears as a black-box model. Explainable machine learning methods such as LIME and SHAP generate explanations for an individual prediction made by the black-box model, providing results such as the most influential features of a prediction. However, such information does not guide agents on how they should improve to move from one class to another. We propose a method based on finite change decomposition and Shapley values to obtain meaningful insights about the direction of concern. The method is applied to several UCI datasets to discuss several types of technical and managerial insights.

2 An Introduction to Interpretable Simple Structure Identifying Algorithm

Gaurav Arwade, Sigurdur Olafsson, Iowa State University, Ames, IA, Contact: gbarwade@iastate.edu

Highly non-linear machine learning models can attain state-of-the-art performance but lack interpretability; whereas top-down simple models on complex data provide poor performance and intangible interpretability. But many complex datasets comprise simple structures consisting of similar instances; and an ensemble of simple models may improve interpretability and accuracy versus models learned on the entire dataset. Such simple structures are predominantly present in healthcare datasets where interpretability is of prime importance. This paper formally defines the simple structure and assumptions satisfied by a dataset consisting of simple structures and proposes a bottom-up simple structure-identifying algorithm. Using synthetic data, we demonstrate the algorithm's robustness, and how it identifies natural decision boundaries.

3 Transformative Potential of Generative AI: Democratization of Data and Augmented Analytics

Darshan Desai, Berkeley College, New Providence, NJ,

Contact: darshudesai@gmail.com
Recent developments in artificial intelligence (AI) and large language models (LLMs) hold significant implications for data democratization, digital transformation, and analytics strategies. These advancements possess transformative potential, empowering organizations with novel enterprise applications, augmented analytics, and self-service business intelligence (BI). By harnessing the power of generative AI models, organizations can unlock new opportunities for innovation and value creation. This paper explores diverse applications of generative AI within these domains and aims to examine key concepts, practices, and emerging trends, presenting real-world applications that highlight its potential implications on enterprise systems, business intelligence, and analytics strategies and practices.

1 Learning in Continuous-Time Stochastic Control: Estimation, Sensitivity and Regret Analysis
Anran Hu, University of Oxford, Oxford, United Kingdom
Recently, reinforcement learning (RL) has attracted substantial research interests. Much of the attention and success, however, has been for the discrete-time setting. Continuous-time RL, despite its natural analytical connection to stochastic controls, has been largely unexplored and with limited progress. In particular, characterizing sample efficiency for continuous-time RL algorithms with convergence rates or regret bounds remains a challenging and open problem. In this talk, we approach this problem by studying two fundamental problems that have been under-explored in the continuous-time stochastic control literature, namely 1) the sensitivity of the control objective w.r.t. feedback controls and the sensitivity of feedback controls w.r.t. model parameters and 2) the estimation error of the model parameters in terms of collected sample trajectories. For episodic linear-convex RL problems, we study the Lipschitz stability of feedback controls by establishing the stability of the associated forward-backward stochastic differential equation, and derive sample complexities of continuous-time least-squares parameter estimations by exploring the concentration properties of sub-Weibull random variables. The analyses lead to a regret bound of the order $O(\sqrt{N\ ln N})$ for the greedy least-squares algorithm, with N the number of episodes. In the special case of the linear-quadratic RL problem, the analysis reduces to the regularity and sensitivity of the associated Riccati equation and the sub-exponential properties of the estimators, which leads to a logarithmic regret.

2 A Mathematical Framework of Transfer Learning
Haoyang Cao, Johns Hopkins University, Baltimore, MD
Transfer learning is to utilize existing knowledge from previous learning tasks to improve the performance of new ones. This work addresses the feasibility issue of transfer learning. It begins by establishing the necessary concepts and constructing a mathematical framework for transfer learning. It then identifies and formulates the three-step transfer learning procedure as an optimization problem, allowing for the resolution of the feasibility issue. It shows that under certain technical conditions, an optimal procedure for transfer learning exists. This work brings additional insights into various transfer learning problems and sheds light on the impact of feature augmentation on model performance, explores potential extensions of domain adaptation, and examines the feasibility of efficient feature extractor transfer in image classification.

3 Community/Committee'S Choice Submission
Francesca Primavera, 1</sup

4 Adversarial Training for Gradient Descent: Analysis Through Its Continuous-Time Approximation
Xinyu Li, 1</sup
Adversarial training has gained great popularity as one of the most effective defenses for deep neural network and more generally for gradient-based machine learning models against adversarial perturbations on data points. This paper establishes a continuous-time approximation for the mini-max game of adversarial training. This approximation approach allows for precise and analytical comparisons between stochastic gradient descent and its adversarial training counterpart; and confirms theoretically the robustness of adversarial training from a new gradient-flow viewpoint. The analysis is then corroborated through various analytical and numerical examples.

Optimal platform design

Community Committee Choice Session

Session Chair: Yunke Mai, University of Kentucky, Lexington, KY

1 Manufacturing Platform Coopetition: Restructuring Lean Operations in Global Supply Chains

Gang Li[1], Yusen Xia[2], [1]Bentley University, Waltham, MA, [2]Georgia State University, Atlanta, GA, Contact: gli@bentley.edu

We propose a new strategy for competing supply chains to share their manufacturing platforms in response to a global crisis. To this end, we start by examining a lean and agile supply chain design that a company can adopt to provide a guaranteed service to consumers faster and cheaper and then discuss a coopetition mechanism for multiple such supply chains in crisis.

2 E-commerce Platform Finance With Dual Channels

Nina Yan[1], Zhineng Chen[2], Xun Xu[3], Xiuli He[4], [1]Central University of Finance and Economics, Beijing, China; [2]University of Delaware, Newark, DE, [3]Cal State, Carson, CA, [4]UNC-Charlotte, Charlotte, NC

In the platform economy era, e-commerce platforms function as distribution channels for sellers and offer online loans to sellers as financing providers. This study focuses on platform finance, where the platform sets a credit line or interest rate to offer either a limited or generous loan to capital-constrained sellers. The sellers may have sufficient initial capital or be capital-constrained but have access to a generous loan, a limited loan, or no loan. We found that the optimal sellers' channel strategy, choosing either a single channel or online-dominant or offline-dominant dual channels, depends on the platform's credit line, consumers' channel preferences, and their switching behavior between online and offline channels.

3 The Effect of Online Company Responses on Review Quality: An Empirical Study of App Developer Company Responses to Customer Reviews

Qiuli Su, Creighton University, Omaha, NE

Online company responses become important communication tools for companies to interact with customers. This study examines why companies respond to reviews, and how online company responses improve the review quality (measured by review comprehensiveness and review readability) over time. Applying text-mining techniques combined with big data analysis, I find that: 1) companies are more likely to respond to reviews with lower sentiment and higher sentiment deviation scores; 2) online company responses improve review comprehensiveness but don't increase review readability; 3) response intensity does not improve review quality, longer responses enhance review comprehensiveness, and more tailoring responses amplify review readability. Our findings could guide companies to improve their online communication strategy and customer engagement quality.

4 Group Fairness in Online Platform's Assortment Planning

Shuzhang Cai[1], Shaojie Tang[2], [1]University of Texas at Dallas, Richardson, TX, [2]University of Texas-Dallas, Mckinney, TX

We present an innovative assortment planning framework to solve the platform's optimization problem while incorporating group fairness constraints. As the recommendation system significantly increases efficiency and becomes a necessity for online platforms, there arises the concern about fairness. Disadvantaged items have little chance of being selected into the assortment, thereby limiting their visibility and potentially harms the platform's long-term interest as well as societal justice. Our approach takes into account all available items and their respective group categorizations, establishing a minimum exposure rate constraint for each group while maintaining the maximization of the clickthrough rate as the primary objective of the platform. The proposed framework successfully delivers a bunch of near-optimal solution within the polynomial time.

Monday, October 16, 8:00 AM - 9:15 AM

On Bus Transportation System Planning

Contributed Session

Session Chair: Anthony Trasatti, ISyE Georgia Tech, Winchester, MA

1 School Bus Routing Problem with Open Offer Policy: Incentive Pricing Strategy for Students that Opt-Out Using School Bus

Juan Pablo Contreras[1], Hernan Caceres[1], Hernán

Lespay[1], Rajan Batta[2], [1]Universidad Catolica del Norte, Antofagasta, Chile; [2]University at Buffalo (SUNY), Buffalo, NY, Contact: juan.contrerasff@gmail.com

This study introduces the School Bus Routing Problem with Open Offer Policy (SBRP-OOP) for the Williamsville Central School District (WCSD) in New York. The problem addresses the underutilization of school buses, with daily capacities ranging from 22 to 72 percent. To improve efficiency, the SBRP-OOP proposes offering monetary incentives to students willing to forgo bus transportation. By excluding incentivized students from the routing process, the aim is to optimize capacity usage and reduce the number of buses required. Mathematical models are developed to determine a pricing strategy that balances incentive payments and bus savings. The effectiveness of the Open Offer Policy is evaluated using real operational data from New York.

2 Strategies for the Electric Bus Scheduling Problem with Battery Degradation: A Stochastic Perspective

Lea Ricard[1], Guy Desaulniers[2], Andrea Lodi[3], Louis-Martin Rousseau[4], [1]University of Montréal, Montreal, QC, Canada; [2]Polytechnique Montreal & Gerad, Montreal, QC, Canada; [3]Cornell Tech, New York, NY, [4]Polythechnique Montreal, Montreal, QC, Canada. Contact: lea.ricard@umontreal.ca

The battery of battery electric buses (BEBs) constitutes a significant portion of the acquisition cost for new BEBs. Over time, the capacity of lithium-ion batteries gradually diminishes. The aging mechanism of BEBs is notably influenced by the average state of charge (SoC) and the SoC deviation. This presentation introduces a chance-constrained model for addressing the Electric Vehicle Scheduling Problem, which incorporates battery degradation and stochastic energy consumption. The model accounts for the aging mechanisms of the battery by imposing a constraint that ensures the SoC remains above a given threshold with a certain probability. Additionally, we propose a tailored branch-and-price algorithm and provide a numerical case analysis. This analysis yields several valuable managerial insights into effective battery management practices.

3 The On-Demand Bus Routing Problem

Kenneth Sörensen, University of Antwerp, Antwerp, Belgium. Contact: kenneth.sorensen@uantwerpen.be

The on-demand bus routing problem (Melis and Sörensen, 2022) optimizes bus routes and schedules based on passenger requests, in an urban environment where pickups and dropoffs are limited to signposted stops. Passengers request service through an app, and routes are determined that minimize total user ride time, while also assigning pickup and dropoff stops to passengers. Researchers have explored variants with stochastic travel times, dynamic demand, and integration with fixed-line systems. This talk presents the state of the art on this problem and its variants, as well as potential future research directions.

4 Service Fleet Transition Planning Using Electric Vehicles for Sustainable Urban Transportation

Zahide O. Ceylan Gungor, Sule Itir Satoglu, Istanbul Techical University, Istanbul, Turkey. Contact: onbaslis@itu.edu.tr

One of the means of achieving the Paris Aggreement's carbondioxide emission reduction target is the transition of the service fleet, including the passenger and commercial fleets, using the alternative fuel vehicles. Especially, in this study, the fleet transition problem of urban rapid transit bus fleet using the electric vehicles is focused. A bi-objective mathematical model is proposed to plan the next 10 years of fleet transition using electric vehicles (EV), such that the net present value of the cost of ownership as well as the total carbondioxide emissions are minimized, simultaneously. During this transition, building of the EV charging stations infrastructure, alternative scenarios regarding the fuel mix used for electricity generation, incentives, carbon tax are considered. An application of the model for Istanbul city is made.

5 Bus Line Design for On-Demand Multimodal Transit Systems

Anthony Trasatti[1], Beste Basciftci[2], Pascal Van Hentenryck[1], [1]ISyE Georgia Tech, Atlanta, GA, [2]University of Iowa, Iowa City, IA, Contact: anthony.j.trasatti@gmail.com

Many transit agencies have started experimenting with adding on-demand services in attempt to maximize their service quality, accessibility, and coverage within a fixed budget, using shuttles to alleviate their first and last mile issues as part of On-Demand Multimodal Transit Systems (ODMTS). This work presents a novel mixed-integer program (MIP) formulation to incorporate bus line design into the network design problem for On-Demand Multimodal Transit Systems that allow the model to accurately capture wait time and transfer costs in addition to travel time and vehicle costs. To solve large-scale instances, a two-stage reformulation is presented where the first-stage problem decides bus arcs to open and which arcs immediately follow and the second-stage problem decides the multimodal path for each individual trip.

Session Chair: Xiaochen Shi, Georgia Institute of Technology, Atlanta, GA

1 Real-Time Object Detection and Traffic Simulation of Autonomous Vehicle Deployment

Shivani Shukla[1], Stavan Dholakia[2], [1]University of San Francisco, San Francisco, CA, [2]Microsoft Corp, Seattle, WA, Contact: sgshukla@usfca.edu

Automated and Autonomous Vehicles have the potential to revolutionize transportation but in the absence of interconnection and data sharing between vehicles pose challenges to urban networks. Business models of on-demand and privately-owned autonomous vehicles (AVs) have the potential to significantly impact traffic volume and vehicle miles traveled (VMT). In this paper we develop a model using state-of-the-art algorithms to detect and track autonomous cars using existing camera infrastructure. The results are used as an input into a visualization platform that simulates scenarios around traffic volume. Our work is a step towards filling the current void in data for travel and traffic patterns surrounding AVs.

2 Simulation-Based Optimization of Autonomous Vehicle Model Parameters for Mixed Transportation Network

Jinkun Lee, East Carolina University, Greenville, NC, Contact: leejin18@ecu.edu

As self-driving technology above SAE level 3 is being competitively developed by major automobile manufacturers, autonomous vehicles (AVs) will prevail in the near future transportation network. A mixed traffic network with human driving vehicles and AVs will show transient system behavior based on penetration rate of AVs thereby requiring different optimal AV settings. We are interested in understanding this system behavior over the transitional period to achieve an optimal traffic performance. We investigate the system behavior with an agent-based simulation with different penetration rates and find optimal AV model parameter set per penetration rate by using genetic algorithm (GA). Simulation results with optimal parameter values reveal improvement in average traffic performance measures.

3 Electric Vehicle Routing And Charging Problem For Cooling Shelters Using V2g Technology

Seong Wook Hwang[1], Sang Jin Kweon[2], [1]Sungshin Women's University, Seoul, Korea, Republic of; [2]Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of. Contact: swhwang@sungshin.ac.kr

In recent years, the world has faced pressing challenges related to global warming and the depletion of limited energy resources. To address these pressing challenges, electric vehicles (EVs) have emerged as a promising solution. In this study we address EV routing and charging problem to effectively evacuate heat-vulnerable residents during heat waves while also incorporating V2G technology to harness the advantages achievable through the use of EVs.

4 A Flow Optimization Approach for Infrastructure Guided Self-Driving Vehicles on Street Network

Xiaochen Shi[1], Anton J. Kleywegt[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: xshi74@gatech.edu

Our previous study has proved that, with Infrastructure guided self-driving (IGSD) technology, flexible platooning significantly improves the throughput at a single intersection. But developing the coordinated solution for the traffic flow of entire network still faces great challenges, considering the knock-on effect among intersections. Based on flexible platooning, we formulate a MILP model for a 100% IGSD environment, that determines the paths and the velocities of vehicles, and minimizes the total travel time. A network platooning algorithm based on dynamic programming is also proposed to produce an initial feasible solution for the MILP and as a heuristic for controlling vehicle platooning in the network. The simulation results show that in terms of delay and throughput, even the heuristic outperform existing approaches.

1 Posterior Sampling from the Spiked Models via Diffusion Processes

Yuchen Wu, Stanford University, Stanford, CA, Contact: wuyc0114@gmail.com

Sampling from the posterior is a key technical problem in Bayesian statistics. Rigorous guarantees are difficult to obtain for Markov Chain Monte Carlo algorithms of common use. In this paper, we study an alternative class of algorithms based on diffusion processes. Our construction of the diffusion is based on the notion of observation process and the related idea of stochastic localization. We apply this method to posterior sampling in the high-dimensional symmetric spiked model. Our sampling algorithm makes use of an oracle that computes the posterior expectation of ⍰ given the data and the additional observation process. We provide an efficient implementation of this oracle using approximate message passing. We thus develop the first sampling algorithm for this problem with approximation guarantees.

2 Diffusion Model-Based Oversampling for Class Imbalanced Problems

Geonhee Jang[1], Wonkeun Jo[1], Sungsu Lim[1], Dongil Kim[2], [1]Chungnam National University, Daejeon, Korea, Republic of; [2]Ewha Womans University, Seoul, Korea, Republic of. Contact: ckrdkg@gmail.com

Oversampling is one of the important approaches to overcome the class imbalanced problems. Several oversampling methods have been studied by utilizing local property of data or generative models. In this work, we propose an oversampling method by employing the denoising diffusion probabilistic models (DDPM) for binary classification. The proposed method adapts the cosine schedular instead of the linear schedular for smooth noising and learns various imbalanced data distributions. We aim to oversample the minority classes' data to make the balance in terms of the frequency of minor to major. The Experimental results demonstrated that our method performed well when compared to existing oversampling methods.

3 Data-Adaptive Threshold Selection for Quantile Feature Screening with FDR Error Rate Control

Saidat Abidemi Sanni, University of Cincinnati, Cincinnati, OH, Contact: sannisa@mail.uc.edu

Selecting an appropriate threshold is of utmost importance when conducting feature screening in ultrahigh-dimensional data. Identifying relevant predictors in such datasets can be highly challenging with heterogeneity and potential OLS assumption violations. We propose the Quantile Data Adaptive Threshold Selection (QDATS), a data-driven and systematic approach for threshold selection with error rate control. We utilize a sample-splitting approach and quantile correlation to differentiate between relevant and irrelevant predictors based on marginally symmetric statistics. The performance of QDATS is demonstrated on ultrahigh dimensional genetic data with blood pressure measurements and simulation studies, achieving reliable true positive rate and false discovery rate control while satisfying the sure screening property under suitable conditions.

4 A Multi Leaders - Follower Framework for Material Discovery

Lan Hoang[1], Michail Smyrnakis[2], [1]IBM, Warrington, United Kingdom; [2]STFC Daresbury, Warrington, United Kingdom. Contact: lan.hoang@ibm.com

Material discovery has been vastly accelerated due to the data revolution and the application of Optimisation and AI. However, there has not yet exist a method that combines optimisation with sequential decision making to utilise the design of material according to a desired property. In this paper, we propose a multi leader - one follower architecture for material discovery to combine human feedback, surrogate models and reinforcement learning.

Community Committee Choice Session

Session Chair: Liz Wanless, Ohio University, Athens, OH

1 Renewable Energy Source Diffusion in Professional Sport Facilities

Liz Wanless[1], Chad Seifried[2], Tim Kellison[3], [1]Ohio University, Athens, OH, [2]Louisiana State University, Baton Rouge, LA, [3]Florida State University, Tallahassee, FL, Contact: wanless@ohio.edu

Professional sport facility sustainability initiatives offer sport organizations an opportunity to demonstrate congruence with societal concern for the environment, an effort that also affects stadia revenue generation. Guided by diffusion of innovations theory, this study harnessed diffusion modeling and logistic regression to determine how quickly renewable energy source adoption is diffusing across 175 professional sport stadia in the United States and Canada and the factors catalyzing early renewable energy source adoption.

2 Rating and Ranking Professional Soccer Player Performance

Elizabeth Bouzarth, Furman University, Greenville, SC

Individual contribution to a successful play in soccer is often hard to determine. We develop a system to assess individual player performance in offense, defense, and ball control categories using only play-by-play data and independent of traditional statistics. In collaboration with ESPN, we develop a theoretical valuation of field position by which to reward offense and defense contributions to ball advancement. Additionally, we promote the significance of pass networks and their centrality to evaluate a ball control metric. These ratings are combined to form an overall rating of player contribution to the team. We present results across several professional soccer leagues and seasons.

3 Sports, Magic Numbers, and Full-stack Development

Frederick Coleman, Colorado School of Mines, Golden, CO, Contact: fcoleman@mines.edu

Sports are a global form of entertainment. As the season progresses, individuals may be curious about how many more games a team needs to win in order to achieve a first-place clinch or post-season play. Magic numbers provide this information. We use integer programs to produce more sophisticated calculations and, correspondingly, more precise numbers, which we then display on a website, RiotSports.net. In this way, users are most up-to-date on their teams' standings. We discuss the development of the website, from data scraping to integer-program output.

4 Improving Sports Media's Crystal Ball for the English Premier League

Alexandra M. Newman[1], Eli Olinick[2], Mark Husted[1], Eric Boone[1], Joseph George[1], Christopher Jones[1], [1]Colorado School of Mines, Golden, CO, [2]Southern Methodist University, Dallas, TX

The English Premier League is one of the world's most prominent soccer associations. At the end of each regularseason, a certain number of teams are relegated to lower-tier play, while others are awarded play in the ChampionsLeague, Europa League, and Europa Conference League. We model the process of being relegated or awarded play againstother European teams as a series of mixed-integer programs, and demonstrate how results from our models compare againstinformation common media outlets currently provide.

Daniel H. Wagner Prize I

Award Session

Session Chair: James J. Cochran, The University of Alabama, Tuscaloosa, AL

1 Smart Parcel Consolidation at Cainiao

Biao Yuan, Shanghai Jiao Tong University, Shanghai, China

Cainiao has constructed a smart parcel consolidation system to consolidate parcels ordered by the same consumer during fulfillment from China to 52 countries since 2020, saving tens of millions of dollars annually and shortening the delivery time by at least 50%. The main innovations of this work are: 1) three analytical methods are integrated to support real-world business process decisions successfully, and 2) a two-stage online optimization algorithm with one parameter is proposed to solve the parcel consolidation problem where a parcel may be involved in several times of decisions.

2 The Sort-Assemble-Blend Routing Problem and its Application to Semiconductors

Karl Kempf, Intel Corporation, Chandler, AZ

Although a recent shift from large monolithic die to multiple small die as the preferred method to realize semiconductor product has important advantages, it adds complexity to the design and manufacturing processes. While manufacturing yields and product performance are enhanced, new problems of sorting small die into categories, developing recipes to combine categories, and routing die to maximize their utilization must be solved. A three level iterative system has been developed to address the resulting non-linear non-convex challenge. The system has yielded over $500M in benefits so far.

INFORMS JFIG Best Paper Competition II

Award Session

Session Chair: Albert Solomon Berahas, University of Michigan, Ann Arbor, MI

1 "Be the Buyer"-Leveraging the Wisdom of the Crowd inE-Commerce Operations

Leela Aarthy Nageswaran, University of Washington, Seattle, WA

We study a new business practice of using crowdvoting, wherein a retailer first seeks input from customers on the desirability of the product and then bases the purchasing decision on their votes. By leveraging the staggered introduction of crowdvoting at a subscription-based apparel rental platform, we find that after the adoption, both short- and long-term rental rates increase. We show that the platform makes better inventory depth decisions and users become more engaged with the platform.

2 **On the Optimization Landscape of Nonconvex Matrix Recovery: When Are True Solutions Identifiable?**
Salar Fattahi, University of Michigan, Ann Arbor, MI
Low-rank matrix recovery is typically solved via a nonconvex method called Burer-Monteiro factorization (BM). If the rank of the ground truth is known and the measurements are noiseless, BM is free of sub-optimal local minima, and its true solutions coincide with the global minima. When the rank of the ground truth is unknown, it must be over-estimated, giving rise to an over-parameterized BM. In this work, we show that, for over-parameterized BM, the true solutions are neither global nor local minima.

3 Approximation Algorithms for Dynamic Inventory Management on Networks
Levi DeValve, University of Chicago, Chicago, IL
We provide the first approximation algorithm for dynamic inventory management on a network with stochastic demand and backlogging. Specifically, under a mild cost condition, we prove the cost of a specially designed base-stock policy is less than 1.618 times the cost of an optimal policy. We develop a novel stochastic programming analysis to prove this result: we carefully calibrate two stochastic programs (providing upper and lower bounds on the optimal policy), and compare their objectives. The upper bound arises from a new class of base-stock policies we define to address the currently unresolved issue of how to assign and fulfill backlogs in a system with fulfillment flexibility. The lower bound is derived through a novel cost accounting scheme that captures the trade-off between current inventory decisions and future backlog decisions. We show that this analysis extends to a variety of settings.

Managing Experiential Learning in Business Analytics

Panel Session

Session Chair: Kenneth E. Murphy, University of California Irvine

1 Managing Experiential Learning in Business Analytics
Kenneth E. Murphy, University of California Irvine
Experiential learning is one of the most valuable elements of our students' education, and this is especially true for those completing OR/MS/Analytics degree programs. Planning and delivering impactful practical experience requires significant effort on the part of faculty and administrators. In this panel our colleagues will share insights on implementing experiential education effectively and efficiently with an eye on the undergraduate student population. Topics to be covered include, but are not limited to Managing Practicum Projects, Student Informs Chapters, and the new Associate Certification for Analytics Professionals (ACAP).

Appointment Scheduling in Healthcare: From Patients to Physicians

Contributed Session

Session Chair: Pelin Damci Kurt, Perfectserve, Danville, CA

1 Selecting and Scheduling Patients on Parallel Non-Homogenous Servers Considering Setup Times and Time Window Constraints
Payman Jula, Simon Fraser University, Vancouver, BC, Canada. Contact: pjula@sfu.ca

This talk addresses the problem of selecting and scheduling different types of patients on parallel servers with sequence dependent setup times and strictly enforced time windows. We depart from existing literature by considering continuous time and introduce a mathematical programming model based on disjunctive constraints to solve small and medium size problems to optimality and propose heuristics to solve large scale problems. The efficiency and effectiveness of proposed algorithms are reported and applications in patient scheduling in healthcare industry are highlighted.

2 Controling Appointment Schedules: How and when to Intervene

Roshan Mahes, University of Amsterdam, Amsterdam, Netherlands. Contact: a.v.mahes@uva.nl

Traditionally, appointment schedules have been determined by minimizing a specific cost function consisting of clients' waiting times and server idling. These schedules are often studied in a static sense; once announced no further updates will follow. However, advancements in technology have opened up the possibility of communicating with upcoming clients, which can lower costs. Yet, excessive updates may cause confusion and frustration among clients. In this study, we consider how many updates one should send and what are the ideal moments to send these updates. On the operational level, the findings have broad applications in the management of appointment scheduling.

3 Fatigue Management Constraints in Physician Scheduling

Pelin Damci Kurt[1], Elizabeth Loggia[2], [1]Perfectserve, Knoxville, TN, [2]Perfectserve, Knoxville, TN, Contact: pelin@lightning-bolt.com

We consider fatigue management constraints in physician scheduling problems based on a study from the aviation industry. We minimize the fatigue level for each physician on a given day of the schedule by adding constraints to a mixed integer programming model. There are different metrics that are used in identifying fatigue such as total hours worked during day and night, maximum length of a shift, amount of breaks and night call per 7 days.

Data Analytics Applications

Contributed Session

Session Chair: Meghna Maity, Kansas State University, Manhattan, KS

1 Enabling and Maximizing Data Potential for Mapping Research Impact

Jane Payumo, Michigan State University, East Lansing, MI, Contact: payumoja@msu.edu

This paper aims to share institutional experience of AgBioResearch - research arm of Michigan State University's College of Agriculture and Natural Resources, in building and maintaining integrated and inclusive research evaluation and data analytics systems that support a thriving academic research enterprise. It will showcase how modern information management systems and associated data and data analytics are used to track and evaluate research performance, productivity, quality, and return on investments expectations for academic research. Thirdly, it will also showcase a framework on how these systems support faculty recruitment and retention, professional development, and diversity, equity, and inclusion. Finally, this paper will showcase some of the requirements and principles that underpin a thriving data and analytics culture at MSU AgBioResearch.

2 Optimizing a Two-Stage Genetic Manufacturing System with Markov Decision Process

Mohammad Maydanchi[1], Gregory Purdy[2], Daniel F. Silva[2], [1]Auburn University, Auburn, AL, [2]Auburn University, Auburn, AL

Synthetic biology and genetic engineering are crucial in biotechnology. Genetic Manufacturing Systems (GMS) streamline genetic construct production. Inspections ensure high-quality outputs. This study models GMS using a Markov decision process, addressing multistage inspection allocation. It examines how GMS characteristics affect optimal inspection strategies. The mathematical model aids in designing optimal inspection strategies for GMS. These findings optimize high-quality genetic construct production, benefiting professionals in synthetic biology.

3 Process Optimization in Cheese Production to Mitigate Bacterial Contamination

Meghna Maity[1], Ashesh Sinha[1], Shing Chang[1], Jayendra Amamcharla[2], [1]kansas state university, Manhattan, KS, [2]kansas state university, Manhattan, KS, Contact: mmaity@ksu.edu

Process Optimization in Cheese
Production to reduce wastage
Due to globalization of markets, perishable products are moving throughout the country and exported. Quality monitoring and traceability along the supply chain is essential. The purpose of our research is to develop a

holistic approach to ensure optimum yield in cheese supply chain by optimizing specified set of parameters involved in cheese production. We developed a reinforcement learning technique (Q-leaning model) to filter relevant parameters impacting cheese quality and yield like temperature, rennet amount, salt quantity etc. The Q-learning model gives us the best action or optimized value of parameters at all stages of cheese production thus ensuring minimum wastage .

Service Systems Operations

Contributed Session

Session Chair: Wouter van Eekelen, Tilburg University, Tilburg, Netherlands

1 Coping with Service Cancellation: Strategic Role of Capacity Allocation

YoungJae Jang[1], YoungSoo Park[2], Bosung Kim[3], Jaeung Sim[4], [1]MineIS, Seoul, Korea, Republic of; [2]Korea Advanced Institute of Science and Technology, Seoul, Korea, Republic of; [3]Kyung Hee University, Seoul, Korea, Republic of; [4]University of Connecticut, Stamford, CT

This paper proposes a game-theoretic framework for the firm's capacity allocation between the two refund options, where customers purchase products considering product availability upon arrival, relative prices between the options, and their uncertainty of future consumption. We identify three main effects of capacity allocation: customer transition, customer replacement, and sales loss effects. Based on this framework, we show that the firm has no incentive to offer both options to all customers. Instead, allocating a slightly higher non-refundable capacity than the first-best demand enables the firm to leverage the customer transition and avoid sales loss. We also show that such restrictions on refund options improve rather than reduce consumer surplus by mitigating misalignments of interests.

2 Impact of Cancellation Policy on Rental Sharing Platforms

Xing Hu[1], Lifei Sheng[2], Hao Zhang[3], Xuying Zhao[4], [1]University of Hong Kong, Hong Kong, China; [2]University of Houston Clear Lake, Houston, TX, [3]University of British Columbia, Vancouver, BC, Canada; [4]Texas A&M University, College Station, TX, Contact: hao.zhang@sauder.ubc.ca

We study the cancellation policies on C2C platforms such as Airbnb. Three parties are considered: the platform, a host, and a sequence of consumers (guests). Two representative policies are considered: a strict cancellation policy (fully refundable if the booking is cancelled before a cutoff date) and a flexible cancellation policy (fully refundable before the check-in date). We identify market conditions under which the host and the platform have misaligned preferences on the cancellation policy. We also find that either cancellation policy can generate higher social welfare than the other under suitable market conditions.

3 Large-scale Service Systems Provisioning An Uncertain Market Of Rational, Delay-sensitive Customers

Wouter van Eekelen, Tilburg University, Tilburg, Netherlands

In this talk, we consider a large-scale service provider that caters to a market of rational, delay-sensitive individuals and operates in an environment in which the market size varies stochastically. Within this uncertain market environment, the firm needs to establish its pricing policy and determine the appropriate service capacity to acquire. We aim to strike the optimal balance between these two control parameters, enabling the firm to maximize its profit while taking into consideration the inherent uncertainty of the market environment.

Plenary Panel: Harnessing the Data Revolution in Supply Chains

Plenary Session

1 Harnessing the Data Revolution in Supply Chains

Anne G. Robinson, Kinaxis, Ottawa, ON, Canada

Supply chains vast scope and impact generate huge amounts of data, which represent a treasure trove of insights. Some areas are amply explored with techniques well known to our field, such as inventory optimization, demand forecasting, production planning and scheduling, and transportation. And yet with the advent of technical advances in the ability to store and calculate data, we can collect and compute in ways never before possible. The internet of things generates signals across the supply chain, and far more external data options exist, ranging from federated sources like microeconomic data, weather, and consumer demand to social media sentiment. Machine learning can ingest these signals to augment insights across the supply chain network. Algorithmic research also provides modern approaches that integrate machine learning and optimization in new ways. All of these changes offer unparalleled opportunity to harness the data revolution in the practice of supply chains, which is fortunate given that disruptions show no sign of ceasing and supply chains are on the board room agenda like never before. This panel of experts bring decades of experience looking at these issues and will share their perspectives on what areas represent the most promise and which the most peril.

Integer Programming Games: A Gentle Computational Overview
Tutorial Session
Session Chair: Douglas R. Shier, Clemson University, Pittsboro, NC

1 Integer Programming Games: A Gentle Computational Overview
Andrea Lodi[1], Margarida Carvalho[2], Gabriele Dragotto[3], Sriram Sankaranarayanan[4], [1]Cornell Tech, New York, NY, [2]University of Montreal & CIRRELT, Montreal, QC, Canada; [3]Princeton University, Princeton, NJ, [4]Polytechnique Montreal
Nash equilibria enlighten the structure of rational behavior in multi-agent decision-making. However, besides its existence, the concept is as helpful as one can efficiently compute it. Little is known about the computation of Nash equilibria in non-convex settings, a relevant context because non-convexities, often in the form of integer requirements. We provide a gentle overview of the recent bundle of work that deals with computing Nash equilibria for integer programming games. We do that by using the general and practically relevant context of attacking and protecting a critical infrastructure, and we highlight the characteristics and compare the differences of a sequential approach (Stackelberg game) versus a simultaneous one (Nash game). Finally, we guide the reader to the use of relevant software for computing Nash equilibria for integer programming games.

Artelys Corp
Technology Tutorial

1 Nonlinear Optimization Using Artelys Knitro
Richard Waltz, Artelys, Los Angeles, CA, Contact: richard.waltz@artelys.com
Artelys Knitro is a leading solver focused on large-scale, nonlinear (potentially non-convex), optimization problems. Knitro offers both interior-point and active-set algorithms for continuous models, as well as tools for handling problems with integer variables and other discrete structures. This tutorial will introduce the key features of Knitro, and demonstrate how to use Knitro to model and solve an optimization problem from within the python environment by working through a real-world application in the energy industry. We will also highlight some of the latest developments in Knitro, focusing on some of the recent advances in solving mixed-integer nonlinear problems, and heuristics for finding global (or improved local) solutions for non-convex problems.

2 Optimizing Hydropower and Reservoir Management: Advanced Modeling and Strategic Optimization
Carlyle Deligny, Artelys, Montreal, QC, Canada. Contact: carlyle.deligny@artelys.com
With 15,300 MW of installed capacity in 8 countries and 85% of hydropower capacity, Brookfield Renewable is one of the biggest hydropower producers worldwide. Artelys has worked closely with Brookfield Renewable to model and optimize the operations of 2 of their major hydropower

plants (650 MW of installed capacity in Pennsylvania, USA). The objective was to develop a software solution to model hydropower plant operations. Artelys carried out a study that led to around 10% potential gain in the annual generated revenue and implemented a software solution based on Artelys Crystal Energy Planner to optimize short-term schedules for the 2 hydropower plants. Using Artelys Crystal Energy Planner, Artelys modelled the Brookfield Renewable system considering all specific operational and market-related constraints to take advantage of all the sources of flexibility to automatically generate reliable least cost production schedules.
This customized solution uses a powerful optimization engine to assist hydropower producers in maximizing their generation benefit while taking into account all specific operational, environmental, and market-related constraints. The objective of the presentation is to present the solution, with a focus on the steps taken to integrate these powerful algorithms into an operational scheduling process.

Market Design and Matching Controls

Community Committee Choice Session

Session Chair: Ali Aouad, London Business School, London, United Kingdom

1 Neural Inventory Control in Networks via Hindsight Differentiable Policy Optimization

Matias Alvo[1], Daniel Russo[2], Yash Kanoria[3], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY, [3]Columbia Business School, New York, NY

Inventory management offers unique opportunities for reliably evaluating and applying deep reinforcement learning (DRL), as one can compare to the optimum itself in several problem classes with hidden structure. Our DRL methods consistently recover near-optimal policies in such settings. In others, they can vastly outperform problem-specific heuristics. We leverage two insights. First, one can directly optimize the hindsight performance of any policy using stochastic gradient descent. This uses (i) an ability to backtest any policy's performance on a subsample of historical demand observations, and (ii) the differentiability of the total cost incurred on any subsample with respect to policy parameters. Second, we propose a natural neural network architecture to address problems with weak coupling constraints between locations in an inventory network.

2 A Nonparametric Framework and Improved Relaxations for Online Decision-Making with Correlated Arrivals

Ali Aouad[1], Will Ma[2], [1]London Business School, London, United Kingdom; [2]Columbia University, New York, NY, Contact: willma353@gmail.com

The design of online policies for stochastic matching and revenue management settings is usually bound by the Bayesian prior that the demand process is formed by a fixed-length sequence of queries with unknown types, each drawn independently. This assumption of serial independence implies that the demand of each type, i.e., the number of queries of a given type is approximately Poisson-distributed. Thus, matching policies are often based on ``fluid'' LPs that only use the expectations of these distributions. This paper explores alternative stochastic models for online matching that allow for nonparametric, higher variance demand distributions. We propose two new models, Indep and Correl, that relax the serial independence assumption in different ways by combining a nonparametric distribution for the demand with standard assumptions on the arrival patterns.

3 Welfare Distribution in Two-Sided Random Matching Markets

Geng Zhao[1], Itai Ashlagi[2], Mark Braverman[3], [1]UC Berkeley, Berkeley, CA, [2]Stanford University, Stanford, CA, [3]Princeton University, Princeton, NJ, Contact: gengzhao@berkeley.edu

We study the welfare structure in two-sided large random matching markets with logit-based preferences. Under a contiguity condition, we provide a tight description of stable outcomes. First, we identify an intrinsic fitness for each agent that represents her relative competitiveness in the market, independent of the realized stable outcome. Second, in every stable (or even approximately stable) matching, the welfare or the ranks of the agents on each side of the market, when scaled by their intrinsic fitness, have an approximately exponential empirical distribution. Moreover, the average welfare of agents on one side of the market is sufficient to determine the average on the other side. Overall, each agent's welfare is determined by a global parameter, her intrinsic fitness, and an extrinsic factor with exponential distribution across the population.

4 Online Matching in Random Graphs

Flore Sentenac, 1</sup

The theory of online matching in graphs received a gain of interest in recent years due to its application to ad allocation on the internet. A large body of work considered the problem in general classes of graphs, introducing algorithms with worst-case guarantees.
Beyond this approach, we study online matching in models of random graphs relevant to the ad allocation problem. In particular, we will look at the so-called configuration model. We estimate the performance of the most straightforward algorithm, GREEDY, by approximating some stochastic discrete processes by their continuous counterparts, which are solutions of an explicit system of partial differential equations. Thanks to these techniques, we theoretically highlight in which instances GREEDY far outperforms its worst-case guarantee.

Value Creation in Online Platforms

Contributed Session

Session Chair: Jiang Jiang, Cornell University, Ithaca, NY

1 Price Obfuscation in Online Platforms: When Can Transparency Pay?

Jose Lopez[1], Edward G. Anderson[2], [1]MIT, Cambridge, MA, [2]University of Texas-Austin, Austin, TX, Contact: jllopez@mit.edu

Many popular consumer-facing platforms offer to reduce search costs and efficiently find lowest prices. Under competitive pressure, however, the platform's incentives may not directly align with those of their consumers. We study the effects of price obfuscation on platform performance, and on consumer welfare, by augmenting current models to incorporate multiple sources of competitive pressure, consumer behavioral learning, and explicitly account for the role of trust, and the effects of reputation building.

2 To Partner or Not to Partner? the Partnership Between Platforms and Data Brokers in Two-Sided Markets

Xin Zhang[1], Lihong Cheng[1], Yugang Yu[1], Yong Tan[2], [1]University of Science and Technology of China, Hefei, China; [2]University of Washington, Seattle, WA, Contact: chenglh@ustc.educ.cn

As data has become an important competitive asset, platforms usually partner with data brokers to acquire external data to enhance their targeting capabilities, but this practice has stoked consumer privacy concerns. This study develops a game-theoretic model to examine the economic mechanism underlying the partnership between competing platforms and a data broker in a two-sided market. Interestingly, our analysis shows that the increase in consumer privacy concerns caused by the data broker may incentivize platforms to partner with the data broker rather than discouraging them. We find that the platform-data broker partnership hurts consumer surplus when platforms adopt a pure ad-sponsored model without charging consumers, but it may benefit consumer surplus when platforms adopt a mixed model with ad-sponsored and subscription-based revenue.

3 Optimal Dynamic Pricing In The Presence Of Strategic Consumers: A Game-theoretic View

Ziqi Zhang[1], Zelin Zhang[2], Guoqing Guo[1], [1]Renmin Univerisity of China, Beijing, China; [2]Renmin University of China, Beijing, China. Contact: zikizhang5@ruc.edu.cn

The current research explores a monopolist's dynamic pricing decisions facing strategic consumers under limited capacity. While previous literature has proved the existence of a unique Nash equilibrium in a seller-consumer game, we challenge this finding and show there may exist multiple Nash equilibria under such pricing policies. We highlight the interdependency (implicit collusion) and mix strategies of customers' decision-making, resulting in the inefficiency of seller's pricing policy. To address this issue, we propose a maximum-matching dynamic pricing strategy that can lead to a unique pure Nash equilibrium while generating significant profits. We also conduct a behavioral experiment to examine the effectiveness of our proposed pricing policy on reducing strategic waiting behavior and creating higher profits, compared to other pricing policies.

4 Information Disclosure Requirements In P2P Lending Platforms

Peng-Chu Chen, Ran Tao, The University of Hong Kong, Hong Kong, Hong Kong. Contact: taoran13@connect.hku.hk

In a peer-to-peer (P2P) lending market, borrowers persuade lenders to grant loans by sending unverifiable information, verifiable information, or both. Although borrowers can exaggerate unverifiable information, lenders may not fully trust such information. In this study, we use a signaling game to model the interaction between borrowers and lenders and study the impact of disclosure requirements imposed by P2P lending platform operators. We show that requirements that allow only unverifiable information to be sent are beneficial to borrowers but harmful to lenders. In contrast, requirements that allow only verifiable information have the opposite effect. Allowing both types of information balances information asymmetry and the difficulty of obtaining financing in the market.

5 Optimizing Hotel Ranking Strategies to Mitigate Off-Platform Purchases at Online Travel Agencies (Otas)

Jiang Jiang, Chris K. Anderson, Cornell University, Ithaca, NY, Contact: jj438@cornell.edu

Online travel agencies (OTAs) face fierce competition with strategic consumers who compare prices across multiple platforms before making a purchase. We investigate how platforms can employ ranking mechanisms to mitigate the loss from off-platform purchases. More specifically, we propose a variant of the multinomial logit model incorporating a ranking discounting factor and off-platform purchase probabilities calculated with competitor price information. The model is estimated on a censored dataset where there is no indication whether consumers did not make a hotel selection or made their purchase through alternative platforms. We used genetic algorithm - expectation maximization (GA-EM) method to increase efficiency of the estimation. Simulation is given to compare various ranking heuristics.

Causal Inference and Machine Learning in Operations

Community Committee Choice Session

Session Chair: Dennis Zhang, Washington University in St Louis, ST LOUIS, MO

Session Chair: Bing Bai, Washington University in St. Louis, Saint Louis, MO

1 Blessing from Human-AI Interaction: Super Reinforcement Learning in Confounded Environments

Jiayi Wang, University of Texas at Dallas, Richardson, TX

As AI becomes more prevalent throughout society, effective methods of integrating humans and AI systems that leverages their respective strengths and mitigates risk have become an important priority. We introduce the paradigm of super reinforcement learning that takes advantage of Human-AI interaction for data driven sequential decision making. This approach utilizes the observed action, either from AI or humans, as input for achieving a stronger oracle in policy learning for the decision maker (humans or AI). In the decision process with unmeasured confounding, the actions taken by past agents can offer valuable insights into undisclosed information. By including this information for the policy search in a novel and legitimate manner, the proposed super reinforcement learning will yield a super-policy that is guaranteed to outperform both the standard optimal policy and the behavior one (e.g., past agents' actions). We call this stronger oracle a blessing from human-AI interaction. Furthermore, to address the issue of unmeasured confounding in finding super-policies using the batch data, a number of nonparametric and causal identifications are established. Building upon on these novel identification results, we develop several super-policy learning algorithms and systematically study their theoretical properties such as finite-sample regret guarantee.

2 A Two-Part Machine Learning Approach to Characterizing Network Interference in A/B Testing

Yuan Yuan[1], Kristen Altenburger[2], [1]Purdue University, West Lafayette, IN, [2]Meta Inc., Menlo Park, CA, Contact: yuanyuan@purdue.edu

This paper introduces a machine learning method for addressing interference in A/B tests, a limitation of conventional testing when a unit's response is affected by others. Traditional literature fails to account for latent network structures of interference and requires human expertise for modeling. Our solution utilizes causal network motifs to automatically characterize interference from local network structures and treatment assignments. We then use decision trees and nearest neighbors to link motifs to an "exposure condition". This approach is validated through a simulated experiment on a Watts-Strogatz network and a large-scale Instagram user test. The result is an automated method that enhances expert capabilities in managing A/B testing interference.

3 Deep-Learning-Based Causal Inference for Large-Scale Combinatorial Experiments

Zikun Ye[1], Zhiqi Zhang[2], Dennis Zhang[3], Heng Zhang[4], Renyu Zhang[5], [1]University of Illinois Urbana Champaign, Urbana, IL, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University in St Louis, ST LOUIS, MO, [4]Arizona State University, Tempe, AZ, [5]The Chinese University of Hong Kong, Hong Kong, China. Contact: philipzhang@cuhk.edu.hk

Online platforms launch hundreds of randomized experiments every day to iterate their operations and marketing strategies. The combinations of these treatments are typically not exhaustively tested. We develop a novel framework combining deep learning and doubly robust estimation to estimate the causal effect of any treatment combination for each user on the platform when observing only a small subset of treatment combinations. Our approach leverages Neyman orthogonality and allows for valid inference. To empirically validate our method, we collaborated with a large-scale video-sharing platform and implemented our framework. Our method significantly outperforms other benchmarks to accurately estimate and infer the average treatment effect of any treatment combination, and to identify the optimal treatment combination.

4 Interference in Experimentation in Two-Sided Markets

Wassim Dhaouadi[1], Ramesh Johari[2], Gabriel Weintraub[1], [1]Stanford Graduate School of Business, Stanford, CA, [2]Stanford University, Stanford, CA

We provide a novel model and associated analysis to study interference arising in experiments in two-sided markets. Our model allows to characterize biases for a broad set of experimental designs and estimators. We use our results to provide ways to alleviate such biases in practice.

1 Effects of Interference on Marketplace Experiments and Decision-Making

Gabriel Weintraub[1], Ramesh Johari[2], Hannah Li[3], Inessa Liskovich[4], [1]Stanford Graduate School of Business, Stanford, CA, [2]Stanford U, Stanford, CA, [3]MIT, Menlo Park, CA, [4]Airbnb, SF, CA, Contact: gweintra@stanford.edu

Online marketplace platforms rely on experiments to aid decision-making. In a marketplace setting, prior work shows that common estimators for the treatment effect can be biased due to interference. These treatment effect biases, however, are not the only source of bias that can affect platform decisions. An additional source of bias arises when estimating the standard error, which can lead to confidence intervals that are too wide or too narrow, leading the platform to be under or over-confident in their decisions. We evaluate the impact of both types of biases on the resulting decisions that a platform makes, as well as the impact of bias corrections for both treatment and standard error bias. Finally, we assess the impacts of biases on decisions made in the Airbnb marketplace.

2 Influence Effects in Social Networks: Inward and Outward Spillovers of One Unit's Treatment

Fei Fang, Laura Forastiere, Yale University, New Haven, CT, Contact: fei.fang@yale.edu

In a social network, users may have varying levels of influence on others when they themselves receive interventions. Evaluating such effects can provide insights for various applications such as targeting strategies. We define the effect of one unit's treatment on the outcome of their network neighbors in two ways: i) the inward spillover effect on a unit's outcome of a neighbor's treatment, and ii) the outward spillover of a unit's treatment on their neighbors' outcomes. In both causal effects, we marginalize over the distribution of the treatment vector in the rest of the network under a hypothetical Bernoulli trial. We compare these two effects with different properties, including the conditions under which they are equivalent. We also develop Horvitz-Thompson estimators for both types of causal effects and their design-based variance in randomized experiments.

3 Design-Based Confidence Sequences: A New Approach to Risk Mitigation in Online Experimentation

David Ham[1], Michael Lindon[2], Martin Tingley[3], Iavor Bojinov[4], [1]Harvard, Cambridge, MA, [2]Netflix, New York, NY, [3]Netflix, Los Gatos, CA, [4]Harvard Business School, Somerville, MA, Contact: ibojinov@hbs.edu

We introduce design-based confidence sequences for analyzing sequential experiments with uniform type-1 error guarantees, allowing managers to “peek” at results as new data becomes available without compromising the validity of the statistical analysis. The proposed method is versatile and applicable to various experiments, including multi-arm bandits, time series, and panel experiments. We conduct comprehensive simulations and analyze three Netflix experiments to validate our approach. The results demonstrate that our confidence sequence method can quickly terminate harmful experiments, reducing costs and mitigating risk. For instance, we show our method could have stopped an experiment on the first day after observing only 63 units.

Online & Dynamic Matching: Innovative Approaches

Community Committee Choice Session

Session Chair: Sophie Yu, Duke University, Durham, NC

1 A Nonparametric Framework for Online Stochastic Matching with Correlated Arrivals

Ali Aouad[1], Will Ma[2], [1]London Business School, London, United Kingdom; [2]Columbia University, New York, NY

Matching decisions are important operational controls for online marketplaces, with applications including order fulfillment, ride-hailing, and service platforms. Existing stochastic models often rely on an assumption of "serial independence," which implies that the demand is approximately Poisson-distributed and low-variance. By relaxing this assumption, we develop a nonparametric framework for online matching that can represent high-variance and correlated arrivals. We demonstrate that fluid relaxations, which rely solely on expected demand information, have arbitrarily bad performance guarantees. Instead, we propose tighter linear programming relaxations that leverage distribution knowledge and use a novel rounding scheme to obtain matching algorithms that achieve optimal (worst-case) performance guarantees.

2 The Power of Greedy for Online Minimum Cost Matching on the Line

Eric Balkanski, Yuri Faenza, Noemie Perivier, Columbia University, New York, NY

In the online minimum cost matching problem, there are n servers and, at each of n time steps, a request arrives and must be irrevocably matched to a server that has not yet been matched to, with the goal of minimizing the sum of the distances between the matched pairs. Online minimum cost matching is a central problem in applications such as ride-hailing platforms and food delivery services. Despite achieving a worst-case competitive ratio that is exponential in n even on the line, the simple greedy algorithm, which matches each request to its nearest available server, performs well in practice and has a number of attractive features such as strategyproofness. A major question is thus to explain greedy's strong empirical performance. In this talk, we aim to understand the performance of greedy on the line over instances that are at least partially random.

3 On the Optimality of Greedy Policies in Dynamic Matching

Süleyman Kerimov[1], Itai Ashlagi[2], Itai Gurvich[3], [1]Rice University, Jones Graduate School of Business, Houston, TX, [2]Stanford University, Management Science and Engineering, Stanford, CA, [3]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: kerimov@rice.edu

We study centralized dynamic matching markets with finitely many agent types and heterogeneous match values. A network topology describes the pairs of agent types that can form a match and the value generated from each match. A matching policy is hindsight optimal if the policy can (nearly) maximize the total value simultaneously at all times. We find that suitably designed greedy policies are hindsight optimal in two-way matching networks.

We first show that the greedy longest-queue policy with a minor variation is hindsight optimal. Importantly, the policy is greedy relative to a residual network, which includes only non-redundant matches with respect to the static optimal matching rates. Moreover, when the residual network is acyclic (eg, as in two-sided networks), we prescribe a greedy static priority policy that is also hindsight optimal.

4 Feature Based Dynamic Matching

Yilun Chen[1], Yash Kanoria[2], Akshit Kumar[2], Wenxin Zhang[2], [1]CUHK Shenzhen, Shenzhen, China; [2]Columbia Business School, New York, NY, Contact: chenyilun@cuhk.edu.cn

We consider a feature-based dynamic matching problem faced by centralized platforms in a highly heterogeneous market. Specifically, a set of heterogeneous supply units, each characterized by i.i.d. supply feature vector, is available initially. In each period, a customer arrives with an i.i.d. demand weight vector describing her type, and requests to consume a supply unit. The platform seeks a dynamic matching policy that assigns supply units to customers to maximize the expected average matching utility. We propose and analyze a simple, simulation-based matching policy, dubbed Simulate-Optimize-Assign-Repeat (SOAR). We prove that SOAR enjoys a surprisingly universal (near) optimality guarantee, achieveing the optimal regret scaling under various modelling assumptions. Extensive numerical simulations support the robustness of the performance of SOAR.

Statistical Methods on Causal Inference, Inference and Reinforcement Learning
Community Committee Choice Session
Session Chair: Raaz Dwivedi, Harvard and MIT, CAMBRIDGE, MA
Session Chair: Kyra Gan, Harvard University, Cambridge, MA

1 Kernel-Based Universal Debiasing for Pathwise Differentiable Parameters
Brian Cho[1], Kyra Gan[2], Ivana Malenica[2], Yaroslav Mukhin[3], [1]Cornell University, New York City, NY, [2]Harvard University, Boston, MA, [3]MIT, Boston, MA, Contact: bmc233@cornell.edu
Modern estimation methods achieve optimal performance by relying on knowledge of the (efficient) influence function (EIF) for the target parameter. We propose a novel way to estimate functions of the data-generating distributions that provides optimal performance without requiring knowledge of the EIF. Distinct from existing approaches, our method requires a single distribution for plug-in estimation for all target parameters. We present a novel use case of Universal RKHS to eliminate the plug-in bias and achieve the nonparametric efficiency bound. Our theoretical results show that any pathwise differentiable parameter estimated utilizing a plug-in approach is asymptotically normal, with the correct limiting variance. We validate these results for several target parameters and show that our approach performs comparably to existing approaches.

2 Role Of Lookahead In Reinforcement Learning Algorithms
Anna Winnicki, R. Srikant, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: annaw5@illinois.edu
A common technique in reinforcement learning is to evaluate the value function from Monte Carlo simulations of a given policy, and use the estimated value function to obtain a new policy which is greedy with respect to the estimated value function. A well-known longstanding open problem in this context is to prove the convergence of such a scheme when the value function of a policy is estimated from data collected from a single sample path obtained from implementing the policy. We present a solution to the open problem by showing that a first-visit version of such a policy iteration scheme indeed converges to the optimal policy provided that the policy improvement step uses lookahead rather than a simple greedy policy improvement. We provide results both for the original open problem in the tabular setting and also present extensions to the function approximation setting.

3 On Counterfactual Inference with Unobserved Confounding
Abhin Shah[1], Raaz Dwivedi[2], Devavrat Shah[1], Gregory W. Wornell[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Harvard and MIT, Cambridge, MA, Contact: abhin@mit.edu
Given an observational study with n independent units, our goal is to learn counterfactuals for each unit in the presence of unobserved confounding using only one p-dimensional sample per unit containing covariates, interventions, and outcomes. Modeling the underlying joint distribution as an exponential family, we reduce learning unit-level counterfactual distributions to learning n exponential family distributions with heterogeneous parameters and only one sample per distribution. We propose a convex objective to jointly learn all n parameter vectors, and provide a unit-wise mean squared error bound that scales linearly with metric entropy of parameter space, e.g., when parameters are s-sparse linear combination of k known vectors, error is O(s log k/p). En route, we derive conditions for compactly supported distributions to satisfy log-Sobolev inequality.

4 On the Identifiability and Interpretability of Gaussian Process Models
Didong Li, UNC
In this talk, we critically examine the prevalent practice of using additive mixtures of Mat\'ern kernels in Gaussian process (GP) models. In particular, we derive a series of theoretical results showing that the smoothness of a mixture of Mat\'ern kernels is determined by the least smooth component, and that a GP with such a kernel is effectively equivalent to the least smooth kernel component. Furthermore, we demonstrate that none of the mixing weights or parameters within individual kernel components are identifiable. Our findings are supported by extensive simulations and real applications. This work provides insights into kernel selection and interpretation for GP models, emphasizing the importance of choosing appropriate kernel structures for different tasks.

Theoretical Foundations of Decision Making under Uncertainty

Community Committee Choice Session

Session Chair: Zaiwei Chen, California Institute of Technology, Atlanta, GA

1 Automatic Outlier Rectification via Optimal Transport

Jiajin Li, Stanford University, CA

This talk proposes a novel conceptual framework to detect outliers using optimal transport. Conventional outlier detection approaches typically use a "two-stage" outlier removal procedure. Instead, we propose an automatic outlier rectification mechanism that integrates rectification and estimation within a joint optimization framework. The key idea is to use an optimal transport distance with a concave cost function to construct a novel rectification set in the space of probability measures. Then, we select the best distribution within this set to perform the estimation task, which introduces a transporter that efficiently rectifies the data and automatically detects outliers during the optimization process. We demonstrative its effectiveness on mean estimation, least absolute regression, and the fitting of option implied volatility surfaces.

2 Sharper Model-Free Reinforcement Learning for Average-Reward Markov Decision Processes

Zihan Zhang[1], Qiaomin Xie[2], [1]Princeton University, Princeton, NJ, [2]University of Wisconsin-Madison, Madison, WI

We develop several provably efficient model-free reinforcement learning (RL) algorithms for infinite-horizon average-reward Markov Decision Processes (MDPs). We consider both the online setting and the setting with access to a simulator. In the online setting, we propose model-free RL algorithms based on reference-advantage decomposition. Our algorithm achieves $O(\sqrt{T})$ regret after T steps. Our results are the first to achieve optimal dependence in T for weakly communicating MDPs. In the simulator setting, we propose a model-free RL algorithm that nearly matches with the minimax lower bound. Our results are based on two new techniques that are unique in the average-reward setting: 1) better discounted approximation by value-difference estimation; 2) efficient construction of confidence region for the optimal bias function with space complexity $O(SA)$.

3 A Finite-sample Analysis Of Payoff-based Independent Learning For Zero-sum Stochastic Games.

Zaiwei Chen, California Institute of Technology, Pasadena, CA, Contact: zchen458@caltech.edu

In this work, we study two-player zero-sum stochastic games and develop a natural variant of best-response learning dynamics that is payoff-based, convergent, rational, and symmetric between players. Our theoretical results present the first last-iterate finite-sample analysis of such learning dynamics. Specifically, in the stateless setting (which corresponds to zero-sum matrix games), we establish a sample complexity of $O(\epsilon^{-1})$ to find the Nash distribution and a sample complexity of $O(\epsilon^{-8})$ to find a Nash equilibrium. For general stochastic games, our learning dynamics also enjoys a sample complexity of $O(\epsilon^{-8})$ to find a Nash equilibrium. To establish the results, we develop a coupled Lyapunov drift approach to capture the evolution of multiple sets of coupled and stochastic iterates, which might be of independent interest.

4 Measure Gradient Descent

Di Yu[1], Raghu Pasupathy[2], Shane Henderson[3], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, [3]Cornell University, Ithaca, NY, Contact: yu1128@purdue.edu

Motivated by certain emergency response problems and certain variational problems, we present the measure gradient descent algorithm for optimizing a convex cost functional over the space of signed measures, and over the space of measures constrained by a budget. Assuming that the cost functional is equipped with a von Mises derivative, we present a useful necessary and sufficient diagnostic for optimality expressed in terms of the influence function. This diagnostic is then used within a descent algorithm over measure space that is reminiscent of stochastic gradient descent. We demonstrate a descent lemma, consistency in the functional space, and a complexity rate result. We also discuss implementation strategies.

Socially Responsible Computing in OR

Community Committee Choice Session

Session Chair: Chara Podimata, UC Berkeley, Allston, MA

1 Model-Sharing Games

Kate Donahue, Cornell, Ithaca, NY

Federated learning is a distributed learning paradigm where multiple agents, each only with access to local data, jointly learn a global model. This talk describes three papers analyzing game theoretic models of federated learning, all joint with Jon Kleinberg. In the first, we propose our framework ("Model-Sharing Games") and analyze the stability of federating coalitions through hedonic game theory. In the second, we provide an efficient algorithm to calculate an optimal (error-minimizing) arrangement and give the first Price of Anarchy bound in this game. In the third, we analyze fairness in error rates between federating agents and provide theoretical guarantees for when two commonly-used notions of fairness can be satisfied: egalitarian fairness (bounds how dissimilar error rates can be) and proportional fairness (rewards players proportional to data size).

2 Multicalibration as Boosting for Regression

Ira Globus-Harris, Declan Harrison, Michael Kearns, Aaron Roth, Jessica Sorrell, University of Pennsylvania, Philadelphia, PA, Contact: igh@seas.upenn.edu

We study the connection between multicalibration and boosting for squared error regression. Characterizing multicalibration in terms of a swap regret condition, we give a simple boosting algorithm that requires only a standard regression oracle to achieve multicalibration with respect to a class H. We give a weak learning assumption on H that ensures convergence to Bayes optimality without the need to make any realizability assumption, giving us an agnostic boosting algorithm for regression. We show that our weak learning assumption on H is both necessary and sufficient for multicalibration with respect to H to imply Bayes optimality, and generalize the weak learning condition to one relative to a constrained class of functions.

3 Learning from a Biased Sample

Roshni Sahoo[1], Lihua Lei[2], Stefan Wager[3], [1]Stanford University, Palo Alto, CA, [2]Stanford University, Palo Alto, CA, [3]Stanford GSB, Stanford, CA, Contact: rsahoo@stanford.edu

When learning data-driven decision rules, we may be concerned that certain groups are over- or under-represented in the training data relative to the test population. We give a model of sampling bias called Γ-biased sampling, where observables can impact sample selection probabilities arbitrarily but the effect of unobservables is bounded by a constant. Applying distributionally robust optimization, we give a method for learning a decision rule that minimizes the worst-case risk incurred under a family of test distributions that can generate the training distribution under Γ-biased sampling. We show that this problem is equivalent to an augmented convex risk minimization problem, provide statistical guarantees for learning the robust model, and give a simple implementation using deep learning.

4 Bidding Strategies for Proportional Representation in Advertisement Campaigns

Judy Hanwen Shen, Stanford

Many companies use advertising platforms for recruitment. However, equitable bidding may not result in equitable outcomes due to heterogeneous competition. We compare two fairness objectives: one in which the advertisers bid equally for yield with group-parity guarantees, and another in which the bids are not constrained; only the yield must satisfy parity constraints. We show that requiring parity for both bids and yield can result in an arbitrarily large decrease in efficiency compared to requiring equal yield proportions alone. We find that autobidding is a natural way to realize this latter objective and extend existing techniques to provide efficient bidding strategies with high utility while satisfying group parity constraints.

1 Confidence Regions on the Efficient and Pareto Sets in Multi-Objective Convex Quadratic Stochastic Programs

Susan R. Hunter, Ziyu Liu, Raghu Pasupathy, Purdue University, West Lafayette, IN

We consider the context of constructing confidence regions on the efficient and Pareto sets of multi-objective convex quadratic stochastic programs. Our main result is a uniform central limit theorem (CLT) on the efficient and Pareto set estimators constructed from a sample-average approximation of the objectives. Importantly, the uniform CLT reflects the structure inherent in the quadratic performance measures, obtained through an exact calculation of the Frechet derivative of the efficient and Pareto sets as a function of a scalarization parameter. The result provides the required theoretical foundation for constructing asymptotically exact confidence regions, which we illustrate with an example.

2 Reference Alternatives Based Knockout Tournament Procedure for Ranking and Selection

Ying Zhong[1], Jianzhong Du[2], Deng-Feng Li[1], Zhaolin Hu[3], [1]University of Electronic Science and Technology of China, Chengdu, China; [2]School of Management, Fudan University, Shanghai, China; [3]Tongji University, Shanghai, China. Contact: yzhong4@uestc.edu.cn

The knockout-tournament procedure is an efficient parallel procedure developed to solve large-scale ranking and selection problems. The procedure selects the best alternative by conducting "matches" between paired alternatives round-by-round. To further improve the procedure's performance from the aspect of the total sample size, we propose a major modification of the procedure. In each round of the selection, before pairing the alternatives, we first select an alternative as the reference alternative and then add the reference alternative to each "match". We show that by carefully choosing the reference alternative and pairing scheme for the remaining alternatives, the procedure can achieve significant improvements in both the average sample size required in each "match" and the total number of "matches", and thus can achieve an overall sample size reduction.

3 Using Generative Adversarial Networks (GANs) for Simulation: A Case Study of Wearable Sensor Data Synthesis

Yining Huang[1], Hong Wan[2], [1]North Carolina State University, Raleigh, NC, [2]NC State University, Raleigh, NC, Contact: yhuang43@ncsu.edu

This study delves into the utilization of Generative Adversarial Networks (GANs) for generating subject-specific time series sensor dat. We undertake an in-depth comparative analysis of DoppelGANger and ctGANs, two prominent GAN variants for time series data generation, evaluating their efficiency and efficacy. The sensor data for this investigation was sourced from The National Health and Nutrition Examination Survey (NHANES), which served as the foundational training set. We evaluated the synthesized subject-specific sensor data, focusing on the temporal and multi-dimensional statistical properties. Our empirical findings underscore the potential of GANs to adeptly capture the time-dependent correlations and the intricate statistical characteristics inherent in multi-dimensional data.

4 All-Purpose Screening Procedures for Ranking and Selection

Jinbo Zhao[1], David J. Eckman[2], [1]Texas A&M Univeristy, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: jinbozhao@tamu.edu

We introduce a class of screening procedures designed for ranking-and-selection problems featuring multiple objectives or stochastic constraints. The procedures guarantee to return either all acceptable systems, or each acceptable system, with high probability, where the definition of acceptability is flexible and can include optimality. Specifically, the procedures construct separate confidence regions for each system's performance and search within these regions for a configuration of performances for which a given system is acceptable. By implementing the procedures within a parallel computing environment, their running time can be reduced without compromising screening power. We demonstrate the effectiveness and efficiency of the procedures through numerical experiments.

Economic Issues of Homeland Security

Community Committee Choice Session

Session Chair: Aniruddha Bagchi, Kennesaw State University, Kennesaw, GA

1 A Model of Fortification Using Bayesian Persuasion

Jomon A. Paul, Abhra Roy, Kennesaw State University, Kennesaw, GA, Contact: jpaul17@kennesaw.edu

We analyze a model of communication between a Sender and multiple Receivers using Bayesian Persuasion in the context of fortification of critical infrastructure. The government receives noisy signals about whether an attack is imminent and searches for an optimal persuasion rule that maximizes the government's payoff under different intelligence settings.

2 Defense and Connectivity of Weakest-Link Networks

Colin Deurlington, University of California, Irvine, Irvine, CA

I study a model of weakest-link network defense, where the defender determines the accessibility of a valuable asset and allocates defensive resources prior to an attack. Under different exogenous parameters, two subgame equilibrium resource allocations can arise: (1) both the defender and attacker allocate a positive level of resources, or (2) the defender spends a sufficient level of resources to deter attacks. As the defender's cost-adjusted valuation of an asset increases relative to the attacker, the defender is more likely to increase access to this asset. If the defender only has a slightly larger cost-adjusted valuation of an asset relative to the attacker, however, the defender's decision to increase access depends on whether she is defending nodes individually or with an infrastructure technology.

3 U.S. Global Hegemony: Military Versus Economic Power

Joao RICARDO Faria, FLORIDA ATLANTIC UNIVERSITY, Boca Raton, FL, Contact: jfaria@fau.edu

Abstract: This paper discusses the US strategies to keep global hegemony. The U.S. can use military, economic power or a combination of both to achieve its objectives. In a dynamic model that allows an incumbent government reelection as a function of success in these strategies, we derive six different scenarios and rank them. With no reelection, if the marginal impact of economic power is greater [smaller] than the marginal impact of military power on world's reaction, the best strategy to keep U.S. global hegemony is through aggressive projections of military [economic] power. With reelection, the best strategy is to use a combination of military and economic power.

4 When Does a Country Attack an Adversary? the Joint Role of Cost of Attack and Quality of Information

Aniruddha Bagchi, Kennesaw State University, Kennesaw, GA

I examine a game between two countries (Home and Foreign) to determine how the quality of intelligence affects the choice between offense and defense. The foreign country is interested in attacking the home country and expends effort in developing a viable plan of attack. The outcome of this effort is uncertain, and the home country spends resources to find out if the foreign country succeeds in developing the plan. I allow for two kinds of intelligence errors- missed alarm and false alarm. Based on the intelligence input, the home country first decides whether to undertake a pre-emptive strike. If it decides not to strike, then in the next period, the home country can choose to fortify itself, while the foreign country decides whether to attack. I examine how the cost of attack and quality of information jointly help the Home country choose between offense and defense.

Session on Socially Responsible and Sustainable Operations

Community Committee Choice Session

Session Chair: Telesilla Olympia Kotsi, The Ohio State University, Columbus, OH

1 Classifying And Quantifying The Impact Of Social Sustainability Issues In Public Firms And Their Supply Chains

Soh Hyun Chu, Christian Blanco, James Hill, The Ohio State University, Columbus, OH, Contact: hill.249@osu.edu

This study explores the impact of different Social Sustainability issues on a firm's financial performance over three decades. We compare the severity of the impact of social misconducts whether they arose in focal firms or supply chains. Text analytics method is used to identify and classify the negative news articles on publicly traded companies appearing across 210 U.S. news outlets from 1990- 2019. We find that the rank of the severity ranges from child labor, forced labor, wage-hour-condition, harassment, health and safety, and discrimination. Notably, the severity of wage-hour-condition and harassment are only salient for the supply chain. We find that the impact of social issues on market values is short-lived, and may be why we see them recur. Finally, we construct an index of social sustainability of the largest publicly traded companies in the U.S.

2 The High Impact of Disasters on Prices in Low-Income Communities

Xabier Barriola[1], William Schmidt[2], [1]INSEAD, Fontainebleau, France; [2]Cornell University, Ithaca, NY
