Responding to natural disasters requires the deployment of food, shelter, and medical assistance to relieve the immediate needs of the victims. Low-income communities may bear a disproportionate burden from these disasters due to disparities in local infrastructure. We test for differences in prices paid between low-income and high-income communities after three Atlantic hurricanes. We find that affected low-income communities endure higher price increases within grocery categories compared to high-income communities. We see that low-income communities experience a larger drop in price promotions, higher price increases at the product level, more stockouts, and more substitution from low-priced products to high-priced products.

Integrated Multi-disciplinary Analysis supporting Deterrence: A Star Wars Story

Community Committee Choice Session

Session Chair: Jonathon Leverenz, Systems Planning and Analysis, Inc, Alexandria, VA

1 Episode I - The Phantom Message

Zachary Hunt, Systems Planning and Analysis, Inc., Alexandria, VA

Meaningful analysis, without meaningful messaging, is actually meaningless. The impact of effective analysis hinges on effective communication. This presentation will address how integration of a communication strategy into the analytic process can amplify message effectiveness and consistency. It will highlight communication techniques that tap into the brain's natural processing to connect with your audience while maintaining the integrity of your analysis.

2 Deterrence Strategy and Policy - A New Hope

Bobby Eldridge, Systems Planning & Analysis, Alexandria, VA

Deterrence strategy and policy is foundational to shaping both national and international security. In extreme circumstances, this means preventing war and requires capability, credibility, and communication to execute. This presentation will demonstrate how understanding the relationship between the qualitative fundamentals of deterrence strategy and policy and the quantitative analysis provided by Operations Research (OR) is critical to the accuracy of both.

3 Or Strikes Back - Objective Analysis for Deterrent Force Structures

Derek R. Shortt, Jonathon Leverenz, Systems Planning and Analysis, Inc, Alexandria, VA, Contact: dshortt@spa.com

Establishing objective measures assists in determining acceptable force structures for achieving deterrence objectives. This presentation covers establishing objective measures from deterrence objectives, and measures candidate force structures that meet those measures using OR techniques.

4 Optimization of Response Bases to Intercept Rogue Aircraft

Ramzi Mirshak, Defence Research and Development Canada, Ottawa, ON, Canada

Intercepting rogue aircraft from a small set of selected air bases creates a challenging optimization problem. Past efforts maximized the ability to respond to key locations within a given time window (for example, arriving in 30 minutes or less). We develop a new approach that instead maximizes the likelihood of intercepting a rogue aircraft sufficiently quickly to affect the outcome. A probabilistic model considers uncertainties in decision times, indications and warning, and threat speed to assess the likelihood of a successful response. Results are then superimposed on a geospatial grid to derive optimal basing using an integer programming approach. This presentation gives an overview of the method and presents results for a notional example.

5 Return of the Analysis (In Less than 12 Parsecs)

Jonathon Leverenz[1], Derek Roy Shortt[2], [1]Systems Planning and Analysis, Inc, Alexandria, VA, [2]Systems Planning and Analysis, Inc., Arlington, VA, Contact: jonathon.leverenz@gmail.com

Effective analysis requires the timely delivery of results. Timeliness is achieved not just through fast hardware and good models, but also by following an analytic framework that builds a path connecting message, measures of effectiveness, models, and data. This presentation explores one such framework and some techniques that can aid operations research analysts consistently deliver results when needed.

Building Blocks Towards Effective Leadership

Panel Session

1 Building Blocks Towards Effective Leadership

Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL

Filling Your Cup - What It Takes To Be an Effective Leader: WORMS invites all attendees to join this special session presentation. The transition from individual contributor to people leader is often unnecessarily painful, and learning how to be an effective leader takes practice. During this session we will talk about the skills necessary to become a successful leader from delegation to setting boundaries, providing impactful feedback to managing up. We will learn how to "Fill our Cups" to become comfortable with the uncomfortable and realize we are right where we are supposed to be. This session is applicable to everyone, regardless of where you are in your career. Session attendees will have an opportunity to sign up for a 1-1 coaching session later in the day.

2 Session Chair: Lavanya Marla, University of Illinois at Urbana-Champaign, Urbana, IL

3 Panelist

Angelika Leskovskaya, SMU Cox School of Business, Dallas, TX

4 **Panelist**

Human Behavior in Service Operations

Community Committee Choice Session

Session Chair: Brett Hathaway, Brigham Young University, Provo, UT

1 Limited Movement Means Vanishing Visits: How Patient Mobility and Signal Coarseness Reordered Healthcare Traffic in the Wake of Covid-19

RJ Niewoehner[1], Bradley R. Staats[2], [1]Kelley School of Business, Indiana University, Bloomington, IN, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: rniewoeh@iu.edu

Traffic represents a key operational input, but with the emergence of COVID-19 in 2020, traffic to many healthcare clinics fell dramatically overnight. Using aggregate measures of patient mobility, we seek to characterize factors that explain the drops in traffic. Our empirical analysis combines observations from healthcare clinics across several US states, anonymized cellphone mobility data, COVID-19 severity measures, and stay-at-home orders. We find (i) increases in personal mobility drive returns to clinic traffic, (ii) decreases in personal mobility lead to drops in traffic, and (iii) both effects are amplified for vaccination traffic. Combining observations from multiple sources allows us to evaluate how traffic to healthcare clinics changed with willingness to travel, stay-at-home orders, and other signals of environmental safety.

2 Multitasking in Livechat Support Centers

Robert Batt[1], Santiago Gallino[2], [1]Wisconsin School of Business, UW-Madison, Madison, WI, [2]University of Pennsylvania, Philadelphia, PA, Contact: bob.batt@wisc.edu

We explore the effect of multitasking on system performance in a livechat customer contact center. We find that while multitasking leads to increased chat handle time, the effect is does not increase linearly with multitasking level. We show that this can effect the optimal work assignment rule.

3 The Effect of Compensation Structure on Consumption Behavior

Paige Tsai, Harvard Business School, Boston, MA

We study the consumption behavior of individuals with multiple sources of labor income as compared to individuals with a sole source of labor income. While mental accounting literature has previously revealed that individuals mentally encode their financial activities differently based on the source of income, research to-date has yet to explore precisely how individuals treat labor income from a secondary labor income source. As part of this, we also examine the effect of income concentration on savings and spending behavior.

4 The Psychology of Virtual Queue: When Waiting Feels Less like Waiting

Kejia Hu[1], Xun Xu[2], Ao Qu[3], [1]Vanderbilt University, Nashville, TN, [2]California State University-Stanislaus, Turlock, CA, [3]MIT, Boston, TN

This study examines the impact of Virtual Queue (VQ) on customers' waiting complaints and overall satisfaction using restaurants' review data from 2015 to 2019. The study finds that VQ reduces customers' pre-process waiting complaints and enhances overall satisfaction but does not affect in-process waiting complaints. Service providers with high substitutability or low-value service benefit the most from VQ. The study recommends implementing VQ to manage perceived pre-process waiting time and generate positive online reviews.

Data-Driven Healthcare Operations

Community Committee Choice Session

Session Chair: Hamsa Bastani, 1</sup

Session Chair: Angel Chung, Wharton School,

Philadelphia, PA

1 A Hybrid Approach To Scalable Real-world Oncology Data Curation By Machine Learning And Human Experts

Holly Mika Wiberg, Carnegie Mellon University, Pittsburgh, PA, Contact: hwiberg@andrew.cmu.edu

Machine learning has the potential to increase the scale of real-world data curated from electronic health records, but maintaining data quality is important to avoid biasing downstream analyses. To increase scale without compromising quality, we propose a hybrid data curation approach that employs both manual abstraction by clinical experts and automated extraction by ML models. Our method determines when to employ manual abstraction using a confidence score associated with each model output. We describe a process for selecting confidence thresholds based on simulations validated against a reference-standard labeled dataset. To establish the fitness of our methodology for retrospective research, we apply it to a cohort selection task on a large real-world oncology database. Joint work: M. Waskom, K. Tan, A. Cohen, B. Wittmerhaus, W. Shapiro (Flatiron Health).

2 Learning Personalized Treatment Strategies with Predictive and Prognostic Covariates in Adaptive Clinical Trials

Andres Alban[1], Stephen E. Chick[2], Spyros Zoumpoulis[3], [1]Harvard Medical School, Boston, MA, [2]INSEAD, Fontainebleau, -, France; [3]INSEAD, Fontainebleau, France

We consider the problem of sequentially allocating sample observations to learn personalized treatment strategies, motivated by the design of adaptive clinical trials that aim to learn the best treatment as a function of patient covariates. In such settings there may be clinical knowledge of which covariates are predictive (they may interact with the treatment choice) and which are prognostic (they may influence the outcome independent of treatment choice). We extend the expected value of information (EVI)/knowledge gradient framework to develop useful heuristics for a context with predictive and prognostic covariates. We show that several of our proposed allocation policies are asymptotically optimal in learning treatment strategies. We run simulation experiments motivated by an application for clinical trial design to assess potential treatments of sepsis.

3 Privacy-Utility Tradeoffs in Healthcare Data

Sukanya Kudva[1], Anil Aswani[2], [1]UC Berkeley, Berkeley, CA, [2]UC Berkeley, Berkeley, CA, Contact: sukanya_kudva@berkeley.edu

Medical data is very valuable in healthcare: for care providers to make better-informed treatment decisions and in building AI algorithms for clinical decision support systems. However, a privacy breach in health data can mean unfair treatment, loss of livelihood, or social boycotts for an individual. The increasing awareness of the importance of data privacy has led to a changing privacy law landscape. In this work, we investigate: Can hospitals be incentivized to pay data dividends for collecting and using health data? Should they invest in protecting patient data? We construct a principal-agent model using a Stackelberg game to calculate hospitals' and patients' optimal decisions and qualitatively discuss the implications in policy.

4 Deep Generative Modeling for Patient Census Prediction

Tianchun Li, Pengyi Shi, Purdue University, West Lafayette, IN, Contact: li2657@purdue.edu

Patient census prediction is essential to hospital flow management and staffing decisions. However, challenges arise when predicting multi-day census time-series driven by correlated arrivals and discharges. We leverage state-of-art generative modeling and machine learning, integrated with patient flow dynamics, to design novel predictions and overcome these challenges.

Advances on Decision Analysis

Contributed Session

Session Chair: HUA CHEN, UGA, Athens, GA

1 As-If and Process Models of Labor Provision: A Case Study of the Taxi Market

Florian Artinger[1], Gerd Gigerenzer[2], Nikita Kozodoi[3], Florian von Wangenheim[4], [1]Berlin International University of Applied Sciences, Berlin, Germany; [2]Max Planck Institute for Human Development, Berlin, Germany; [3]Amazon Web Services, Berlin, Germany; [4]ETH Zürich, Zürich, Switzerland. Contact: florian.artinger@gmail.com

A fundamental assumption of expected utility models is that agents make predictions by formulating rational expectations. Building on this assumption, the literature has addressed to what extent neoclassical or behaviorally informed utility models best describe intertemporal substitution of labor and leisure, focusing on the taxi market. Using data from

10 million taxi trips, we find that hourly earnings are barely predictable. Under such uncertainty, satisficing models predict behavior of drivers better than utility models. These models do not require calculating expected earnings and terminate shifts when reaching an aspiration level on shift duration or earnings.

2 On the Disclosure of Defensive Posture: Adversarial Belief Formation and Target Selection Decisions

Kyle J. Hunt[1], Richard S. John[2], Sule Guney[3], Jun Zhuang[4], [1]University at Buffalo, Buffalo, NY, [2]University of Southern California, Los Angeles, CA, [3]University of California, Irvine, Irvine, CA, [4]University at Buffalo, Buffalo, NY, Contact: kylehunt@buffalo.edu

We focus on the problem of technology deployment and information disclosure in security and defense settings. We conduct human subject experiments (N = 975) to study (i) adversarial beliefs regarding where new defense technology is deployed (including how such beliefs are formed) and (ii) target selection/attack decisions. In the experiments, the participants played the role of an adversary, and were tasked with making target selection decisions in response to (potentially deceptive) information released by a defender. Among many interesting insights, we find that the information released by the defender, and the defender's target valuations (which is treated as common knowledge), have a significant effect on the participants' beliefs regarding where the new technology is deployed. These beliefs also transfer to the participants' target selection decisions.

3 Training Scalable Personalization Policies with Constraints

Haihao Lu[1], Duncan I. Simester[2], Yuting Zhu[3], [1]University of Chicago Booth School of Business, Chicago, IL, [2]MIT, Cambridge, MA, [3]National University of Singapore, Singapore, Singapore. Contact: y.zhu@nus.edu.sg

Personalization has attracted broad attention in both academia and industry. While most research has focused on training personalization policies without managerial constraints, in practice, many firms face managerial constraints when implementing these policies. For example, firms may face volume constraints on the maximum or minimum number of actions they can take. They may also face similarity (fairness) constraints, that require similar actions with different groups of customers. These constraints can introduce difficult optimization challenges, particularly when the firm intends to implement personalization policies at scale. We show how recent advances in linear programming can be adapted to the personalization of marketing actions. We implement the proposed method, and compare it with benchmark methods on feasibility and computation speed.

4 Decision-Making as Categorization

Yifan Hong[1], Chen (Mavis) Wang[2], [1]Tsinghua University, Beijing, China; [2]Tsinghua University, Beijing, China. Contact: hongyf19@gmail.com

Humans can make quick decisions in complex environments. One possible explanation is that: humans perform rule-based decision-making based on the inferred category of the context, which reduces task-irrelevant information and supports powerful generalization to different contexts. We transform common decision models (including typical normative and descriptive models) into categorization tasks that directly map contextual features to decision options. We propose a categorization model based on a hierarchical mixture of probabilistic principal components that simultaneously learn a parsimonious set of categories and features. We validate the model through simulation and large-scale behavioral experiments.

5 Does Information Matter: Contests in a Complex Structure

Hua Chen[1], Kevin Chung[2], [1]The University of Georgia, Athens, GA, [2]University of Wisconsin-Madison, Madison, WI, Contact: huachen@uga.edu

Consider a contest conducted in a 3-tier organization where the owner provides a winning prize for branches to compete and the manager of each branch offers a reward to motivate his agents. The standard economic theory predicts that the information on total winning prize or the reward offered to the opponent agents would have no impact on the effort decisions by the focal agent. Using an incentive-aligned lab experiment, however, the authors find that: 1) the agents adjust their effort based on their knowledge about the total winning prize or the reward offered to the opponent agents; 2) the managers modify their reward upward (downward) when either (both) of the information is revealed to the agents. These behavioral regularities are explained by a model that incorporates the fairness concerns (vertical and horizontal) into the agent's utility function.

Health and Public Policy

Flash Session

Session Chair: Sze-chuan Suen, University of Southern California, Los Angeles, CA
Session Chair: Suyanpeng Zhang, University of Southern California, Los Angeles, CA

1 A Greedy Discretization for Continuous State Dynamic Programming in Infectious Disease Control

Suyanpeng Zhang, Sze-chuan Suen, University of Southern California, Los Angeles, CA

The Covid-19 outbreak emphasized the need to study policies to prevent and control the transmission of infectious diseases. However, the continuous state space of compartmental models for describing infectious disease render it difficult to implement tractable Markov decision processes (MDPs) to identify the optimal disease control policy over time. We therefore develop an algorithm for discretizing continuous states for approximate MDP solutions in this context and demonstrate its performance against several benchmarks in a example of COVID-10 in Los Angeles County.

2 Forecasting the 10-Year Evolution of the Covid-19 Surgical Procedure Gap in Ontario, Canada

Rachel Stephenson[1], Vahid Sarhangian[1], David Gomez[2], Timothy C. Y. Chan[1], [1]University of Toronto, Toronto, ON, Canada; [2]Unity Health, Toronto, ON, Canada

The COVID-19 pandemic has caused major disruption to surgery rates worldwide, resulting in significant procedure gaps that must be addressed. We used Negative Binomial regression to estimate the expected size of procedure gaps for a set of procedure groups in Ontario, Canada as of June 2022. We applied Monte Carlo simulation to estimate the evolution of the procedure gaps over 10 years under different future COVID and surgical capacity scenarios. We found that significant increases in surgical capacity are required to reduce the procedure gap in the near term. For these investments to be fair and effective, they must consider the heterogeneity of the impacts of COVID on different procedure groups. Procedure groups with the largest current gaps may not be the ones most in need of increased capacity.

3 A Mechanistic Simulation Model for Integrating Social Conditions and STIs: A Case Study of HIV and HPV

Xinmeng Zhao[1], Chaitra Gopalappa[2], [1]University of Massachusetts Amherst, Amherst, MA, [2]University of Massachusetts, Amherst, Amherst, MA, Contact: xinmengzhao@umass.edu

Social conditions are among key drivers of behaviors that increase the risk of sexually transmitted infections (STI). In addition to common behavioral factors, presence of one STI can biologically increase the risk of another. We developed methods to mechanistically model behaviors as function of social conditions and jointly simulate STIs, for analyses of structural and behavioral intervention decisions.

4 Modelling Trade-Offs in Efficiency, Equity, and Fairness in Public Defibrillator Placement

K.H. Benjamin Leung[1], Gareth Clegg[2], Diane Lac[2], Timothy Chan[1], [1]University of Toronto, Toronto, ON, Canada; [2]The University of Edinburgh, Edinburgh, United Kingdom. Contact: benkh.leung@mail.utoronto.ca

The maximum coverage location problem (MCLP) is a useful approach to determine optimal locations to publicly accessible defibrillators for out-of-hospital cardiac arrest, and has been shown to outperform population-guided heuristics and clinical guidelines. Prior research has focused on maximizing spatial coverage of cardiac arrests across the whole study region; however, this may lead to allocations that are inequitable or unfair across communities of varying geographies, demographics, and socioeconomic levels. We introduce formulations that incorporate trade-offs between the efficiency, equity, and fairness of coverage across study subregions, and compare the standard MCLP with our proposed formulation using cardiac arrest and defibrillator location data from Scotland.

5 Novel Renewable Energy Network Optimization for Global Health Clinics

Rebecca Alcock[1], Justin J. Boutilier[2], [1]University of Wisconsin–Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, Contact: ralcock@wisc.edu

We have devised a framework for the sizing of solar + storage + EV energy systems for rural health clinics in resource-limited settings. The results allow stakeholders to explore the tradeoff between upfront cost and the system's resilience to unusual weather and demand events. We will present a case study of an indigenous community in northern Colombia, who have partnered with us on this effort.

6 A Microsimulation Model of Mpox in Los Angeles County: The Impact of Vaccination Strategies and Sexual Behavior Changes Among Men Who Have Sex with Men (Msm)

Citina Liang[1], Sze-chuan Suen[1], Chenglin Hong[2], Andrea Kim[3], Rita Singhal[3], Paul Simon[3], Mario Perez[3], Ian Holloway[2], [1]University of Southern California, Los Angeles,

CA, [2]University of California, Los Angeles, Los Angeles, CA, [3]Los Angeles County Department of Public Health, Los Angeles, CA, Contact: citinal@usc.edu

The 2022 mpox outbreak in Los Angeles County (LAC) emphasized the need to prepare for preparedness in addressing emergent infectious diseases. We developed an individual-level microsimulation model of MSM in LAC that tracked mpox health and vaccination states over time. Our study assessed the impact of varying vaccination rates, timing of vaccination roll-out, and allocation strategies targeting different racial/ethnic groups and PLWH, along with a delayed reduction or rebound in sexual behavior. Results emphasized the significance of prompt interventions, strategic vaccination approaches, and focusing on vulnerable risk groups like PLWH in controlling mpox. Moreover, our model demonstrated the potential effectiveness of adjusting sexual contact rates and combining these factors to optimize disease control.

7 Assessing the Impact of Covid-19 on HIV Outcomes: A Modeling Study

Evin Jacobson, CDC, Atlanta, GA

To better understand the implications of COVID-19 on HIV outcomes in the United States, we used a national-level compartmental model. We ran the model accounting for pandemic-related changes in behavior and HIV care provision and then ran it again without those changes in a hypothetical comparator scenario. The COVID-19 scenario had lower ART adherence, viral suppression, and diagnosis rates compared with the comparator scenario, leading to higher incidence over the period 2020-30. Our analysis suggested that disruptions from COVID-19 may have led to sustained adverse effects on national HIV outcomes. These results underscore the need for increased HIV testing, prevention, and care services to offset setbacks in the fight against HIV.

8 Modeling the Impact of Injectable Versus Oral Pre-Exposure Prophylaxis (PrEP) on HIV Incidence and Cost Outcomes in the United States

Nidhi Khurana[1], Katherine A. Hicks[2], Justin Carrico[2], Evin Jacobson[1], Paul G. Farnham[1], [1]CDC, Atlanta, GA, [2]RTI, Research Triangle Park, NC, Contact: kqt3@cdc.gov

Oral PrEP programs for HIV prevention continue to face the challenges of low adherence and high dropout rates. Injectable PrEP could help overcome some of these challenges. We used a dynamic compartmental model to estimate HIV incidence and cost outcomes in the United States from 2022 to 2031 for different portions of people initiating and re-initiating PrEP using injectable versus oral PrEP starting with its introduction in 2022. The model included two levels of adherence, which affected cost and effectiveness of PrEP. We assumed lower dropout rates, higher annual costs, and higher efficacy for injectable PrEP compared with oral PrEP. Our results showed that the scenarios with increasingly higher injectable PrEP versus oral PrEP uptake resulted in more people on PrEP overall, fewer new HIV infections, higher PrEP spending, and lower HIV treatment and care spending.

9 Sexual Mixing Matrix Calculator

Shalome Hanisha Anand Tatapudi, University of South Florida, Tampa, FL, Contact: tatapudi@mail.usf.edu

Understanding human mixing behavior is pertinent to developing disease transmission models, especially for sexually transmitted infections. Models commonly use aggregate behavior patterns and interactions from survey data or assumptions to develop contact matrices that consider age and sexual activity levels as the main factors. However, such models fail to examine the inherent heterogeneities in human interactions that are dictated by sexual orientation, race, occupation, geography, and partnership type. In this study we developed an agent-based model that aims to simulate heterogenous features in human behavior and track contacts based on mixing patterns related to sexual behavior. The output is a dynamic contact matrix that evolves over time, with sexual preferences based on behavior, and can be integrated with existing models that use contact matrices.

Healthcare Delivery Analytics

Community Committee Choice Session

Session Chair: Yichuan Ding, McGill University, Montreal, QC, Canada

Session Chair: Yiwen Jin, University of British Columbia, Sauder School of Business, Vancouver, BC, Canada

1 Network Models for Centralized Surgical Scheduling with Heterogeneous Operating Time Distributions

Andre Augusto Cire[1], Carlos Henrique Cardonha[2], Adam Diamant[3], [1]University of Toronto Scarborough, Rotman School of Management, Toronto, ON, Canada; [2]University of Connecticut, Storrs, CT, [3]Schulich School of Business, Toronto, ON, Canada. Contact: andre.cire@rotman.utoronto.ca

We propose an approximation architecture for prescriptive models with probabilistic constraints that utilizes network-based encodings. Each network represents a compressed decision tree that establishes a sequence of decisions, and the size of these decision trees can be adjusted to relax or restrict the risk associated with violating the probabilistic constraint. We apply our approach to determine how best to schedule and sequence surgeries to reduce the surgical backlog brought on by the COVID-19 pandemic. In contrast to existing work, the network-based approach allows us to account for surgeon-specific surgical durations. We compare our model to existing approximations for chance-constrained models using a dataset of approximately 24,000 surgeries and 80 surgeons to demonstrate its effectiveness at reducing the surgical backlog in a real-world setting.

2 A Data-Driven Approach to Address Fragmented Hospital Readmission Among Older Adults

Vedat Verter[1], Somayeh Ghazalbash[2], Manaf Zargoush[3], [1]Queen's University, Kingston, ON, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]Health Policy & Management, DeGroote School of Business, McMaster University, Hamilton, ON, Canada. Contact: vedat.verter@queensu.ca

Disruption in the continuity of care occurs when a patient receives the same level of care (e.g., primary, acute, or specialty care) from different providers. To help mitigate fragmented readmissions and associated inequities, we aim at predicting its occurrence and suggest targeting the interventions on patients with a high risk of this undesirable event. We examine the fairness implications of the proposed analytical framework at both predictive and prescriptive stages to ensure parity among patients and comprehensively assess algorithmic bias using eleven prominent notions of fairness. The resulting framework includes equity considerations in the data-driven decision-making process to reduce disparities among equity-seeking populations through fair resource allocation, potentially reducing direct and indirect costs associated with care fragmentation.

3 Health It Adoption and Outpatient Market Competition: The Role of Patient Portals

Yao Li[1], Lin Qiu[1], Susan F. Lu[2], Lauren Xiaoyuan Lu[3], [1]Southern University of Science and Technology, Shenzhen, China; [2]Purdue University, West Lafayette, IN, [3]Dartmouth College, Hanover, NH

Patient portals provide patients online access to their health information without constraints of time and location. This smooths the communication between patients and care providers and may influence patients' selection of hospitals. This study examines the impacts of patient portal adoption on the outpatient traffic of hospitals, with hospital-level yearly outpatient visit data from 2008 to 2017. We find that patient portal adoption increases outpatient visits by 7.8% and this effect is moderated by hospital size, regional market condition, and patient portal adoptions of neighboring hospitals. We further conduct a patient-visit level analysis, suggesting that the attracting effect of the patient portal diminishes as patients' traveling distance to hospitals increases.

4 Patient Arrival Times in Hospitals: A Dynamic Queueing Game and Mechanism Design

Yichuan Ding, McGill University, Montreal, QC, Canada. Contact: daniel.ding@mcgill.ca

In this study, we analyze patients' decision-making regarding arrival times at an endoscopy center operating on a first-come, first-served basis. While patients prefer to complete their treatment as early as possible, arriving too early can result in longer waiting times. Our research focuses on a queueing game in which each patient selects an arrival time that minimizes their expected cost. Utilizing data from an endoscopy center, we investigate patients' arrival time choices within a dynamic game framework. We then model this scenario as a repeated game and demonstrate that the arrival times converge to a Nash equilibrium. Furthermore, we explore the design of mechanisms that can guide the system toward an equilibrium with improved social welfare.

Using Data Analytics to Improve Healthcare Systems

Community Committee Choice Session

Session Chair: Shan Liu, University of Washington, Seattle, WA

1 Variation in Ineligible Donor use in the Us is Mostly Driven by Decisions at the Level of the Transplant Center Rather than the Organ Procurement Organization

Yili Wang, Luke DeRoos, Mariel Sofia Lavieri, David W. Hutton, Peter Todd, Neehar Parikh, University of Michigan, Ann Arbor, MI

Rising organ demand and improved transplantation practices boosted the use of ineligible donors. Enhancing the utilization of these donors is crucial to provide more lifesaving organ transplantation. This study investigates how demographic and system-level factors, such as waitlist size, organ discard rates, and number of donors, affect ineligible donor use at both the organ procurement organization (OPO) and transplant center (TC) levels. Using donor data from the Organ Procurement and Transplantation Network's Standard Transplant Analysis and Research (January 2008 to December 2021), beta regression models were developed to analyze these factor relationships. At the TC level, higher donation volume, larger waitlist, and increasing waitlist size were associated with higher ineligible donor use, but these associations were not significant at the OPO level.

2 Mechanistic Modeling of Social Conditions into Disease Predictions for Public Health Intervention-Analyses

Chaitra Gopalappa[1], Amir Khosheghbal[2], [1]University of Massachusetts, Amherst, Amherst, MA, [2]UMass Amherst, Amherst, MA, Contact: chaitrag@umass.edu

Decision analytic models typically simulate infection spread as a function of behaviors, and evaluate the impact of behavioral interventions. As social conditions are key determinants of health, some models superficially consider the need for structural interventions as part of behavioral interventions. Using HIV as a case study, we developed a methodological framework, using Markov random field model to estimate joint probability distributions between social conditions and behaviors, and mechanistically modeled behaviors as functions of social conditions, prior to simulating HIV transmissions as a function of behaviors. We present the methodology and sample what-if intervention analyses to demonstrate its potential use in informing intervention decisions.

3 Estimated Effectiveness and Cost-Effectiveness of Opioid use Disorder Treatment Under U.S. Regulatory Relaxations: A Model-Based Analysis

Gary Qian[1], Margaret L. Brandeau[2], [1]Stanford, Stanford, CA, [2]Stanford University, Stanford, CA

The COVID-19 pandemic prompted new flexibilities in treatment for opioid use disorder, including telehealth treatment and take-home doses of medications for OUD (MOUD). A current legislative proposal aims to make several of these regulatory relaxations permanent. We used a model-based analysis to assess thepotential effectiveness and cost-effectiveness of MOUD provision under the proposed regulatory relaxations, allowing for both potential benefits (increased access to and retention in treatment) and harms (misuse or diversion of take-homedoses). Our findings underscore the importance of rigorous ongoing evaluation and flexible policy design to adapt to evolving healthcare landscapes and patient needs.

4 Queueing-Location-Allocation Model Under Stochastic Demand

Yinsheng Wang, Shan Liu, Chaoyue Zhao, University of Washington, Seattle, WA, Contact: yinshw@uw.edu

Minimizing turnaround time for HIV viral load testing by placing point-of-care testing machines in a hub-and-spoke network is crucial to improve HIV care, particularly in resource limited settings. Our previous research has successfully developed practical decision-support tools for HIV viral load and drug resistance testing in western Kenya. In light of demand uncertainty in testing samples, we extend our work to formulate and solve a Queueing-location-allocation model with integer programming, leveraging Conditional Value at Risk (CVaR). By incorporating CVaR, we effectively manage uncertainties and risks associated with testing demand, thereby enhancing the delivery of HIV care.

Continuous Location Analysis I

Community Committee Choice Session

Session Chair: Pawel J. Kalczynski, California State University-Fullerton, Fullerton, CA

Session Chair: Zvi Drezner, California State University Fullerton, Fullerton, CA

1 Stochastic Multipurpose Shopping Trips and Location

Zvi Drezner[1], Morton O'Kelly[2], Pawel J. Kalczynski[3], [1]California State University Fullerton, Fullerton, CA, [2]Ohio State University, Columbus, OH, [3]California State University-Fullerton, Fullerton, CA, Contact: pkalczynski@fullerton.edu

In the competitive multi-purpose (MP) trips model, it is assumed that the proportion of customers that do MP trips is given. In this paper, we investigate the model with a stochastic proportion of MP trips. Five decision analysis criteria are analyzed for finding the best location for a new facility under these circumstances. Such an analysis can be applied to other location models (not necessarily competitive) when a parameter of such models is stochastic.

For example, in conditional location or competitive models, there is uncertainty about whether one of the existing facilities will stay in business. In the leader-follower (Stackelberg equilibrium) model, there is a probability that a future competitor will establish a competing facility. The probability is not necessarily equal to 1.

2 On the Combined Inverse-square Effect of Multiple Points in Multidimensional Space

Keaton P. Coletti[1], Pawel J. Kalczynski[2], Zvi Drezner[3], [1]University of Georgia, Athens, GA, [2]California State University-Fullerton, Fullerton, CA, [3]California State University Fullerton, Fullerton, CA, Contact: keaton.coletti@uga.edu

The inverse-square law states that the effect a source has on its surroundings is inversely proportional to the square of the Euclidean distance from that source. Its applicability spans fields including physics, engineering, and computer science. This study investigates the combined effect of multiple point sources surrounding a region in multidimensional space. It shows that, regardless of source configuration and region shape, the maximum effect in D dimensions is on the region's boundary if D≤4, and the minimum is on the boundary if D≥4.

3 Solving Unconstrained Optimization Problems by a Trajectory Solution Approach

Zvi Drezner[1], Malgorzata Miklas-Kalczynska[2], [1]California State University Fullerton, Fullerton, CA, [2]California State University - Fullerton, Fullerton, CA

We propose solving non-constrained optimization problems by a trajectory method. A parameter is introduced into the optimization problem. For a particular value = 0, the optimal solution is easily obtained. The original optimization problem is defined for another value = 1. A trajectory connects the easily obtained solution for 0, to the desired solution for 1. We trace the trajectory and the solution for 1 is at the end of the trajectory. The procedure is tested on a competitive location problem with good results.

Emerging Topics in Decision-Making Under Uncertainty

Community Committee Choice Session

Session Chair: Hansheng Jiang, University of California, Berkeley, Berkeley, CA

1 An Active Learning Framework for Multi-Group Mean Estimation

Abdellah Aznag[1], Rachel Cummings[2], Adam Elmachtoub[2], [1]Columbia University, New York City, NY, [2]Columbia University, New York, NY, Contact: aa4693@columbia.edu

We consider an active learning framework for estimating the means of multiple distinct groups. In each period, we observe a single sample from a group of our choice and update the corresponding mean estimate. The goal is to dynamically collect samples to minimize the norm of the vector of variances of our estimators after T rounds. Using a UCB-like algorithm, we show that the regret of our algorithm is O(T^-2) for finite norms and O(T^-1.5) for the infinite norm. Moreover, we provide matching lower bounds to prove tightness of our algorithm.

2 Pricing in On-Demand (And One-Way) Vehicle Sharing Networks

Xiaobing Shen, Saif Benjaafar, University of Minnesota, Minneapolis, MN, Contact: shen0341@umn.edu

We consider the dynamic pricing problem that arises in the context of an on-demand vehicle sharing system with one-way trips. In this paper, we use a recursive relationship that relates system availability in a system with K vehicles to one with K-1 vehicles to produce a sequence of increasingly tight bounds. The worst of these bounds is given by K/(N+K-1+/μ), where is the total demand (sum of all trip requests) rate and 1/μ is the average trip travel time, implying a convergence rate that is at least of order 1- O(1/K) in the number of vehicles for fixed /μ. The same recursive relationship can be used to obtain a bound that is independent of /μ and that is tighter than previous bounds, implying a convergence rate that is at least of order 1-O(1/√K).

3 Partitioning with a Move Budget

Elaheh Fata[1], Mina Dalirrooyfard[2], Majid Behbahani[3], Yuriy Nevmyvaka[4], [1]Queen's University, Kingston, ON, Canada; [2]Morgan Stanley, London, United Kingdom; [3]Morgan Stanley, Montreal, QC, Canada; [4]Morgan Stanley, New York City, NY

Given a set of k terminals, the Multiway cut problem asks for a partitioning of the graph into k partitions such that each partition has exactly one terminal and the sum of the weights of the edges between partitions (i.e., the cut value) is minimized. In many real-world scenarios, there already exists a k-partitioning of an underlying graph and the goal is to reduce the cut value by only moving a few nodes across partitions. This motivates us to introduce and study the r-move k-partitioning problem. Given a graph, a set of k terminals and an initial partitioning, the r-move k-partitioning problem asks to find a k-partitioning with minimum-weighted cut among all the k-partitioning that are created by moving at most r non-terminal nodes to partitions different from their initial ones. We develop several approximation algorithms for this problem.

4 Online Discrete Convex Optimization

Jefferson Huang[1], Louis Chen[2], [1]Naval Postgraduate School, Monterey, CA, [2]Naval Postgraduate School, Monterey, CA

In online optimization, a decision-maker (DM) plays the following repeated game: In each round, after selecting a feasible decision, the DM receives feedback from a (possibly adversarially chosen) cost function. We consider online discrete optimization where the cost functions have properties that are analogous to convexity, which are also relevant to many operations models. Specifically, we present algorithms and performance guarantees for online L-natural convex minimization, and for online M-natural concave maximization. When the decision vectors are binary, the former corresponds to online submodular minimization, while the latter corresponds to a special case of online submodular maximization.

5 A General Equilibrium Model for Transportation Systems with Ride-Hailing Services and Customer Waiting

Wei Gu, Maged Dessouky, Jong-Shi Pang, Qin Ba, University of Southern California, Los Angeles, CA, Contact: weig@usc.edu

In this study, we develop a general equilibrium model to understand the relationship between ride-hailing services and customers' waiting time in urban transportation networks. The equilibrium model includes three interacting sub-models: ride-hailing company choice, customer choice, and customer waiting time. The ride-hailing companies' choices and customers' choices are formulated as a generalized Nash equilibrium, while customers' waiting times are formulated using queueing theory. Then we provide the conditions under which there exists an equilibrium solution. The proposed model is validated using numerical experiments.

Recent Advancements in Healthcare Operations

Community Committee Choice Session

Session Chair: Jong Myeong Lim, Tuck School of Business at Dartmouth, Hanover, NH

1 Improving Broader Sharing to Address Geographic Inequity in Liver Transplantation

Shubham Akshat, Carnegie Mellon University, Pittsburgh, PA

In the transplant community, broader organ sharing is believed to mitigate geographic inequity (intergeographic variation in transplant rates, patient survival rates, waiting times, and offers) in organ access, and recent policies are moving in that direction in principle. In this study, we develop a patient's dynamic choice model to analyze the patient's strategic response to a policy change. We use this to evaluate several (existing and proposed) organ-allocation policies. On historical data, we show that our model's predictions are more precise than the existing liver simulated allocation model. It more accurately captures (1) a patient's change in organ offer acceptance probability (with their sickness level) and (2) the behavioral change of a patient in terms of organ offer acceptance probability with a change in policy. Next, we conduct counterfactual studies.

2 Assortment Optimization of Crowdsourcing Contests for Medical Diagnosis Based on "revealed Motivations" of Participants

Olumurejiwa Fatunde[1], Gonzalo Romero[2], [1]Rotman School of Management, Toronto, ON, Canada; [2]Rotman, University of Toronto, Toronto, ON, Canada

In this paper we study how contest offerings can be selected optimally to improve crowdsourcing, using data from a healthcare platform that runs rank-order tournaments to collect and aggregate diagnostic opinions. The platform owners can tailor contest offerings/ prizes in order to attract users and improve accuracy. We borrow from the dynamic assortment planning literature by framing the contest offering decision as an assortment problem with independent search, perishable goods and non-independent demand. We use historical data to "learn" whether users are primarily driven by learning opportunities, monetary prizes, or affinity for competition. We define the optimal assortment, considering both motivation-specific user utility and platform aims. This paper applies assortment planning in a unique setting, incorporating the behavioral factors shaping demand.

3 Health on Loan: The Effect of Local Creditavailability on Hospital (Re)admissions

Yuan Ma, Andrew Wu, Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI, Contact:

yuanmato@umich.edu
Bank loans are crucial sources of finance for hospitals. This paper assesses the effect of increases in localcredit supply on healthcare outcomes. We show that the total admission drop when there are more creditsavailable in local banks, and the decrease is driven by decreases in readmission.

4 It Takes Two to Make It Right: How Nurses' Response to Sepsis Alerts Impacts Physicians' Process Compliance

Zahra Mobini[1], Mehmet U.S. Ayvaci[2], Ozalp Ozer[3], [1]Georgia Tech, Atlanta, GA, [2]The University of Texas at Dallas, Richardson, TX, [3]Amazon, Richardson, TX, Contact: zahra.mobini@gatech.edu

We empirically examine how a clinical team, consisting of the two roles of nurse and physician, provides care in compliance with evidence-based standards using a sepsis alert system. In particular, we study whether and when nurses' timely response to sepsis alerts (i.e., acknowledging the alert and notifying physicians within a designated time frame) impacts physicians' compliance with sepsis care standards (i.e., performing diagnostic or treatment actions within a designated time frame). Using data from a hospital system in the US, we find that nurses' timely response to alerts has a positive spillover effect on physicians' compliance, and this effect becomes stronger as workload increases and weaker as the number of false alerts increases.

New Developments in the Operations-Finance Interface

Community Committee Choice Session

Session Chair: Kashish Arora, Indian School of Business, Hyderabad, India

1 Can Risk Disclosures Contribute to Supply Chain Risk Transparency? Evidence from the Covid-19 Pandemic

Keno Theile[1], Kai Hoberg[2], Vinod R. Singhal[3], [1]Kuehne Logistics University, Hamburg, Germany; [2]Kühne Logistics University, Hamburg, Germany; [3]Georgia Institute of Technology, Atlanta, GA, Contact: keno.theile@the-klu.org

Materialized supply chain risks have detrimental operational and financial outcomes. Gathering a priori risk information is challenging for firms. Publicly traded firms must disclose risks in 10-K reports, but the informativeness of this information remains uncertain. Using COVID-19 as a natural experiment, we find that firms disclosing pandemic risks experience increased equity and idiosyncratic risks, but no change in systematic risk. Risk disclosures are valuable, as disclosing firms are riskier when the risk materializes.

2 Operational and Financial Hedging Decisions in the Presence of Business Cycles

Rene A. Caldentey[1], Abel Cadenillas[2], [1]The University of Chicago, Chicago, IL, [2]University of Alberta, Edmonton, AB, Canada. Contact: rene.caldentey@chicagobooth.edu

We consider a corporation whose operational cashflows evolve according to a jump-diffusion process that is partially correlated with capital returns in the financial market. The corporation selects investment and operational policies continuously to maximize its expected utility of terminal wealth. We obtain explicit solutions for logarithmic and power utility functions. We study the impact of the corporation's risk aversion, the correlation between the operational and the capital returns, and the regime of the economy on the optimal policy. We find, among other things, that the regime of the economy, and the correlation between the operational and the capital returns, have a significant effect on the optimal policy.

3 A Structural Model of Operating Cash Flow Management

Kashish Arora[1], Vishal Gaur[2], [1]Indian School of Business, Hyderabad, India; [2]Cornell University, Ithaca, NY, Contact: kashish_arora@isb.edu

A firm's cash flow from operations is a function of the contemporaneous and lagged values of its operational variables---sales, operating cost, inventory, payables, etc. Estimating this function is important for forecasting and managing cash flows. However, cash flow forecasting and management are challenging problems. In this paper, we propose a generalizable model of a firm's operations to disentangle this endogeneity and estimate causal impacts among variables. By estimating our model using quarterly public financial data from S\&P's Compustat database for 1990-2020, we obtain several results. We provide evidence that cash flow has both endogenous and lagged relationships with sales and inventory. Also, our model helps quantify the short- and long-run impacts of structural shocks in variables on the entire system.

Service Operations with Strategic Queueing

Community Committee Choice Session

Session Chair: Andrew E. Frazelle, The University of Texas at Dallas, Richardson, TX

Session Chair: Pnina Feldman, Boston University, Boston, MA

1 Matching Technology and Competition in Ride-Hailing Marketplaces

Kaitlin Daniels[1], Danko Turcic[2], [1]Washington University in St. Louis, Olin Business School, Saint Louis, MO, [2]University of California, Riverside, 900 University Ave., CA, Contact: k.daniels@wustl.edu

Operational differences distinguish taxis from Uber. To form matches, taxis use street hailing while Uber uses central dispatch. Moreover, taxi supply is regulated while individual driver decisions determine Uber's supply. We provide a novel characterization of the distribution of street hailing wait times, which we compare to the established wait distribution with central dispatch. While central dispatch typically delivers much shorter average wait, street hailing can offer a higher chance of a short wait. We construct a model of competition between taxis and Uber over heterogeneous and wait-sensitive passengers and ask whether taxis capture more market share if they imitate Uber's central dispatch. While this strategy improves matching efficiency, the reaction to this change among Uber drivers and heterogeneous passengers can leave taxis worse off.

2 On The Value Of Service-age Information

Ricky Roet-Green[1], Lin Zang[2], [1]Simon Business School, University of Rochester, Rochester, NY, [2]University of Rochester, Rochester, NY, Contact: ricky.roet-green@simon.rochester.edu

We study how service-age information, which is the information regarding the time elapsed since the beginning of the current service, influences customers' strategic joining decisions in queueing systems with general service distributions. We analyze the joining behavior of a new arriving customer who observes both the queue length and the current service age. To explore the value of information, we compare the results with those of an observable M/G/1 queue without service-age information. We show that customers decisions are simplified when service age is provided. We find that disclosing service-age information can increase both throughput and social welfare. Our results imply that a revenue-maximizing provider (social planner) should disclose (conceal) service-age information when system congestion is high and conceal (disclose) it otherwise.

3 Strategic Double-Booking and Its Impact on Healthcare Operations

Olga Bountali[1], Arseniy Gorbushin[2], Opher Baron[3], Binyamin Oz[4], [1]Rotman School Of Management, University of Toronto, Toronto, ON, Canada; [2]Rotman School of Management, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Hebrew University of Jerusalem, Jerusalem, Israel. Contact: arseniy.gorbushin@rotman.utoronto.ca

During the COVID-19 vaccination process, a significant mass of patients booked double (or multiple) appointments for their vaccines with the hope of receiving treatment faster. This led to many unfulfilled appointments (a.k.a. no-shows) worldwide, left capacity under-utilized, and hindered the efficiency of the vaccination process during a very crucial period. We introduce a queuing model with strategic patients to capture the single- vs. double-booking decisions and examine their impact of system performance and patient outcomes. We use a benchmark representative of transparency, where a central mechanism allows patients to only single book, and quantify the corresponding loss/gain induced by double-booking. We further explore potential interventions for central planners and policy makers to mitigate the negative effects of double-booking.

4 Two-Sided Subsidies for Complementary Products: The Case of Electric Vehicles

Runyu Tang[1], Saed Alizamir[2], Michael Blair[2], [1]Xi'an Jiaotong University, Xi'an, China; [2]Yale University, New Haven, CT

Electric Vehicles (EVs) are touted as the future of urban transportation and a solution to climate change. Many governments have introduced financial incentive policies, ranging from directly supporting EV purchasers to hybrid policies that subsidize both buyers and station developers. We analyze a government's problem of designing subsidy policies for EVs and investigate the benefits of implementing a hybrid policy. Our model captures the complementarity between EVs and charging stations, which helps us characterize the optimal subsidy mechanism for both sides of the market. We examine the impact of different technology and market characteristics on the government's policy and calibrate our model with real-life data and measure the benefits of subsidizing purchasers and investors simultaneously.

Emerging Topics in Inventory and Revenue Management

Community Committee Choice Session

Session Chair: Zhichao Feng, Hong Kong Polytechnic University

1 Sample Complexity of Policy Learningfor Inventory Control with Censored Demand

Xiaoyu Fan, Stern School of Business, New York University, New York, NY

We consider the newsvendor problem with unknown demand distribution and propose sampling-based approximation policies using censored demand data. We develop both upper and lower bounds for the number of samples required to guarantee that the performance of our proposed policy is close to that of the true optimal policy at any given accuracy level.

2 M/M/s on Demand: Queues with On-Demand and Reserved Servers

Zhichao Feng[1], Milind Dawande[2], Ganesh Janakiraman[3], Anyan Qi[2], [1]Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas- Dallas, Richardson, TX, Contact: zhi-chao.feng@polyu.edu.hk

We analyze a canonical M/M/s queueing system that employs both "reserved" and "on-demand" servers - the number of reserved servers is decided at the beginning of the time horizon while the number of on-demand servers is decided dynamically as needed, in real time. We study two problems. The first is that of minimizing the infinite-horizon, expected discounted cost incurred in the hiring of the servers and in the waiting of the jobs in the queue. The second is that of minimizing the long run average cost. Our main result is the structure of the optimal policies for these two problems. In particular, we show that, in each of these problems, the optimal on-demand capacity control is a threshold-based bang-bang policy: If the number of jobs in the system is below a threshold, then no on-demand servers are employed. Otherwise, the number of on-demand servers is chosen such that no jobs wait.

3 Selling to a Market with a Finite Population

Arnoud den Boer, University of Amsterdam

Much of the dynamic pricing literature assumes Poisson arrivals of buyers. This implies that demand is in principle unbounded, which is not always realistic. We therefore consider dynamic pricing for a finite population of potential buyers. This completely changes the dynamics. With calculus-of-variations techniques we are able to derive an explicit expression for the optimal price as function of time. The firm does not need to know the market size to derive this function. Interestingly, the dynamic nature of prices turns out to be a first-order effect: even without inventory constraints, the optimal price changes over time. In contrast, dynamic pricing is merely a second-order effect in the Poisson arrival model, where a fixed-price policy is optimal in a large-inventory regime or if inventory is infinite.

4 Multi-Product Dynamic Upgrades

Xiao Zhang, Justin Goodson, Saint Louis University, Saint Louis, MO, Contact: xiao.zhang@slu.edu

Upgrades in travel industry are often static and offered either at the booking time or at the check-in time. In this paper, we study dynamically-offered upgrades by a multi-product firm via notifications (e.g., emails) between the booking and the check-in times. We investigate a general multi-level upgrade policy in which a customer may be upgraded to any better products and two single-level upgrade heuristics which are less computationally intensive. Both heuristics have clean structures and are easy to implement. We adopt discrete concavity concepts into our analysis and identify monotonicity properties for the optimal single-level upgrade policies.

5 Taylor Approximation of Inventory Policies for One-Warehouse, Multi-Retailer Systems with Demand Feature Information

Jingkai Huang[1], Kevin Shang[2], Yi Yang[1], Weihua Zhou[1], Yuan Li[3], [1]Zhejiang University, Hangzhou, China; [2]Duke University, Durham, NC, [3]Alibaba, Hangzhou, China. Contact: khshang@duke.edu

We consider a distribution system in which retailers replenish perishable goods from a warehouse. Demand at each retailer depends on exogenous features and a random shock, and unfulfilled demand is lost. To obtain an effective data-driven replenishment and allocation policy, we first develop the Talyor Approximation (TA) policy by using Taylor expansion to approximate the retailer's inventory cost and show its asymptotic optimality in the number of retailers. Next we estimate the TA solution from data to obtain the Data-Driven Taylor Approximation (DDTA) Policy and prove its consistency. Using a real data set provided by Fresh Hema, we find the DDTA policy reduces the cost by 10.9%

compared to Hema's policy. Finally, we show that the main results still hold in the cases of correlated demand features, positive lead times, and censored demand.

CC-North 132B

Managing the Transition to Cleaner Energy

Community Committee Choice Session

Session Chair: Michael Blair, Yale University, New Haven, CT

1 Dynamic Valuation and Optimal Control of a Battery Under Performance Degradation

Joonho Bae[1], Roman Kapuscinski[2], John M. Silberholz[1], [1]University of Michigan Ross School of Business, Ann Arbor, MI, [2]Ross School of Business, Ann Arbor, MI, Contact: baejh@umich.edu

We consider a battery providing energy arbitrage (buying at low prices and selling at high prices) over some time period. One key difficulty of profitably operating a battery over time is that battery performance degrades in two ways (capacity and efficiency degradation), each having a nonlinear dependency on the usage profile. To study the effect of different degradation dynamics, we consider three degradation models: (1) capacity-degradation-only, (2) efficiency-degradation-only, and (3) both degradations. To the best of our knowledge, this paper is the first analytical modeling paper characterizing optimal dynamic policies under different degradation models of battery capacity and efficiency. This work shows systematic differences in the desired use of batteries when facing different types of battery degradation.

2 Clean Energy Transition, Scarcity and Urban Mining

Clara Carrera[1], Serasu Duran[2], Atalay Atasu[1], Luk N. Van Wassenhove[1], [1]INSEAD, Fontainebleau, France; [2]Haskayne School of Business, Calgary, AB, Canada. Contact: clara.carrera@insead.edu

Clean energy technologies require large amounts of critical materials such as cobalt and lithium for energy storage, rare earth minerals for wind turbines, and silver and silicon for solar panels. The supply of these critical materials cannot keep up with skyrocketing demand, and maintaining the clean energy transition momentum requires alternative strategies. We formulate an analytical model that represents the key trade-offs of the two prevalent strategies: (i) Material Reduction, i.e., changes to production technology to reduce the critical materials used; (ii) Urban Mining, i.e., recovering and recycling critical materials from end-of-life clean energy products. We study how the effectiveness of these two approaches depends on the levels of material scarcity and systemic leakage in circular infrastructures and discuss policy implications.

3 Sustainable Bioeconomy as Climate Change Mitigation

Hannah Wang, Yale University, New Haven, CT, Contact: hannah.wang.sw2285@yale.edu

Bioeconomy is an economic system that utilizes renewable biomass, such as plants, to produce goods, services, and energy. Past studies have separately discussed the climate benefits of those bio-based products - bioenergy, biochar, and bioplastic - to name a few. Nevertheless, none investigated the synergistic sustainability effects of distributing biomass to produce the various product pathways. As a result, large-scale deployment for a mixture of biomass circular economy is still limited. Therefore, this study aims to address the research gap. The objective of the talk is two-fold - (1) investigate various aspects of life cycle sustainability impacts for disparate bio-based products; (2) build a dynamic model that designs an optimal biomass utilization strategy according to the market demand, budgets, and resource constraints for any given location.

4 Reducing Energy Consumption Through Targeted Thermostat Interventions

Michael R. Blair[1], Saed Alizamir[2], Shouqiang Wang[3], [1]Wilfrid Laurier University, Waterloo, ON, Canada; [2]University of Virginia, Charlottesville, VA, [3]The University of Texas at Dallas, Richardson, TX, Contact: mrblair@wlu.ca

Residential energy consumption for heating and cooling is one of the largest end uses of energy, and the amount of energy is significantly influenced by the weather. As we continue to feel the effects of climate change, these energy requirements will rise and become more volatile, leading to increased operational costs and challenging capacity decisions for power generators.

Smart thermostats have great potential to reduce household energy consumption. However, recent works show that how the thermostat is used plays a critical role in energy savings. In this preliminary work we use a dataset of smart thermostat users to illustrate the potential value of targeting interventions such as occupancy detection and temperature setbacks. We then discuss ongoing efforts to test the impact of different appeals (financial vs. environmental benefits) through a field experiment.

Advances in Theory of Innovation and Product Development

Community Committee Choice Session

Session Chair: Onesun Steve Yoo, UCL School Of Management, University College London, London, United Kingdom

1 Advances in Theory of Innovation and Product Development

Qiong Chen[1], Mengyang Pan[2], Wenli Xiao[3], [1]Southwestern University of Finance and Economics, Chengdu, China; [2]Swufe, Chengdu, China; [3]University of San Diego, San Diego, CA, Contact: wenlixiao@sandiego.edu

In the context of radical innovation, we draw from knowledge network theory to investigate how the firm can manage its alliance portfolio to speed up radical innovation. We examine the effects of the firm's current innovation alliance composition and its position in its previous innovation alliance network on radical innovation speed. In analyzing the empirical data on COVID-19-related radical innovation projects, we find that the presence of an industry partner slows down innovation speed, while the presence of a research partner speeds up the radical innovation process. The presence of a government partner does not influence innovation speed unless the firm has a high level of collaboration experience with its current partner. As for the position of the firm in its alliance network, a firm that is more centrally located experiences faster radical innovation speed.

2 Empowering Women and Combating Harassment: The Women Powerline Initiative in Uttar Pradesh, India

Anupam Agrawal, Texas A&M University, College Station, TX, Contact: anupam@tamu.edu

We study deployment of a mobile-based call center in India to track and reduce crimes against women, particularly those that are rarely reported to the police such as eve-teasing, violence, and online bullying. The program takes a holistic approach to harassment, targeting both the victim and the harasser, with the aim of educating and rehabilitating the offender, thereby reducing the likelihood of future incidents. Simultaneously, the program strives to ensure the safety and comfort of the victim, offering recourse for women in even the most remote areas. This research seeks to draw policy implications from the growth of this program, with a particular focus on the adoption of technology by women in rural areas to report crimes, changes in this adoption over time, and the potential for deployment of similar programs in other regions of India and other countries.

3 The Matthew Effect in an Experimental Market-Entry Game

Jeeva Somasundaram[1], Kostas Stouras[2], Sanjiv Erat[3], [1]INSTITUTO DE EMPRESA, Madrid, Spain; [2]UCD, Dublin, Ireland; [3]University of California-San Diego, La Jolla, CA, Contact: konstantinos.stouras@ucd.ie

In this study, we present the first experimental investigation of the Matthew effect in market-entry games, namely that an entrant's past market earnings reinforce their future earnings. Across all of our 2×2×2 between-subject conditions, we find that the Matthew effect leads to more inequality in terms of the Gini coefficient, as well as, in terms of the standard deviation in earnings. Building on Cumulative Prospect Theory, we develop interventions to reduce the Matthew effect and we test them via a second experiment. Our findings illustrate that showing average past earnings and letting agents communicate with each other promotes equity and prevents attrition in sharing economy platforms.

4 Optimal Management of Renewable Energy Certificates: A Reinforcement Learning Approach

Daeho Kim[1], Dong Gu Choi[2], Michael Lim[3], [1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of; [3]Seoul National University, Seoul, Korea, Republic of. Contact: milim@snu.ac.kr

Renewable Portfolio Standards (RPS), which require electricity suppliers to purchase Renewable Energy Certificates (RECs) from renewable energy generators to meet the standard levels, have led to the emergence of a brokerage service for renewable generators. Our research focuses on optimizing REC management for brokerage service providers. We use a Markov Decision Process framework to formulate the problem and identify key structural properties of the optimal policy. We then develop a deep reinforcement learning (DRL) algorithm and verify its performance based on real market data. Finally, we employ eXplainable AI techniques to understand the logic behind our black-box DRL algorithm.

Modeling Smart Mobility Markets with Multi-players: Matching, Pricing, and Design

Community Committee Choice Session

Session Chair: Bingqing Liu, New York University, Brooklyn, NY
Session Chair: Joseph Y J Chow, New York University, Brooklyn, NY

1 How Would Mobility-as-a-Service (MaaS) Platform Survive as an Intermediary? from the Viewpoint of Stability in Many-to-Many Matching

Rui Yao[1,2], Kenan Zhang[3,1], [1]École polytechnique fédérale de Lausanne - EPFL, Lausanne, Switzerland; [2]Technical University of Denmark, Copenhagen, Denmark; [3]ETH Zurich, Zurich, Switzerland

Mobility-as-a-service (MaaS) provides seamless door-to-door trips by integrating different transport modes. Although many MaaS platforms have emerged in recent years, most of them remain at a limited integration level. This study investigates the assignment and pricing problem for a MaaS platform as an intermediary in a multi-modal transportation network, which purchases capacity from service operators and sells multi-modal trips to travelers. The analysis framework of many-to-many stable matching is adopted to decompose the joint design problem and to derive the stable condition such that both operators and travelers are willing to participate in the MaaS system.

2 A Smart Mobility Platform with Equitable Peer-to-Peer Congestion Pricing and Its Policy and Equity Implications

Siwei Hu[1], Daisik Nam[2], Pengyuan Sun[1], R. Jayakrishnan[1], Michael Hyland[1], [1]University of California, Irvine, Irvine, CA, [2]Inha University, Incheon, Korea, Republic of. Contact: siweih3@uci.edu

Researchers have investigated different congestion pricing schemes to alter travelers' selfish driving behaviors to direct the state of transportation networks from User Equilibrium (UE) to System Optimal (SO). However, the unfair feelings among drivers about the tolls and the unclear toll usage and distribution among the population make congestion pricing difficult to implement. To address those issues, we proposed a smart mobility platform with an equitable peer-to-peer envy-based congestion pricing scheme that allows travelers to coordinate their path choices through monetary exchanges. The simulation results show that with as little as 5% of travelers engaging in peer-to-peer route choice coordination, the transportation system state could be directed from UE to an SO equitably, resulting in a 13% increase of network space mean speed from 31 mph to 35 mph.

3 Dynamic Usage Allocation and Pricing for Curbside Space Operation

Jisoon Lim, Neda Masoud, University of Michigan, Ann Arbor, MI

The importance of curbside management is quickly growing in a modernized urban setting. Dynamic allocation of curbspace to various usages and dynamic pricing for those usages can together attract more users and promote user turnover. To model such operations, we develop a Stackelberg leader-follower game between a leader who sets curbspace allocation and pricing of each curbside usage and multi-followers who accept or reject the proposed prices. We model this game as a bi-level nonlinear program, and reconstruct it into a single-level convex program by applying the Karush-Kuhn-Tucker conditions, objective function transformation, and constraints linearization. We then devise a Benders decomposition algorithm to ensure the tractability of the problem, and perform numerical experiments to show the practicability of the model and draw curbside management insights.

4 On-Demand Ridesharing with Autonomous Modular Vehicles

Xi Cheng[1], Jane Lin[2], [1]University of Illinois, Chicago, Chicago, IL, [2]University of Illinois-Chicago, Chicago, IL, Contact: xicheng5@uic.edu

This paper presents an on-demand ridesharing system operated with the emerging autonomous modular vehicle (MAV) technology. Modularity enables flexible capacity configuration through in-motion joining and disjoining, which also brings potential energy savings (similar to platooning). A design framework is proposed to assign shared-ride trip requests to MAVs to minimize the total operating cost (in terms of both agency and passenger costs). The problem is formulated into integer linear programming. We investigate the feasibility of such a system in terms of potential cost and energy savings by ridesharing and in-motion joining and disjoining.

5 Prediction of Pareto Fronts for Multimodal Travel Itineraries

Jan F. Ehmke[1], Thomas Horstmannshoff[2], Marlin Wolf Ulmer[2], [1]University of Vienna, Vienna, Austria; [2]Otto-von-Guericke Universität Magdeburg, Magdeburg, Germany.

Contact: jan.ehmke@univie.ac.at

Integrated mobility platforms promise travelers to create door-to-door itineraries considering their individual preferences considering the breadth of mobility services such as trains, buses, flights, and ridesharing services. Finding the complete Pareto-optimal set of itineraries with multiple traveler preferences in a multimodal setting is a significant challenge. We approximate the set of Pareto-optimal itineraries by solution sampling equally distributed over the solution space. We also investigate offline learning (with a random-forest prediction model) and online learning (with Gaussian Process Regression) to make our solution framework smarter. Based on a large real-world data set, we investigate the performance and the effectiveness of our framework.

Contributions to the Theory of Integer Programming

Community Committee Choice Session

Session Chair: Prachi Shah, ISyE, Georgia Institute of Technology, Atlanta, GA

1 Consistency of Branching Rules with Respect to Cutting Planes

Prachi Shah[1], Santanu Dey[2], [1]ISyE, Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: prachi.shah@gatech.edu

Better IP formulations obtained by adding cuts, give better dual bounds at the root node and are expected to be solved by smaller branch-and-bound trees. In this work, we address the question of whether adding cuts always leads to improved branching decisions. Contrary to the expectation, we prove that there exists instances where adding a single valid cut, which improves the dual bound at the root note, increases the size of branch-and-bound trees by an exponential factor for some of the most popular branching rules.

2 Copositive Dual and Sensitivity Analysis of 0-1 MILP

Jingye Xu, Santanu Dey, Diego Cifuentes, Georgia Tech, Atlanta, GA, Contact: jxu673@gatech.edu

Burer proved that every 0-1 MILP can be exactly reformulated as a conic convex completely positive program. We study properties of the dual of this convex program which helps in sensitivity analysis corresponding to changes in the right-hand-side of the IP. In particular, we prove that optimal solution of the dual has be constructed in closed form using the knowledge of the solution of the original MILP.

3 M-Decomposable Sets in Integer Programming

Diego A. Moran[1,2], [1]Universidad Adolfo Ibañez, Santiago, Chile; [2]Rensselaer Polytechnique Institute, Troy, NY, Contact: diego.moran@uai.cl

An M-decomposable set is a closed convex set which is the sum of a compact convex set and a closed convex cone. We present properties of these sets in the context of integer programming. In particular, we present properties of their integer hull, some cutting plane closures and subadditive duality.

4 Decomposition-Based Polyhedral Disjunctive Cuts

Ricardo Fukasawa[1], Aleksandr M. Kazachkov[2], [1]University of Waterloo, Waterloo, ON, Canada; [2]University of Florida, Gainesville, FL

Traditionally, cutting planes, or cuts, for mixed-integer linear programs are generated via rounds of “shallow” cuts to obtain a significant bound improvement. As this can be computationally costly and lead to numerical instability, an alternative is to find a single large disjunction that forms a tighter relaxation of the mixed-integer feasible region, reducing the need for recursion. However, the resulting disjunctive cuts can be dense, causing the linear relaxation to solve more slowly. In this work, we generate globally-valid disjunctive inequalities from subproblems of an instance using a decomposition of the constraint matrix. We present conditions under which these sparse subproblem-based inequalities also cut into the original problem’s linear relaxation. Finally, we report on preliminary computational experiments with a variant of our procedure.

5 Generalized Scaling for the Constrained Maximum-Entropy Sampling Problem

Zhongzhu Chen, The University of Michigan, Ann Arbor, MI, Contact: zhongzhc@umich.edu

The best practical techniques for exact solution of instances of the constrained maximum-entropy sampling problem, a discrete optimization problem arising in the design of experiments, are via a branch-and-bound framework applied to a variety of concave continuous relaxations of the objective function. A standard and computationally-important bound-enhancement technique in this context is scaling, via a single positive parameter. Scaling adjusts the shape of continuous relaxations to reduce the gaps between the upperbounds and optimal value. We extend this technique to generalized scaling, employing a positive vector of parameters, which allows much more flexibility and thus significantly reduces the gaps further. We give mathematical results aimed at supporting algorithmic methods and computational results demonstrating the state-of-art performance.

Network Expansion

Community Committee Choice Session

Session Chair: Anthony Degleris, Scalable Multi-Value Joint Transmission and Generation Expansion Planning via Implicit Differentiati, Stanford, CA

1 Approximation Algorithms for Augmenting Network Connectivity

Michael Zlatin, Carnegie Mellon University, Pittsburgh, PA, Contact: mzlatin@andrew.cmu.edu

Given a k-edge-connected graph G, how do we add a cheapest subset of links to G so that it becomes (k+1)-edge-connected? This is the Connectivity Augmentation Problem and is a fundamental problem in network design and combinatorial optimization. Primal-dual methods and iterative rounding achieve an approximation ratio of 2, which was the state of the art until recent breakthroughs by Traub and Zenklusen - bringing the approximation ratio down to 1.5+epsilon.

In this work, we consider the generalization of the Connectivity Augmentation Problem to Steiner networks, where we are only interested in connectivity between a special subset of nodes. We give improved algorithms for this setting, and open the door to tackling many variants of classic problems in network connectivity.

2 Power Grid Operation During Severe Weather: Application of Stochastic Optimization and Machine Learning

Mostafa Sahraei-Ardakani, University of Utah

Extreme weather events are the leading cause of power outage in the United States. The outages are mainly due to the failure of transmission and distribution elements. Transmission failures can be mitigated through a preventive dispatch. To compute this dispatch line outage probabilities should be integrated within grid operation problems, resulting in extremely large stochastic mixed-integer linear programs. Unfortunately, the formulated problems cannot be solved within the industry time limits. This talk discusses three techniques that we have developed to reduce the solution time: (i) enhanced formulation and constraint screening, (ii) efficient scenario selection, and (iii) the use of machine learning. Together, these methods enable computation of an efficient preventive dispatch within strict industry limits, resulting in reduced power outages.

3 Locating Obnoxious Facilities Using a Mixed-Integer Programming-Based Heuristic

Tamara Bigler, University of Bern, Bern, Switzerland

Obnoxious facilities refer to facilities that have negative side effects on the nearby population. In the obnoxious p-median problem, a set of clients and a set of potential locations for obnoxious facilities are given. From these potential locations, p facilities must be opened such that the total distance from each client to the nearest open facility must be maximized. We propose a matheuristic for this problem in which diverse initial solutions are improved iteratively using mixed-integer programming. We compare different improvement strategies, such as facility removal and addition and facility replacement. Our computational results indicate that the remove-add strategy yields superior solution quality compared to other strategies.

4 Joint Expansion of Power and Water Distribution Systems

Sai Krishna Kanth Hari, Los Alamos National Laboratory, Los Alamos, NM, Contact: hskkanth@gmail.com

Power and water networks are interdependent through elements such as pumps and hydro plants. However, their design and operations are planned independently. While the joint planning of these networks is believed to offer benefits such as reliability, flexibility, and efficiency, its practical realization is hindered by two major reasons: 1) lack of quantitative understanding of the benefits offered, and 2) lack of computational methods to support such large-scale planning. In this work, we address the first challenge by solving a Mixed Integer Nonlinear Program that considers the nonlinear governing physics of individual networks, constraints modeling the interdependency between the networks, and discrete expansion and operational decisions.

5 Scalable Multi-Value Joint Transmission and Generation Expansion Planning via Implicit Differentiation

Anthony Degleris, Abbas El Gamal, Ram Rajagopal, Stanford University, Stanford, CA, Contact: degleris@stanford.edu

We introduce the multi-value expansion planning (MEP) problem, a general bilevel optimization problem in which a planner can optimize arbitrary functions of the dispatch outcome in the presence of an uncontrolled, competitive electricity market. This framework can, for example, be used to identify grid investments that minimize emissions in lieu of carbon tax, or to maximize the profit of a portfolio of renewable investments and long-term energy contracts. The MEP problem is nonconvex, making it difficult to solve exactly for large real-world systems. We propose a fast stochastic implicit gradient-based heuristic that scales well to large networks and many scenarios. We further evaluate the performance of our heuristic using a scalable convex relaxation-based lower bound. We demonstrate the model and algorithm using a large model of the U.S. Western Interconnect.

Recent Advances in Policy Optimization and Reinforcement Learning - Part I

Community Committee Choice Session

Session Chair: Yan Li, Georgia Tech, Atlanta, GA

Session Chair: Guanghui Lan, Georgia Institute of Technology, Atlanta, GA

1 Policy Value Descent Method for Regularized MDPs

Tianjiao Li, Georgia Institute of Technology, Atlanta, GA, Contact: tli432@gatech.edu

In this work, we propose a new policy optimization algorithm, named policy value descent, for solving reinforcement learning (RL) problems. The proposed method achieves an O(1/epsilon) sample complexity for solving the RL problems with strongly convex regularizers.

2 Online Switching Control with Stability and Regret Guarantees

Yingying Li[1], James Preiss[2], Na Li[3], Yiheng Lin[2], Adam Wierman[4], Jeff Shamma[5], [1]UIUC, Urbana, IL, [2]Caltech, Pasadena, CA, [3]Harvard University, Cambridge, MA, [4]California Institute of Technology, Pasadena, CA, [5]University of Illinois Urbana-Champaign, Champaign, IL, Contact: yl101@illinois.edu

This paper considers online switching control with a finite candidate controller pool, an unknown dynamical system, and unknown cost functions. The candidate controllers can be unstabilizing policies. We only require at least one candidate controller to satisfy certain stability properties, but we do not know which one is stabilizing. We design an online algorithm that guarantees finite-gain stability throughout the duration of its execution. We also provide a sublinear policy regret guarantee compared with the optimal stabilizing candidate controller. Lastly, we numerically test our algorithm on quadrotor planar flights and compare it with a classical switching control algorithm, falsification-based switching, and a classical multi-armed bandit algorithm, Exp3 with batches.

3 On the Global Convergence of Risk-Averse Policy Gradient Methods with Expected Conditional Risk Measures

Xian Yu[1], Lei Ying[2], [1]The Ohio State University, Columbus, OH, [2]The University of Michigan, Ann Arbor, Ann Arbor, MI, Contact: yu.3610@osu.edu

Risk-sensitive reinforcement learning (RL) has become a popular tool to control the risk of uncertain outcomes and ensure reliable performance. While policy gradient methods have been developed for risk-sensitive RL, it remains unclear if these methods enjoy the same global convergence guarantees as in the risk-neutral case. In this paper, we consider a class of dynamic time-consistent risk measures, called Expected Conditional Risk Measures (ECRMs), and derive policy gradient updates for ECRM-based objective functions. Under direct and softmax parameterization, we provide global convergence guarantees and iteration complexities of the corresponding risk-averse policy gradient algorithms. We test a risk-averse variant of REINFORCE algorithm on a stochastic Cliffwalk environment to demonstrate the efficacy of our algorithm and the importance of risk control.

Recent Progress in Optimization Software I

Community Committee Choice Session

Session Chair: Hans Mittelmann, Arizona State University, Tempe, AZ

1 Recent Advances in the Cardinal Optimizer

Benjamin Mueller[1], DongDong Ge[2], [1]COPT GmbH, Berlin,

Germany; [2]Shanghai University of Finance and Economics, Shanghai, China. Contact: mueller@copt.de

In this talk, we present the recent developments in the Cardinal Optimizer (COPT). We discuss some key techniques that contributed to the performance improvements of our MIP solver and present performance numbers of the latest COPT release for all problem classes.

2 New Performance Techniques in the Gurobi Optimizers

Zonghao Gu[1], Ed Klotz[2], [1]Gurobi Optimization, Beaverton, OR, [2]Gurobi Optimization, Incline Village, NV

This talk will discuss various new techniques or ideas to improve the performance to solve linear programs, mixed integer programs, quadratic programs and nonlinear mixed integer programs.

3 Recent Progress in Optverse Solver

Zirui Zhou, Huawei Technologies Canada, Burnaby, Canada

In this talk, we present latest development of Optverse solver and some of its successful applications. We also show some new advances in harnessing large language models for enhanced modelling workflow.

Robust Prescriptive Analytics

Community Committee Choice Session

Session Chair: Li Chen, National University of Singapore, Singapore, Singapore

1 Range Value-At-Risk Under Distributional Ambiguity: Tight Bounds with Support Information

Zhi Chen[1], Zhenyu Hu[2], Guangwu Liu[3], Ruiqin Wang[4], [1]College of Business, City University of Hong Kong, Kowloon, Hong Kong; [2]National University Singapore, Singapore, Singapore; [3]City University of Hong Kong, Kowloon, Hong Kong; [4]National University of Singapore, Singapore, Singapore. Contact: ruiqin_wang@u.nus.edu

Estimating risk measures, such as value-at-risk (VaR) and conditional value-at-risk (CVaR), plays an important role when making decisions with limited information. In this paper, we examine the problem of bounding a more general class of risk measures called, range value-at-risk (RVaR), over mean-variance and Wasserstein ambiguity sets. While existing results all assume unbounded support, we characterize tight upper and lower bounds when there is support information. Our numerical results further demonstrate the significant value of support information.

2 Differential Privacy via Distributionally Robust Optimization

Aras Selvi, Imperial College London

In recent years, differential privacy has emerged as the *de facto* standard for sharing statistics of datasets while limiting the disclosure of private information about the involved individuals. This is achieved by randomly perturbing the statistics to be published, which in turn leads to a privacy-accuracy trade-off: larger perturbations provide stronger privacy guarantees, but they result in less accurate statistics that offer lower utility to the recipients.

We develop a class of mechanisms that enjoy non-asymptotic and unconditional optimality guarantees. To this end, we formulate the mechanism design problem as an infinite-dimensional distributionally robust optimization problem and show that the problem affords a strong dual, and we exploit this duality to develop converging hierarchies of finite-dimensional upper and lower bounding problems.

3 Robust Workforce Management with Crowdsourced Delivery

Chun Cheng[1], Sim Melvyn[2], Yue Zhao[3], [1]Ecole Polytechnique de Montreal, Montreal, QC, Canada; [2]National University of Singapore, Singapore, Singapore; [3]Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore. Contact: zhaoyue6174@gmail.com

We investigate the crowdsourced delivery problem, where the objective is to minimize the hiring costs of contracted couriers and the crowdsourcing costs of ad-hoc couriers while considering the uncertain availability and behavior of the latter. Due to the complication of calibrating these uncertainties through data-driven approaches, we instead introduce a basic reduced information model to estimate the upper bound of the crowdsourcing cost and a generalized reduced information model to obtain a tighter bound. Subsequently, we formulate a robust satisficing model associated with the generalized reduced information model and show that a binary search algorithm can tackle the model exactly by solving a modest number of convex optimization problems. Experiment with Solomon and simulation data demonstrate the merits of our models.

4 A Distribution-Free Approach to Long Chain Resilience

Qinghe Sun[1], Li Chen[2], Mabel C. Chou[3], [1]The Hong Kong

Polytechnic University, Hong Kong, Hong Kong; [2]National University of Singapore, Singapore, Singapore; [3]National University of Singapore, SG, SG, Singapore. Contact: qinghe.sun@polyu.edu.hk

Process flexibility has been a well-established supply chain strategy that enhances responsiveness to demand uncertainty. In this study, we extend the scope of this strategy to supply disruption mitigation by analyzing a long chain system. We investigate the effectiveness of long chain systems in the face of random supply disruption and under ambiguous demand. Our study derives a closed-form, tight bound on the ratio of expected sales under supply disruption for the long chain system relative to that of a fully flexible system. To comprehensively handle supply disruption and demand uncertainties, we introduce a moment decomposition approach that easily adapts to general piece-wise polynomial performance metrics. Our approach can also incorporate higher moment information of the random demand while maintaining tractability through a semi-definite program (SDP).

5 Joint Capacity Allocation and Job Assignment Under Uncertainty

Peng Wang[1], Yun Fong Lim[2], Gar Goei Loke[3], [1]Singapore University of Social Sciences, Singapore, Singapore; [2]Singapore Management University, Singapore, Singapore; [3]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands. Contact: peng.wang.2016@pbs.smu.edu.sg

We consider a multi-period joint capacity allocation and job assignment problem. The planner simultaneously decides on allocating resources across J different supply nodes, and assigning jobs from I different demand origins to these J nodes, so as to maximize the reward for matching or minimize the cost of failure to match. The setting can be applied in many service management settings such as ride-sharing fleet re-positioning, and patient management in healthcare. We introduce a distributive decision rule, which decides the proportion of jobs to be served by each of the supply nodes. Our model has a convex reformulation and can be solved by a sequence of linear programs. We test our model against state-of-the-art models that focus solely on capacity allocation or job assignment decisions. The result records 1-15% reductions in costs and shorter computation times.

ONR Program Review: Optimization with Uncertainty

Community Committee Choice Session

Session Chair: David Phillips, Office of Naval Research, University of New Mexico, Catonsville, MD

1 New Methods for Solving Stochastic Integer Programming Problems

Jim R. Luedtke, University of Wisconsin-Madison, Madison, WI

We summarize two recent directions for solving stochastic integer programs. The first direction is a method for generating valid inequalities to be used in Benders decomposition derived from multi-term disjunctions defined by a partial enumeration of the first-stage variables. We demonstrate how restricting the support of such cuts to be sparse enables efficient cut generation, while empirically yielding strong bound reduction. In the second direction we present results exploring techniques for “learning” from the process of solving one sampled SAA approximation of a SIP to enable more efficient solution of SAA approximations defined by different samples.

2 Principles of Noisy Nonlinear Optimization

Jorge Nocedal, Northwestern University, Evanston, IL

The question of how to design nonlinear optimization algorithms that are robust in the presence of noise in the function and/or gradient has recently received much attention. Established methods for deterministic optimization have proved to be successful in a wide range of disciplines but are not directly applicable in the stochastic setting. In this talk, we argue that one can design effective methods by preserving the underlying properties of deterministic methods and making judicious modifications following certain design principles presented here. We test our new algorithms on an optimal design problem where the goal is to optimize the efficiency of an acoustic horn assuming that some of the physical properties of the system are only known through a distribution.

3 Confidence Regions in Infinite-Dimensional Stochastic Optimization

Raghu Pasupathy[1], Yi Chu[2], Di Yu[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: pasupath@purdue.edu

We investigate operator recursions for constrained stochastic optimization (SO) problems, where the decision variables lie in an infinite-dimensional space, e.g., the space of smooth functions, or space of probability measures. Example settings include fluid flow, emergency response, and optimal transport. We highlight the question of statistical inference (or uncertainty quantification), in particular, how to compute a confidence region on the optimal value or solution in SO using iterates generated by a recursion? Using a Bahadur representation theorem that we show to hold across a wide variety of SO settings, we construct a simple but compute-intensive batching method for confidence regions. The method is valid in the sense of being consistent, and implementable in the sense of the classical Student's t statistic, that is, there are no unknown parameters.

4 Next Generation Algorithms for Stochastic Optimization with Constraints

Albert S. Berahas[1], Frank E. Curtis[2], Baoyu Zhou[3], Daniel Robinson[4], [1]University of Michigan, Ann Arbor, MI, [2]lehigh university, Bethlehem, PA, [3]University of Chicago, Chicago, IL, [4]Lehigh University, Bethlehem, PA, Contact: albertberahas@gmail.com

Stochastic gradient and related methods for solving stochastic optimization problems have been studied extensively in recent years. It has been shown that such algorithms and much of their convergence and complexity guarantees extend in straightforward ways when one considers problems involving simple constraints, such as when one can perform projections onto the feasible region. However, settings with general nonlinear constraints have received less attention, and many of the approaches that have been proposed for solving such problems resort to using penalty or (augmented) Lagrangian methods, which are often not the most effective strategies. In this work, we propose and analyze stochastic optimization methods based on the sequential quadratic optimization (commonly known as SQP) methodology. We discuss advantages and disadvantages of such techniques.

1 Fractal-Like Growth of Urban Congestion and Its Control Based on Deep Reinforcement Learning

Hao Zhou, University of South Florida, Tampa, FL, Contact: zhouhao@gatech.edu

Recently it has been found that congested urban networks tend to be insensitive to signal control, and the success of deep reinforcement learning (DRL) could quickly deteriorate in congested networks given random rerouting. As a sequel study, we verified those findings with more realistic network settings and found that similar challenges hold for perimeter control, and those learning instabilities mainly result from frequent spillback queues or gridlock, where the flow (reward) and the queue length (state) both have a long-tail/power-law distribution. Those findings imply that congestion grows as fractals and its complexity can be responsible for the deterioration of DRL. The paper further presents a novel DRL algorithm designed to control the growth of fractals, which can be potentially transferred to other complex systems with similar issues.

2 A Deep Reinforcement Learning Based Distributed Control Strategy for Connected Automated Vehicles in Mixed Traffic Platoon

Haotian Shi[1], Danjue Chen[2], Nan Zheng[3], Xin Wang[1], Yang

Zhou[4], [1]University of Wisconsin–Madison, Madison, WI, [2]University of Massachusetts Lowell, Lowell, MA, [3]Monash University, Australia; [4]Texas A&M University, College Station, TX

This paper introduces a novel control strategy for connected automated vehicles in mixed traffic, addressing the stochasticity of human-driven vehicle behaviors. Instead of focusing on individual HDV trajectories, we treat consecutive HDVs as a unit to capture the macroscopic features to reduce HDVs' adverse impact. Macroscopic traffic properties are modeled on the Newell model to capture aggregated HDV behaviors based on the generic 'CAV-HDVs-CAV' pattern. Physics-informed deep reinforcement learning is employed to develop the controller. Simulations validate our approach regarding oscillation dampening, eco-driving, and generalizability.

3 Solving System Optimum with Uncertain Demands and System Dynamics: A Reinforcement Learning Framework Enhanced by Traffic Models

Zemian Ke, Carnegie Mellon University, Pittsburgh, PA, Contact: zemiank@andrew.cmu.edu

System optimal routing can mitigate congestion by assigning vehicles routes that minimize the system travel time. However, solving the optimal routing policy is challenging with uncertain demands. In this paper, we propose a novel reinforcement learning algorithm named TransRL, which not only captures the uncertainties of the system dynamics but also learns the optimal policies efficiently by utilizing the information from a traffic model-based policy (i.e., the teacher policy). The experiments unveiled three appealing features of TransRL: (1) Compared with the deterministic method, TransRL can better adapt to demand uncertainties by learning from experiences; (2) Leveraging the teacher policy, TransRL explores more efficiently than model-free reinforcement learning; (3) TransRL is robust to inaccurate traffic models with proper confidence parameters.

4 Artificial Intelligence-Enabled Perimeter Metering Control Methods

Dongqin Zhou, Penn State University, PA

Perimeter metering control based on macroscopic fundamental diagrams has attracted increasing research interests over the past decade. While numerous control methods have been proposed in the literature, most of them require detailed information regarding the traffic dynamics modeling. This work presents several perimeter control methods as enabled by artificial intelligence techniques. These methods can serve as an introduction to more broader application of AI methods on macroscopic traffic control.

5 Enhancing Real-Time Bus Arrival Time Prediction with a Machine Learning-Driven Markov Process Approach

Xiaoyu Ma, Xiaozheng He, Rensselaer Polytechnic Institute, Troy, NY, Contact: max8@rpi.edu

Accurate bus arrival information is crucial for riders' satisfaction, operation efficiency, and equity. However, some highly dynamic and uncertain factors, such as traffic and weather conditions, make it challenging to accurately train traditional prediction models that require massive data collection and complicated analysis. Our research formulates the sequential bus arrival time at each stop as a Markov process. For a given bus route, the transition matrices between the arrival times at every two adjacent stops are learned from historical bus arrival data. The trained model can then run online to predict the arrival times for subsequent stops using the latest bus arrival information. In essence, the proposed model learns the dynamic arrival patterns affected by the uncertainties without relying on the detailed data.

Advances in Nonlinear Programming

Contributed Session

Session Chair: Utku Tarik Bilgic, University of Pittsburgh, Pittsburgh, PA

1 State-Constrained Optimization Problems Under Uncertainty: A Tensor Train Approach

Akwum Onwunta, Lehigh University, Bethlehem, PA, Contact: ako221@lehigh.edu

We present a tensor-train decomposition approach to solve optimization problems constrained by partial differential equations under uncertainty, with almost sure constraints on the state variable. The state constraints are handled using Moreau-Yosida regularization. In the most general setting, we derive constraint violation estimates. When the optimization problem is strongly convex, we establish strong convergence of the regularized solution to the optimal control. This result mimics the deterministic setting and provides a rate of convergence. A second order Newton type method with a fast matrix-free action of the approximate Hessian is presented. Both function and gradient approximations are carried out using tensor-train decomposition. We test our algorithm on benchmark high dimensional problems to illustrate that our proposed algorithm is efficient.

2 Automatic Decomposition and Modified Progressive Hedging Algorithms for Solving Mixed-Integer Programs

Sheng-I Chen, Yu-Ting Tseng, National Yang Ming Chiao Tung University, Hsinchu, Taiwan. Contact: sichen@nycu.edu.tw

We develop algorithms to decompose a mathematical program automatically based on Bender's decomposition scheme. Our decomposition algorithm aims to obtain similar size sub-problems as many as possible. The progressive hedging algorithm is then applied to solve the problem using the decomposition result. Additionally, we enhance the progressive hedging algorithm in order to deal with integer decision variables in the decomposed master problem. The computational experiment tests our algorithms using stochastic integer programs from the public problem instance. The result shows that our method outperforms the commercial solver for large-scale problem instances.

3 A Rank-Adaptive Augmented Lagrangian Approach To Solving Large-Scale SDPs

Arnesh Sujanani[1], Renato D.C. Monteiro[1], Diego Cifuentes[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: asujanani6@gatech.edu

This work presents a rank-adaptive augmented Lagrangian approach to solving large-scale SDPs. At each iteration, our method constructs an augmented Lagrangian subproblem, which is factorized using the Burer-Monteiro approach. Each subproblem is approximately solved using a combination of the Frank-Wolfe method and an accelerated proximal point method. Our method begins with a small rank in the Burer-Monteiro factorization of the AL-subproblem and the rank is gradually increased as the method proceeds, helping reduce storage costs. A global complexity bound for finding an approximate optimal solution of the SDP is also established. Computational experiments on large-scale SDPs illustrate the effectiveness of our approach.

4 New Randomized Coordinate Optimistic Gradient Algorithms for Nonlinear Inclusions and Applications

Tran-Dinh Quoc, The University of North Carolina at Chapel Hill, Chapel Hill, NC

In this talk, we will present two randomized block-coordinate optimistic gradient algorithms to approximate a solution of nonlinear inclusions involving both monotone and co-hypo-monotone operators. We establish the best-known convergence rates of both algorithms under mild assumptions. Then, we apply them to solve a finite-sum inclusion arising from federated learning systems. We show that our new algorithms cover a broader class of problems in federated learning, including optimization and minimax models, than previous work.

5 A Study of Admm for Hierarchical Decision Making

Utku Tarik Bilgic[1], Xiaoning Qian[2], Bo Zeng[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]Texas A&M University, College Station, TX, [3]University of Pittsburgh, Pittsburgh, PA, Contact: utb3@pitt.edu

In this talk, we present our findings on solving hierarchical decision making problems in a distributed manner by making use of modified alternating direction method of multipliers (ADMM) algorithm.

1 Roundtable session of RAS I

Jay Baillargeon, Federal Railroad Administration, Pueblo, CO

Rail is one of the safest and most efficient means of moving both goods and people. Regulatory agencies were established with the authority to ensure compliance with safety standards to protect the lives of those working on or living near the railroad. With new technologies enabling large volumes of data to be collected regularly, regulators are finding ways to use these technologies to achieve their mission. This session will provide an overview of the regulators' role in safety compliance and how they collaborate with operators to advance railroad safety, as well as a look at the ways in which new technology and analytics are being leveraged to ensure safe and efficient rail transportation for all.

1 A Learning-Based Approach for High Capacity Ridesharing
Xu Chen, Columbia University, New York, NY
This work proposes a learning framework to tackle a combinatorial optimization problem in high-capacity ridesharing systems. In particular, we focus on how vehicles can pick up passengers with multiple origin-destination (OD) pairs, which refers to the sequence of chaining OD pairs. Unlike pick-up sequences in traditional VRP, the OD sequence requires the preliminary consideration of visiting order for vehicles' pick-up and drop-off decisions. To address the challenge of enumerating all possible combinations of OD pairs, this work designs a learning operator that can efficiently explore feasible OD sequences. We demonstrate the performance of our approach in dispatching problems with different sizes. Our learning operator provides a computationally efficient tool for studying high-capacity ridepooling systems.

2 Advanced Manufacturing: Reinforcement Learning And Surrogate Model Applied To Wire Arc Additive Manufacturing
Sam St John, Anahita Khojandi, University of Tennessee, Knoxville, TN, Contact: sstjohn3@vols.utk.edu
Wire Arc Additive Manufacturing (WAAM) is a metal 3D printing approach that uses arc welding to create layers of material. The deposition process includes a potential for defects in deposition, such as waviness, humping, and crookedness. As subsequent layers are deposited, these defects can have an additive impact and drastically impact the shape of the generated part. Therefore, we investigate methods to leverage WAAM settings and prior deposition details to predict a future height profile. Our surrogate model is then used in a reinforcement learning model to create a map of actions that drive toward a consistent bead height. This approach builds upon prior research through a unique approach to the surrogate model that allows a clearer understanding of the small-scale build process.

3 A Reinforcement Learning Method to Accelerate the Benders Decomposition in Stochastic Unit Commitment
Nur Banu Altinpulluk[1], Murat Yildirim[1], Paritosh Ramanan[2], [1]Wayne State University, Detroit, MI, [2]Oklahoma State University, Stillwater, OK, Contact: nurbanu@wayne.edu
Stochastic unit commitment (SUC) is a fundamental optimization problem in power systems with significant computational challenges, which are exacerbated by increasing grid complexity, and operational uncertainty. Evidently, effective SUC solution methodologies play a pivotal role in ensuring competitiveness and reliability. In this talk, we propose a hybrid reinforcement learning and optimization approach for the SUC problem. Our approach accelerates Benders decomposition algorithm by leveraging reinforcement learning to intelligently select a subset of Benders optimality cuts to yield the fastest convergence. We demonstrate that our approach provides significant solution time improvements over traditional Benders decomposition approaches.

4 A Unified State Representation Framework for the Two-Sided Marketplace of Ridesharing
Alex Chin, Zhiwei (Tony) Qin, Lyft, San Francisco, CA
Ridesharing platforms are a particular type of two-sided marketplace where `supply-demand (SD) balance' is critical to the market efficiency and is also complex to analyze.

We describe an analytical framework based on the graph equilibrium metric (GEM) for quantifying the supply-demand spatiotemporal state of a ridesharing marketplace. GEM was developed as a generalized Wasserstein distance between the supply and demand distributions in a ridesharing market and has been used as an evaluation metric for algorithms expected to improve SD alignment. We extend the GEM framework to support a dual-view (supply and demand side) of balance in a market. We show that there are often disparities between the two views and how this dual-view leads to the notion of market efficiency, in which we propose a test statistic for capturing improvement.

5 Analysis of Search Time for Target Search Applications Under Different Behavior Policies

Carlos Hurtado[1], Lei Fang[2], Ze-xu Li[2], M. Amin Rahimian[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: cah259@pitt.edu

In search theory, we want to find an object considering the following elements involved in every search operation: searcher kinematics, detection uncertainties, and target location probability and optimization of the search. In our problem setting, our goal is to minimize the time an agent takes to find a hidden object with a static but unknown location, which can be learned using detection devices. We guided the agent under different movement rules using sequential decision-making. Thus, in each round, the agent has to make a trade-off between exhaustive searches, which lead to a good estimation (exploration), and efficient searches, which lead to optimum cost-benefit ratios (exploitation). We provide upper bounds on the expected search time under different search paradigms: pure exploration, pure exploitation, fixed threshold hold policy, and multi-armed bandit.

Machine Learning for Discrete and Global Optimization 1

Community Committee Choice Session

Session Chair: Can Li, Purdue

Session Chair: Rohit Kannan, Los Alamos National Laboratory, Los Alamos, NM

1 Optimization Proxies for Continuous and Discrete Optimization

Pascal Van Hentenryck, ISyE Georgia Tech, Atlanta, GA

Optimization proxies aim at replacing an optimization model by the combination of a machine-learning model and a repair step. They have been shown to be particularly useful in real-time applications in a variety of areas including energy systems, supply chains, and transportation systems. This talk will provide an overview of the science, engineering, and applications of optimization proxies.

2 Learning Convex Approximations for AC Optimal Power Flow with Zero-Injection Feasibility Guarantees

Gonzalo E. Constante-Flores[1], Can Li[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: geconsta@purdue.edu

This work presents a convex approximation of the AC optimal power flow problem (AC-OPF) based on the prediction of a subset of primal and dual variables. The AC-OPF is formulated as a difference of convex functions programming problem and convexified around the set of predicted nodal voltages. To avoid infeasibilities in the convexified constraints, we add a slack variable whose penalty weight in the objective function is predicted from a subset of dual variables of the AC-OPF. To predict the primal and dual variables, we propose a neural network that guarantees that zero-injection buses are enforced using an explicit projection layer, whose weights are fixed and determined offline solely based on the power system's topology.

3 Learning to Accelerate the Global Optimization of Quadratically-Constrained Quadratic Programs

Rohit Kannan, Harsha Nagarajan, Deepjyoti Deka, Los Alamos National Laboratory, Los Alamos, NM, Contact: harsha@lanl.gov

Non-convex QCQPs arise in several practical applications such as synthesis of process networks and power grids, to name a few. Efficient algorithms to solve such QCQPs to near global optimality is a key to addressing these applications. Leveraging recently-developed efficient MIP relaxation of a QCQP, we propose the novel problem of "strong partitioning" (SP) to optimally partition variable domains "without" sacrificing global optimality guarantees. We design a local method for solving the SP problem and replace this "ideal strategy" with a machine learning (ML) approximation for homogeneous QCQP families. Numerical studies demonstrate that SP and its ML approximation can significantly reduce the average run times of partitioning-based algorithms by factors of "3.5 - 16.5" and "2 - 4.5", respectively, on different families of non-convex QCQPs.

4 Le^{2}Go: Learning an End-To-End Partitioning Policy for the Global Optimization of Quadratically-Constrained Quadratic Programs

Rohit Kannan, Harsha Nagarajan, Deepjyoti Deka, Los Alamos National Laboratory, Los Alamos, NM, Contact: rohitk@alum.mit.edu

We use machine learning to accelerate the guaranteed global minimization of families of nonconvex quadratically-constrained quadratic programs (QCQPs). Specifically, we consider how to optimally partition variable domains while constructing mixed-integer programming (MIP) relaxations of nonconvex QCQPs and train a feedforward neural network (NN) end-to-end to map the features of a QCQP instance to its set of prescribed partitioning points. The goal of our end-to-end learning setup is to maximize the average MIP-based lower bound for the QCQP family. Numerical experiments demonstrate the advantages of end-to-end learning over a two-step strategy that fits an NN model to predict optimal partitioning points.

Strategies for Resilience and Social Justice

Community Committee Choice Session

Session Chair: Himadri Sen Gupta, University of Oklahoma, Norman, OK

Session Chair: Andres Gonzalez, University of Oklahoma, Norman, OK

1 Risk-Informed Community Resilience Planning Considering Social Vulnerability and Equity

Tasnim Ibn Faiz[1,2], Kenneth Harrison[1], [1]National Institute of Standards and Technology, Gaithersburg, MD, [2]University of Maryland, College Park, MD, Contact: tasnimibn.faiz@nist.gov

Proactive mitigation actions can improve a community's resilience against natural hazards. However, the mitigation planning problem is challenging due to the diverse and numerous stakeholders and the uncertainty associated with the hazard events. A decision-making framework is constructed to identify risk-informed mitigation decisions to achieve community resilience goals while ensuring equitable allocation of resources. The usefulness of the proposed framework in developing alternative mitigation strategies is presented with a case study of a community in Shelby County, Tennessee, subjected to earthquake hazards.

2 Mitigating Food Under-Served Areas: The Policy-Maker Problem

Sofía Pérez-Guzmán[1], Jose Holguin-Veras[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Rensselaer Polytechnic Institute, Troy, NY

This research proposes a mathematical formulation to reduce food under-served areas (FUAs), also known as food deserts. The proposed formulation, the Policy-Maker Problem (PMP), seeks to capture the decision-making behavior of a policy-maker interested in achieving the most appropriate tradeoff between benefits to the community and public-sector investments to mitigate FUAs. Such public-sector investments fund demand and supply-side initiatives that foster increased food distribution to small food outlets. This research also proposes the integration of the PMP with the Food Distributor Problem (FDP). The FDP, previously proposed by the same authors, is a Prize Collecting Traveling Salesman Problem that recreates the mechanisms by which food distributors decide whether or not to serve a food outlet.

3 Optimizing Treatment Facility Locations in Oklahoma Using Haversine Distance Optimization

Karen R. Roberts-Licklider, Theodore B. Trafalis, University of Oklahoma, Norman, OK

Drug court data was used for each county in Oklahoma to optimize the placement of treatment facilities. The objectives of this model were to optimally place treatment facilities minimizing cost and total haversine distance and maximizing the total number of facilities located, while not exceeding the number of facilities allowed to be located according to the maximum covering location problem. An integer multi-criteria nonlinear programming model was utilized with several models comparing the results with and without fairness constraints, using a fairness measures such as Hoover and Gini coefficient at various thresholds.

4 Justice Will be Served, One Slice of Cake at a Time: A Bilevel Programming Approach for Fair Resource Allocation in Interdependent-Network Flow Problems

Samuel Rodriguez[1,2], [1]University of Oklahoma, Norman, OK, [2]Universidad de los Andes, Bogotá, Colombia. Contact: s.rodriguez@ou.edu

This research addresses self-interested behavior undermining fair resource allocation in interdependent-network flow problems. Inspired by Shelby County's Gas, Water, and Power networks, certain end users allocations must transit through others, allowing intermediate users to act selfishly and withhold allocated resources. To address this, we propose a mixed integer bilevel linear programming approach with supervision mechanisms. Leveraging fair cake cutting, we allocate homogeneous divisible cake pieces to promote fairness among users while considering self-interest. The approach minimizes deviation from the egalitarian Nash allocation scheme, addressing "anarchic behavior" within the network.

Integration of Machine Learning and Statistical Approaches for Quality Improvement

Community Committee Choice Session

Session Chair: Haoqian Li, University of Wisconsin-Madison, Pittsburgh, PA

Session Chair: Kaibo Liu, UW-Madison, Madison, WI

1 Directed Graphical Models for Multimodal Systems Collecting Heterogeneous Data

Manni Zhang, Ana Maria Estrada Gomez, Purdue University, West Lafayette, IN

Complex sensing systems collect heterogeneous data, including scalars, functional signals, images, and point clouds. We use directed graphical model to represent the relationships between variables in such system and aim to predict its structure and perform root cause analysis. Methods considering single type of data in the system have been proposed whereas dealing with heterogeneous data does not have a clear solution. In this article, we propose a universal tensor representation for data and assume linear interactions between the variables. When the structure is known, we learn the parameters of fitted tensor regressions; when it is unknown, we minimize the sum of least squares, group lasso, and penalties using a cyclic coordinate accelerated proximal gradient decent algorithm. The performance of our method on simulation experiments shows its advantages.

2 Adaptive Sampling and Quick Anomaly Detection in Large Networks

Xiaochen Xian[1], Alexander Semenov[2], Yaodan Hu[3], Andi Wang[4], Yier Jin[1], [1]University of Florida, Gainesville, FL, [2]University of Florida, Shalimar, FL, [3]Idaho State University, Pocatello, ID, [4]Arizona State University, Mesa, AZ, Contact: asemenov@ufl.edu

The monitoring of data streams with a network structure have drawn increasing attention due to its wide applications in modern process control. In these applications, high-dimensional sensor nodes are interconnected with an underlying network topology. In such a case, abnormalities occurring to any node may propagate dynamically across the network and cause changes of other nodes over time. We incorporate network structure information into the monitoring and adaptive sampling methodologies for quick anomaly detection in large networks where only partial observations are available. We develop a general monitoring and adaptive sampling method and further extend it to the case with memory constraints, both of which exploit network distance and centrality information for better process monitoring and identification of abnormalities.

3 Plural: 3D Point Cloud Transfer Learning via Contrastive Learning with Augmentations

Michael Biehler[1], Jianjun Shi[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: mbiehler3@gatech.edu

Unlocking the power of 3D point cloud models can be a challenge due to the need for extensive labeled datasets. Transfer learning can help overcome this challenge. Traditional (2D) transfer learning methods struggle with 3D domain adaptation, due to differences in physical environments and sensor configurations. To address this issue, we propose a novel methodology based on contrastive learning with augmentations. We propose a co-training architecture and extend the approach of contrastive instance alignment to 3D point cloud modeling by considering physics-informed hard sample mining. Our experiments on simulation and real-world datasets demonstrate that PLURAL outperforms state-of-the-art transfer learning methods by a significant margin.

4 Online Monitoring of High-Dimensional Partially Observable Data Streams with Statistical Double Dueling Deep Q-Network

Haoqian Li[1], Ziqian Zheng[2], Kaibo Liu[3], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, [3]UW-Madison, Madison, WI, Contact: hli788@wisc.edu

With the fast advancements in Internet of Things (IoT) technology and sensing infrastructure, a wide range of systems generate a massive amount of data. Meanwhile, the practical resources constraint such as limited bandwidth or processing capability, and the exorbitant price of collecting high-frequency information from all sensors restrict the full observability of data streams. In this article, we propose a deep reinforcement learning framework to online monitor high dimensional data streams based on dynamically sampled partial observations at each data acquisition time. A Double Dueling Q-network is trained which can automatically decide the most informative data streams to monitor in each time epoch. Both simulations and a case study are thoroughly conducted to evaluate the performance and demonstrate the superiority of the proposed method.

Session Chair: Apurv Shukla, [1</sup]

Session Chair: Le Xie, Texas A&M University, College Station, TX

1 Frequency-Secured Unit Commitment: Tight Approximation Using Bernstein Polynomials

Bo Zhou[1], Ruiwei Jiang[1], Siqian Shen[2], [1]University of Michigan, Ann Arbor, MI, [2]U of Michigan/NSF, Ann Arbor/Alexandria

As we replace conventional synchronous generators with renewable energy, the frequency security of power systems is at higher risk. We study the frequency-secured unit commitment (UC) under significant wind power uncertainty. To depict the frequency dynamics, we incorporate a differential-algebraic equation (DAE) with the dead band and variable inverter droop factors into the UC model. Notably, we apply Bernstein polynomials to derive tight inner approximation of the DAE and obtain mixed-integer linear constraints. Case studies demonstrate the tightness and effectiveness of the proposed method in guaranteeing frequency security.

2 Learning and Control for Decarbonized Energy Systems

Apurv Shukla, Texas A&M, New York, NY

We analyze the lookahead dispatch policy for power system dispatch problems. We propose tight performance bounds for such a policy pertaining to the power system context. These results are further demonstrated on synthetic and real-world sized synthetic grid datasets.

3 Integrating Distributed Solar and Battery Resources into the Wholesale Energy Market: A Mean-Field Game Approach

Chen Feng[1], Andrew Lu Liu[2], [1]PURDUE UNIVERSITY, WEST LAFAYETTE, IN, [2]Purdue University, West Lafayette, IN, Contact: feng219@purdue.edu

Utilizing battery storage and demand response allows better alignment of distributed renewable energy supply with the overall system's demand patterns. However, prosumers lack the expertise to directly participate in wholesale energy markets. We propose a mean-field game framework to help prosumers (automatically) learn optimal decision policies in response to market price fluctuations and their own variable solar outputs. We prove the existence of a mean-field equilibrium (MFE) for the wholesale energy market. Our numerical experiments point to convergence to an MFE and show that our framework effectively reduces peak load and price fluctuations, especially during exogenous demand or supply shocks.

4 Optimal Control with Discrete Technologies and Market Frictions Under a Carbon Budget Constraint

Christoph Weber, University Duisburg-Essen, Essen, Germany

Countries around the world, including the US, Germany, the EU and China, have defined target years for attaining climate neutrality. Also climate science suggests that there is a maximum total budget of GHG emissions which must not be exceeded if global warming is to be limited to 2° C or less (cf. IPCC 2021). In this contribution, the optimal strategy for staying within a predefinied carbon budget is investigated in a stylized two-technology case (e.g. gas heating vs. electric heating with zero carbon electricity). The standard optimal control approach is contrasted with a setting where there is heterogeneity both in technology cost and consumer preferences. Also the effect of a present bias among decision makers is analysed, Both analytical and numerical results are provided.

Energy, Health, Equity Nexus

Community Committee Choice Session

Session Chair: Rodrigo Fernandez, 1</sup

1 Inequalities in Electricity Consumption, Subsidies, and Cooling Comfort in Mexico

Mauricio Hernandez Hernandez, Dalia Patino-Echeverri, Adli Imam Muhammad, Duke University, Durham, NC, Contact: mauricio.hernandez@duke.edu

This paper estimates electricity consumption and subsidies of 100,000 Mexican households surveyed in Mexico in 2018. Using information from the Mexican Utility Federal Electricity Commission, we expand these two datasets into a comprehensive source data representative of all of Mexico. Our estimates show that large consumers receive large subsidies, with the top 20 % of the highest consuming households receiving 50 % of the subsidies. We also find that electricity consumption is determined by socio-economic status. In the extremely hot region, families in the highest income decile consume 57 %-66 % more than those in the lowest. For this reason, Mexicans in the highest income brackets benefit the most from subsidies; the average subsidy per household for those in the two highest income brackets is almost twice the average subsidy for those in the lowest bracket.

2 A Spatial Analysis of Power-Dependent Medical Equipment and Extreme Weather Risk in the Southeastern United States

Taylin Spurlock, Appalachian State University, NC

Extreme weather events endanger critical health infrastructure, and many individuals rely on infrastructure to meet their basic needs, such as heat, water, and medical devices. The purpose of this study is to identify spatially explicit at-risk populations for power outages due to these extreme weather events. Through our analysis, we identified vulnerable areas for high rates of disasters and electricity-dependent durable medical equipment (DME) to be located in communities along the coast. We also found higher concentrations of DME in rural areas compared to urban areas. These results will inform public health officials where to target interventions to ensure continuity of care for vulnerable populations during power outages at the community level.

3 Distributed Energy Resources for Rural Resilience: The Nexus of Energy and Health

Rodrigo Mercado Fernandez, Tecnologico de Monterrey, Guadalajara, Mexico

This study explores the impacts of power outages on the rate of hospitalizations for various physical and mental health conditions in North Carolina. Using several years worth of power outage and health data, we merged the two datasets to quantify the impacts of power outages on household health. Our objective is to provide a comprehensive analysis of the impact of power outages on the health of North Carolina residents. We also aim to identify the most vulnerable populations during power outages. This study provides important insights for policymakers and stakeholders in the energy and healthcare sectors to address the impacts of power outages on household health.

4 Spatiotemporal Distribution of Power Outages with Climate Events and Social Vulnerability in the USA

Vivian Do[1], Heather McBrien[1], Nina Flores[1], Alexander Northrop[2], Jeffrey Schlegelmilch[3], Mathew Kiang[4], Joan Casey[5,1], [1]Columbia Mailman School of Public Health, New York City, NY, [2]Vagelos College of Physicians and Surgeons, New York City, NY, [3]National Center for Disaster Preparedness at the Columbia Climate School, New York City, NY, [4]Stanford, Palo Alto, CA, [5]University of Washington, Seattle, WA, Contact: vd2349@cumc.columbia.edu

STUDY AIM US power outages remain under-studied. We aim to identify the spatiotemporal distribution of outages at a county level and characterize their relationship to vulnerability and climate events. METHODS With PowerOutage.US data, we defined an outage to be whenever >0.5% of county customers were without power for 8+ and 1+ hours. Vulnerability was the Centers for Disease Control and Prevention's Social Vulnerability Index and Medicare electricity-dependent durable medical equipment (DME) use. We ran descriptive and bi-variate local indicators of spatial association analyses. RESULTS From 2018-2020, there were 17,484 8+ and 231,174 1+ hour outages, occurring frequently in the South, Northeast, and Appalachia. Outages were more frequent with increasing social vulnerability and often co-occurred with weather/climate events like cyclones and wildfires.

Data-Driven Optimization for Energy Systems

Community Committee Choice Session

Session Chair: Kai Pan, The Hong Kong Polytechnic University, Hung Hom, Hong Kong

1 Optimized Dimensionality Reduction for Moment-Based Distributionally Robust Optimization

Jianqiang Cheng[1], Shiyi Jiang[2], Kai Pan[3], Zuo-Jun Max Shen[4], [1]University of Arizona, Tucson, AZ, [2]Hong Kong Polytechnic University, Hong Kong, China; [3]The Hong Kong Polytechnic University, Hung Hom, Hong Kong; [4]University of California Berkeley, Berkeley, CA

In this talk, we propose an optimized dimensionality reduction approach to solve moment-based distributionally robust optimization (DRO). We first show that the ranks of the matrices in the SDP reformulations are small, by which we are then motivated to integrate the dimensionality reduction of random parameters with the subsequent optimization problems. Such integration enables two outer and one inner approximations of the original problem, providing two lower bounds and one upper bound correspondingly. As these approximations are nonconvex low-dimensional SDPs, we develop modified Alternating Direction Method of Multipliers algorithms to solve them efficiently. Numerical results show significant advantages of our approach on the computational time and solution quality over the three best possible benchmark approaches.

2 Optimal Planning of Preventive Maintenance Tasks on Electric Power Transmission Systems

Mariana Rocha[1], Miguel F. Anjos[2], Michel Gendreau[1], [1]Polytechnique Montreal, Montreal, QC, Canada; [2]University of Edinburgh, Edinburgh, United Kingdom. Contact: anjos@stanfordalumni.org

Preventive maintenance scheduling of transmission lines must be carefully planned to ensure uninterrupted power supply while reducing equipment failures and maintaining network reliability. The transmission maintenance scheduling problem is concerned with selecting the optimal periods to remove specified lines from operation to carry out preventive maintenance. We propose a mixed-integer linear optimization formulation that schedules preventive maintenance for one year while ensuring that the system stays connected even in case of an unexpected line failure. The resulting large-scale optimization problem is solved using a decomposition approach. We report computational results demonstrating that our algorithm achieves the required accuracy and solves the problem more efficiently than solving the complete formulation without decomposition.

3 Distributionally Robust Trading in Two-Stage Energy Markets with a Single-Price Balancing Stage

Bob Pepin, Technical University of Denmark, Kgs. Lyngby, Denmark

We will show how to use Distributionally Robust Optimization and Optimal Transport to derive robust bidding strategies in two-stage energy markets. The market consists of a forward and a balancing stage with a single-price scheme and we assume that we have access to a set of samples from the joint distribution of forward and balancing prices. The main challenge is the presence of a discontinuity in the objective function as a function of prices and we show how to derive explicit optimal transport plans for the worst-case distribution, leading to robust bidding decisions.

4 A Data-Driven Approach to Unit Commitment Under Uncertainty Using Contextual Information
Ogun Yurdakul, Argonne National Laboratory, Lemont, IL
To take unit commitment (UC) decisions under uncertain net load, most stochastic optimization (SO) frameworks adopt a generic representation of uncertainty. While net load levels that materialize on a particular day are influenced by various covariates (such as the day of the week or temperature), SO frameworks typically disregard such side observations, squandering useful information that could markedly enhance decision quality. In this talk, we discuss contextual stochastic optimization frameworks for taking UC decisions under uncertain net load, which can effectively exploit covariate observations together with machine learning algorithms to improve the out-of-sample performance of UC decisions. Using real-world data harvested from the New York ISO grid, we compare the performance of the frameworks against alternative methods proposed in the literature.

Sustainable Electricity Markets and Transportation

Community Committee Choice Session

Session Chair: Arash Khojaste, 1</sup

Session Chair: Golbon Zakeri, University of Massachusetts - Amherst, Amherst, MA

1 Who Bears the Risk? the Case of Battery Market Models
Mahan Mansouri, Pacific Gas and Electric (PG&E), Oakland, CA, Contact: mahan.ma@gmail.com
In California, battery operators co-located with other electric generation resources choose between two market models which may have differential risks and rewards for batteries and the system operator. The choice of market model may substantially affect resource valuation and bidding strategies due to risk asymmetries.

2 Hybrid Electricity Market Models: Combining Zonal and Nodal Pricing for Congestion Management
Endre Bjørndal, Benjamin Fram, Mette Bjørndal, Norwegian School of Economics, Bergen, Norway. Contact: endre.bjorndal@nhh.no
We propose several novel hybrid pricing models for congestion management in electricity markets. Hybrid models manage congestion by allowing certain market areas to use nodal pricing and others to use zonal pricing and have been previously shown to offer significant welfare improvements over zonal pricing models. We present two classes of hybrid models: simultaneous and sequential. Simultaneous models clear the market in a single step where nodal and zonal pricing areas are both cleared at once. Sequential models first clear a fully zonal model, fix the resulting power flow quantities between market areas, and then re-clear the nodal pricing areas in a second modelling step. We also present several subvariants of these models where we aggregate, partially disaggregate, and fully disaggregate the transfer capacities of lines connecting market areas.

3 Prequalifying Residential Distributed Energy Resources (DERs) for Providing Flexibility to Power Markets
Yijiao Wang[1], Ben Field Hobbs[2], Michael Blonsky[3], Elina Spyrou[4], Mengmeng Cai[3], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]National Renewable Energy Laboratory, Golden, CO, [4]Imperial College London, Golden, CO, Contact: ywang303@jhu.edu
With increasing amounts of intermittent renewables in the electricity mix, managing the high variability and high uncertainty of these renewables is a growing challenge for grid operators. Operators can use the flexibility of DERs to hedge system reliability risks (supply-demand imbalances). This study develops an advanced prequalification technique for demand-based DERs to select aggregated small-scale residential customers for flexibility provision in day-ahead markets based on numerous user characteristics. Specifically, a set of indices depicting the reliability of DERs can be developed focusing on control of HVAC systems and water heaters. Based on the reliability indices, grid operators are able to identify most valuable small-scale aggregation for various power market applications.

4 Optimizing Fleet Electrification Strategies for Sustainable Bus Transit
Mahsa Arabi, Jimi Oke, University of Massachusetts Amherst, Watertown, MA

The transition to electric fleets is essential for public transit agencies aiming to achieve timebound climate change targets sustainably. We present a decision-making framework for bus electrification strategies to minimize emissions. Our framework incorporates a machine learning-enhanced vehicle-specific energy consumption model for conventional, hybrid and battery electric powertrains and considers various constraints, including budget and charging capacity. Using a case study of the Pioneer Valley Transit Authority, we evaluate competing strategies in terms of fleet composition and timeline, analyze vulnerabilities and provide recommendations. By empowering fleet managers with informed decision-making capabilities, our research contributes to the acceleration of sustainable transportation and the reduction of greenhouse gas emissions.

Exploring the Intersection of Machine Learning and Discrete Optimization: Techniques and Applications

Community Committee Choice Session

Session Chair: Mikhail Bragin, University of California, Riverside, Riverside, CA
Session Chair: Bing Yan, Rochester Institute of Technology, Rochester, NY
Session Chair: Anbang Liu, 1</sup

1 Learn to Solve Large-Scale Job Shop Scheduling by Integrating Machine Learning and Mathematical Optimization

Anbang Liu[1], Peter B. Luh[2], Kailai Sun[1], Mikhail Bragin[3], Bing Yan[4], [1]Tsinghua University, Beijing, China; [2]University of Connecticut, Storrs, CT, [3]Southern California Edison, Rosemead, CA, [4]Rochester Institute of Technology, Rochester, NY, Contact: liuab19@mails.tsinghua.edu.cn

In this talk, we focus on machine learning (ML) for complex job-shop scheduling problems. However, direct learning suffers from difficulties in large-scale instances. To overcome this, we developed a novel approach that integrates ML methods within the price-based decomposition-and-coordination framework of the Surrogate Lagrangian Relaxation. Specifically, the approach involves learning to solve part subproblems, which are easier to learn by establishing surrogate subproblems, developing a DNN based on Pointer Network, and devising a masking mechanism for feasibility. The numerical results on several large-scale instances demonstrate that subproblem solutions can be obtained based on predictions in less than 0.01 seconds, and high-quality overall solutions are thus obtained in a computationally efficient manner.

2 Synergistic Integration of Interpretable Machine Learning and Mathematical Optimization for Sub Hourly Unit Commitment

Jianghua Wu[1], Bing Yan[2], Yonghong Chen[3], Zongjie Wang[1], Mikhail Bragin[4], [1]University of Connecticut, STORRS, CT, [2]Rochester Institute of Technology, Rochester, NY, [3]National Renewable Energy Laboratory, Golden, CO, [4]Southern California Edison, Rosemead, CA, Contact: bxyeee@rit.edu

To adapt to renewable intermittency and to enhance power system flexibility, sub-hourly Unit Commitment (UC) has been suggested. However, for sub-hourly UC, traditional optimization is time-consuming, and machine learning (ML) poses feasibility concerns. To resolve these difficulties, an ML model combining Gated Recurrent Units, Attention, and Masking Operations is utilized to swiftly predict subproblem solutions within our advanced decomposition and coordination framework. Compared to the overall solution of the entire problem, subproblem solutions are much easier to learn. Moreover, the learning process based on "shadow prices" is highly interpretable and consistent with the supply-demand principle. ML successfully predicts 78% of subproblem solutions in <1% of total CPU time, and this ratio is expected to be further increased through advanced ML models.

3 Deep Learning-Based Transmission Line Screening for Unit Commitment

Farhan Hyder, Sriparvathi Bhattathiri, Bing Yan, Michael Kuhl, Rochester Institute of Technology, Rochester, NY, Contact: fh6772@rit.edu

Unit commitment is a challenging discrete optimization problem in power systems. A way to obtain high-quality solutions fast is to remove redundant network constraints. Traditional optimization methods are too conservative while machine learning methods fail to maintain feasibility. To resolve these issues, a novel regression-based classification deep-learning approach is developed to safely identify redundant constraints by capturing the temporal relationships between past line-loading levels, nodal demands, and future line-loading levels. Once trained, the model can be used under different classification thresholds. Results show that CPU time reduces by 60% by safely removing 75% of network constraints while maintaining the same solution quality. The approach can be extended to identify redundant constraints in other discrete optimization problems.

Empirical Insights into Platform Service Delivery and Health Equity

Community Committee Choice Session

Session Chair: Ming Hu, University of Toronto, Minneapolis, MN

Session Chair: Zhoupeng Zhang, NULL, NULL

1 An Empirical Analysis of the Impact of On-Time Delivery on a Grocery Platform

Hailong Cui[1], Guo Li[2], Na Li[3], [1]University of Minnesota, Minneapolis, MN, [2]Beijing Institute of Technology, Beijing, China; [3]Nankai University, Tianjin, China

We empirically study the effects of early or late delivery of grocery orders on an online platform in terms of customer's subsequent order frequency, order amount and order size. We collect unique panel data sets from the online grocery delivery platform and use piecewise regression models and generalized method of moments (GMM) as empirical strategies to identify the effects.

2 Designing a Mental Health Service Recommender System: Sensing and Responding to the Personalized Support Needs and Advancing Equity in Mental Healthcare Delivery

Yi Tang[1], Kingshuk K. Sinha[2], Adam Moen[3], [1]Carlson School of Management, Minneapolis, MN, [2]University of Minnesota SCO, Minneapolis, MN, [3]Real EmPowerment Solutions Inc., Minneapolis, MN, Contact: tangx688@umn.edu

Online platforms have recently become a space where people with mental health concerns would gather and exchange peer support. However, such platforms lack the ability to refer users to mental health services when chatting in online platforms is not enough. In this study, we develop a mental health service recommender system to address this need. By applying natural language processing techniques, the system is capable of capturing the core concern of users, interacting with users via a chatbot, and finally providing them with personalized recommendations to care options, taking into consideration of their preferences for mental health providers such as gender, experience serving certain sexuality / race-ethnicity populations. We develop this recommender system following an intervention study approach by collaborating with a panel of mental health professionals.

3 Timing Matters:Sourcing On-Demand Workers on Freight Matching Platforms

Guangwen (Crystal) Kong[1], Ziqi Dong[1], Jingxuan Geng[1], Qiuping Yu[2], [1]Temple University, Philadelphia, PA, [2]Georgetown University, Washington, DC, Contact: guangwen.kong@temple.edu

We study the time that a freight matching platform sourcing truck drivers

4 Product Development in Crowdfunding: Theoretical and Empirical Analysis

Sidika Tunc Candogan[1], Philipp Benjamin Cornelius[2], Bilal Gokpinar[3], Ersin Korpeoglu[4], Chris S. Tang[5], [1]NUS Business School, Singapore, Singapore; [2]Rotterdam School of Management, Rotterdam, Netherlands; [3]UCL School of Management, London, United Kingdom; [4]University College London, London, United Kingdom; [5]University of California-Los Angeles, Los Angeles, CA, Contact: sidika.c@nus.edu.sg

We study an entrepreneur's product development and improvement decisions in crowdfunding. Analyzing a game-theoretical model and testing its predictions empirically, we show that as the product's level of enhancement at campaign launch increases, the likelihood of product improvement during a campaign first increases and then decreases. Furthermore, although our theoretical model intuitively predicts that the likelihood of campaign success always increases with the level of enhancement at campaign launch, our empirical analysis shows that the likelihood of campaign success first increases but then decreases. This counterintuitive result may be due to customers being overwhelmed with the complexity of highly enhanced products.

New Advances in Low-Rank Optimization

Community Committee Choice Session

Session Chair: Ryan Cory-Wright, MIT, Cambridge, MA

1 On the Partial Convexification of the Low-rank Constrained Optimization

Yongchun Li, Weijun Xie, Georgia Institute of Technology, Atlanta, GA, Contact: ycli@gatech.edu

The low-rank constrained optimization arises in various machine learning and optimization problems. It minimizes a linear objective function subject to multiple linear inequalities and a low-rank domain set, which is generally NP-hard. A viable approach is to convexify the domain set, known as "partial convexification"; however, its solution quality lacks theoretical guarantees. To fill this gap, (i) we investigate when the partial convexification is exact; and (ii) we guarantee the worst-case rank of the partial convexification solution. To solve the partial convexification, we develop a column generation algorithm combined with a rank-reduction algorithm, which ensures that the output solution satisfies the theoretical guarantees. Finally, we numerically verify the strength of the partial convexification and the efficacy of the proposed algorithms.

2 Sparse and Low Rank Matrix Decomposition: A Discrete Optimization Approach

Nicholas Andre G. Johnson, Massachusetts Institute of Technology, Cambridge, MA, Contact: nagj@mit.edu

We study the Sparse Plus Low-Rank decomposition problem (SLR) - a fundamental problem in Operations Research and Machine Learning which arises in various applications. We introduce a novel formulation for SLR for which we develop an alternating minimization heuristic that computes high-quality solutions and a novel semidefinite relaxation that provides meaningful bounds for the solutions returned by our heuristic. We also develop a custom branch-and-bound algorithm to solve small instances of SLR to certifiable (near) optimality. Given an input n-by-n matrix, our heuristic scales to n=10000 in minutes, our relaxation scales to n=200 in hours, and our branch-and-bound algorithm scales to n=25 in minutes. Our numerical results demonstrate that our approach outperforms existing state-of-the-art approaches while maintaining a comparable runtime.

3 Optimal Low-Rank Matrix Completion: Semidefinite Relaxations and Eigenvector Disjunctions

Ryan Cory-Wright[1], Dimitris Bertsimas[2], Sean Lo[3], Jean Pauphilet[4], [1]Imperial College London, London, United Kingdom; [2]Massachusetts Institute of Technology, Cambridge, MA, [3]MIT, Cambridge, MA, [4]London Business School, London, United Kingdom

Low-rank matrix completion consists of computing a matrix of minimal complexity that recovers a given set of observations as accurately as possible. Unfortunately, existing matrix-completion methods are heuristics that, while highly scalable, do not possess optimality guarantees. We reexamine matrix completion with an optimality-oriented eye, by reformulating low-rank matrix completion as a convex problem over the non-convex set of projection matrices, and proposing a disjunctive branch-and-bound scheme that solves low-rank problems to provable optimality. In numerical experiments, we showcase the performance of our branch-and-bound method and demonstrate that it solves problems over 150 x 150 matrices to optimality in hours.

Quantum Linear Algebra and Optimization

Community Committee Choice Session

Session Chair: Mohammadhossein Mohammadisiahroudi, Lehigh University, Bethlehem, PA

1 Inexact Feasible Quantum Interior Point Methods for Linear and Semidefinite Optimization

Tamas Terlaky[1], Mohammadhossein Mohammadisiahroudi[2], Ramin Fakhimi[2], Brandon Augustino[3], Giacomo Nannicini[4], Luis F. Zuluaga[2], [1]Lehigh University, Bethlehem, PA, [2]Lehigh University, Bethlehem, PA, [3]Lehigh University, Landing, NJ, [4]University of Southern California, Los Angeles, CA, Contact: terlaky@lehigh.edu

We apply Quantum Linear System Algorithms (QLSAs) to Newton systems within Interior Point Methods (IPM) to gain quantum speedup in solving linear and semi-definite optimization problems. Due to their inexact nature, direct use of QLSAs lead to inexact infeasible variants of IPMs (II-IPMs). By developing novel Newton systems, we propose Inexact-Feasible IPMs (IF-IPMs) that compute inexact but feasible iterations. We show that IF-IPMs enjoy the to-date best iteration complexity. Further, we explore how iterative refinement schemes can be used efficiently both at the QLSA and optimization problem levels to find an exact optimal solution without excessive calls to QLSAs.

2 New Developments to Reduce Cost Per Iteration in Interior Point Methods

Mohammadhossein Mohammadisiahroudi[1], Ramin Fakhimi[1], Brandon Augustino[2], Zeguan Wu[1], Giacomo Nannicini[3], Tamas Terlaky[1], [1]Lehigh University, Bethlehem, PA, [2]Lehigh University, Landing, NJ, [3]University of Southern California, Los Angeles, CA, Contact: mom219@

lehigh.edu
Interior Point Methods (IPMs) are the most prevailing methods to solve linear optimization problems with fast convergence. However, the cost per iteration can be considerably high for large-scale problems. We highlight how quantum linear system algorithms can reduce the cost per iterations in IPMs. However, the significant challenge is that the efficiency of these methods depends on the condition number of the coefficient matrix. It is known that the condition number of the linear systems arising in IPMs may grow to infinity as optimality is approached. To address this challenge, we use three tools: iterative refinement methods, preconditioning, and regularization. We also compare the performance of these methods from both the theoretical and practical aspects.

3 Hybrid Quantum-classical Algorithms For Linear Optimal Control
Jiaqi Leng[1], Connor Clayton[2], Yiling Qiao[2], Kaiqing Zhang[3], Ming Lin[2], Xiaodi Wu[4], [1]University of Maryland, College Park, College Park, MD, [2]University of Maryland, College Park, College Park, MD, [3]University of Maryland, College Park, College Park, MD, [4]University of Maryland, College Park, College Park, MD, Contact: jiaqil@umd.edu
Linear optimal control naturally arises in the control of linear dynamical systems and constitutes the foundation of nonlinear control theory. Given their simplicity, linear control problems could still be challenging for classical computers due to high dimensionality. In this paper, we propose an efficient hybrid quantum-classical algorithm for the Linear-Quadratic Regulator (LQR). The quantum advantage of our algorithm is established. The hybrid design significantly reduces the quantum resources (qubits, coherent times, etc.) required by our algorithm, making it feasible on early fault-tolerant or even near-term devices. Furthermore, we show that our hybrid quantum-classical algorithm is readily adapted to solve nonlinear control problems via linearization. Numerical simulations of our algorithm for both linear and nonlinear control are presented.

4 Fast Algorithms for Quantum Signal Processing
Yulong Dong[1], Jiasu Wang[1], Xiang Meng[2], Hongkang Ni[3], K. Birgitta Whaley[1], Lin Lin[1], [1]University of California, Berkeley, Berkeley, CA, [2]MIT, Cambridge, MA, [3]Stanford University, Stanford, CA, Contact: dongyl@berkeley.edu
The recently developed quantum singular value transformation (QSVT) provides a unified viewpoint of a large class of practically useful quantum algorithms. At the heart of QSVT is a perhaps new way of representing polynomials, called quantum signal processing (QSP), which encodes a polynomial using parameterized products of matrices in SU(2). For a given polynomial, finding the parameters (called "phase factors") is a challenging problem. I will introduce optimization based fast algorithms, which are able to solve a large-scale QSP problem parameterized by more than 10,000 phase factors. I will then discuss the energy landscape of the optimization problem, which allows us to solve the open problem of finding phase factors using only standard double precision arithmetic operations.

CC-North 232C
Sustainability and Energy
Contributed Session
Session Chair: Alva Dillon, Alva Dillon, Tyngsborough, MA

1 Optimal Decision Tree-Based Feature Selection for Enhanced Renewable Carbon Content Quantification in Co-Processed Fuels
Liang Cao, Kaixun Hua, Yankai Cao, University of British Columbia, Vancouver, BC, Canada. Contact: huakaixun@gmail.com
Addressing the challenge of accurately quantifying renewable carbon in co-processed fuels, we propose a method utilizing an optimal decision tree model. Existing methods are designed to process the feature selection on the whole dataset, without considering different working conditions. Our approach partitions the dataset into subsets based on the decision tree model. Each subset independently establishes a robust linear regression model, using features from the corresponding decision tree prediction path. This method has demonstrated its effectiveness in real-world oil refining data, offering a precise renewable fuel content assessment tool.

2 Optimal Subsidy Policy to Manage Solar Adoption in a Region
Swapnil Rayal, University of Washington, Seattle, WA, Contact: srayal@uw.edu
A central planner of a region aims to achieve a certain level of solar adoption at the end of the planning horizon. The two products available in the region are roof-top and subscription solar. The region is heterogenous in the household income and the demand for electricity. We model the demand evolution as a stochastic differential equation and derive a closed form expression for the distribution of optimal adoption time of each income level for a given subsidy using a optimal stopping formulation. Using the

derived distribution function of random adoption times and given income distribution, we develop a contrainted non-linear optimization model to derive optimal subsidy policy to ensure fair and efficient solar adoption in presence of heterogenity in the region.

3 Electric Vehicle Routing Problem with Dynamic Pricing and Carryover

Chihiro Maeda, Hiroshi Morita, Osaka University, Suita, Japan. Contact: chihiro.maeda@ist.osaka-u.ac.jp

The trend toward decarbonization has led to the introduction of EVs in the home delivery business. In addition, the oversupply of electricity during the daytime due to solar power generation is causing electricity prices to fluctuate depending on the time of day. In this study, we propose a mathematical model to determine the optimal delivery route and charging plan in response to fluctuating electricity prices. In addition, we also consider the electricity price not only on the day of the delivery but also on the following day.

4 Data Monitoring for Environmental Safety

Alva Dillon, Brandeis University, Waltham, MA, Contact: devondillon333@gmail.com

The C-10 Research & Education Foundation has been operating a 24-hour radiation monitoring network in communities surrounding the Seabrook Station nuclear power plant since 1991.Through actively monitoring and analyzing radiation levels C-10 provides valuable insight regarding potential radiation hazards to ensure the safety of the community.To meet their needs we developed an interactive application using the Python framework Streamlit. The application allows authenticated users to visualize the radiation time series and related wind data over a desired time frame.Specific users can also update the database with the most recent data using an automated procedure.The program's user-friendly interface empowers the organization's experts to quickly analyze and communicate radiation information to stakeholders.

Negotiation Models

Community Committee Choice Session

Session Chair: Eduarda Asfora Frej, Universidade Federal de Pernambuco, Recife, Brazil

1 The Consequences of Preference Correlation for Fair Division of Indivisible Items

Fahimeh Ziaei, Wilfrid Laurier University, Waterloo, ON, Canada

The fair allocation of indivisible items among multiple individuals is a fundamental problem in collective decision-making. In this paper, we consider only the problem of allocating two of four indivisible items to each of two players based on strict rankings. We Investigate preference correlation (Kendall Tau) and fair allocation properties (envy-free, Pareto-optimal, maximin, max BordaSum). We also examine correlation's impact on Fallback Bargaining, including depth of agreement and a (two-way) tie probability. Our results suggest that as preferences correlate more, Pareto-optimal and maximin allocations increase, while envy-free allocations decrease. Correlation also makes Fallback Bargaining less compelling. We provide insights into the trade-offs between allocation properties and preference correlation in fair allocation of indivisible items.

2 Bargaining-Based Surplus-Sharing Rules for Restoring Equality

Juan C. Gómez[1], P.V. Balakrishnan[2], [1]University of Washington, Bothell, Bothell, WA, [2]University of Washington, Bothell, WA, Contact: jcgomez@uw.edu

We consider surplus-sharing problems where a fixed amount of money is allocated among agents with different claims. We introduce two new rules that are inspired by bargaining solution concepts and aim to reduce inequality among agents. We show that these rules are part of a parametric family of surplus-sharing rules and contrast them with traditional proportional rules. We analyze their properties and performance in various settings.

INFORMS Minority Issues Forum (MIF) Early Career Award 2023

Award Session

Session Chair: Wesley Javier Marrero, Thayer School of Engineering at Dartmouth, Hanover, NH

1 2023 Informs MIF Early Career Award Presenter

Wesley Javier Marrero, Thayer School of Engineering at Dartmouth, Hanover, NH

The INFORMS Minority Issues Forum (MIF) Early Career Award recognizes outstanding contributions to the theory or practice of OR/MS *and* service made by early career, active members of MIF. The award recognizes exceptional researchers who have shown promise early in their academic or industrial career. Scholars who are pre-tenure and within 8 years of receiving their doctorate (or equivalent) degree are eligible to apply.

2 Melding Socio-theoretical Principles and Optimization into Novel Decision Technologies

Adolfo Escobedo, North Carolina State University, Raleigh, NC

In recent years, there has been a growing interest in the development of decision-making mechanisms that infuse socio-theoretical principles. Such efforts are meant in part to serve as a counterbalance against "black box" decision-making technologies, and they have led to improved outcomes in business, technology, and various other domains. Yet, real-world implementation of the more robust methodologies—in the sense that their outputs guarantee desirable socially beneficial properties—remains severely limited due to a combination of incompatible assumptions and computational challenges.

The first part of this talk will highlight our prior work in melding novel socio-theoretical insights and optimization techniques to make theoretical and computational advances in two research areas. One is preference aggregation, where we have derived exact and inexact methods with formal guarantees and introduced social choice concepts to handle preference data that may be high-dimensional, incomplete, and/or contain ties. The other is territorial districting, where we have developed optimization models and algorithms for satisfying definite planning criteria that are beneficial to logistics and service applications. The talk will also summarize additional prior contributions and future research directions.

The second part this talk will provide an overview of my prior service activities, with a focus on ongoing efforts to provide broader educational and research opportunities to undergraduate and master's students. This includes the organization of a summer research internship program, four years running, for students from various universities in the U.S. and abroad

Modeling to Improve Local Communities

Community Committee Choice Session

Session Chair: Emily L. Tucker, Clemson University, Clemson, SC

Session Chair: EunSu Lee, New Jersey City University, Jersey City, NJ

1 Improving Equity in Access to Local Parks

Emily L. Tucker, Clemson University, Clemson, SC

Local parks are foundational for neighborhoods and communities. Yet, disparities persist in who has access to high-quality parks. We present a model to optimize locations for new parks by minimizing inequity in access. Access is a function of distance, crowding, and environmental factors. We consider a case study of Asheville, NC and evaluate several policies to improve access.

2 An Investigation into Retirement Decision-Making

Mehrnaz Behrooz, Ilbin Lee, Ivor Cribben, University of Alberta, Edmonton, AB, Canada. Contact: mbehrooz@ualberta.ca

Retirement, as a significant life transition, requires careful planning and decision-making. Our research leverages the data revolution to optimize retirement decision-making. By combining the analysis of rich aging date resources with advanced optimization models, we strive to enhance the retirement planning process. Using longitudinal data on aged individuals, we identified which and how different factors affect retirement decisions and developed a mathematical model to personalize the optimal age of retirement and retirement saving plans. These findings have implications for policy-makers to improve pension programs, while individuals can make more informed decisions on retirement planning, ultimately enhancing their retirement outcomes.

3 Predicting and Understanding Residential Water use with Interpretable Machine Learning

Benjamin Rachunok[1], Sarah Fletcher[2], Aniket Verma[2], [1]North Carolina State University, Raleigh, NC, [2]Stanford Universty, Stanford, CA, Contact: barachun@ncsu.edu

Predicting household water use is critical to efficiently manage urban water resource systems. Current approaches examining residential water use either identify the drivers of household water through parametric or non-parametric statistical approaches. Here, we use recent advances in interpretable machine learning to understand the drivers of residential water use. Specifically, we use post-hoc interpretability methods to examine how drivers of water use interact, focusing on environmental, demographic, physical housing, and utility policy factors. We find all four categories of factors are important for estimating water use with environmental and utility policy factors playing the largest role. We show this approach provides high predictive accuracy and identification of complex water use factors, offering important insight for urban water management.

4 Where is Oasis in Urban Dessert? Using GIS and Location Analytics

EunSu Lee, New Jersey City University, Jersey City, NJ

This study demonstrates a community mapping approach in community-engaged learning to investigate grocery stores selling fresh food in an urban desert. Spatial analytics using geographic information systems is utilized to map the locations and potential locations of oases in the urban desert.

Humanitarian and Disaster Response Logistics

Community Committee Choice Session

Session Chair: zhili Tian, NULL

1 Mobilizing Firms for Climate Action: Paris Climate Agreement, National Instutions, and Corporate Green Bonds

Yifan Wei[1], Kenneth Guang-Lih Huang[2], Ya Gao[3], [1]University of Manitoba, Winnipeg, MB, Canada; [2]National University of Singapore, Singapore, Singapore; [3]University of Manitoba, Winnipeg, MB, Canada. Contact: ya.gao@umanitoba.ca

We examine firms' voluntary environmental practices under mounting regulatory pressure and consider a quasi-natural experiment to identify the causal effect of the Paris Climate Agreement on the issuance of corporate green bonds (CGBs), a new financial instrument for sustainability. Using a difference-in-differences analysis, we find that firms in the affected industries are more likely to issue CGBs after the Agreement than firms in the minimally affected industries. Also, such effect is stronger in countries with more media attention but weaker in countries with stronger legal enforcement. Our study contributes to the management literature on corporate environmental behaviors by highlighting the temporal dimension of firms' responses to the changing institutional environment and adds to the burgeoning literature on green financing.

2 Social Determinants of Health: Multi-Level Models to Understand Spatiotemporal Variation of Social Vulnerabilities During Hurricane-Pandemics

Arda Vanli, Florida A&M University, Florida State University (FAMU-FSU) College of Engineering, Tallahassee, FL, Contact: oavanli@eng.fsu.edu

A spatiotemporal modeling approach is proposed to understand spatially varying social, demographic and health drivers of pandemic spread during hurricanes from longitudinal infection data collected from geographical units. A multilevel mixed-effects model is developed to investigate the association between census tract-level Covid-19 case count trajectories and demographic, socioeconomic and health factors. A case study for modeling the spatiotemporal variation of social vulnerability with data from Covid-19 pandemic and Hurricane Sally in Florida is presented to illustrate the application of the approach.

3 Truckload Transportation Procurement During Disasters

Shraddha Rana, Massachusetts Institute of Technology, Cambridge, MA, Contact: srana@mit.edu

During disasters, as the demand for truckload transportation increases to stock up and distribute emergency supplies, the ability decreases due to infrastructure damage. With the increase in frequency of natural disasters it is important to model historical impact in order to be prepared for transportation procurement for future disasters. First, we quantify the causal effects of disaster conditions and public sector disaster relief activities on private sector truckload transportation spot prices. For this we use a difference-in-difference methodology. Next, we assess the efficiency of existing truckload transportation procurement process for disaster relief use by public sector and identify improved alternate strategies. We use a segmentation approach for the same and test it on a real life case study of Hurricane Ian.

Service Science Best Student Paper Award Competition (I)

Award Session

1 A Multi-Treatment Forest Approach for Analyzing the Heterogeneous Effects of Team Familiarity

Minmin Zhang[1], Guihua Wang[2], Wallace J. Hopp[3], Michael Mathis[4], [1]University of Texas at Dallas, Richardson, TX, [2]The University of Texas at Dallas, RICHARDSON, TX, [3]University of Michigan, Ann Arbor, MI, [4]University of Michigan Medical School, Ann Arbor, MI

Extensive research has revealed that prior collaborative experiences among team members (called "team familiarity") enhance outcomes of group work in many different environments. In this study, we examine the effect of team familiarity on surgery duration and extend the literature on team dynamics by examining whether the effect of team familiarity is heterogeneous across patients. We find (1) an increase in team familiarity score, especially the anesthesiologist-nurse and surgeon-anesthesiologist familiarity scores, significantly reduces surgery duration, and (2) the effect of team familiarity is heterogeneous across patients with different features. Finally, we develop an optimization model to assess the value of leveraging the heterogeneous effects of team familiarity to better match surgical teams with patients.

2 Pricing Under The Generalized Markov Chain Choice Model: Learning Through Large-scale Click Behaviors

Mo Liu[1], Junyu Cao[2], Zuo-Jun Max Shen[1], [1]University of California Berkeley, Berkeley, CA, [2]The University of Texas at Austin, Austin, TX

We study how to leverage large-scale random click behaviors of customers for online retailers in the pricing problem. We present a new click model that is developed based on the generalized Markov chain choice model (GMCCM), which we justify both theoretically and empirically using real-world data. Based on our click model, we propose a data-driven framework to learn customers' browsing and purchasing behaviors from the click data, where we consider the low-rank structure of the transition matrix. For the static pricing problem, our theoretical results reveal that a higher click rate does not necessarily lead to higher optimal prices. For the dynamic pricing problem in the online setting, we design an exploration-free algorithm and prove a significantly lower regret bound compared to the algorithms that do not consider the low-rank structure of the transition matrix.

3 Can Predictive Technology Help Improve Acute Care Services? Investigating the Impact of Virtual Triage Technology Adoption

Jiatao Ding[1], Michael Freeman[1], Sameer Hasija[2], [1]INSEAD, Singapore, Singapore; [2]Insead, Singapore, Singapore

This paper investigates the operational implications and policy impacts of virtual triage adoption within the acute care service setting. A central problem in this context is patients' (in)ability to self-triage accurately, a notable contributor to emergency department overcrowding and treatment delays. While traditional triage solutions, such as phone services, can mitigate these issues to an extent, they struggle with accessibility and accuracy problems. However, recent developments in predictive analytics have led to the development and deployment of virtual triage tools, which offer immediate, cost-effective, and potentially more accurate triage recommendations. Despite their potential benefits and increasing adoption, the impact of virtual triage tools on healthcare systems remains poorly understood. This paper, therefore, develops a queueing game model to examine how virtual triage influences patient behavior and system performance, and explores policy actions that maximize the operational advantages of these tools. Our findings underline the pressing need for effective regulation and thorough assessment of operational consequences to harness the full potential of virtual triage in improving acute care system performance.

4 Optimizing Equitable Resource Allocation In Parallel Any-scale Queues With Service Abandonment And Its Application To Liver Transplant

Shukai Li, Sanjay Mehrotra, Northwestern University, Evanston, IL

We study the problem of equitably and efficiently allocating resources, modeled as service rates, to multiple queues with abandonment. The problem is motivated by the national liver allocation system, which includes numerous small-scale patient waitlists in terms of arrival intensities, with the possibility of patients abandoning (death) until the required service is completed (matched donor livers arrive). We model each waitlist as a GI/MI/1+GI queue. To evaluate the queue performance, we develop a finite approximation method, which is further used within an optimization model. We find that increasing the proportion of livers allocated to waitlists with small scales or high abandonment (death) risks improves allocation equity. This suggests a proportionately greater allocation of organs to smaller transplant centers and those with more vulnerable populations.

Data Analytics in Social Media Platforms

Community Committee Choice Session

Session Chair: Sagar Mahesh Badve, Virginia Tech, Blacksburg, VA

1 Branding Effects in the Era of Content Entrepreneurship: Decoding Consumer Associations with Family and Individual Content Creators

Gajanan L. Ganji, Stephanie Brooke Escudero, The University of Texas at Arlington, Arlington, TX, Contact: gajananlaxmanra.ganji@mavs.uta.edu

We seek to answer the questions (1) What cognitive associations do family content-creators evoke in the minds of consumers? and (2) How do these perceptions affect interactions in the comments? To do so, we examine differences between family and individual YouTube channels on the six Organizational Virtue Orientation (OVO) dimensions - Integrity, Empathy, Warmth, Courage, Conscientiousness, and Zeal. We hypothesize that, similar to "family-owned" firms, family YouTube channels demonstrate higher levels of OVO, positively influencing consumer perception. We discuss domain-specific implications for the established role of family branding on consumer perception in the context of content creation-based platforms.

2 Everyone Can Communicate in Emergencies, UGC Aids EMS

Varada Krishnaswamy, Virginia Tech, Chantilly, VA

Information systems research can help organizations use social media data for crisis management by promoting its benefits and overcoming organizational and technological constraints. Everyone can communicate in emergencies. User-generated content can help EMS. Researchers in information systems could create a social media analytics tool for crisis management that provides customizable filter functions while maintaining a high level of usability even under duress.

3 Through the Eyes of Employees: Measuring Firm Reputation Using Glassdoor Data

Siddhi Nair, Roopa Ramesh Desai, Gajanan L. Ganji, The University of Texas at Arlington, Arlington, TX, Contact: siddhi.nair@mavs.uta.edu

In this paper, we draw from research in information systems on topic modeling and strategic management to conceptualize firm reputation using employee reviews and measure its implication on an organization's market impression. Building on firm reputation literature and positioning employees as key stakeholders, our hypotheses elaborate on the relationship between key themes emerging from employee reviews and different firm performance measures and how the underlying themes are distinct from commonly used rankings.

TIMES Best Dissertation Award

Award Session

Session Chair: Hyunwoo Park, Seoul National University, Seoul, Korea, Republic of

1 Exploit or Explore? an Empirical Study of Resource Allocation in Scientific Labs

Ran Zhuo, University of Michigan, Ross School of Business, Ann Arbor, MI

Allocating innovation resources to their most productive uses is a challenge because innovators have incomplete information about which projects are productive. I empirically study how a group of large scientific labs traded off the exploitation of safe projects to maximize short-term productivity versus the exploration of high-variance projects to acquire information and improve long-term productivity. To recover how these labs made the tradeoff, I estimate a dynamic decision model, assuming the labs approximated the value of exploration with an Upper Confidence Bound (UCB) index. The model captures the labs' decisions well. Estimates of its free parameters suggest that the labs explored extensively. Counterfactual simulations show that, had the labs not explored, their output quantity would have decreased by 51%, and their citations would have decreased by 57%.

2 Impacts of Innovative Technologies and Services in Supply Chain via Mobile Apps

Zenan Zhou, Arizona State University, Tempe, AZ

This dissertation examines the profound impact of emerging mobile app technologies on diverse supply chain stakeholders like carriers, brokers, and customers. It investigates how these innovations affect productivity, profitability, and customer welfare, recognizing the mutual evolution of business practices and technology innovations. Adopting a dynamic competition perspective, the dissertation empirically explores in-app baggage tracking's impact on airlines' baggage operations, and the effects of digital freight matching apps on carriers/brokers and their spillover effects from trucking to air freight, respectively. The findings reveal non-trivial benefits and potential challenges of mobile app innovations, offering actionable insights.

3 From Shakira to Van Gogh: Operations for the World of Culture

Abhishek Deshmane, Georgia Institute of Technology, Barcelona, Spain

Cultural markets encompass diverse sectors like music, art, and tourism, holding economic and social significance. The advent of digitalization has facilitated the analysis of production and consumption data, offering insights into this sector. This dissertation employs an Operations Management perspective to investigate two themes: (I) Product Innovation and Diffusion to study product portfolios, and (II) Sequential Consumption of Experiences directed towards experience curation. Theoretical contributions link service and people-centric operations, vital for capturing cultural sector nuances. Empirical models utilizing retrospective and experimental data establish causal links, while analytical models provide prescriptions. Industry collaborations, including the Van Gogh Museum and Deezer, contribute real-world relevance. The dissertation concludes by summarizing insights from six chapters and suggesting future research avenues for cultural markets.

4 Innovation and Supply Networks

Shubhobrata Palit, Esade, Barcelona, Spain

The doctoral dissertation aims to improve our understanding of how external partners of a firm in its supply chain can drive its innovation. Specifically, it examines the influence of a firm's network of direct buyers and suppliers as a source of external technological knowledge spillovers and, subsequently, on its innovation performance. Such understanding is important for effectively managing technological knowledge, which is critical to enhancing a firm's manufacturing and service capabilities by improving existing products and processes, and generating new products and processes.

5 Behavioral Aspects in Project Management—A Comparison of Agile and Waterfall Project Management

Tobias Lieberum, Technical University of Munich, München, Germany

This dissertation compares agile project management with the traditional waterfall approach in light of human behavior. The first study shows quantitatively higher performance from agile sprints, which mitigate the newly described "Progression Fallacy" present in traditional project management. The second study shows qualitatively ambiguous performance effects from agile sprints. In conclusion, the choice of project management approach should depend on the project.

Disaster Management: Networks and Grids

Community Committee Choice Session

Session Chair: Hootan Kamran, 1</sup

Session Chair: Ozlem Cosgun, Montclair State University, Wayne, NJ

1 Defense Critical Supply Chain Networks and Risk Management with the Inclusion of Labor

Anna B. Nagurney, University of Massachusetts Amherst, Amherst, MA

A rigorous methodological framework is presented for defense critical supply chain networks that captures the behavior of defense firms, who care about revenues as well as risk. Variational inequality theory is used to provide alternative formulations of the governing Nash Equilibrium conditions. A defense supply chain network efficiency/performance measure is proposed and an associated importance indicator for the supply chain network components. A resilience measure is also given that quantifies the resilience of the defense supply chain network economy to disruptions in labor. The modeling and algorithmic framework, as well as the measures, are illustrated via numerical examples.

2 Holistic Asset Management to Counter Dynamic Risks in Power Infrastructure: The Role of Big Data, Iot, and Analytics in Disaster Management

Massoud Amin, Energy Policy & Security Associates, Minneapolis, MN, Contact: massoud@eps-associates.com

Big Data, IoT, and advanced analytics are transforming the power and energy industries. This presentation focuses on the security and resilience of Smart Grids, IoT, Smart Cities, and Big Data in disaster management. Adopting a holistic asset management approach, energy companies can weigh the risks and economics of maintenance, repair, retrofit, and replacement or retirement for infrastructure elements, leveraging capabilities to improve reliability and service quality. Aging infrastructure poses risks like physical vulnerability and cyber threats, leading to system-wide outages. Probabilistic risk management can identify high-risk substations and lines to tailor resiliency investments. Resource allocation can achieve optimal solutions specific to utility needs, legacy systems, location, asset management, and technology roadmap.

3 Assessment of Telehealth Utilization Across Us States During the Covid-19 Outbreak

Ying-Chih Sun[1], Ozlem Cosgun[2], Raj Sharman[3], [1]Bradley University, Peoria, IL, [2]Montclair State University, Wayne, NJ, [3]State University of New York-Buffalo, Buffalo, NY, Contact: ysun@fsmail.bradley.edu

The surge in telehealth utilization during the COVID-19 outbreak results from the need to prevent exposures for providers who demand telehealth to ensure the service's commitment and ease various staffing shortage issues. This research focuses on the efficiency perspective. It investigates the optimal allocation of resources such as healthcare resources and other social determinants of health factors by combining Data Envelopment Analysis (DEA) with ML (ML-DEA) to make a statewide comparison on the efficiency of telehealth utilization.

4 NEEDS TITLE

Atoosa Rezaei, Harrisburg University of Science and Technology, Harrisburg, PA, Contact: arezaei@my.harrisburgu.edu

This proposal outlines a research project on using artificial intelligence (AI) with a cognitive architecture for stock trade prediction and recommendation. The project aims to develop a system that can learn from historical data, analyze current trends, and make accurate predictions about future stock prices. The proposed system will be built on a cognitive architecture that allow the system to use a feedback loop to enable the system to observe the results of the made decisions and enhance its performance over the time.The research will involve the use of machine learning algorithms and neural networks to train the AI model on historical stock data, as well as the evaluation of different cognitive architectures to identify the most effective approach for stock prediction and recommendation.

Graph Mining for Business Intelligence

Community Committee Choice Session

Session Chair: Jeongsub Choi, West Virginia University, Morgantown, WV

1 Competitor Identification in Interfirm Transaction Networks

Jeongsub Choi[1], Byunghoon Kim[2], [1]West Virginia University, Morgantown, WV, [2]Hanyang University, Sangnok-Gu, Ansan-Si, Korea, Republic of

Competitor identification (CI) in complex business environments is essential to establish an effective competitive strategy. Recently, network-based CI methods have been studied in the literature, aiming to shed light on blind spots in the radar of organizations. However, interfirm financial transactions were overlooked in the existing CI, although financial transactions contain critical information as basic business units. In this talk, we present new network-theoretic CI methods based on networks constructed using interfirm financial transactions.

2 Robust Asymmetric Non-Negative Matrix Factorization for Clustering Nodes in Directed Networks

Yi Yu, Rutgers University, Piscatawat, NJ, Contact: yy479@scarletmail.rutgers.edu

Directed networks appear in an expanding array of applications. A critical task in analyzing directed networks is clustering, where the goal is partitioning the network's nodes based on their similarities while accounting for the direction of relationships between nodes. Non-negative matrix factorization (NMF) has been used to cluster the nodes in directed networks efficaciously. However, the errors could deviate from the Gaussian distributions assumed in various real-world networks. In this presentation, we propose a robust asymmetric non-negative matrix factorization method to cluster the nodes in directed networks. The proposed method assumes that the errors follow a Cauchy distribution instead of the Gaussian distribution. Experiments using real world as well as artificial networks show that the proposed method outperforms existing NMF methods.

3 A New Customer Recommendation Method for Identifying Potential Entrants in a B2B Transaction Network

Byunghoon Kim[1], Jeongsub Choi[2], Aparajita Bose[1], [1]Hanyang University, Sangnok-Gu, Ansan-Si, Korea, Republic of; [2]West Virginia University, Morgantown, WV, Contact: bhkim825@gmail.com

A financial transaction network is composed of nodes and links that respectively represent firms and transactions. Link prediction in transaction networks is a useful approach to identify unknown customers of a focal firm, enabling the focal firm to recognize new customers based on predicted links. However, an existing study recommends competitors of the focal firm as new customers, rather than new entrants. To overcome this limitation, we propose a novel method to predict potential customers who are new entrants in the financial transaction network. Additionally, we propose a novel similarity measure to identify new entrants in the network. Our experimental results show that our proposed method outperforms existing work in terms of the AUC score of link prediction.

4 Leveraging Heterogeneity in the Network Structure for Link Prediction in Inter-Firm Transaction Networks

Ali Tosyali, Rochester Institute of Technology, Rochester, NY

Link prediction in inter-firm transaction networks is used to predict future connections between firms based on their past transaction history and it is critical because it can help firms identify potential business partners or customers, as well as assess the risk of doing business with certain firms. In this study, we propose a new link prediction approach that leverages the heterogeneity in the inter-firm transactions. The proposed method is validated using a real-world transaction database.

Data Analytics and Optimization

Community Committee Choice Session

Session Chair: Tulay Flamand, Colorado School of Mines, Golden, CO

1 Online Contextual Decision Making with a Smart Predict-then-Optimize Method

Paul Grigas, UC Berkeley, Berkeley, CA, Contact: pgrigas@berkeley.edu

We study an online contextual decision-making problem with resource constraints. At each time period, the decision-maker first predicts a reward vector and resource consumption matrix based on a given context vector and then makes a decision. The final goal is to maximize the summation of the reward and the utility from resource consumption, while satisfying the resource constraints. We propose an algorithm that mixes a prediction step based on the "Smart Predict-then-Optimize (SPO)" method with a dual update. The regret bound is sublinear and depends on the risk bounds of the surrogate loss used to learn the prediction model. Our algorithm and regret bounds apply to a general convex feasible region for the resource constraints, including both hard and soft constraints, and they apply to a wide class of prediction models in contrast to linear context or finite policy spaces.

2 Towards a Nonparametric Bump Hunting Algorithm in High-Dimensional Data

Rym Nassih, Abdelaziz Berrado, Mohammed V University in Rabat, Rabat, Morocco. Contact: berrado@emi.ac.ma
PRIM is a Bump Hunting algorithm that is used in a supervised learning setting to find regions in the input variables subspace specified by the data analyst, that are associated with the highest or lowest occurrence of a target label of a class variable. We present in this ongoing work a non-parametric version of PRIM that involves all the relevant attributes for rule generation and that provides an additional post processing step for rule pruning and organization.

3 Exponential Tail Bounds and Large Deviation Principle for Heavy-Tailed U-Statistics

Milad Bakhshizadeh, Stanford University, Stanford, CA, Contact: miladba@stanford.edu
We study deviation of U-statistics when samples have heavy-tailed distribution so the kernel of the U-statistic does not have bounded exponential moments at any positive point. We obtain an exponential upper bound for the tail of the U-statistics which clearly denotes two regions of tail decay, the first is a Gaussian decay and the second behaves like the tail of the kernel. For several common U-statistics, we also show the upper bound has the right rate of decay as well as sharp constants by obtaining rough logarithmic limits which in turn can be used to develop LDP for U-statistics. In spite of usual LDP results in the literature, processes we consider in this work have LDP speed slower than their sample size n.

4 Identifying Bayesian Optimal Experiments for Uncertain Biochemical Pathway Models

Natalie M. Isenberg[1], Susan D. Mertins[2], Byung-Jun Yoon[3,1], Kristofer Reyes[4,1], Nathan M. Urban[1], [1]Brookhaven National Laboratory, Shirley, NY, [2]Frederick National Laboratory for Cancer Research, Frederick, MD, [3]Texas A&M University, College Station, TX, [4]University at Buffalo, Buffalo, NY, Contact: nisenberg@bnl.gov
Mathematical models of protein signaling pathways are useful tools for studying the dynamics of novel therapeutic drugs. However, pathway models are known to possess significant uncertainty with respect to parameter data. This uncertainty leads to an inability to discriminate between the performance of different drug molecules. Therefore, we must restore reliable model predictions via parameter uncertainty reduction to use these models for novel drug candidate screening. In this work, we utilize Bayesian optimal experimental design (BOED) and high-performance computing capabilities to identify experimental measurements that decrease uncertainty in key model parameters in a pathway model for PARP1-inhibited cell apoptosis. We show that BOED can constrain the pathway model output and restore model predictability by recommending optimal experiments.

5 AI and Remote Sensing in Port Operations: Estimating Cargo Volume and Identifying Usable Industrial Outdoor Storage for Congestion Alleviation

Minseok Kim, Rutgers University, New Brunswick, NJ
Recent years have witnessed port congestion disrupting the global supply chain, highlighting the need for real-time and affordable monitoring. In response, our research proposes an innovative approach that employs image processing and AI techniques to gauge port operational levels through remote sensing. We deploy advanced segmentation models for cargo identification and shadow extraction techniques on satellite imagery to estimate cargo volume accurately. Moreover, the model identifies alternative storage sites, providing comprehensive solutions to mitigate disruptions. By harnessing diverse data and advanced AI techniques, our research offers insights that enhance operational performance and sustainability, benefiting both academia and industry professionals.

1 Designing Live Streaming Advertisement Per User Engagement: Evidence from a Field Experiment

Keran Zhao[1], Ni Huang[2], Gordon Burtch[3], [1]University of Houston, Stafford, TX, [2]University of Miami, Gilbert, AZ, [3]Boston University, Boston, MA, Contact: krzhao@uh.edu
Digital advertising plays an essential role in the live streaming ecosystem. However, real-time advertising is challenging as the insertion policies can only be evaluated counterfactually. In this study, we propose two engagement-triggered live advertisement policies and conduct a field experiment on Twitch.tv, the most popular live streaming platform worldwide, to evaluate the advertisement performance of the proposed policies. By randomly assigning 677 streams into

three groups, we compare the difference in ad performance and examine the post-ads viewership. The main result shows that ad insertion at a low engagement time point has a higher clickthrough rate and clicks than the insertions for high engagement and base group (every 12 minutes). And the low engagement insertion has lower risks of losing viewers after ads than the high engagement insertion policy.

2 Ai Ground-Truth Uncertainty in Professional Judgment Contexts: Mechanisms and a Paradoxical Approach

Hengqi Tian[1], Arun Rai[2], Angelos Kostis[3], Jonny Holmström[3], [1]University of Colorado Denver, Denver, CO, [2]Georgia State University, Atlanta, GA, [3]Umeå University, Umeå, Sweden

A labeled dataset is the foundation for supervised AI/ML development. In contrast to the dominant objective view on ground truth labels, we aim to uncover and approach ground-truth uncertainty (GTU) inherent in professional judgment contexts. Drawing on human cognition and sensemaking literature, we conceptualize GTU as a multi-faceted phenomenon comprised of both epistemic and interpretive uncertainty and theorize their interplays in shaping data label discrepancies. We further propose a paradoxical perspective to adopt a both/and labeling logic and incorporate multiple "ground truth" labels in training and evaluating ML models. The expected contributions are to provide a novel GTU perspective and a paradoxical approach to transform how we define and generate "ground-truth" labels for AI/ML development in professional judgment contexts.

3 Using Store AI to Enhance Consumer Purchase Decisions by Promoting the Sense of Autonomy

Jinghui Hou[1], Shuai Yang[2], Guiyang Xiong[3], Paul Pavlou[4], [1]University of Houston, Houston, TX, [2]Donghua University, Shanghai, China; [3]Syracuse University, Syracuse, NY, [4]University of Houston, Houston, TX

Many retailers have started using store AI systems to help consumers choose products that "best" fit their preferences, and thus enhance consumer purchase decisions. For AI that is aimed to improve consumers' decisions, it is critical to examine how such an AI can be designed and used to work *for* humans and enhance human decisions. We theorize the mechanism of the sense of autonomy in making decisions with AI to support purchase decisions. Across five lab and two field experiments, we show that promoting consumers' sense of autonomy leads them to consider more of their personal needs and preferences in the decision process, and consequently improve consumer decision-making. We show that a novel design of a smartphone-based store AI can promote the sense of autonomy. With field data, we also show the real-world significance of positive impacts in real-life settings.

4 How Does the Stock Market View Firms' AI-Related Initiatives?

Junyoung Park, Auburn University, Auburn, AL

Recent advances in generative artificial intelligence (AI), such as ChatGPT, have led to increased adoption of similar technologies by firms seeking to enhance their businesses through AI-supported products and labor inputs supplemented by AI. This research examines the financial impact of public announcements of U.S. firms related to generative AI and investigates how this impact varies based on firm characteristics. I also compare the impact with that of general information technology investment announcements. The study aims to provide insights into the disruptive nature of generative AI and its market valuation.

5 The Impact of AI Explanation Timing on Users' Subsequent AI-Aided Decision-Making Performance

Renzhi (Fred) Zhao, Georgia State University, J. Mack Robinson College of Business, Atlanta, GA, Contact: fredrzz@hotmail.com

When artificial intelligence (AI)-aided decision results under-perform, explanations are crucial for enabling adjustment in subsequent decision-making. This study examines how the timing of delivering AI explanations affects subsequent AI use for decision-making. Via the agentic IS artifacts delegation framework and psychological bias theories, I hypothesize that the effects of AI explanation timing on subsequent AI-aided decision-making performance are predicated on the underperformance sources. Pre- or post-outcome AI explanations are most effective when the underperformance source is algorithm limitations or unpredictable environmental factors. I test these hypotheses in a series of experiments involving a financial investing task. The findings contribute to AI transparency literature and offer practical implications for explainable AI design.

Recent Advances on the Unified Frameworks of Stratified Models and Multi-Task/Transfer/Few-Shot Learning

Community Committee Choice Session

Session Chair: Junzi Zhang, Amazon.com Services LLC, Bellevue, WA

1 Incremental Proximal Multi-Forecast Model Predictive Control

Xinyue Shen[1], Stephen P. Boyd[2], [1]Meta, Menlo Park, CA, [2]Stanford University, Stanford, CA, Contact: xinyueshen@outlook.com

Multi-forecast model predictive control (MF-MPC) is a control policy that creates a plan of actions over a horizon for each of a given set of forecasted scenarios or contingencies, with the constraint that the first action in all plans be the same. In this note we show how these coupled plans can be found by solving a sequence of single plans, using an incremental proximal method. We refer to this policy as incremental proximal model predictive control (IP-MPC). We have observed that even when the iterations in IP-MPC are not carried out to convergence, we obtain a policy that achieves much of the improvement of MF-MPC over single-forecast model predictive control (MPC).

2 Graph Neural Networks for Modeling Volatility Spillover Effects

Chao Zhang, Oxford University, United Kingdom

We propose a novel methodology for forecasting multivariate realized volatilities using graph neural networks. This approach extends "Graph-based methods for forecasting realized covariances" and explicitly incorporates the spillover effects from multi-hop neighbors and nonlinear relationships into the volatility forecasts. Our findings provide strong evidence that the information from multi-hop neighbors does not offer a clear advantage in terms of predictive accuracy. However, modeling the nonlinear spillover effects significantly enhances the forecasting accuracy of realized volatilities over up to one week. Our model allows for training with different loss functions, and the results generally suggest that using Quasi-likelihood as the training loss can significantly improve the model performance, compared to the commonly-used mean squared error.

3 Joint Graph Learning And Model Fitting In Laplacian Stratified Models

Junzi Zhang[1], Ziheng Cheng[2], Akshay Agrawal[3], Stephen P. Boyd[4], [1]Citadel Securities, Chicago, IL, [2]Peking University, Beijing, China; [3]Marimo Inc., Palo Alto, CA, [4]Stanford University, Stanford, CA, Contact: saslascroyale@gmail.com

Laplacian regularized stratified models (LRSM) leverage categorical features to enhance parameter learning by drawing data from neighboring groups. LRSM has been widely applied in machine learning and signal processing, however, existing works either assume a known graph or are restricted to specific applications. We propose a generic approach to jointly learn the graph and fit model parameters by solving a single optimization problem, with convergence guarantees and efficient algorithm implementation. Numerical examples demonstrate the efficiency of our approach compared to existing methods.

Machine Learning in Finance

Community Committee Choice Session

Session Chair: Paul Glasserman, Columbia University, New York, NY

1 Neural Optimal Stopping Boundary

Max Reppen[1], H. Mete Soner[2], Valentin Tissot-Daguette[2], [1]Boston University Questrom School of Business, Boston, MA, [2]Princeton University, Princeton, NJ

A method based on deep artificial neural networks and empirical risk minimization is developed to calculate the boundary separating the stopping and continuation regions in optimal stopping. The algorithm parameterizes the stopping boundary as the graph of a function and introduces relaxed stopping rules based on fuzzy boundaries to facilitate efficient optimization. Several financial instruments, some in high dimensions, are analyzed through this method, demonstrating its effectiveness. The existence of the stopping boundary is also proved under natural structural assumptions.

2 Robust Hedging GANs - Towards Automated Robustification of Hedging Strategies

Yannick Limmer[1], Blanka Horvath[2], [1]University of Oxford, Oxford, United Kingdom; [2]University of Oxford, Oxford, United Kingdom. Contact: yannick.limmer@maths.ox.ac.uk

The deep hedging framework has revolutionized hedging under different market conditions. However, models are prone to errors, and deviations from market reality can lead to risks. This raises the question of how to deal with model ambiguity in an automated way. We propose a GAN-based solution using concepts from rough-path theory to automate robustification in hedging. Our method uses a hedging engine, a market generator, and a metric to measure distances between data and beliefs. It can operate independently of the data generating process and is easily adaptable for existing functional settings. We demonstrate this in various examples, and this approach is expected to inspire solutions for related challenges.

3 Deep Learning Statistical Arbitrage

Greg Zanotti[1], Markus Pelger[2], Jorge Guijarro-Ordonez[3], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA, [3]Stanford University, Stanford, CA, Contact: gzanotti@stanford.edu

Statistical arbitrage exploits temporal price differences between similar assets. We develop a unifying conceptual framework for statistical arbitrage and a novel data driven solution. First, we construct arbitrage portfolios of similar assets as residual portfolios from conditional latent asset pricing factors. Second, we extract their time series signals with a powerful machine learning time series solution, a convolutional transformer. Lastly, we use these signals to form an optimal trading policy that maximizes risk-adjusted returns under constraints. Our comprehensive empirical study on daily US equities shows a high compensation for arbitrageurs to enforce the law of one price. Our arbitrage strategies obtain consistently high out-of-sample mean returns and Sharpe ratios, and substantially outperform all benchmark approaches.

4 Does Overnight News Explain Overnight Returns?

Paul Glasserman, Kriste Krstovski, Paul-Robert Laliberte, Harry Mamaysky, Columbia University, New York, NY

Over the past 30 years, nearly all the gains in the U.S. stock market have been earned overnight, while average intraday returns have been negative or flat. We find that a large part of this effect is explained by differences between intraday and overnight news. Our analysis uses a collection of over a million news articles. We apply a novel technique for supervised topic analysis that selects news topics based on their ability to explain contemporaneous market returns. We find that differences in the mix of news topics and differences in the responses to news topics both contribute to the difference in intraday and overnight returns. In out-of-sample tests, our approach forecasts which stocks will do particularly well overnight and particularly poorly intraday.

1 Matchmaking Strategies for Maximizing Player Engagement in Video Games

Mingliu Chen[1], Adam N. Elmachtoub[1], Xiao Lei[2], [1]Columbia University, New York, NY, [2]University of Hong Kong, New York, NY

We propose a general framework to analyze the dynamic matching problem in online video games, aiming to maximize player engagement. Players have different skill levels, which affect the outcomes of matches, and the win-loss record influences their willingness to remain engaged. We fully characterize the optimal matching policy on a stylized model where there are two skill levels, and players churn only when they experience a losing streak. The optimal policy always matches as many low-skilled players who are not at risk of churning to high-skilled players who are one loss away from churning. Compared to the industry status quo that matches players with the same skill level together, we prove the benefit of optimizing the matchmaking system grows linearly with the number of skill levels. Our framework can also handle the addition of AI bots and pay-to-win system.

2 The Challenge of Understanding What Users Want: Inconsistent Preferences and Engagement Optimization

Manish Raghavan, Massachusetts Institute of Technology, Cambridge, MA

Online platforms have a wealth of data, run countless experiments and use industrial-scale algorithms to optimize user experience. Despite this, many users seem to regret the time they spend on these platforms. We suggest the problem stems in part from a mistaken revealed-preference assumption: To understand what users want, platforms look at what users do. Yet we often make choices in the moment that are inconsistent with what we actually want. In this work, we develop a model of media consumption where users have inconsistent preferences. Our model highlights how user engagement and welfare can be at odds with one another. By linking these effects to abstractions of platform design choices, our model thus creates a theoretical framework and vocabulary in which to explore interactions between design, behavioral science, and social media.

3 Optimizing and Learning Assortment Decisions with Platform Disengagement

Mika Sumida[1], Angela Zhou[2], [1]Marshall School of Business, University of Southern California, Los Angeles, CA, [2]USC Marshall School of Business Data Sciences and Operations, Los Angeles, CA

We consider a problem where customers repeatedly interact with a platform. During each interaction with the platform, the customer is shown an assortment of items and selects among these items according to a MNL choice model. The probability that a customer interacts with the platform in the next period depends on the customer's purchase history. The goal of the platform is to maximize the total revenue obtained from each customer over a finite time horizon. First, we study a non-learning version of the problem and prove structural properties of the optimal policy. Next, we provide a formulation in a contextual episodic reinforcement learning setting, where the parameters governing contextual consumer preferences and return probabilities are unknown. We develop an algorithm based on the principle of optimism under uncertainty and provide a regret bound.

4 Diverse Assortments in Online Recommendations

Mahsa Hosseini[1], Shreyas Sekar[2], Opher Baron[2], Azarakhsh Malekian[3], [1]Rotman School of Management, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University of Toronto Joseph L Rotman School of Management, Toronto, ON, Canada

This paper explores the business benefits of incorporating diverse content into recommendation systems, particularly in online marketplaces and platforms that rely on ranking algorithms. While promoting popular content in the short term may improve user engagement, it can also lead to a lack of diversity and undermine the long-term health of the marketplace. In this paper, we make a connection between customer engagement and satiation. We find conditions under which a more diverse policy is optimal. Moreover, we show that optimal policy favors diversity in earlier periods, and after some time, the optimal policy keeps offering the product with the largest value. This implies that a more diverse recommendation is preferred over longer time horizons. We show that we have a satiation threshold policy, determining the optimal policy for any satiation value at every period.

Charging Infrastructure Management for Electric Vehicles

Contributed Session

Session Chair: Kaize Yu, School of Management and Economics, University of Electronic Science and Technology of China, Chengdu, China

1 Electrifying Travels Along the Lake Michigan Circle Tour

Amirali Soltanpour[1], Alireza Rostami[1], Mehrnaz Ghamami[1], Ali Zockaie[1], Jessica Crawford[2], Robert Jackson[3], [1]Michigan State University, East Lansing, MI, [2]Michigan Department of Environment, Great Lakes, and Energy, Lansing, MI, [3]Lawrence Technological University, Southfield, MI

Electric vehicles (EV) are a sustainable substitution for conventional vehicles reducing emissions and fossil fuel dependence. However, alleviating EV's range anxiety requires significant investment in infrastructure. This study proposes an integrated modeling framework to find the optimal location and number of chargers in an interconnected network of destination and fast chargers around Lake Michigan. The main contribution of this study is capturing the variety of travel and charging behaviors and their interconnections. The model minimizes total system costs, including charger, queuing, and detour costs. A metaheuristic algorithm is developed to solve the proposed computationally complex optimization model. Findings suggest that the circuit would benefit from the combination of destination and fast chargers as it has the optimal total system cost.

2 Optimizing Fast Charging Infrastructure for Electric Vehicles in Urban Networks Using an Activity-Based Approach

Alireza Rostami, Amirali Soltanpour, Ali Zockaie, Michigan State University, East Lansing, MI, Contact: alireza.darzian.rostami@gmail.com

This study focuses on optimizing the configuration of fast charging infrastructure for electric vehicles (EVs) in urban networks considering EV users' daily activities, and charging behavior. The study proposes a simulation model for charging behavior that considers factors such as initial state of charge (SOC), travel distance, availability of home chargers, and daily trip schedules. The problem is formulated as a Mixed-Integer Nonlinear Programming that considers travel time and distance dynamics, the interdependency of trips made by each driver, the limited range of EVs, spatiotemporal charging pricing, waiting time in queue, and the detour to charging stations. This problem is solved using a metaheuristic approach for a large-scale case network under different charging powers, battery efficiency, electricity pricing, and utility cost scenarios.

3 Real-Time Optimizing Electric Vehicles' Charging Policy with Battery Degradation Awareness by Using Multi-Agent Reinforcement Learning

Pengyu Yan[1,2], Kaize Yu[2], Yang Liu[3], [1]Yangtze Delta Region Institute (Huzhou), University of Electronic Science and Technology of China, Chengdu, China; [2]School of Management and Economics, University of Electronic Science and Technology of China, Chengdu, China; [3]Department of Civil and Environmental Engineering, National University of Singapore, Singapore, Singapore. Contact: yanpy@uestc.edu.cn

Given the substantial replacement costs associated with electric vehicle (EV) batteries, effectively managing battery depreciation has become increasingly crucial. Because drivers' charging habits can accelerate battery degradation, this paper focused on charging policies for EVs on e-hailing platforms, aiming to maximize driver revenue while minimizing battery degradation in a stochastic environment. We formulate the problem as a Markov decision process and propose an efficient multi-agent reinforcement learning (MARL) approach. The MARL allows each EV (agent) to interact with the environment, facilitating real-time information exchange and updating charging policies. Numerical experiments demonstrate that the learned charging policy can effectively extend the lifespan of EV batteries and increase revenue for drivers simultaneously.

Methods for Traffic Monitoring

Contributed Session

Session Chair: Viswanath Potluri, Arizona State University, Mesa, AZ

1 Learning to Control and Coordinate Hybrid Traffic Through Robot Vehicles at Complex and Unsignalized Intersections

Dawei Wang[1], Weizi Li[2], Lei Zhu[3], Jia Pan[1], [1]University of Hong Kong, Hong Kong, Hong Kong; [2]University of Memphis, Memphis, TN, [3]University of North Carolina at Charlotte, Charlotte, NC

Ever-existing traffic congestion demands an innovative and transformative solution. Robot vehicles have the potential to revolutionize our transportation system, but the timeline of a fully automated transportation system is unknown and the mechanism for smoothing traffic via robot vehicles remains elusive. Observing that a mixture of robot and human-driven vehicles, i.e., hybrid traffic, will be the dominant transport mode in the decades to come, we explore the potential of controlling hybrid traffic by harvesting the latest capability of AI. As a result, we show the first successful evidence of controlling and coordinating hybrid traffic through robot vehicles at complex and unsignalized intersections. This work paves the road for city-scale hybrid traffic control and sheds light on obtaining the hypothetical benefits of integrating robot vehicles into traffic.

2 Integrating Physical Laws into Neural Networks for Enhanced Data Cleaning and Fusion in Traffic Model Calibration

Xiangyong Luo[1], Xuesong Zhou[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: xluo70@asu.edu

This presentation introduces a comprehensive framework that incorporates physical laws into Physics-Informed Neural Networks (PINNs) for traffic model calibration. Leveraging diverse data sources such as Probe Vehicle Data, High-Resolution Vehicle Trajectory Data, Connected and Automated Vehicle (CAV) Data, and Crowd-sourced Platforms Data, this framework addresses the challenges associated with data reliability, accuracy and granularity. By integrating knowledge of physical laws, including conservation laws, flow-density relationships, shockwave theory, car-following models, and lane-changing models, our approach enables accurate prediction and analysis of traffic conditions. The computational graph representation of the model is solved using a forward-backward method, with numerical experiments with real-world datasets.

3 A Customized Column Generation for Network Design and Routing of Patrol Police Vehicles

Asya Atik[1], Leila Hajibabai[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, Raleigh, NC, Contact: aatik@ncsu.edu

This study introduces a novel location-routing approach for optimizing patrol vehicle deployment, combining Lagrangian relaxation and column generation techniques. The approach is integrated with a density-based spatial clustering of applications with noise (DBSCAN) technique that aggregates the demand nodes. The proposed scheme aims to minimize travel time and deployment costs. The algorithm was tested using real-world instance from Raleigh, NC, and the results confirm the efficacy of the proposed methodology. Comparison with current police district limits highlights the potential benefits of implementing the proposed approach in practice to optimize patrol vehicle deployment.

4 Real-Time Proactive Traffic Control of Fully Autonomous Vehicles Through Unsignalized Intersections Using V2x Communication

Viswanath Potluri[1], Pitu Mirchandani[2], [1]Arizona State University, Maricopa, AZ, [2]Arizona State University, Tempe, AZ, Contact: vpotlur1@asu.edu

This abstract centers around *harnessing the data revolution* in the context of proactive traffic control for fully autonomous vehicles at unsignalized intersection without conventional traffic lights. The talk will specifically focus on leveraging *Vehicle-to-Infrastructure (V2I)* and *Vehicle-to-Vehicle (V2V)* communication to enable *real-time* vehicular control. To achieve this, deep *reinforcement learning* techniques will be developed and applied, enabling agent learning that generalizes across various scenarios. The objective is to optimize *traffic flow*, *enhance safety*, and *improve efficiency* in autonomous vehicle interactions at these intersections.

1 Understanding Children’s Digital Maturity: A Machine Learning Approach

Aqib Siddiqui[1], Konstantina Valogianni[2], [1]IE Business School - IE University, Madrid, Spain; [2]IE Business School - IE University, Madrid, Spain. Contact: aqib.siddiqui@student.ie.edu

Our research utilizes sophisticated machine learning to identify patterns of ICT usage in children & analyze their Digital Maturity. Using a data-driven approach we classify children into different categories based on their digital maturity & ICT usage patterns with high accuracy. Our findings suggest that children with high digital maturity are responsible, respectful self-learners, while children with moderate digital maturity lack individual growth. Those with low digital maturity are prone to maladaptive behaviors, cybercrimes & poor wellbeing. Our research provides valuable insights into digital inequalities among children, allowing targeted interventions to alleviate differences & improve family functioning. The implications of this research extend to schools as our results can inform effective programs promoting higher digital maturity in children.

4 Challenges and Opportunities of Using AI for Retail Demand Planning in the Post-Covid World

Sriram Sambasivam, Estee Lauder, Long Island City, NY, Contact: sriramsambasivam@gmail.com

The COVID-19 pandemic has significantly impacted the retail industry, making demand planning more challenging than ever. Retailers are now turning to artificial intelligence (AI) to help with decision-making. This paper examines the challenges and opportunities of using AI for retail demand planning. AI can improve demand forecasting accuracy, optimize inventory levels, and enhance customer satisfaction. However, it also poses challenges like data quality, privacy, and bias, which can be addressed through better data management and algorithmic transparency. The benefits of AI in retail demand planning include cost savings and increased profitability. By leveraging the opportunities and addressing the challenges of AI in retail demand planning, retailers can improve their overall performance and adapt to the rapidly changing market.

2 Simple Two-Stage Forecast Upscaling for Long Horizon Intermittent Demand

Yigit M. Arisoy, Amazon.com Services LLC, Atlanta, GA, Contact: yarisoy@amazon.com

Intraday forecasts have broad applications in the industry. When combined with long-horizon requirements, forecasting at a high temporal resolution is often a challenging problem due to high memory requirements, training times and cost, especially with some Deep Learning models. The problem becomes even more challenging when the data is intermittent / sparse, and when various feature interactions need to be considered. We propose a new method that can convert low temporal resolution (e.g., weekly) forecasts to higher resolution (e.g., intraday) forecasts as a secondary step on top of an existing forecasting model of choice, provided that the higher resolution data is available in the in-sample set. On real-world datasets, our method achieves similar or better results with less costs compared to other methods that directly forecasts at high resolution.

3 A Novel Discretization Method Based on CACC and Ant Colony Optimization

Uijong Hwang[1], Dong-Joon Lim[2], [1]Sungkyunkwan University, Suwon, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of. Contact: huj1024@skku.edu

In this paper, we present a novel multivariate discretization approach that considers feature interactions. Our method begins by generating candidate sets of cut points for each feature using CACC, a popular discretization method. We then employ Ant Colony Optimization to search for the optimal discretization scheme by combining these candidates. The main advantage of our method is its ability to address the limitations of CACC, excessive splitting of continuous features and premature termination of the discretization process, both of which are undesirable for constructing effective discretization schemes. To evaluate our approach, we compared it with three other discretization methods using 23 different datasets. The results demonstrate that our proposed method generates more suitable discretization schemes, leading to improved classification performance.

1 Inefficient Forecasts at the Sportsbook: An Analysis of Real-Time Betting Line Movement

Jay Simon, American University, Washington, DC, Contact: jaysimon@american.edu

This paper tests the efficiency of a set of sports betting markets using detailed betting line movement from opening until closing for four different sportsbooks for each of 3,681 Major League Baseball games. The reliability of the markets' forecasts are assessed at several lead times. They are mostly reliable, but there are simple betting strategies that would have yielded significant profit. Forecasts do not always improve monotonically as the games get closer; forecasts at weekend day games' start times are significantly worse than forecasts 90 minutes earlier. Furthermore, there is sufficient evidence to reject weak form market efficiency; specifically, betting lines tend to overreact, exhibiting significant negatively autocorrelated changes that could be exploited by sophisticated bettors.

2 Real-Time Analytics: The Next Frontier for Women's Car Ball Esports

Walt DeGrange, CANA, Chapel Hill, NC

This presentation is a review of the development, deployment, and challenges faced in 2022 and 2023, providing real-time analytics to a worldwide eSports league. This effort provided insights into player performance, and analytics helped viewers better understand the game and increase engagement. Analytics also helped commentators provide more in-depth analysis and commentary, which enhanced the viewer experience.

3 Decision Science And Football -- A Few Examples

Scott Nestler, Sumer Sports LLC, Granger, IN

This presentation is based on a series of recent articles about applying decision science to decision-making in (American) football. It will include a variety of tools and methods (e.g. decision trees, decision-making under uncertainty, multi-criteria decision-making and more) applied to a variety of decisions in football. These situations will range from off-season roster building to in-game decisions, and everything in-between.

4 Elo Ratings, Betting Lines, and NFL Win Probabilities

Christopher Gaffney, Drexel University, Philadelphia, PA, Contact: ctg39@drexel.edu

Elo ratings are calculated for NFL teams under varying assumptions. These ratings are subsequently used to derive game winning probabilities for historical games. These probabilities are compared to those implied by betting lines and to actual game results. Finally, we create an ensemble model for probability prediction.

1 Delta Coverage: The Analytics Journey to Implement a Novel Nurse Deployment Program

Pengyi Shi, Purdue University, West Lafayette, IN

We embarked on a journey in partnership with Indiana University (IU) Health System, the largest health system in Indiana with 16 hospitals, to jointly develop a suite of advanced data and decision analytics to support their new internal travel nursing program. This program leverages a flexible pool of resource nurses that can be moved between the 16 hospitals. To support this program, we developed an integrated decision support tool (DSS), which was implemented in October 2021 with annualized savings estimated at over $400K with over 220 understaffed shifts being avoided.

Algorithmic Foundation in Non-smooth Optimization

Community Committee Choice Session

Session Chair: Jiajin Li, 1</sup

Session Chair: Jiawei Zhang, MIT, Cambridge, MA

1 Risk-Adaptive Decision Rules

Johannes Royset, Naval Postgraduate School, Monterey, CA

For mixed-binary optimization problems dependent on unsettled parameters, we construct decision rules that prescribe near-optimal courses of action across a set of parameter values. The decision rules are constructed by solving risk-adaptive training problems over classes of continuous mappings and thus we permit affine, piecewise affine, and polynomial decision rules as well as those based on common neural networks. In asymptotic and nonasymptotic analysis, we establish that the decision rules are locally near-optimal for specific parameter values of the actual problem of interest without relying on linearity, convexity, or smoothness. The development also accounts for practically important aspects such as inexact computation of functions, solution tolerances in training problems, regularization, and reformulations to solver-friendly models.

2 Optimization Problem with Superquantile Constraints: A Fast Computational Approach

Ying Cui, University of California, Berkeley, Berkeley, CA, Contact: yingcui@berkeley.edu

We consider an efficient and scalable second-order framework for solving large-scale optimization problems with superquantile constraints. Unlike empirical risk models, superquantile models have non-separable constraints that make typical first-order algorithms difficult to scale. We address the challenge by adopting a hybrid of the second-order semismooth Newton method and the augmented Lagrangian method, which takes advantage of the structured sparsity brought by the superquantiles. The key to make the proposed computational framework scalable in terms of the number of training data is that the matrix-vector multiplication in solving the resulting Newton system can be computed in a reduced space due to the aforementioned sparsity. Our developed solver is expected to help control the risk of adverse events for safety-critical applications.

3 An Away-Step Frank-Wolfe Method for Minimizing Logarithmically-Homogeneous Barriers

Renbo Zhao, University of Iowa, Iowa City, IA, Contact: renboz@mit.edu

We present and analyze a new away-step Frank-Wolfe method for the convex optimization problem ${\min}_{x\in\mathcal{X}} f(\mathsf{A} x) + \langle c, x\rangle$, where f is a θ-logarithmically-homogeneous self-concordant barrier, A is a linear operator, $\langle c, \cdot\rangle$ is a linear function and $\mathcal{X}$ is a nonempty polytope. We establish the global linear convergence rate of our Frank-Wolfe method in terms of both the objective gap and the Frank-Wolfe gap. This, in particular, settles the question raised in Ahipasaoglu, Sun and Todd (2008) on the global linear convergence of the away-step Frank-Wolfe method specialized to the D-optimal design problem.

4 Testing Stationarity Concepts for ReLU Networks: Hardness, Regularity, and Robust Algorithms

Lai Tian, Anthony Man-Cho So, The Chinese University of Hong Kong, Hong Kong, China. Contact: tianlai.cs@gmail.com

We study the computational problem of the stationarity test for the empirical loss of ReLU neural networks. We show that checking a certain first-order approximate stationarity concept for a piecewise linear function is co-NP-hard. As a corollary, we prove that testing so-called first-order minimality for functions in abs-normal form is co-NP-complete, which was conjectured by Griewank and Walther (SIAM J. Optim., vol. 29, 2019). Then, we establish a necessary and sufficient condition for the validity of an equality-type subdifferential chain rule in terms of various subdifferentials of the empirical loss of two-layer ReLU networks. Finally, we introduce an algorithmic scheme to test near-approximate stationarity in terms of both Clarke and Fréchet subdifferentials. This is the first practical and robust stationarity test approach for two-layer ReLU networks.

5 First-Order Algorithms for Machine Learning: Smoothed-GDA and Adam

Zhi-Quan Luo[1], Jiawei Zhang[2], Yushun Zhang[1], Ruoyu Sun[1], Peijun Xiao[3], Congliang Chen[1], Naichen Shi[4], [1]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]Massachusetts Institute of Technology, Cambridge, MA, [3]University of Illinois, Champaign, IL, [4]University of Michigan, Ann Arbor, MI

Consider nonconvex-concave min-max problems (e.g. robust adversarial training). A popular approach to solve this problem is the Gradient Descent-Ascent (GDA) algorithm, which unfortunately can exhibit oscillation in case of nonconvexity. We propose a new algorithm called Smoothed-GDA with a new "smoothing" scheme to stabilize the oscillation and ensure convergence. We prove that Smoothed-GDA algorithm achieves the best known convergence rate for a wide class of nonconvex-concave problems. We also analyze the Adaptive Moment estimation (Adam) algorithm, which is the main workhorse for modern neural-network training. Under practical settings, we prove that Adam converges without any modification on update rules. Under a relaxed condition, we establish faster convergence rate of Adam over Stochastic Gradient Descent (SGD).

1 Impact of Remort Work on Firms' Data Breach Risks

WANG Kedi, Baofeng HUO, Zhejiang University, Hangzhou, China. Contact: drkediwang@zju.edu.cn

As firms switch to long-term remote workforces as the effects of COVID-19 linger, how to effectively deal with data breach risks has become a critical and thorny issue. Does remote work increase firms' data breaches? If yes, under what circumstances can the negative impact be offset? To answer these research questions, we manually integrate data breach leakage data from two major databases and match the data breach data with firms' remote work arrangement data. We also employ a quasi-experimental design using the PSM-DID analysis method to compare the treated and control groups. The results reveal that remote work arrangements significantly increase firms' data breaches. We further examined that the negative impact may be mitigated if firms have prior data breach experience before WFH arrangements and have a high level of IT input.

2 A Certificate Focused Major in Business Analytics

Frederick Kelly Augustine, Joseph Woodside, William Sause, Judson P. Stryker, Stetson University, DeLand, FL, Contact: faugusti@stetson.edu

As organizations attempt to harness the power of data, there we have seen a significant increase in use of analytics in business and the proliferation of curricula which feature analytics. Thus, it is important for educators and academic administrators to evaluate and improve their academic offerings in this area. Whether for competitive reasons or to exhibit the continuous improvement required by accreditation agencies, it is essential that the academic programs that we create are both meaningful and distinctive. This paper offers an example of an academic major in Business Analytics that offers added value to the curriculum and course offerings by focusing on the attainment of certificates by the students participating in the major.

3 Teaching or Using R

Timothy R. Anderson, Portland State University, Portland, OR, Contact: tim.anderson@pdx.edu

After years of teaching introductory management science using spreadsheets, I recently pivoted to using R and the R eco-system of tools as a way to introduce analytics to future technical professionals. This has a number of benefits including making them aware of platforms, documentation practices, reproducible research, and version control. This enables students with different technical backgrounds to do participate more deeply as well including making github contributions. In this presentation, we talk about the journey from spreadsheets to R and links to the developed open resources.

Empirical Evaluation of Health System Performance and Outcomes

Contributed Session

Session Chair: Alshwarya Shukla, Simon Fraser University, Burnaby, BC, Canada

1 The Impact of Hospital and Patient Characteristics on Psychiatry Readmissions

Hossein Hejazian[1], Beste Kucukyazici[2], Javad Nasiry[3], Vedat Verter[2], Daniel Frank[4], [1]McGill University, MONTREAL, QC, Canada; [2]Queen's University, Kingston, ON, Canada; [3]McGill University, Montreal, QC, Canada; [4]Jewish General Hospital, MONTREAL, QC, Canada. Contact: hossein.hejazian@mail.mcgill.ca

The "practice makes perfect" constituting a positive volume-outcome relationship in operations management problems, may change in people-centric environments. We study hospitals' operational characteristics contributing to the readmission of psychiatry patients. We find that the number of patients admitted to a hospital increases the risk of readmission. In contrast, this risk reduces with the degree to which a hospital specializes in a specific diagnosis class. We propose that length of stay (LOS) mediates these effects and patient characteristics moderate them. We provide evidence on the negative volume-outcome and nonlinear LOS-outcome relationships. Our results provide insights for policymakers to manage the flow of psychiatry patients and the burden imposed on the health systems by unplanned readmissions from patients with chronic disorders.

2 The Effect of Removing the Four-Hour Access Standard in the Ed: A Retrospective Observational Study

Tomas Momesso[1], Bilal Gokpinar[1], Rouba Ibrahim[1], Adrian Boyle[2], [1]UCL School of Management, London, United Kingdom; [2]Addenbrooke's Hospital, Cambridge, United Kingdom. Contact: tomas.momesso.20@ucl.ac.uk

Time-based targets are used to improve patient flow and quality of care within Emergency Departments. While previous research often highlighted the benefits of these targets, some studies found negative consequences of their implementation. We found that lifting the four-hour standard was associated with a drop in short-stay admission and an increase in the average length of stay in the ED.

3 The Effect of the Clinical and Non-Clinical Practices on Mortality Rate: An Econometric Analysis

Aber Elsaleiby, Georgetown University, Washington, DC

Physicians believe in linking results to only the clinical treatment with little to no tendency to believe in anything other than the clinical treatment (Tonelli, 2016). Our study investigates the effect of the clinical and non-clinical care on mortality rate using longitudinal data from all US acute care hospitals.

4 Identifying Fake Physician Reviews Using Transformers and Generative Models: Evidence from a Novel Dataset

Jaspal Singh[1], Avinash Saraswat[1], Alshwarya Deep Shukla[2], Jie Mein Goh[2], Ketan Paithankar[1], Laksh Agarwal[2], [1]Konverge AI, Nagpur, India; [2]Simon Fraser University, Burnaby, BC, Canada

This study compares state-of-the-art language models, GPT-3 and BERT in recognizing textual patterns to detect fraudulent reviews. The dataset consists of pre annotated physician reviews, labelled as fraudulent if self-authored by the doctors and authentic if provided by the patients. This work highlights the comparative capabilities of the two models and establishes the efficacy of pattern recognition with GPT-3. GPT-3's sequential text generation facilitates enhanced interpretability, providing a more intuitive understanding, whereas BERT's word-level embeddings pose challenges in straightforward interpretation. GPT-3 excels in capturing subtle nuances leveraging its vast parameter size, and showcases generalizability of findings.

Agricultural Supply Chains

Contributed Session

Session Chair: Haitao Li, University of Missouri - St. Louis, Saint Louis, MO

1 A Model for Perishable Inventory Management in Cold Chains
Ulku Gurler, Bilkent University, Ankara, Turkey. Contact: ulku@bilkent.edu.tr
We consider a single location perishable inventory model in which items are shipped in a cold chain, which maintains their freshness either perfectly or to a large extent in comparison with traditional media. Upon arrival items start aging and expire after a fixed time. A modified (Q,r) policy is employed for inventory control with a single batch retained on the shelf at any time - usable items are discarded in a secondary market when a new batch is received. We study the impact of various freshness-preserving technologies on the performance of the inventory system. We present theoretical findings as well as some numerical examples.

2 A Study of Cold Chain Practices Across Four Sectors
Sundaravalli Narayanaswami, Indian Institute of Management Ahmedabad, Ahmedabad, India. Contact: sundaravallin@iima.ac.in
We study and analyse Cold chain practices for perishable goods. India has a total installed capacity of 34.9 Mn MT of cold storage to support perishable goods supply chain. Despite an impressive producing capacity in dairy, meat, fisheries and agriculture, the country has a capacity to store only 11% of its total production of all perishable goods. This results in significant loss in perishable supply-chain yield. Overall market size for Indian Cold Chain is projected to a CAGR of 14.8% by 2025. However with a highly fragmented structure, 10% of the market share is held by top ten players. Classifying the business of Cold Chain as three verticals: Cold Storage, Cold Transport, and Other Value-added services, we analyse in-depth the perishable goods supply chain as fisheries, pharma, agri-good, and dairy products, along with state policies. Inferences and insights are discussed

3 Blockchain-enabled Traceability Of Greenhouse Gas Emissions: Evidence From Moroccan Agriculture Production
Zakaria El Hathat[1], Tarik Zouadi[1], V. Raja Sreedharan[2], [1]Rabat Business School, International University of Rabat, Rabat, Morocco; [2]Cardiff School of Management, Cardiff Metropolitan University, Cardiff, United Kingdom. Contact: zakaria.elhathat@uir.ac.ma
In the face of climate change, the food supply chain stands vulnerable and affected. The escalating global demand for transparency, traceability, and sustainability pushes firms to explore emerging technologies. Among these, blockchain emerges as a robust tool. This study introduces a pioneering approach utilizing blockchain-enabled traceability smart contracts. These smart contracts monitor and capture the intricacies of greenhouse gas emissions (GHG) within the Moroccan olive oil supply chain in three critical phases: farm, processing plant, and transportation to the port.

4 The Economics and Optimal Design of Indoor Farming Supply Chains
Haitao Li, University of Missouri - St. Louis, Saint Louis, MO, Contact: lihait@umsl.edu
Indoor farming is one of the fastest-growing industries in the U.S. Its projected compound annual growth rate averages more than 27% between 2016 and 2026. Although indoor farming has well-known advantages over traditional farming, the high initial technology and setup investments plus operating costs related to production, packaging, distribution can outweigh the benefits. In this presentation, I will talk about the need for economics study and sustainability of indoor farming startups. An optimization model will be presented to demonstrate how the use of data and mathematical programming can provide valuable data-driven decision-support for the optimal design and operation of an end-to-end indoor farming supply chain.

Stockpyl: A Python Package for Inventory Optimization and Simulation

Tutorial Session

Session Chair: Ebru Korular Bish, University of Alabama, Tuscaloosa, AL

1 Stockpyl: A Python Package for Inventory Optimization and Simulation

Larry V. Snyder, Lehigh University, Bethlehem, PA

Stockpyl is a Python package for inventory optimization and simulation. It implementsclassical single-node inventory models like the economic order quantity (EOQ),newsvendor, and Wagner-Whitin problems. It also contains algorithms for multiecheloninventory optimization (MEIO) under both stochastic-service model (SSM)and guaranteed-service model (GSM) assumptions. And, it has extensive features forsimulating multi-echelon inventory systems. In this tutorial, we provide an overview of Stockpyl, including a short primer on the inventory models and algorithms that underlie the modules in Stockpyl. Python code snippets are used throughout, and a Jupyter notebook containing all of the code is available on the GitHub repository for the Stockpyl project.

Learning and Experimentation in Markets

Community Committee Choice Session

Session Chair: Yichun Hu, Cornell University, New York, NY

1 Adaptively Learning to Rank in Online Platforms

Ruohan Zhan, Hong Kong University of Science and Technology, Stanford, CA

We aim to adaptively rank items on online platforms to maximize cumulative user engagement. Using a contextual-bandits approach, we adjust predicted engagement scores with an upper confidence bound, balancing exploration and exploitation. Our algorithm aggregates these adjusted scores across the item list, using maximum weight matching techniques. We show that our algorithm achieves sublinear regret, reduces dependency on the factorial growth of the action space size, and outperforms various benchmarks on both simulated and real-world datasets.

2 Learning to Price Under Competition for Multinomial Logit Demand

Vineet Goyal[1], Shukai Li[2], Sanjay Mehrotra[3], [1]Columbia University, New York, NY, [2]Department of Industrial Engineering and Management Sciences, Northwestern University, Evanston, IL, [3]Northwestern University, Evanston, IL

We study the multi-seller sequential price competition with multinomial logit (MNL) customer demand. The MNL parameters are unknown a priori, and the sellers do not communicate sale histories or future prices after the start of the selling horizon. We develop the first online learning algorithm that converges to the static price competition's Nash equilibrium while maximizing sellers' individual revenues. The algorithm lets each seller learn the model using its own data as if this seller were the only seller in a market under logit customer demand. Thus in our context Nash equilibrium can be interpreted as an outcome of learning. Our algorithm admits a regret bound of $O(T^{\ frac{2}{3}}\log T\log ^2N)$ for each seller, where N and T are the number of sellers and customers, respectively.

3 Multi-Armed Bandit Experimental Design: Online Decision-Making and Adaptive Inference

David Simchi-Levi, Chonghuan Wang, Massachusetts Institute of Technology, Cambridge, MA, Contact: chwang9@mit.edu

Multi-armed bandit has been famous for its efficiency in online decision-making in terms of minimizing participants' welfare loss during experiments (i.e., regret). In clinical trials and many other scenarios, inferring treatment effects (i.e., gaps between mean outcomes of different arms) is also crucial. However, minimizing the regret entails harming the statistical power of estimating the treatment effect, since the observations from some arms can be limited. We investigate the tradeoff between efficiency and statistical power by casting the multi-armed bandit experimental design into a minimax multi-objective optimization. We introduce Pareto optimality to characterize the situation where neither statistical power nor efficiency can improve without degrading the other. We derive a useful sufficient and necessary condition for Pareto optimal solutions.

4 Expansion Of Interference W.r.t. Tightness And Linear Regression Design

Nian Si[1], Zhihua Zhu[2], Zheng Cai[3], Ramesh Johari[4], [1]The University of Chicago Booth School of Business, Chicago,

IL, [2]Tencent, Shenzhen, China; [3]Tencent, Shezhen, China; [4]Stanford University, Stanford, CA, Contact: niansi@chicagobooth.edu

Interference in two-sided markets arises when sellers and buyers compete for limited resources. Recently, Johari et al. (2022) and Bajari et al. (2022) introduced a novel experimental design known as two-sided randomization (TSR). This approach involves randomization on both the seller and buyer sides. While their simulation study showed promising empirical results with minimal bias and variance, no theoretical evidence has been provided to justify the superior performance of TSR.

In this paper, we propose a new variant of TSR and identify a specific regime in which TSR achieves asymptotic optimality. Furthermore, we derive an expansion of market interference with respect to the budget tightness. To validate our proposed methods, we conducted A/B tests in a real-world industrial environment, yielding valid testing results.

5 Leveraging Consensus Effect to Optimize Ranking in Online Discussion Boards

Gad Allon[1], Joseph Carlstein[1], Yonatan Gur[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Stanford University, Stanford, CA

We formalize the level of consensus in discussion boards as an engagement driver, and study how it could be leveraged by ranking algorithms to increase engagement. We propose a new dynamic model for ranking optimization, and a class of algorithms that account for consensus when prescribing rankings. In a randomized experiment held in an education setting, our proposed algorithm outperformed the approach used in current practice.

Recent Advances in Revenue Management

Community Committee Choice Session

Session Chair: Xiao Lei, University of Hong Kong, New York, NY

1 Demand Balancing in Primal-Dual Optimization for Blind Network Revenue Management

Yining Wang[1], Sentao Miao[2], [1]University of Texas at Dallas, Richardson, TX, [2]McGill University, Montreal, QC, Canada

This paper proposes a practically efficient algorithm with optimal theoretical regret which solves the classical network revenue management (NRM) problem with unknown, nonparametric demand. Over a time horizon of length T, in each time period the retailer needs to decide prices of N types of produc tswhich are produced based on M types of resources with unreplenishable initial inventory. In this paper, we improve the previous result by proposing a primal-dual optimization algorithm which is not only more practical, but also with an improved regret free from additional high-order terms. A key technical contribution of the proposed algorithm is the so-called demand balancing, which pairs the primal solution (i.e., the price) in each time period with another price to offset the violation of complementary slackness on resource inventory constraints.

2 On the Performance of Myopic and Revenue-Ordered Policies for a Multi-Period Assortment Optimization Under an MNL Model with Popularity Bias

Izak Duenyas[1], Stefanus Jasin[2], Zhuodong Tang[3], [1]University of Michigan-Ann Arbor, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, Contact: zdtang@umich.edu

We consider a monopoly firm that aims to maximize its total revenue over a finite horizon by optimizing the assortments across different periods. Customers make their purchase decisions according to a variant of the MNL model that incorporates popularity bias, which is quantified as an increasing concave function of cumulative historical sales. We show that the assortment optimization problem is NP-Hard, and we focus on studying the performance of the myopic and revenue-ordered policies. We show that the myopic policy can perform arbitrarily badly compared to the optimal policy. In contrast for a fixed number of periods, the best stationary revenue-ordered policy guarantees a constant fraction of the optimal revenue regardless of the problem instances. Moreover, this guarantee is tight in the worst-case sense within the class of all feasible revenue-ordered policies.

3 Socially Responsible Pricing

Hongqiao Chen[1], Ming Hu[2], Jing Peng[3], [1]Nanjing University, Nan Jing Shi, China; [2]University of Toronto, Minneapolis, MN, [3]University of Toronto, Toronto, ON, Canada

We examine three socially responsible pricing schemes with the same corporate social responsibility (CSR) level. The social responsibility (S) scheme is to maximize the firm's profit plus the CSR level times the consumer surplus. The Nash bargaining (B) scheme follows a weighted proportional fairness notion with the weight on consumer surplus to be the CSR level. The Rawlsian fairness (R) scheme aims at generating consumer surplus to be a fraction of the social welfare at the given CSR level. For a given customer valuation distribution and CSR level, we show that B leads to a lower price than S and R. Moreover, when the firm has to commit to a scheme while facing the uncertainty of valuation distributions, we show that with the same CSR level, S is robustly preferred from the profit perspective, while B is robustly preferred from the consumer surplus and social welfare perspectives.

4 Online Resource Allocation with Convex-Set Machine-Learned Advice

Negin Golrezaei[1], Patrick Jaillet[2], Zijie Zhou[3], [1]Massachusetts Institute of Technology, Lexington, MA, [2]M.I.T., Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: zhou19981107@gmail.com

Decision-makers are frequently equipped with a machine-learned uncertainty set or advice, which can be utilized for online decision-making. However, relying on this advice can be difficult due to its potential lack of accuracy. To address this challenge, we propose a framework that enhances resource allocation decisions by incorporating potentially unreliable machine-learned advice. Our framework utilizes a general convex uncertainty set to account for the uncertain nature of the demand vector. We design a parameterized class of Pareto-optimal algorithm, which balances both consistent and robust ratios. The consistent (resp. robust) ratio measures algorithm performance under the adversarial demand when the ML advice is accurate (resp. inaccurate). Specifically, our algorithm maximizes the robust ratio while ensuring that the consistent ratio is at least C.

Data-Driven Methods and Revenue Management

Community Committee Choice Session

Session Chair: Santiago Balseiro, Columbia University, Armonk, NY

Session Chair: Christian Kroer, Columbia University, New York, NY

1 Online Resource Allocation with Costly Overbooking: Optimal Algorithms via Primal-Dual

Rad Niazadeh[1], Yiding Feng[2], Farbod Ekbatani[3], [1]Chicago Booth School of Business, CHICAGO, IL, [2]Microsoft Research, Cambridge, MA, [3]Chicago Booth School of Business, Chicago, IL, Contact: rad.niazadeh@chicagobooth.edu

Motivated by applications in cloud spot markets and selling banner ads, we study online resource allocation with “costly overbooking.” To model this problem, we consider the classic edge-weighted online matching problem where the decision maker can recall (i.e., buyback) any fraction of an offline resource that is pre-allocated to an earlier online vertex; however, by doing so, not only the previously allocated reward is lost, there will be a non-negative constant factor f of this lost reward as an extra penalty. Parameterizing by the buyback factor f, our main result is obtaining optimal competitive algorithms for all values of f through a novel primal-dual family of algorithms. We show how algorithms in our family of primal-dual algorithms can obtain the exact optimal competitive ratio in all of these variants, demonstrating the power of our algorithmic framework.

2 Equilibria in Repeated Games Under Regret Minimization with Dynamic Benchmarks

Ludovico Crippa, Stanford University, Stanford, CA

In repeated games of incomplete information strategies are often evaluated by their ability to guarantee the performance of the single best action in hindsight, property called Hannan consistency (HC). Yet, the efficacy of this yardstick is limited as any static action may perform poorly in dynamic settings. We formalize dynamic benchmark consistency (DBC) property, requiring strategies to guarantee the performance of any dynamic sequences of actions (that exhibit number of changes that scales sublinearly with the horizon). We show that many DBC strategies exist, and that they result in distributions of play that coincide with coarse corelated equilibria of the stage game (the Hannan set). Then, relative to HC, DBC strategies provide stronger guarantees against arbitrary strategies, but maintain the same worst case social welfare when all players adopt DBC strategies.

3 Online Resource Allocation Under Horizon Uncertainty

Santiago Balseiro, Christian Kroer, Rachitesh Kumar, Columbia University, New York, NY

We study stochastic online resource allocation: a decision maker needs to allocate limited resources to stochastically-generated sequentially-arriving requests in order to maximize reward. At each time step, requests are drawn independently from a distribution that is unknown to the decision maker. Online resource allocation and its special cases have been studied extensively in the past, but prior results crucially and universally rely on the strong assumption that the total number of requests (the horizon) is known to the decision maker in advance. However, in many applications such as revenue management and online advertising, the number of requests can vary widely because of fluctuations in demand or user traffic intensity. This work aims to address this disconnect by developing online algorithms that are robust to the horizon uncertainty.

4 Context-Based Offline Pricing and Demand Learning with Separable Demand Models

Menglong Li[1], David Simchi-Levi[2], Renfei Tan[2], Chonghuan Wang[2], Michelle Xiao Wu[2], [1]City University of Hong Kong, Hong Kong, China; [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: rftan@mit.edu

Motivated by a collaboration with a leading retailer of consumer electronics in the Middle East, this paper explores the problem of demand forecasting and pricing using separable demand models. The retailer faces an unknown expected demand function that follows a separable structure f(p)+g(x), where p R and x R^d denote the product's price and contextual features respectively. The exact expressions of f(p) and g(x) are unknown, and the retailer's objective is to use an offline dataset to find optimal prices that maximize expected revenue. We analyze the statistical complexity of the demand learning problem with the separable structure, highlighting how the separable structure helps reduce the sample size needed for learning. Additionally, we propose an efficient iterative algorithm for learning f(p) and g(x) with convergence guarantees.

Community Committee Choice Session

Session Chair: Yifan Feng, NUS Business School, Singapore, Singapore

Session Chair: Pin Gao, The Chinese University of Hong Kong, Shen Zhen, Shenzhen, China

1 Distribution-Free Model-Agnostic Regression Calibration via Nonparametric Methods

Shang Liu, Zhongze Cai, Martin Haugh, Xiaocheng Li, Imperial College Business School, London, United Kingdom. Contact: z.cai22@imperial.ac.uk

In this paper, we consider the uncertainty quantification problem for regression models. Specifically, we consider an individual calibration objective for characterizing the quantiles of the prediction model. We propose simple nonparametric calibration methods that are agnostic of the underlying prediction model. Our approach enables a better understanding of the possibility of individual calibration, and we establish matching upper and lower bounds for the calibration error of our proposed methods. Numerical experiments show the advantage of such a simple approach under various metrics, and also under covariates shift. We hope our work provides a simple benchmark and a starting point of theoretical ground for future research on regression calibration.

2 Bayesian Design Principles for Frequentist Sequential Learning

Yunbei Xu, Assaf Zeevi, Columbia University, New York, NY, Contact: yunbei.xu@gsb.columbia.edu

We develop a general theory to optimize the frequentist regret for sequential learning problems, where efficient bandit and reinforcement learning algorithms can be derived from unified Bayesian principles. We propose a novel optimization approach to create "algorithmic beliefs" at each round, and use Bayesian posteriors to make decisions. This is the first approach to make Bayesian-type algorithms prior-free and applicable to adversarial settings, in a generic, optimal, and computationally efficient manner. As a major application, we present a novel algorithm for multi-armed bandits that achieves the "best-of-all-worlds" empirical performance in the stochastic, adversarial, and non-stationary environments. And we illustrate how these principles can be used in linear bandits, bandit convex optimization, and reinforcement learning.

3 Myopic Quantal Response Policy: Thompson Sampling Meets Behavioral Economics

Jingying Ding[1], Yifan Feng[2], Ying Rong[1], [1]Shanghai Jiao Tong University, Shanghai, China; [2]NUS Business School, Singapore, Singapore. Contact: jingyding@sjtu.edu.cn

We study a new family of multi-armed bandit (MAB) algorithms called Myopic Quantal Response (MQR). It prescribes a simple way to randomize over arms according to historical data and a "coefficient of exploitation," which explicitly controls the exploration-exploitation trade-off. We show that MQR partially extends the Thompson Sampling (TS) algorithm. It is also a dynamic version of quantal response models where the expected utilities are directly estimated from historical rewards. Based on theoretical analysis and numerical experiments, we believe the significance of MQR is: it provides a conceptual framework to understand further the exploration-exploitation trade-off; it can be used as a structural estimation tool to learn from realized actions and rewards how much a given policy (either generated by human beings or algorithms) is "under" or "over" exploring.

Novel Applications of Online Allocation Algorithms

Community Committee Choice Session

Session Chair: Deeksha Sinha, Facebook Inc., Freemont, CA

Session Chair: Xuan Zhang, Meta, Core Data Science, Menlo Park, CA

1 Fair Notification Optimization: An Auction Approach

Deeksha Sinha, Facebook Inc., Freemont, CA

Notifications are important for the user experience in mobile apps. A typical mobile app usually has several types of notification, managed by distinct teams with objectives that are possibly conflicting with each other. In this work, we study a novel centralized approach for notification optimization designed as an auction market.We show that an Eisenberg-Gale-style convex program allows us to find an allocation that is fair to all notification types in hindsight. Further, we present an online algorithm that allocates notifications via auctions using a pacing-multiplier approach. Through an A/B test, we show that the auction system improves over a decentralized optimization system, leading to its launch in production.

2 Algorithmic Size Improvements for Mobile Apps

Mine Su Erturk, Meta, Menlo Park, CA

ReDex is an open-source Android bytecode optimizer originally developed at Meta, which aims to make mobile apps faster and smaller via various optimization passes. In this talk, we will introduce a new optimization pass in ReDex, called Interdex Reshuffle Pass, that can significantly reduce the uncompressed sizes of apps through a class reordering scheme.

3 Fully Dynamic Online Selection Through Online Contention Resolution Schemes

Riccardo Colini Baldeschi, Meta

We study fully dynamic online selection problems in an adversarial/stochastic setting subject to combinatorial constraints. This models, for example, the online matching of tasks to workers with task/worker-dependent working times. A successful approach to online selection problems in the adversarial setting is given by the notion of Online Contention Resolution Scheme (OCRS), that uses a priori information to formulate a linear relaxation of the underlying optimization problem, whose optimal fractional solution is rounded online for any adversarial order of the input sequence. Our main contribution is providing a general method for constructing an OCRS for fully dynamic online selection problems. Then, we show how to employ such OCRS to construct no-regret algorithms in a partial information model with semi-bandit feedback and adversarial inputs.

Learning on Networks

Community Committee Choice Session

Session Chair: Souvik Dhara, 1</sup

1 All-Something-Nothing Phase Transitions in Planted Subgraph Recovery

Jiaming Xu[1], Julia Guadio[2], Colin Sandon[3], Dana Yang[4], [1]Duke University, Durham, NC, [2]Northwestern University, Evanston, IL, [3]EFPL, Lausanne, Switzerland; [4]Cornell University, Ithaca, NY, Contact: jiaming.xu868@duke.edu

This presentation delves into the problem of recovering a spanning k-regular graph embedded within an ER random graph. We discover an intriguing "all-something-nothing" phase transition phenomenon. Specifically, we show that as the average degree surpasses a critical threshold of 1/k, the inference problem undergoes a transition from near-perfect recovery (“all” phase) to partial recovery (“something” phase). Moreover, as the average degree continues to grow to infinity, the accuracy of recovery diminishes to zero, leading to the onset of the “nothing” phase. This discovery complements the recent result by Mossel et al., which identified an “all-or-nothing” phase transition for certain sufficiently dense subgraphs, jumping from near-perfect recovery to near-zero accuracy.

2 Graphons in Machine Learning
Luana Ruiz, Johns Hopkins University, Baltimore, MD, Contact: ruizl@mit.edu
Graph neural networks are successful at learning representations from graph data but suffer from limitations in large graphs. Yet, large graphs can be identified as being similar to each other in the sense that they share structural properties, and indeed graphs can be grouped in families converging to a common graph limit---the graphon. In this talk, I discuss how graphons can be used to deepen our understanding of machine learning on large-scale graphs.

3 Mean-Field Analysis for Load Balancing on Spatial Graphs
Daan Rutten[1], Debankur Mukherjee[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA
The analysis of large-scale, parallel-server load balancing systems has relied heavily on mean-field analysis. A pivotal assumption for this framework is that servers are exchangeable. However, modern data-centers have data locality constraints, such that tasks of a particular type can only be routed to a small subset of servers. An emerging line of research, therefore, considers load balancing algorithms on bipartite graphs where vertices represent task types and servers, respectively. In this talk, I will present a novel coupling-based approach to establish mean-field approximation for a large class of graphs which includes spatial graphs. The method extends the scope of mean-field analysis far beyond the classical full-flexibility setup.

4 Attributed Random Networks: Local Weak Limits, Pagerank and Sampling
Sayan Banerjee, University of North Carolina-Chapel Hill, Chapel Hill, NC
We investigate growing random networks, comprising nodes with different attribute types (communities), which evolve under the combined effect of node popularity (graph degree) and interaction between attributes (some attribute propensity kernel). Using stochastic approximation techniques, we show that local neighborhoods of typical nodes in large networks approach limiting random graphs given in terms of randomly stopped multi-type branching processes. This is used to obtain detailed information on the limiting distributions of centrality scores like degree and PageRank. We also see how our theoretical results shed light on sampling schemes ensuring prescribed representation of minorities, and on competition between majority and minority communities in the growing network. Based on joint work with Nelson Antunes, Shankar Bhamidi and Vladas Pipiras.

Large Deviations and Global Dynamics of Heavy-Tailed Systems
Community Committee Choice Session
Session Chair: Chang-Han Rhee, Northwestern University, Chicago, IL

1 Large Deviations for Scale-Free Random Graphs
Bert Zwart, Centrum Wiskunde Informatica, Amsterdam, Netherlands. Contact: bert.zwart@cwi.nl
We provide large deviations estimates for the upper tail of the number of triangles in scale-free inhomogeneous random graphs where the degrees have power law tails with index −[illegible],[illegible] (1,2). We show that upper tail probabilities for triangles undergo a phase transition at the point 4/3.
Our proofs are based on various concentration bounds, including a novel concentration bound well-suited to study large deviations of U-statistics.
[illegible]<4/3. Our proofs are partly based on various concentration inequalities. In particular, we tailor concentration bounds for empirical processes to make them well-suited for analyzing heavy-tailed phenomena in nonlinear settings.
Joint work with Clara Stegehuis (UT)

2 Sample Path Large Deviations for Levy Processes and Random Walks with Log-Normal Increments
Zhe Su, Chang-Han Rhee, Northwestern University, Chicago, IL
In the past two decades, the understanding of rare event asymptotics has greatly expanded, acknowledging both single and multiple jump principles. Recent works have characterized the ‘catastrophe principle’ with sample path large deviations for regularly varying and Weibull uncertainties. This leaves the log-normal case, one of the

three main classes of distributions for modeling heavy-tailed phenomena, unexplored. In this presentation, we delve into this open issue, establishing the sample path large deviations for random walks and Lévy processes, and characterizing the catastrophe principle for the log-normal case. We also discuss implications for tail asymptotics of queueing systems with log-normal job sizes.

3 Eliminating Sharp Minima from SGD with Truncated Heavy-Tailed Noise

Xingyu Wang[1], Sewoong Oh[2], Chang-Han Rhee[1], [1]Northwestern University, Evanston, IL, [2]University of Washington, Seattle, WA, Contact: xingyuwang2017@u.northwestern.edu

Recently, there have been discourses in machine learning literature that heavy-tailed noises in deep learning tasks enable SGDs to efficiently escape from sharp minima, which are known to lead to poor generalization. In this work, we show that by truncating the stochastic gradients in SGD under heavy-tailed noises, we can achieve a much stronger notion of the (almost) complete elimination of sharp local minima from the training trajectories of SGD. First, we establish an Eyring-Kramers type first exit time formula for truncated heavy-tailed SGD. Moreover, under appropriate structural conditions, we prove that the path-wise dynamics of truncated heavy-tailed SGD converge to a continuous-time Markov chain that never visits sharp minima. Our deep learning experiments confirm that truncated heavy-tailed SGD finds "flatter" minima with better generalization.

4 Theoretical Framework for Global Dynamics and Metastability Analysis of Heavy-Tailed Systems

Chang-Han Rhee[1], Xingyu Wang[2], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Evanston, IL, Contact: chang-han.rhee@northwestern.edu

Stochastic dynamical systems often exhibit local stability (metastability) and phase transition between the domains of local stability. Understanding such phenomena is crucial in characterizing the global behaviors of dynamical systems. In this talk, we propose a new local uniform formulation of the heavy-tailed large deviations and show that one can transform such a large deviations formulation into local stability analysis. This machinery provides a streamlined framework for the heavy-tailed counterpart of the Freidlin-Wentzel theory and Eyring-Kramers formula. Moreover, we show that this can be further elevated to a crisp characterization of the global dynamics of the stochastic systems. We illustrate this in the context of heavy-tailed SGDs and show that it successfully captures intricate mathematical structures that are unique to the heavy-tailed SGDs.

Simulation Modeling and Applications

Community Committee Choice Session

Session Chair: Yuan Zhou, University of Texas at Arlington, Arlington, TX

1 Sustainable Blood Donor Recruitment and Retention via Social and Mobile App Campaigns

Lin Li[1], Robert Keyser[2], [1]Kennesaw State University, Marietta, GA, [2]Kennesaw State University, Marietta, GA, Contact: lli19@kennesaw.edu

The aging baby boomer blood donor base, coupled with decreases from younger age groups, is an ongoing public health concern and impacts all people in need of blood transfusions regardless of gender, age, racial, or ethnic background. There is an urgent need to expand the blood donor pool to include more younger generations, first-time donors, and minorities. This project supports a larger study effort of recruiting and retaining young blood donors (age 18-39). Collaborating with Medic Regional Blood Center, our focus for this project is to create a framework that effectively recruits and sustains a younger, diverse generation of blood donors.

2 Calibrated Queueing Models as Low-Fidelity Controllable Representations for Discrete Event Simulations: An Application in Biomanufacturing

Danielle F. Morey[1], Giulia Pedrielli[2], Zelda B. Zabinsky[1], [1]University of Washington, Seattle, WA, [2]Arizona State University, Tempe, AZ, Contact: dmorey43@uw.edu

Simulation models are extremely useful tools for analyzing a system. It is often necessary, however, to develop a surrogate model for more efficient computation. Commonly used surrogate models (e.g., Gaussian process, neural network) can be difficult to interpret because they use hyperparameters with no real-world equivalent. For a biomanufacturing application, we construct a queueing model as a surrogate for a simulation. This surrogate queueing model has explainable parameters, such as arrival rate or service time, and can be solved analytically. In addition to the creation of a model that is easier to interpret, we can exploit the known structure of the queueing model for additional analyses not possible with traditional surrogates.

3 An Agent-Based Model for Simulating Covid-19 Transmissions on University Campus and Its Implications on Mitigation Interventions

Yuan Zhou[1], Lin Li[2], [1]University of Texas at Arlington, Arlington, TX, [2]Kennesaw State University, Marietta, GA, Contact: yuan.zhou@uta.edu

Universities across the USA are facing challenging decision-making problems amid the COVID-19 pandemic. The purpose of this study is to facilitate universities in planning disease mitigation interventions as they respond to the pandemic. An agent-based model is developed to mimic the virus transmission dynamics on campus. Scenario-based experiments are conducted to evaluate the effectiveness of various interventions including course modality shift (from face-to-face to online), social distancing, mask use and vaccination. A case study is performed for a typical US university. This study provides useful implications for supporting universities in mitigating transmissions on campus and planning operations for the upcoming semesters and future pandemics.

4 Nested Heteroscedastic Gaussian Process Metamodeling for High-Dimensional Large-Scale Datasets

Jin Zhao, Xi Chen, Virginia Tech, Blacksburg, VA, Contact: zjin20@vt.edu

We investigate the nested heteroscedastic Gaussian process (NHGP) metamodeling technique, a novel approach to tackling large-scale, high-dimensional heteroscedastic datasets. We analyze the asymptotic properties of NHGP and study the convergence rate of its mean squared error bound under various parameter configurations. Recognizing the challenges posed by high-dimensional problems, such as the stringent smoothness requirements mandated by the Sobolev embedding theorem, we devise a strategy that effectively mitigates the issues. Specifically, we employ sparse grid designs using Smolyak's algorithm and separable Matérn kernels, proving more effective for high-dimensional problems. This research significantly advances simulation metamodeling with large-scale heteroscedastic datasets, particularly in high-dimensional contexts.

Leveraging Data Analytics and AI to Manage Complex Value Chains and Natural Resources

Community Committee Choice Session

Session Chair: Dan Andrei Iancu, Stanford University, Stanford, CA

1 Managing Forests for Profit and Carbon Sequestration

Zhuoyang Liu, Dan Andrei Iancu, Erica Plambeck, Stanford University, Stanford, CA, Contact: zyliu@stanford.edu

How should policymakers better incentivize the private sector to profitably manage working forests in ways that align with social welfare and carbon-neutral goals? To study this question, we build a Markov decision process model to capture the stochastic evolution of forest stands

and investigate how forestry companies should optimally adjust their forest management (thinning, harvesting, and restoration) strategies to cope with natural disturbances and uncertainties associated with the timber and carbon offset markets. We derive structural results on the optimal timber management policies and use these to examine how various carbon accounting and crediting policies would impact the companies' profits as well as the long-run carbon stock on working forest stands. We leverage these results to generate insights for policymakers.

2 Optimal Control of Multiclass Fluid Queueing Networks: A Machine Learning Approach

Cheol Woo Kim[1], Dimitris Bertsimas[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: acwkim@mit.edu

We propose a machine learning approach to the optimal control of multiclass fluid queueing networks (MFQNETs). MFQNETs are continuous, deterministic approximations of multiclass queueing networks (MQNETs) that offer tractable approaches for the analysis and control of MQNETs.
We prove that a threshold type optimal policy exists for MFQNET control problems, where the threshold curves are hyperplanes passing through the origin. Based on this result, we use Optimal Classification Trees with hyperplane splits (OCT-H) to learn an optimal control policy for MFQNETs. We use numerical solutions of MFQNET control problems as a training set and apply OCT-H to learn explicit control policies. Our experimental results demonstrate that the learned policies achieve 100% accuracy on the test set.

3 An Improved Diet You Could Follow: Combining Machine Learning and Optimization to Generate More Realistic Dietary Shifts

Felipe Vizzoto[1], Antoine Desir[1], Dan Andrei Iancu[2], [1]INSEAD, Fontainebleau, France; [2]Stanford University, Stanford, CA, Contact: felipe.vizzoto@insead.edu

A dietary shift is an imperative to fighting climate change and the epidemic of non-communicable diseases. This work combines machine learning techniques with optimization to build more accurate models of compliance with dietary recommendations and to optimize such recommendations in view of nutritional and environmental considerations. We calibrate our models using data from the Brazilian Dietary Survey and we compare our optimized diets that suitably account for compliance with other recommendations from the literature.

Casey King, Yale University, New Haven, CT

2 Approaches to Extending Game-Theoretic Analyses to Complex, Real-World Scenarios

Scott Neal Reilly, Charles River Analytics, Cambridge, MA, Contact: snealreilly@cra.com

I will present a novel methodology to describe and solve formal games that change some standard assumptions of game theory to make it easier to describe, solve, and analyze real-world adversarial scenarios. I will describe a software implementation of this methodology that helps analysts understand the various possible outcomes of these situations. Finally, I will describe some initial evaluations we have undertaken to demonstrate the usefulness of this approach to better understanding and reasoning about real-world scenarios.

3 Strategic Dimensions of Economic Resilience

Mark Flood, DARPA, Arlington, VA

An introduction an overview of several of DARPA's research efforts that model economic and financial systems with a view to monitoring and enhancing their resilience.

4 Frontiers in Non-Kinetic Grey Zone Conflict

David Rushing Dewhurst, D R Dewhurst, Inc., Wareham, MA, Contact: david@drdewhurst.com

Non-kinetic grey-zone (NKGZ) conflict is characterized by ambiguity, uncertainty, novelty, and adaptation: ambiguity of intentions and outcomes; uncertainty in state space; novelty in domain of conflict; and adaptation to operations in these new domains. This talk first provides a background on NKGZ conflict, including historical and recent examples, and then outlines multiple frontiers in NKGZ conflict: (a) details of newly important operational domains (e.g., financial, economic, and supply chain); (b) strategic models of NKGZ conflict; and (c) emergent operations research, statistical, and artificial intelligence techniques with direct applications to NKGZ operations.

5 Financial Cartography In The Gray Zone

Corey L. Lofdahl, Leidos, Inc., Arlington, VA, Contact: corey.lofdahl@leidos.com

Modern strategic competition among nations centers less on the military than the diplomatic, informational, and economic elements of national power. This trend is captured by the term “gray zone” in which great power competition takes place in the continuum between the poles of peace and war. Instead of defeating a country militarily, today it is preferable to do so economically. In the gray zone, economies and markets are not attacked quickly and directly. Instead, they are compromised in a more nuanced, pervasive, and temporally extended manner such as with crime. This study uses Russian money laundering through European banks as an example and discusses the use of cartographic mapping techniques that allows analysts to conceptualize these normally opaque transactions.

People-Centric Operations: Teams

Community Committee Choice Session

Session Chair: Guillaume Roels, INSEAD, Fontainebleau, France

1 Fairness Concerns in Heterogeneous Teams: Optimal Team Composition and Contract

Lin Chen[1], Antoine Desir[2], Guillaume Roels[1], [1]INSEAD, Fontainebleau, France; [2]INSEAD, 263 Avenue Daumesnil, France. Contact: lin.chen@insead.edu

In homogeneous teams, inequality aversion increases team output. However, in heterogeneous teams, uneven profit distribution may cause guilt or envy, potentially affecting output. In such cases, is there a fairness-efficiency tradeoff? We consider a principal multi-agent model in which heterogeneous agents are subject to envy and guilt among each other. We show that when agents are highly inequality-averse but not too heterogeneous, it is optimal to involve a team and offer an envy- and guilt-free contract, leading to higher team output than if agents were inequality-neutral. Thus, heterogeneity in abilities combined with endogenous fairness concerns does not necessarily create a fairness-efficiency trade-off. Instead, stimulating inequality aversion may be beneficial for both the principal and the agents in providing a fairer and more efficient solution.

2 Physician Discretion and Patient Pick-Up: How Familiarity Encourages Multitasking in the Emergency Department

Robert Niewoehner[1], Diwas S. KC[2], Bradley R. Staats[3], [1]Indiana University Bloomington, Bloomington, IN, [2]Emory University, Atlanta, GA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: bstaats@unc.edu

Emergency Department (ED) physicians generally respond to the rising demand by increasing the level of multitasking. What leads the physicians to select which patients, and how many patients, to treat? Using observations from two EDs, we explore whether familiarity alters patient pick-up behavior, we determine the effect of familiarity on multitasking, and we measure the combined impact of familiarity and multitasking on other ED outcomes. Among ED physicians, greater average familiarity leads to an increase in patient pick-up rate, observed multitasking, and shorter patient wait time, with no identifiable negative impact to patient processing time or length of stay. Moreover, the effects intensify at the end of a physician’s shift and for patients in severe condition. Within more familiar groups, physicians appear willing to exert more effort.

3 Sequential Selection of Candidates: An Experimental Investigation

Morvarid Rahmani, Karthik Ramachandran, Chris Green, Georgia Institute of Technology, Atlanta, GA, Contact: morvarid.rahmani@scheller.gatech.edu

In many settings, managers make sequential selection decisions where they are constrained by the number of selections and uncertainty about forthcoming candidates. We develop hypotheses based on the optimal solution to a theoretical model. We then conduct a set of experimental studies and evaluate the impact of pool size on selection decisions.

4 Incentives for Modular, Interdependent and Uncertain Projects

Jeremy Hutchison-Krupat[1], Antoine Feylessoufi[2], Stylianos Kavadias[1], [1]University of Cambridge, Cambrige, United Kingdom; [2]University College London, London, United Kingdom. Contact: a.feylessoufi@ucl.ac.uk

The role of modularity has received some attention at the product/service level and its link with organizational design, product quality and organizational performance is well established. There has been, however, much less theory to specifically guide the incentive design for the development of a modular system within an organization.

Human-Algorithm Interaction and the Future of Work

Community Committee Choice Session

Session Chair: Leon Valdes, University of Pittsburgh, Pittsburgh, PA

1 Improving Worker Learning in the Gig Economy

Shunan Jiang, Park Sinchaisri, University of California, Berkeley, Berkeley, CA, Contact: shunan_jiang@berkeley.edu

The gig economy is experiencing exponential growth, with an increasing number of workers engaging in on-demand platforms across various sectors, from grocery delivery to healthcare. These gig workers, often independent contractors, face unique challenges in their work environment as they lack structured training programs and supervision. Therefore, understanding how these workers learn and improve their performance becomes crucial. In collaboration with a grocery delivery platform, our work aims to explore the decision-making and learning processes employed by on-demand shoppers and inform the development of effective training and scheduling programs tailored to the unique needs of gig economy workers.

2 Designing Fundraising Campaign Mechanisms

Pramit Ghosh[1], Ignacio Rios[2], Anyan Qi[2], [1]The University of Texas at Dallas, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX

Charitable donations are a vital source of funding for non-profit organizations, enabling them to carry out their mission of addressing social issues and providing support to those in need. To enhance donations, non-profits employ various designs aimed at inducing pro-social behavior. This paper investigates the effectiveness of two specific design choices, i.e., matching funds and gift unlock, in the context of fundraising.

3 Nonfungible Tokens: How to Match Supply with Demand in the Metaverse

Dmitrii Sumkin[1], Pavel Kireyev[2], Serguei Netessine[3], [1]University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, [2]INSEAD, Paris, France; [3]The Wharton School, Philadelphia, PA, Contact: dsumkin@illinois.edu

Organizations like Formula One, Hermitage Museum, and the NBA have started issuing digital collectibles (NFTs) on blockchain-enabled marketplaces. Digital collectible sales rose to $25bn in 2021 and $24.7bn in 2022. However, supply policies in these markets are not well understood. We analyze data from Decentraland, a metaverse platform, and build a structural model to study supply, demand, and price formation. Our findings reveal a trade-off between transaction frequency and market prices, influenced by supply policies, impacting platform revenues. Counterfactual analysis shows marketplace revenue is nonlinear with respect to the number of assets introduced, even if the minting cost is zero. Our framework highlights the importance of considering customers' incentives and can be utilized by marketplaces to measure potential effects of supply adjustments.

4 A Behavioral Study of Self-other Adoption Discrepancies in XAI

Fernanda Bravo[1], Zezhen (Dawn) He[2], Yaron Shaposhnik[2], Leon Valdes[3], [1]UCLA Anderson School of Management, Los Angeles, CA, [2]Simon Business School, University of Rochester, Rochester, NY, [3]Katz Graduate School of Business, University of Pittsburgh, Pittsburgh, PA, Contact: zezhen.he@simon.rochester.edu

Despite major recent developments in machine learning (ML), there is ample empirical evidence that users do not always follow ML recommendations. However, the question of whether the subject that is affected by the prediction impacts adherence is not well understood. This question is relevant as many ML applications, from medicine to the judicial system to lending decisions, are made by a user but affect a third party. In this work, we conduct behavioral experiments to study whether the party that is affected by a user's decision (the user, or another participant) impacts the adoption of ML recommendations. In addition, we explore whether the presence vs. absence of ML explanations moderates our results. We find no difference in adoption without explanations. In the presence of explanations, however, users are more willing to use ML when they are the affected party.

Privacy and Fairness in Optimization and Learning

Community Committee Choice Session

Session Chair: Rachel Cummings, Columbia University, New York, NY

1 Improving Communication with End Users About Differential Privacy

Rachel Cummings[1], Priyanka Nanayakkara[2], Mary Anne Smart[3], Gabriel Kaptchuk[4], Elissa Redmiles[5], [1]Columbia

University, New York, NY, [2]Northwestern University, Evanston, IL, [3]University of California San Diego, San Diego, CA, [4]Boston University, Boston, MA, [5]Georgetown University, Washington DC, DC

This talk will cover a series of user studies aimed at improving communication with non-technical end users about differential privacy (DP). Prior work (Cummings et al., 2019) found that the ways in which DP is described in-the-wild set users' privacy expectations haphazardly, which can be misleading depending on the deployment. In this work, we develop and evaluate prototype descriptions designed to help end users understand DP guarantees. These descriptions target two important technical details in DP deployments that are often poorly communicated to end users: the privacy parameter epsilon (which governs the level of privacy protections) and distinctions between the local and central models of DP (which governs who can access exact user data).

2 Thompson Sampling is Itself Differentially Private

Tingting Ou, Rachel Cummings, Marco Avella-Medina, Columbia University, New York, NY, Contact: to2372@columbia.edu

In this work we show that the classical Thompson sampling algorithm for multi-arm bandits is differentially private as-is, without any modification. We provide per-round privacy guarantees as a function of problem parameters and show composition over T rounds; since the algorithm is unchanged, existing $O((NT\log N)^{1/2})$ regret bounds still hold and there is no loss in performance due to privacy. We provide an intuitive explanation using a combination of existing and novel privacy analysis methods. We also show that simple modifications -- such as pre-pulling all arms a fixed number of times, increasing the sampling variance or using improved privacy composition methods -- can provide even tighter privacy guarantees.

3 Bayesian Approach to Measuring Algorithmic Fairness: A Case Study on Compas Recidivism Risk Score

Saeyoung Rho, Junzhe Zhang, Elias Bareinboim, Columbia University, New York, NY, Contact: s.rho@columbia.edu

Algorithmic fairness is receiving increasing attention due to the wide adoption of algorithms in critical areas with significant socioeconomic implications, such as criminal justice. Despite various definitions of algorithmic fairness proposed based on a counterfactual framework, the identification of counterfactual probabilities remains challenging without a concrete solution. In this paper, we propose a Bayesian approach to evaluate counterfactual fairness conditions, given a graphical structure and data. To demonstrate the process, we analyze COMPAS recidivism risk score to identify three variations of counterfactual fairness conditions for protected attributes (race, age, sex) on the algorithm's risk score. Our results indicate that the degree of fairness/discrimination varies depending on the choice of the fairness definition.

Recent Advancement of Organ Transplantation

Community Committee Choice Session

Session Chair: Yue Hu, 1</sup

1 A Data-Driven Approach for Identifying Candidates for Xenotransplant Human Clinical Trials

Baris Ata[1], Robert A. Montgomery[2], Jesse D. Schold[3], Y. Naz Yetimoglu[1], [1]The University of Chicago, Chicago, IL, [2]NYU Langone Health, New York, NY, [3]University of Colorado Anschutz Medical Campus, Aurora, CO, Contact: yyetimog@chicagobooth.edu

Xenotransplantation offers a potential solution to the scarcity of deceased-donor kidneys. The successful investigational transplants of genetically engineered pig kidneys to brain-dead patients suggest that the first human clinical trials are near. We use a data-driven approach to identify viable candidates for the first human clinical trials. Our method can flag patients with high statistical accuracy and suggest viable candidates for the first human clinical trials. That is, the great majority of the flagged patients have lower life expectancy under the status quo than with a xenotransplant. However, it has a relatively low capture rate, i.e., it doesn't flag every viable patient. This poses a challenge for the later stages of clinical trials. A bucketing approach for grouping patients alleviates this problem by identifying a larger fraction of viable candidates.

2 Using Machine Learning Predictions to Improve Utilization and Reduce Discards in Deceased Donor Organ Allocation

Nikhil Agarwal[1], Itai Ashlagi[2], Grace Guan[2], Paulo Somaini[3], Jiacheng Zou[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Stanford University, Stanford, CA, [3]Stanford Graduate School of Business, Stanford, CA, Contact: gzguan@stanford.edu

While there are over 100,000 patients waiting for a kidney transplant in the U.S., over 20% of procured deceased donor kidneys are discarded. It is important to identify when a kidney is at risk of being discarded, because organ procurement organizations can expedite the organ to a more accepting transplant center lower down on the waiting list to avoid discard. We develop a machine learning model to predict whether a donor will be at risk of being discarded, and we conduct randomized field experiments to evaluate the efficacy of this tool.

3 Targeted Priority Mechanisms in Organ Transplantation

Ruochen Wang[1], Sait Tunc[2], Matthew Ellis[3], Burhaneddin Sandıkçı[4], [1]Virginia Tech, Blacksburg, VA, [2]Virginia Tech, Blacksburg, VA, [3]Duke Health, Durham, NC, [4]Istanbul Technical University, Istanbul, Turkey. Contact: rcwangise@vt.edu

This paper designs and analyzes implementable voluntary nudge mechanisms that promote, but not enforce, higher utilization of organs as well as efficient matching between organs and patients without mandating a complete redesign of of the system. In particular, we study targeted priority mechanisms, which give priority to a target class of candidates on a pre-defined set of organs if they agree to limit their pool of organ offers to this targeted set. We then characterize the equilibrium behavior of the agents under such mechanisms, identify the impact of these mechanisms on several performance metrics, and investigate their optimal design.

4 Structural Estimation of Kidney Transplant Candidates' Quality of Life Scores

Baris Ata[1], John Friedewald[2], Yue Hu[3], A. Cem Randa[4], [1]University of Chicago, Chicago, IL, [2]Northwestern University, Evanston, IL, [3]Stanford University, Stanford, CA, [4]Uber, San Francisco, CA

We develop a framework for assessing the impact of changes to the deceased-donor kidney allocation policy taking into account transplant candidates' endogenous organ acceptance behavior. To be specific, we construct a dynamic structural model of transplant candidates' acceptance and rejection decisions for organ offers, and perform various counterfactual studies to assess policy changes.

Rethinking Healthcare and Pharmaceutical SCs

Community Committee Choice Session

Session Chair: Benjamin Grant, Clemson University, Greenville, SC

Session Chair: John Lowrey, Northeastern University, Boston, MA

1 E-Access versus Physical Access: An Examination of Telehealth Adoption

Eric Xu, [1</sup]

As interest in telehealth has expanded in recent years, it is more important than ever to understand the tradeoffs patients make when deciding about whether to use in-person services or telehealth services. Therefore, we examine the impact of telemedicine adoption on primary care use, specifically examining the conditions by which telehealth consultations become a substitute for in-person care or a compliment to in-person care. Using a unique dataset of insurance claims for primary care visits, we examine in-person, asynchronous, and synchronous primary care visits.

2 Place-Based Care Continuity and Childhood Obesity

John Lowrey[1], Ben Grant[2], [1]Northeastern University, Boston, MA, [2]Clemson University, Clemson, SC, Contact: j.lowrey@northeastern.edu

Primary care continuity has been linked to better health outcomes. Yet, higher continuity could also be the result of low healthcare access, since patients with low access may be forced to see the same provider. We account for differences in health access and outcomes using information on the patients' residence-based social determinants of health. Using a two-stage least squares approach, we find that care continuity improves health outcomes. While care continuity effect generally improves health for youth in more affluent areas, provider switching may be beneficial for youth in more deprived areas. Thus, place-based social determinants of health appear to condition the effect of operational interventions like continuity.

3 Balancing Speed-Safety Tradeoffs in the Drug Approval Process

Hanu Tyagi[1], Junghee Lee[2], Rachna Shah[1], [1]University of Minnesota, Minneapolis, MN, [2]University of Notre Dame, Notre Dame, IN

Getting new products to market fast is advantageous. However, increased speed could negatively impact product safety. We study the speed-safety tradeoff in the context of the US pharmaceutical industry. We compile a unique dataset of drugs approved by the FDA and find that speed negatively impacts safety.

Emerging Topics in Personalized Medicine

Community Committee Choice Session

Session Chair: Esmaeil Keyvanshokooh, Mays Business School, Texas A&M University, College Station, TX
Session Chair: Kyra Gan, Harvard University, Cambridge, MA

1 Resource-Constrained Optimal Dynamic Treatment Rules for HIV Treatment Success

Lina M. Montoya, University of North Carolina at Chapel Hill, Chapel Hill, NC

A recent sequential multiple assignment randomized trial (ADAPT-R) of HIV-positive patients in Kenya showed that, on average, conditional cash transfers (CCTs) for on-time clinic visits increased viral suppression (VS) compared to standard of care. We estimated an optimal dynamic treatment rule for CCT use; this rule would assign CCTs to all persons. In practice, however, resources may constrain the proportion of persons who can receive a CCT. One response is to selectively administer CCTs to only those most likely to benefit. Thus, we estimated the optimal stochastic allocation rule under a range of constraints on the proportion of patients who can receive a CCT. We then evaluated the counterfactual probability of VS under each resource-constrained optimal rule and contrast it with the counterfactual probability under the static rule in which everyone receives CCTs.

2 Practical Considerations when Designing an MRT for an App-Based mHealth Intervention

Madeline Abbott, Michael Dorsch, Xutong Zhang, Juan Arzac, Walter Dempsey, University of Michigan, Ann Arbor, MI, Contact: mrabbott@umich.edu

The ubiquitous nature of mobile health technology has expanded opportunities for integration of online learning into traditional clinical trial designs and thus allows researchers to learn individualized treatment policies using approaches such as micro-randomized trials (MRTs). In a trial aimed at reducing dietary sodium intake, we embed a Thompson sampler into an MRT to optimize delivery of an app-based intervention. We encountered various challenges during implementation, including how to: (i) define a relevant proximal outcome, (ii) specify a robust statistical model that allows for automation, (iii) balance model flexibility with computational cost, and (iv) address missing values in gradually collected data. In this work, we describe important factors to consider when developing solutions to these practical issues using this specific MRT as an example.

3 Contextual Reinforcement Learning Under Safe Exploration with Application to Type 2 Diabetes

Esmaeil Keyvanshokooh[1], Junyu Cao[2], [1]Mays Business School, Texas A&M University, College Station, TX, [2]The University of Texas at Austin, Austin, TX, Contact: keyvan@tamu.edu

Inspired by medical decision-making applications, this work formulates a Contextual Markov Decision Process under safety constraints. We develop a class of new reinforcement learning algorithms that accounts for personalization, safety, and general statistical models for modeling uncertainty. We prove that our algorithm admits a sublinear regret. We leverage clinical trial data on type 2 diabetes to evaluate the effectiveness of our algorithms in clinical practice.

4 Contextual Bandits with Budgeted Information Reveal

Kyra Gan[1], Esmaeil Keyvanshokooh[2], Xueqing Liu[3], Susan Murphy[4], [1]Cornell Tech, New York City, NY, [2]Mays Business School, Texas A&M University, College Station, TX, [3]Duke-NUS Medical School, Singapore, NA, Singapore; [4]Harvard University, Cambridge, MA, Contact: kyragan@cornell.edu

In digital health, to ensure the effectiveness of the treatments, patients are often requested to take actions that have no immediate benefit to them, which we refer to as pro-treatment actions. In practice, clinicians have a limited budget to encourage patients to take these actions and collect additional information. We introduce a novel optimization and learning algorithm to address this problem. This algorithm effectively combines the strengths of two algorithmic approaches in a seamless manner, including 1) an online primal-dual algorithm for deciding the optimal timing to reach out to patients, and 2) a contextual bandit learning algorithm to identify the best personalized treatment via the digital health interface. We prove that this algorithm admits a sub-linear regret bound. We illustrate the usefulness of this algorithm on both synthetic and real-world data.

Continuous Location Analysis II

Community Committee Choice Session

Session Chair: Zvi Drezner, California State University Fullerton, Fullerton, CA

1 Suboptimality of Hospital Locations in Southeastern USA

Joy Bhadury, Univ of North Carolina Greensboro, Greensboro, NC, Contact: joy-bhadury@uncg.edu

In this paper, we will study the impact ofsuboptimal locations of hospitals in four Southeastern states: North Carolina,South Carolina Virginia and Tennessee. Two different models will be proposedstudying inefficiencies engendered by the suboptimal locations and the impactof hospital closures on the same.

2 A Trajectory Based Heuristic for the Planar P-Median Problem

Zvi Drezner[1], Jack Brimberg[2], Anita Schoebel[3], [1]California State University Fullerton, Fullerton, CA, [2]The Royal Military College of Canada, Kingston, ON, Canada; [3]TU Kaiserslautern, Kaiserslautern, Germany. Contact: zdrezner@fullerton.edu

We present a novel approach for solving the planar p-median problem. A sub-class of the distributed p-median problem is identified that allows a continuous trajectory of local optima to be constructed as a parameter alpha decreases from 1 to 0. The trajectory converges to a local optimum of the planar p-median problem as alpha approaches 0. Computational results are very encouraging. For larger instances tested, the proposed trajectory method finds better solutions in a small fraction of the time taken by a conventional multi-start local search. The methodology is readily extended to continuous p-median problems in higher dimensional spaces.

3 Trade-Offs of Facility Location, Market Penetration and Long-Term Sustainability

Farhood Rismanchian[1], Mozart Menezes[2], Farzad Zaerpour[3], [1]The University of Winnipeg, Winnipeg, MB, Canada; [2]Area of Excellence The Complexity Advantage, NEOMA, Paris, France; [3]The university of winnipeg, Winnipeg, MB, Canada. Contact: f.rismanchian-ra@uwinnipeg.ca

The addition of new facilities, like sales points, to increase market share and sales is a common strategic decision. It assumes that higher market share leads to increased profit. Traditional facility location problems prioritize cost minimization, not profit maximization. However, incorporating new facilities may result in additional costs affecting overall profit. Our study explores the trade-off between profit, location, and design characteristics. We developed a flexible model considering sales revenue, inventory costs, setup costs, and market share to maximize system profitability. Additionally, we assess carbon emissions and profits in a sustainable, low-carbon supply chain network.

Novel Revenue Management Approaches in Service Industries

Community Committee Choice Session

Session Chair: Metin Cakanyildirim, The University of Texas at Dallas, Richardson, TX

Session Chair: Milad Armaghan, Richardson, TX

4 Joint Optimization of Pricing and Personalized Recommendations in Online Retailing

Murray Lei[1], Zhong-Zhong Jiang[2], Dan Zhang[3], Rui Zhang[4], Yunwei Qi[5], [1]Queen’s University, Kingston, ON, Canada; [2]Northeastern University-China, Shenyang, China; [3]University of Colorado, Boulder, CO, [4]University of Colorado Boulder, Boulder, CO, [5]Alibaba, Hangzhou, China. Contact: rui.zhang@colorado.edu

We study the problem of pricing and personalized recommendations in online retailing. A set of products is offered to different types of customers. The prices can vary over time but must be consistent across customer groups. Also, customers’ decisions can be influenced by personalized product recommendations. But, there is a limit on the number of products that can be recommended to each customer. We formulate the problem as a finite-horizon stochastic dynamic program. We propose a solution strategy based on Lagrangian relaxation. We further obtain two sets of theoretical results. First, we show that the LP formulation of the Lagrangian relaxation admits a compact reformulation. Second, we prove a performance guarantee for a heuristic control method based on the solution. The policies and bounds are validated with data from a leading online retailer in China.

5 Buyout Price Optimization in the Rent-To-Own Business

Milad Armaghan, Metin Cakanyildirim, Andrew E. Frazelle, The University of Texas at Dallas, Richardson, TX, Contact: milad.armaghan@utdallas.edu

We study the multidimensional price optimization problem faced by a rent-to-own (RTO) firm, which rents a product for a periodic fee and offers it for sale at a sequence of prices during rental. RTO industry prices decrease steeply initially and gradually later. However, we prove for a special case that the optimal prices are in contrast concave decreasing. To overcome the nonconcavity of the profit, we formulate an equivalent bilevel optimization and transform the inner problem into a deterministic dynamic program to find the globally optimal price path. We also apply our methodology to jointly optimize prices and inventory. Applying our algorithm in a case study, we again find that optimal prices decrease gradually early in the agreement and steeply later. Moreover, our methodology yields approximately a 22% profit improvement relative to industry prices.

6 Luxury Brands' Fight Against Counterfeits, Public or Dark?

Lai Wei, Larisa Kovalenko, Boston College, Chestnut Hill, MA, Contact: weilx@bc.edu

Luxury products can face both deceptive and non-deceptive counterfeits at the same time. We characterize the optimal anti-counterfeit policies in generating higher revenues and policies that effectively decrease the volume of counterfeits sales, in a market consisting of two groups of customers, naive and sophisticated customers.

7 Managing Equipment Rentals: Unreliable Fleet, Impatient Customers, and Finite Commitment Capacity

Mohammad Firouz[1], Linda Li[2], Burcu B. Keskin[3], [1]The University of Alabama at Birmingham, Birmingham, AL, [2]Missouri State University, Springfield, MO, [3]University of Alabama, Tuscaloosa, AL

In this paper, we discuss fleet size decisions of an equipment rental firm. In our setting, we allow for partial backordering, reneging, and finite commitment capacity. Moreover, we explicitly consider the breakdown possibility of the available equipment fleet. We develop an efficient recursive algorithm to solve the underlying two-dimensional stochastic single-player model. Our algorithm determines the global optimal fleet size of the firm for the same reneging and equipment return rates. Extending our model to a two-player game, we propose an approximation heuristic to derive closed-form solutions to estimate equilibrium fleet sizes under complete information. Using our heuristic as the initial solution, we develop a simulation model to determine the exact equilibrium fleet sizes and draw a detailed comparison between the two-player and single-player models.

Healthcare Analytics

Community Committee Choice Session

Session Chair: Zhichao Zheng, Singapore Management University, Singapore, Singapore

1 Behavioral Responses to Kidney Allocation Priority: A Regression Discontinuity Analysis

Jiayi Liu[1], Diwas S. KC[2], [1]Virginia Tech, Blacksburg, VA, [2]Emory University, Atlanta, GA, Contact: jyliu@vt.edu

The severe shortage of deceased-donor kidneys has turned the allocation into a rationing problem. Prior research and policy guidance on the allocation system design often makes restrictive assumptions about patient behavior. This study provides quasi-experimental evidence on how patients respond to allocation rules. We exploit a national kidney allocation policy that assigns priority based on an exogenous cutoff. Allocation priority produces a positive supply shock: prioritized patients receive more frequent kidney donors with generally higher quality. We find that prioritized patients become more selective; they are much less likely to accept an organ donor of a given quality, which can lead to an increasing number of organs being discarded, further exacerbating the organ shortage. These findings have implications for kidney allocation policy making.

2 Small Area Estimation of Case Growths for Timely Covid-19 Outbreak Detection

Zhaowei She[1], Zilong Wang[2], Jagpreet Chhatwal[3], Turgay Ayer[4], [1]Singapore Management University, Singapore, Singapore; [2]Georgia Institute of Technology, Industrial Systems and Engineering, Atlanta, GA, [3]Harvard Medical

School, Mass General Hospital, Boston, MA, [4]Georgia Tech, Atlanta, GA

Rapid and accurate detection of local outbreaks is critical to tackle resurgent waves of COVID-19. A fundamental challenge in case growth rate estimation, a key epidemiological parameter, is balancing the accuracy vs. speed tradeoff for small sample sizes of counties. We develop an algorithm, Transfer Learning Generalized Random Forest (TLGRF), that balances this tradeoff. Through transfer learning, TLGRF can accurately estimate case growth rates for counties with small sample sizes based on relevant day and county-level features affecting the disease spread. TLGRF outperforms established growth rate estimation methods and demonstrated that it can greatly improve the timely detection of outbreaks. We thus developed a open source tool for timely detection of COVID-19 outbreaks in each U.S. county, which received substantial attention by policymakers.

3 Estimating Patient Health Transition from Data Censored by Treatment-Effect-Based Policies

Qian Luo[1], Yan He[2], Hai Wang[3], Zhichao Zheng[3], Haidong Luo[4], Oon Cheong Ooi[4], [1]Xi'an Jiaotong-Liverpool University, Suzhou, China; [2]Biofourmis, Singapore, Singapore; [3]Singapore Management University, Singapore, Singapore; [4]National University Hospital, Singapore, Singapore

Treatment-effect-based decision policies in healthcare can censor patient health transition observations and distort transition probability matrix (TPM) estimation. We introduce a structural model to recover true TPMs from censored data, proving consistency, asymptotic normality, and log-likelihood maximization. Using hypothetical data, we highlight our model's advantages over benchmarks ignoring censoring. Applied to extubation in ICU, our method, with more accurate TPMs accounting for policy censoring, reduces patient ICU stay compared to benchmarks.

4 A Two-Stage Stochastic Deceased-Donor Organ Allocation Model for Kidney Transplants

Daniela Cantarino, Jorge Andrés Acuna, Jose L. Zayas-Castro, University of South Florida, Tampa, FL, Contact: danieladuran@usf.edu

Chronic kidney disease (CKD) affects 1 in 7 adults in the United States, decreasing the duration and quality of life of 37 million individuals nationwide. Studies have shown that renal transplants in CKD patients add an average of 10 years to life compared to dialysis. However, the highest unsatisfied demand among all main organs is linked to the kidney, with over 70% of its registered patients still waiting for a renal replacement. We propose a two-stage stochastic deceased-donor organ allocation model considering pre- and post-transplant processes aimed at improving the quality and quantity of matches. Factors considered include waitlist mortality, expected survival, traveled distances, organ decay and biological compatibilities.

Supply Chain Sustainability and Risk Analysis

Contributed Session

Session Chair: Qiang Qiang, Penn State, Malvern, PA

1 Non-Committed Cost Auditing in Supply Chain Contracts

Jing Li[1], Wanshan Zhu[1], Zhengping Wu[2], [1]Renmin University of China, Haidian District, Beijing, China; [2]Syracuse University, Syracuse, NY, Contact: rmbslijing@ruc.edu.cn

As a widely used means in supply chain practice, audit can be used as an auxiliary means to alleviate the supply chain incoordination problem under asymmetric information that cannot be solved by profit-sharing contract and other means. Although some studies have considered audit issues under supply chain contracts in the literature, few studies are conducted from the perspective of principal-agent theory, not to mention the situation where retailers do not commit to audit strategies under the principal-agent model. In this paper, under the principal-agent theory model, we consider the optimal audit strategy when the retailer makes no commitment to the audit mechanism. We explore the unique features of the audit strategy and the sensitivity of the optimal strategy to various factors.

2 Financing Risky Supplier: Green Technology Investment and Regulation

Yutian Li, University of Science and Technology of China, Hefei, China. Contact: liyutian@ustc.edu.cn

As sustainability plays a prominent role everywhere, supply chain disruption frequently occurs because of supplier's violation to environmental regulation. In a supply chain consist of a supplier and a manufacture, both of them try to invest in green technology to reduce the risk of regulation violation. However, this investment aggravates the supplier's financial problem which is a significant risk of supply disruption as well. In this paper, we explore how a manufacture financially subsidizes supplier to mitigate the disruption risk from regulation violation and bankruptcy. Meanwhile, we will show that an aggressive regulation is not always encouraging investment on green technology.

3 The Multi-Period Interactive CLSC Network
Qiang Qiang, Penn State, Malvern, PA, Contact: qzq10@psu.edu
Inspired by the recent business cases, we develop a coupled multi-period CLSC network model dealing with heterogeneous products facing different demand markets. The end-of-life product from the forward supply chain is collected, recycled and the raw material is extracted to be used as an input for the reverse supply chain which produces another type of product. In particular, interactions between the two supply chains with inventory cost and innovation competition are analyzed. An algorithm is introduced to study the network equilibrium. Numerical examples are used to illustrate the model.

Novel Operational Strategies in Service
Community Committee Choice Session
Session Chair: Yang Li, Ivey Business School, Western University, London, ON, Canada

1 In-Queue Queueing: Gaining Utility Through Ancillary Service While Waiting
Yang Li[1], Baolong Liu[2], Rowan Wang[3], [1]Ivey Business School, Western University, London, ON, Canada; [2]ShanghaiTech University, Shanghai, China; [3]Southern University of Science and Technology, Shenzhen, China. Contact: liubl@shanghaitech.edu.cn
We examine a queueing system with the primary service provider also offering an ancillary service. The customers are categorized into two groups: the ones who exclusively come to the primary service (Type-P) and the ones who are also interested in the ancillary service (Type-A). While both types come for the primary service, Type-A customers line up in an embedded queue for the ancillary service which attracts more demand but increases the expected waiting time. Thus, there exists a trade-off between demand expansion and the queue congestion effect. With queueing models, the results show that not only does the ancillary service expand demand, but also improves welfare, although it may lead to a lower profit for providers compared to the primary queue without ancillary service and the primary priority queue, due to the cost of providing ancillary service.

2 To App or Not to App: Omnichannel Competition
Abhishek Ghosh[1], Achal Bassamboo[2], Martin Lariviere[2], [1]Freeman School of Business, Tulane University, New Orleans, LA, [2]Northwestern University, Evanston, IL, Contact: aghosh2@tulane.edu
We use a game theoretic model to study, from an operations perspective, why some omnichannel firms offer an app and others don't.

3 On the Social Loss from Balking
Guanling Yang, Ricky Roet-Green, Simon Business School, University of Rochester, Rochester, NY, Contact: gyang15@simon.rochester.edu
Empirical studies and observations have demonstrated that social loss due to balking is significant, yet this phenomenon has not been adequately addressed in canonical strategic queueing literature. In this study, we examine the individual equilibrium strategy and the socially optimal policy for both observable and unobservable fundamental M/M/1 queueing models, while taking into account social loss.

4 Sales Versus Subscription Business Models in Retail: Price and Assortment Competition
Mehmet Sekip Altug[1], Tolga Aydinliyim[2], Oben Ceryan[3], Aditya Jain[4], [1]George Mason University, Fairfax, VA, [2]Baruch College, CUNY, New York, NY, [3]City, University of London, London, United Kingdom; [4]Baruch College, Zicklin School of Business, New York, NY, Contact: aditya.jain@baruch.cuny.edu
Motivated by retailers' introduction of subscription services, we study consumers' self-selection between "buying from seller firms" versus "subscribing to renter firms." Modeling price and assortment competition among sellers and renters, we characterize a solution wherein the renter's large assortment at premium prices and the seller's limited assortment split equilibrium demand.

Monday, October 16, 12:45 PM - 2:00 PM

MC28

CC-North 132A
Data Analytics in Operations Management
Community Committee Choice Session

Session Chair: Qi Annabelle Feng, Purdue University, West Lafayette, IN
Session Chair: Jian Wu, Purdue University, West Lafayette, IN

1 Vehicle Rebalancing in a Shared Micromobility System with Rider Crowdsourcing

Ziliang Jin[1], Yulan Amanda Wang[2], Yun Fong Lim[3], Kai Pan[2], Zuo-Jun Max Shen[4], [1]The Hong Kong Polytechnic University, Hong Kong, China; [2]The Hong Kong Polytechnic University, Hung Hom, Hong Kong; [3]Singapore Management University, Singapore, Singapore; [4]University of California Berkeley, Berkeley, CA, Contact: kai.pan@polyu.edu.hk

We consider a shared micromobility operator who can crowdsource individual riders with reward incentives in addition to engaging a third-party logistics provider (3PL) to relocate the vehicles. We construct a time-space network with multiple service regions and formulate a two-stage stochastic mixed-integer program considering uncertain customer demands. We develop an efficient solution approach that incorporates scenario-based and time-based decomposition techniques. We solve large-scale problem instances based on real data and provide extensive managerial implications. Introducing rider crowdsourcing to the 3PL can increase profit, reduce demand loss, and improve vehicle utilization rate without affecting existing 3PL commitments. The 3PL is more efficient for mass relocation, while rider crowdsourcing is more efficient for sporadic relocation.

2 Contextual Data-Integrated Newsvendor Solution with Operational Data Analytics (ODA)

Qi Annabelle Feng, J. George Shanthikumar, Jian Wu, Purdue University, West Lafayette, IN, Contact: wu1549@purdue.edu

We analyze the inventory decision for an unknown demand that may be learned from historical data of the demand and related covariates. We apply the operational data analytics (ODA) framework to formulate the data-integration model and the validation model. The ODA solution demonstrates superior performance with a finite sample size.

3 Federated Learning on Adaptively Weighted Nodes by Bilevel Optimization

Yankun Huang[1], Qihang Lin[1], Nick Street[1], Stephen Baek[2], [1]Tippie College of Business, The University of Iowa, Iowa City, IA, [2]School of Data Science, The University of Virginia, Charlottesville, VA, Contact: yankun-huang@uiowa.edu

We propose a federated learning method with weighted nodes in which the weights can be modified to optimize the model's performance on a separate validation set. The problem is formulated as a bilevel optimization where the inner problem is a federated learning problem with weighted nodes and the outer problem focuses on optimizing the weights based on the validation performance of the model returned from the inner problem. A communication-efficient federated optimization algorithm is designed to solve this bilevel optimization problem. Under an error-bound assumption, we analyze the generalization performance of the output model and identify scenarios when our method is in theory superior to training a model only locally and to federated learning with static and evenly distributed weights.

4 E-Commerce Order Fulfillment with Limited Time Window

Quan Zhou, Mehmet Gumus, Sentao Miao, McGill University, Montreal, QC, Canada. Contact: quan.zhou3@mail.mcgill.ca

We studied a multi-warehouse multi-location order fulfillment problem under limited logistic resources. Orders are fulfilled in batches, and each order has a fixed lifetime to be fulfilled before being lost. We formulate this problem as a finite-horizon dynamic program. We first characterize the structural properties of an optimal fulfillment policy and then utilize these properties to design effective heuristics. We proposed two heuristic policies based on Lagrangian relaxation. Both heuristics are asymptotically optimal when the number of locations becomes large. Our results suggest that allowing a multi-period fulfillment window is a solution to alleviate logistic capacity constraints and that incorporating this information into the decision-making process can bring additional benefits.

Innovative Energy Operations: Empirical and Theoretical Studies

Community Committee Choice Session

Session Chair: Nil Karacaoglu, The Ohio State University, Columbus, OH
Session Chair: Nur Sunar, 1</sup

1 Electricity Pricing with Limited Consumer Response

Fariba Farajbakhsh Mamaghani[1], Saed Alizamir[2], Shouqiang Wang[3], [1]Tulane University, River Ridge, LA, [2]Yale University, New Haven, CT, [3]The University of Texas at Dallas, Richardson, TX, Contact: fariba@tulane.edu

Implementing demand response (DR) programs in the residential electricity market to reduce demand-supply mismatches has generated mixed results. As a distinctive feature of this market, the retail prices are typically set in advance and hence cannot incorporate the random demand shocks that may occur closer to the consumption point. In this paper, we construct a demand model to describe how consumers make consumption decisions in response to random external factors representing their ambient environment (e.g., outdoor temperature) for a given price. Analyzing their behavior under "rational inattention" identifies responsive and non-responsive regions to demand shocks. This research contributes to understanding DR programs and provides insights for designing effective pricing mechanisms.

2 Optimal Maintenance Scheduling on Power Plants

Abdullah Coskun, Omer Karaduman, Stanford University, STANFORD, CA, Contact: ACOSKUN@STANFORD.EDU

Using rich data on hourly physical productivity and maintenance schedules from US power plants, we study the effects of maintenance schedules on efficiency. Our research aimed to gain a comprehensive understanding of how different maintenance strategies impact the productivity and performance of power plants. Building upon the evidence derived from the empirical data, we developed a theoretical model to determine the optimal maintenance schedules. This model takes into account various factors, such as the frequency and duration of maintenance activities, the specific needs and characteristics of power plants, and the potential impact on efficiency.

3 IoT-Based Nudging for Energy Saving: More Can be Less for Organizations and Environment

Jacob Zijian Zeng[1], Serasu Duran[2], Nil Karacaoglu[3], Sunar Nur[1], [1]UNC Kenan-Flagler Business School, Chapel Hill, NC, [2]Haskayne School of Business, Calgary, AB, Canada; [3]The Ohio State University, Columbus, OH, Contact: jacob_zeng@kenan-flagler.unc.edu

We estimate the impact of IoT-based nudging on energy saving for organizations.

4 Ppas in the Context of Renewable Electricity

Subas Acharya[1], Roza Galeeva[1], Helyette Geman[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, Contact: sa.subas@gmail.com

The first part of the paper analyzes the shapes over the day of electricity prices and generation from renewables, particularly solar and wind. Using these factors as a foundation, our objective is to analyze the valuation of Power Purchase Agreements (PPAs) and the risks associated with electricity produced by renewable sources - thus enriching the Environmental, Social, and Governance (ESG) profile of the buyer. We further present a methodology for determining optimal hedge ratios to minimize risk for buyers or sellers of renewable facilities. We focus on the two regions: Texas (Electric Reliability Council of Texas (ERCOT)) and California.

Technology and Innovation Management

Community Committee Choice Session

Session Chair: Wenli Xiao, University of San Diego, San Diego, CA

Session Chair: Qiong Chen, Southwestern University of Finance and Economics, Chengdu

1 Does Network Help? Innovation During Distressed Times

Pankaj Kumar[1], Xiaojin Liu[2], Anant Mishra[3], [1]Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Virginia Commonwealth University, Richmond, VA, [3]Carlson School of Management, University of Minnesota, Minneapolis, MN, Contact: xliu22@vcu.edu

Collaboration is generally viewed as a strategic resource to augment innovation output. In this study, we empirically investigate how an employee's network of relationships within a firm affects their creativity and innovation productivity during times of distress.

2 Technological Resource Reconfiguration in Declining Firms

Yang Ye, Southwestern University of Finance and Economics, Chengdu, China

Most firms face declining problems, but handling organizational decline through technological resource reconfiguration is not well studied. Previous studies have extensively investigated how innovation strategies can help declining firms turn around, but technological resource reconfiguration is different from broad innovation strategies as it focuses on a processed examination of resource flows and stocks. This study examines the content and timing requirements of technological resource reconfiguration by analyzing patent reassignments of declining firms. It also investigates how different causes of decline and firms' technological and distress experiences play a role in initiatives to reconfigure with technological resources.

3 Achieving Performance in Innovative Projects: Strategies for Planning and Adapting

Gulru Ozkan-Seely[1], Surya D. Pathak[1], Mohan V. Tatikonda[2], P.V. Balakrishnan[1], [1]University of Washington, Bothell, WA, [2]Indiana University, Indianapolis, IN, Contact: gulru@uw.edu

We investigate adaptive mechanisms and planning strategies for innovative projects with characteristics such as complexity, uncertainty, ambiguity, novelty and scale. Data is collected from sixteen NPD projects from one high-tech organization, and an analytical optimal control model is developed to capture adaptation and planning strategies that maximize performance at project completion. We show that initial levels of project structuring, uncertainty resolution and performance potential result in wide range of strategies, varying from focusing on expending high rate of efforts early in the project to extending peak efforts to later in the project. Also, we show that adaptive range widely, from taking no action to modifying ultimate goals.

4 Innovation Investments Of Firms, Efficiency Enhancement And Spillover Effect In Supply Chain

Shucheng MIAO[1], Andy Yeung[2], [1]The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]The Hong Kong Polytechnic University, Kowloon, Hong Kong. Contact: jason.miao@connect.polyu.hk

Although innovation applications have been frequently studied, it is unclear whether and when innovation investments lead to true improvement of operational efficiency, which is a key factor in operations management. Specifically, we apply SFA and GMM techniques to examine this impact and relevant moderators. By using innovation investment data from Lightcast, we show the positive impact of innovation investments, and this impact is stronger for firms with higher R&D intensity or in complex environments. Moreover, we illustrate the spillover effect of innovation investments in supply chain networks. Drawing on the social network perspective, we show this relationship is continuous and stronger for more concentrated and complex networks. These findings highlight strategies that make innovation capability a more crucial asset in the supply chain network.

Amazon Supply Chain Optimization

Community Committee Choice Session

Session Chair: Garrett J. van Ryzin, Amazon, New York, NY

1 Configurable Simulation-Based Search for Heterogeneous Opportunity Costs of Capacity

Michael Bloem, Amazon, Bellevue, WA

In recent years, the Amazon Fulfillment Network (AFN) has grown in scale and evolved into multiple layers. This creates new challenges for inbound and placement optimization under labor, transportation, and storage capacity constraints. Inbound and placement optimization models penalize capacity consumption with opportunity costs. Appropriate opportunity costs are found using a high-fidelity AFN simulator. This talk will describe a configurable cost search approach that enables simultaneous search for heterogenous costs of capacity. The approach decomposes costs into groups based on constraint type, topology, or other considerations. Group cost updates are independent and can use different first- or second-order sub-gradient-based algorithms. We demonstrate how this approach allows us to find acceptable costs for thousands of heterogenous constraints.

2 Simulation-Based Storage Fullness Control and Optimization

Nanjing Jian[1], Garrett J. van Ryzin[2], Lee Dicker[2], Yan Xia[1], [1]Amazon.com, Bellevue, WA, [2]Amazon.com, New York, NY, Contact: nanjjian@amazon.com

Amazon, being "the everything store", sells hundreds of millions of products. The products share the warehouse storage capacity across multiple weeks before peak. High storage fullness negatively impacts the labor throughput, increasing the variable cost for processing inventory. While the current inventory management systems treat those costs as constants, this leads to high operational inefficiency around peak. We propose to incorporate nonlinear labor costs as functions of storage fullness into the existing large-scale, simulation-based capacity control system. The algorithm is inspired by multi-agent distributed optimization. It searches for the primal storage fullness target and dual capacity cost over iterations of stochastic simulations, and at convergence, outputs storage fullness targets that optimize the end-to-end supply chain costs.

3 Order Fulfillment Optimization at Amazon

Weihong Hu[1], Yash Kanoria[2], Andrea Qualizza[3], Jikai Zou[4], [1]Amazon, Bellevue, WA, [2]Columbia University, Cambridge,

MA, [3]Amazon.com, McLean, VA, [4]Amazon Web Service, Seattle, WA

We will discuss how Amazon makes order assignment decisions at scale for tens of millions of orders daily. Order assignment decisions take into account several customer experience and network objectives to determine how to consolidate demand, where, when and how to fulfill each shipment. Historically our models encoded the various objectives as different cost components at the unit or shipment levels. As we recently transitioned the U.S. fulfillment network to a regionalized model, we pivoted away from shipment level optimization and towards an approach where we explicitly optimize for and trade-off network level objectives without sacrificing customer experience.

4 Consensus Planning Protocol

Garrett J. van Ryzin, Amazon, New York, NY

Consensus Planning Protocol (CPP) is a methodology developed to coordinate decision-making among distributed agents. While initially created for the Amazon supply chain, it has broad applications in distributed optimization settings. This talk provides a practical introduction to CPP, focusing on key concepts, features, and intuition without excessive technicalities. We examine three Amazon applications to provide practical examples of CPP and describe optimization and software tools for implementing it.

CC-North 221B

Behavior-Informed Operation of Urban Transportation Systems

Community Committee Choice Session

Session Chair: Tianming Liu, University of Michigan, Ann Arbor, MI

1 Understanding The Dwelling Behavior Of Ride-sourcing Drivers At Transportation Hubs From Behavioral Queuing Perspective

Tianming Liu[1], Zhengtian Xu[2], Yafeng Yin[1], Jussi Keppo[3], [1]University of Michigan, Ann Arbor, MI, [2]The George Washington University, Washington, [3]National University of Singapore, Singapore, Singapore. Contact: tianmliu@umich.edu

Urban transportation hubs, such as airports and railway stations, serve as major locations for ride-hailing services, where drivers frequently wait to pick up passengers. This waiting often leads to the formation of driver queues, resulting in increased fleet idleness and decreased system efficiency. This study aims to the dwelling behavior of ride-sourcing drivers at transportation hubs from a behavioral queueing perspective. Through an analysis of a comprehensive dataset of idle drivers during a natural experiment at a large city airport, valuable insights are generated regarding drivers' strategies and behavioral biases in the dwelling process, along with corresponding management strategies.

2 Is Free Transit Just? Quantifying the Impact of Ethical Principles on Transit Design and Finance

Tianxing Dai, Hongyu Zheng, Marco Nie, Northwestern University, Evanston, IL, Contact: tianxingdai2025@u.northwestern.edu

This study investigates the impact of ethical principles on transit design and finance. We develop a stylized, accessibility-based transit design model that finances transit operations from fixed subsidy, farebox revenue, and supplementary taxation. Our results confirm egalitarian designs prioritize carless population, whereas utilitarian designs favor drivers. We also find free public transit is desirable only when accompanied with aggressive tax schemes dedicated to improving transit services, even when the design is guided by an egalitarian principle.

3 Understanding Multi-Homing and Switching by Platform Drivers

Xiaotong Guo[1], Andy Haupt[1], Hai Wang[2], Jinhua Zhao[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Singapore Management University, Singapore, Singapore. Contact: xtguo@mit.edu

Freelance drivers in the shared mobility market frequently switch or work for multiple platforms, affecting driver labor supply. Due to the importance of driver labor supply for the shared mobility market, understanding drivers' switching and multi-homing behavior is vital to managing service quality on---and effective regulation of---mobility platforms. However, a lack of individual-level data on driver behavior has thus far impeded a deeper understanding. This paper taxonomizes and estimates perceived switching and multi-homing frictions on mobility platforms. Based on a structural model of driver labor supply, we estimate switching and multi-homing costs in a platform duopoly using public and limited high-level survey data in a shared mobility market with a transportation network company duopoly.

4 Planning, Policy, and Operational Implications of Post-Pandemic Travel Patterns on Urban Transportation Systems

Michael Leong, Massachusetts Institute of Technology, Cambridge, MA, Contact: mleong1@mit.edu

The emerging structure of post-pandemic travel behavior has widespread implications on the long-range planning, policy, and operations of transportation systems and city form. Using anonymized mobile phone data from the Washington DC Metropolitan Area in partnership with WMATA, this study creates a replicable framework to quantify these post-pandemic mobility changes with a focus on the future of work, public transit adaptation, and achieving the climate goals of the century. Key findings include that there are wide divergences by mode, built environment, activity type, and spatial distribution of activity, where suburban centers and downtowns exhibit different roles than pre-pandemic times. Consequently, we articulate infrastructural and operational frameworks to make public transportation, transportation systems, and cities more resilient to the future.

5 Evaluating Service Reliability Of Electrified Freight Networks Using Multi-agent Reinforcement Learning

Aron Brenner[1], Ting Bai[2], Karl H. Johansson[2], Saurabh Amin[3], [1]MIT, Cambridge, MA, [2]KTH, Stockholm, Sweden; [3]MIT, Cambridge, MA, Contact: abrenner@mit.edu

Decarbonizing the freight transportation sector requires strategic allocation of fast charging infrastructure for heavy duty vehicles along major freight corridors. Importantly, this investment in charging infrastructure must be made with consideration towards consequent freight routing and charging behaviors emerging from both inter-fleet competition resulting from public charging resource constraints and cooperation induced by cross-fleet platooning. To this end, we propose a multi-agent reinforcement learning framework for evaluating fleet costs, station revenues, and system reliability under different charging infrastructure allocations and apply our framework to a case study on the Stockholm-Malmö freight corridor.

Discrete Optimization for Trustworthy Machine Learning

Community Committee Choice Session

Session Chair: Connor Lawless, Cornell University, Oakville, ON, Canada

1 Learning Optimal Classification Trees Robust to Distribution Shifts

Nathan Justin[1], sina Aghaei[2], Andres Gomez[1], Phebe Vayanos[1], [1]University of Southern California, Los Angeles, CA, [2]USC, Los Angeles, CA, Contact: njustin@usc.edu

We consider the problem of learning classification trees that are robust to distribution shifts between training and testing/deployment data. This problem arises frequently in high stakes settings such as public health and social work where survey data is highly sensitive to distribution shifts. We demonstrate that the problem of learning an optimal robust classification tree can be cast as a single-stage mixed-integer robust optimization problem with a highly nonlinear and discontinuous objective. We reformulate this problem equivalently as a two-stage linear robust optimization problem for which we devise a tailored solution method. We show an increase of up to 14.16% in worst-case accuracy and of up to 4.72% in average-case accuracy across several datasets and distribution shifts from using our robust tree in comparison to a regularized, non-robust optimal tree.

2 Screening Rules for L0-L2 Regression

Anna Deza, Alper Atamturk, IEOR, UC Berkeley, Berkeley, CA, Contact: annadeza@berkeley.edu

Logistic regression with a large number of features compared to available labels presents numerous challenges for learning. We present screening rules that safely remove features from the sparse logistic regression with L0-L2 regularization before solving the problem. The screening rules are based on the Fenchel dual of strong conic relaxations of the sparse logistic regression problem. Numerical experiments with real and synthetic data suggest that a high percentage of the features can be effectively and safely removed apriori, leading to substantial speed-up in the computations.

3 Shattering Inequalities for Learning Optimal Decision Trees

Zachary Zhou, Justin J. Boutilier, Carla Michini, University of Wisconsin-Madison, Madison, WI, Contact: zzhou246@wisc.edu

Recently, mixed-integer programming (MIP) techniques have been applied to learn optimal decision trees. Empirical research has shown that optimal trees typically have better out-of-sample performance than heuristic approaches such as CART. However, the underlying MIP formulations often suffer from weak linear programming relaxations. We introduce a class of valid inequalities for learning optimal multivariate decision trees, called shattering inequalities. We propose a separation procedure for shattering inequalities and show how to use them as part of the solution process. Numerical experiments show that in most instances, our approach outperforms other approaches from the literature. Theoretical results show that under mild assumptions on the dataset, a well-defined subset of the shattering inequalities are facet-defining.

4 Learning to Branch with Interpretable Machine Learning Models

Selin Bayramoglu[1], George L. Nemhauser[2], Nikolaos Sahinidis[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: sbayramoglu3@gatech.edu

Machine learning is being increasingly used in improving decisions made within branch-and-bound algorithms for solving mixed integer programming (MIP) problems. In this work, we build simple and interpretable models to approximate strong branching scores, a costly expert branching rule. Our method selects important features for a given problem domain and produces statistically significant models for the MIPs studied. We compare our models with built-in branching rules of SCIP, a state-of-the-art solver, and other ML-based rules.

Machine Learning and Mean Field Games

Community Committee Choice Session

Session Chair: Gokce Dayanikli, University of Illinois Urbana-Champaign, Urbana-Champaign, IL

Session Chair: Mathieu Lauriere, New York University Shanghai, Shanghai, China

1 Model-Free Mean-Field Reinforcement Learning: Mean-Field MDP and Mean-Field Q-Learning

Rene A. Carmona, Princeton University, Princeton, NJ

We study infinite horizon discounted Mean Field Control (MFC) problems with common noise through the lens of Mean Field Markov Decision Processes (MFMDP). We allow the agents to use actions that are randomized not only at the individual level but also at the level of the population. This common randomization allows us to establish connections between both closed-loop and open-loop policies for MFC and Markov policies for the MFMDP. In particular, we show that there exists an optimal closed-loop policy for the original MFC. Building on this framework and the notion of state-action value function, we then propose reinforcement learning (RL) methods for such problems, by adapting existing tabular and deep RL methods to the mean-field setting. The main difficulty is the treatment of the population state, which is an input of the policy and the value function. We provide convergence guarantees for tabular algorithms based on discretizations of the simplex. We also show that neural network based algorithms are more suitable for continuous spaces as they allow us to avoid discretizing the mean field state space. Numerical examples are provided.

2 Mean-field Singular Control Problem: Regularitiy And Related Mean-field Reflected Diffusion

Jiacheng Zhang, UC berkeley, Berkeley, CA

We study a class of mean-field control problems with singular controls. Such a model represents the limit of the control problems in which a controller can adjust, through a bounded variation process, an underlying diffusion, which in turn affects an n-particle system. Adopting appropriate notions of convexities, we are able to establish the regularity of the value function of the problem and to show the existence of the optimal control. The regularity of the value function allows to characterize the solution of the problem in terms of a related mean-field Skorokhod problem. This consists in keeping the optimally controlled state process in a region prescribed by the derivative of the value function, by using the optimal control in order to reflect the state at its boundary.

3 Multi Scale Deep Reinforcement Learning for Mean Field Problems in Continuous Spaces

Andrea Angiuli[1], Jean-Pierre Fouque[2], Alan Raydan[3], [1]Amazon Prime Science, Santa Barbara, CA, [2]University of California-Santa Barbara, Santa Barbara, CA, [3]UC Santa Barbara, Santa Barbara, CA

We present how to solve Mean Field (MF) problems in continuous spaces based on model free deep Reinforcement Learning (RL). MF problems consist in games with infinity symmetric players. We can distinguish cooperative (MF control), non-cooperative (MF game) and mixed frameworks (MF control game). Each is characterized by a different solution. Our algorithms are characterized by multi scale learning rules. The first two are inherited from the actor critic paradigm, a classic RL method to solve Markov decision processes by coordinate learning of the optimal strategy (actor) and the value function (critic). The other ones relate to the parametric representation of MF distributions through score function and Langevin dynamics. Numerical results on linear quadratic examples show the crucial role of calibrating the learning rates in the converge to different solutions.

Recent Advances in Policy Optimization and Reinforcement Learning - Part II

Community Committee Choice Session

Session Chair: Yan Li, Georgia Tech, Atlanta, GA
Session Chair: Guanghui Lan, Georgia Institute of Technology, Atlanta, GA

1 Federated Methods to Speedup Reinforcement Learning

sajad Khodadadian, Georgia Institute of Technology, Atlanta, GA, Contact: skhodadadian3@gatech.edu

It is known that Reinforcement Learning (RL) algorithms are data-intensive, and require a large set of data to train. In this talk, we consider a federated RL framework where multiple agents collaboratively learn a global model, without sharing their sensitive individual data and policies. Although having N agents enables the sampling of N times more data, it is not clear if it leads to proportional convergence speedup. We consider federated versions of on-policy TD, off-policy TD and Q-learning, and establish that there is a speedup in learning that is linear in the number of agents. In particular, we show this even in the presence of Markovian noise and multiple local updates. We do this by developing a federated stochastic approximation algorithm with Markovian noise (FedSAM) and establishing linear speedup under a very general framework.

2 A Model-Free First-Order Method for Linear Quadratic Regulator

Caleb Ju[1], Georgios Kotsalis[2], Guanghui Lan[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Amazon, Seattle, WA, [3]Georgia Institute of Technology, Atlanta, GA, Contact: cju33@gatech.edu

We consider the classic stochastic linear quadratic regulator (LQR) problem under an infinite horizon average stage cost. Leveraging policy gradient methods from reinforcement learning, we obtain a first-order method with a sampling complexity that seems to have the best dependence on the error term for the model-free case without assuming the generated policies are stable. Our proposed method is an actor-critic algorithm. The actor involves a variational inequality formulation of the stochastic LQR, while in the critic we utilize a shrinking multi-epoch conditional stochastic primal-dual method to obtain the optimal rate of convergence.

3 Robust Average-Reward Markov Decision Process

Yue Wang[1], Alvaro Velasquez[2], George Atia[3], Ashley Prater-Bennette[4], Shaofeng Zou[5], [1]University at Buffalo, The State University of New York, Buffalo, NY, [2]CU Boulder, Boulder, CO, [3]UCF, orlando, FL, [4]AFRL, Rome, NY, [5]University at Buffalo, the State University of New York, Buffalo, NY

In robust Markov decision processes (MDPs), the uncertainty in the transition kernel is addressed by finding a policy that optimizes the worst-case performance over an uncertainty set of MDPs. In this paper, we focus on robust average-reward MDPs, where the goal is to find a policy that optimizes the worst-case average reward over an uncertainty set. We first take an approach that approximates average-reward MDPs using discounted MDPs. We design a robust dynamic programming approach, and theoretically characterize its convergence to the optimum. Then, we investigate robust average-reward MDPs directly. We derive the robust Bellman equation, prove that the optimal policy can be derived from its solution, and further design a robust relative value iteration algorithm that provably finds its solution, or equivalently, the optimal robust policy.

4 Offline Policy Learning Under The F-sensitivity Model

Jingyuan Wang[1], Ruohan Zhan[2], Zhimei Ren[3], Zhengyuan Zhou[1], [1]Stern School of Business, New York University, New York City, NY, [2]Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong; [3]University of Chicago, Chicago, IL

Offline learning uses observational data (from employing an unknown policy) to make better decisions, which is a crucial application if online experiments are not available. However, such learning process is very sensitive to distribution shifts, i.e., the discrepancies between the data-generating and the policy-deploying environment. Whereas the current literature commonly assumes such distributional shifts to be KL-divergence, we propose the first offline learning algorithm, adopting empirical risk minimization (ERM) techniques, under the f-sensitivity model which includes the violation of unconfoundedness and assumes the selection bias due to unmeasured confounding is bounded “on average”. By finding the worst-case performance of any policy under environment shifts, our algorithm is able to maximize this value in order to establish the optimal policy.

CC-North 222C

Recent Progress in Optimization Software II

Community Committee Choice Session

Session Chair: Hans Mittelmann, Arizona State University, Tempe, AZ

1 What is New in Xpress Solver

Michael Perregaard, FICO, Birmingham, United Kingdom

We will present on the latest developments in the Xpress Solver. Emphasis will be on the new Global Solver for solving general mixed integer non-linear optimization problems to global optimality, and how it extends the high performance MIP engine of Xpress.

2 Heuristics for Global Optimization with Artelys Knitro

Richard Waltz, Artelys, Los Angeles, CA

Artelys Knitro is a solver focused on large-scale, nonlinear (potentially non-convex) optimization problems. Knitro offers both interior-point and active-set algorithms for continuous models, as well as tools for handling problems with integer variables and other discrete structures. By default, Knitro applies fast local optimization techniques to non-convex problems converging to locally optimal solutions. However, Knitro also offers heuristics to search for global (or improved local) solutions at a cost that is often not much more than the cost of a single local solve. This talk will highlight some of the latest developments in Knitro for finding global (or improved local) solutions on non-convex problems. In particular, we will focus on new multi-start initial point heuristics applied to non-convex QPs/QCQPs.

3 Recent Developments in Optimization with MATLAB

Steve Grikschat, MathWorks, Natick, MA

MATLAB has solvers for continuous and discrete optimization problems. They can solve both analytical and black-box models, including those with multiple objectives and those black-box models with discrete variables where relaxations do not exist. Recent enhancements to these solvers and the capabilities for modeling optimization problems will be presented.

4 The SAS Optimization Solvers: Recent Improvements and Future Developments

Philipp M. Christophel[1], Menal Guzelsoy[2], Amar Kumar Narisetty[3], Laszlo Ladanyi[2], Rob Pratt[4], [1]SAS Institute GmbH, Heidelberg, Germany; [2]SAS, Cary, NC, [3]SAS Institute Inc, Youngstown, NY, [4]SAS Institute, Inc., Cary, NC, Contact: philipp.christophel@sas.com

In this talk we present the recent improvements to the SAS linear and mixed-integer optimization solvers and discuss future developments. Topics include simplex, crossover, presolve, and cuts.

Monday, October 16, 12:45 PM - 2:00 PM

Healthcare Applications in Long-term Sequential Decision-making Under Uncertainty

Community Committee Choice Session

Session Chair: Zeyu Liu, West Virginia University, Morgantown, WV

1 Personalized and Interpretable Diabetic Retinopathy Screening Recommendations

Soroush Akbarijokar[1], Poria Dorali[2], Christina Weng[3], Taewoo Lee[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Houston - Cullen College of Engineering, Houston, TX, [3]University of Houston, Houston, TX, [4]University of Pittsburgh, Pittsburgh, PA

Diabetic retinopathy (DR) is the leading cause of blindness among working-age Americans. Teleretinal imaging (TRI) has emerged as an affordable tool that has the potential to increase screening rates among patients with limited access to care, yet little is known how TRI-based screening should be recommended in conjunction with traditional screening exams. We develop a POMDP model that determines personalized screening policies that take into account patient-specific characteristics such as age, A1C level, cost savings preferences, and adherence behavior. We then use statistical learning techniques to translate the POMDP-based policy into a more interpretable policy.

2 Optimizing Pre-Positioning and Transportation of Medical Supplies Under the Uncertainty of Epidemic Outbreaks

Zeyu Liu, West Virginia University, Morgantown, WV

The Covid-19 pandemic has inflicted tremendous economic. To alleviate the impact, it is vital to establish a robust relief system for medical supplies under demand and supply uncertainties. We utilize a novel sequential decision-making framework to optimize facility locations, inventory management, and distribution of medical supplies in an extended planning horizon. To address the computational challenge of multistage stochastic programming (MSP) in prolonged horizons, we adopt a worst-case robust approach to reduce the scenario tree. Our approach optimizes the future recourse to ensure minimized risks, expanding the modeling capability of current MSP methods. Theoretical analyses are conducted to facilitate algorithm design that solves large-scale instances. We also conduct numerical experiments to validate model performances and draw insights.

3 Optimal Prioritization and Discharge Policies for Medicaid Waiver Services

Yuqing Chen[1], Qiushi Chen[2], Can Zhang[3], [1]The Pennsylvania State University, University Park, PA, [2]Penn State University, University Park, PA, [3]Duke University, Durham, NC, Contact: ykc5346@psu.edu

Medicaid waiver programs provide critical services for patients with developmental disabilities to support the care in home and community-based settings. Due to both rapid increase in demand and limited resources for such services, the current waiting time is extensive and detrimental to the patients. Prior studies have focused on identifying either optimal prioritization or discharge policies in managing the waitlist. We propose a Markov Decision Process (MDP) model to examine jointly optimal prioritization and discharge decisions in the single server setting and study how the option of early discharge can lead to different structures of prioritization decisions. The policies of the same structure also achieve good performance when generalized in multi-server settings.

4 Adaptive Robust Radiotherapy Planning to Manage Radioresistance

Arkajyoti Roy[1], Shaunak Dabadghao[2], Ahmadreza Marandi[3], [1]The University of Texas at San Antonio, San Antonio, TX, [2]Eindhoven University of Technology, Eindhoven, Netherlands; [3]Eindhoven University of Technology, Tilburg, Netherlands. Contact: arkajyoti.roy@utsa.edu

Managing uncertainties in radiotherapy is crucial towards the success of the treatment and improving the patient's quality of life. We develop robust radiotherapy planning models that can account for radioresistance, which is often caused by tumor hypoxia. While standard robust treatment planning can overcome this, it can also produce overly conservative or suboptimal decisions, especially when there are changes during the treatment as often caused by reoxygenation of hypoxic cells. To overcome this, an adaptive framework is proposed that can adapt to updated information during the treatment. Using this framework, we explore the value of multiple diagnostics to update the treatment.

Data-driven Decision Making: Robustness, Learning, and Optimization

Community Committee Choice Session

Session Chair: Andrew E.B. Lim, National University of Singapore, Singapore, Singapore

1 Bayesian Risk-Averse Q-Learning with Streaming Data

Yuhao Wang[1], Enlu Zhou[2], [1]georgia institute of technology, atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: yuhaowang@gatech.edu

We consider an off-policy reinforcement learning problem with streaming data, where we need to solve a discounted infinite-horizon Markov decision process (MDP) with an unknown transition model. We adopt a Bayesian risk MDP (BRMDP) formulation, which uses Bayesian posterior to estimate the transition model and imposes a risk functional on rewards at each stage with respect to the posterior distribution to account for the mis-specification of the transition model. We develop a multi-stage Bayesian risk-averse Q-learning algorithm by solving BRMDP with dynamically updated Bayesian posterior on the transition model. The proposed algorithm learns a risk-averse policy that is optimal conditional on all the observed data. In particular, the learned policy converges to the true optimal policy if we have an infinite number of observed data for each state-action pair.

2 Target-Oriented Regret Minimization for Satisficing Monopolists

Napat Rujeerapaiboon, Yize Wei, Yilin Xue, NUS, Singapore, Singapore. Contact: napat.rujeerapaiboon@nus.edu.sg

We study a robust monopoly pricing problem where a seller aspires to sell an item to a buyer. We assume that the seller ambitiously optimizes over a space of all individually rational and incentive compatible mechanisms with a regret-type objective criterion. Using robust optimization, a mechanism that minimizes the worst-case regret has been previously derived. In this paper, we alternatively adopt robust satisficing which minimizes the excess regret that is above the predetermined target level. We analytically show that the optimal mechanism involves the seller offering an infinite menu of lotteries. Additionally, we consider two other analytically-solvable variants of the problem where the seller restricts her attention to a class of only deterministic posted price mechanisms and where the seller is relieved from specifying the target regret in advance.

3 Bayesian Metric Learning for Cold-Start Item Recommendations with User Preference Drifts

Viet Anh Nguyen, Chinese University of Hong Kong, Hong Kong, Hong Kong

Recommending new items without prior interactions with existing users remains a challenge for today's recommender systems. While content-based filtering can initialize new items' embeddings for cold-start recommendations, it may fail structurally when the user's taste in new items drifts away from that in existing items. We model this drift through a user-specific perturbation of the local metric on the embedding space, which results in the shift in the distance evaluation and rankings between the user's and the new item's embeddings. We identify this local metric using a Bayesian learning model that acquires the user's feedback on a few new items in a personalized manner and updates our belief on the user-specific preference metric. This learning framework leads to empirical improvement in recommendation quality, demonstrated through popular performance criteria.

4 Optimal Trade Execution With Learning

Andrew Lim[1], Galvin Ng[2], [1]National University of Singapore, Singapore, Singapore; [2]Ecole Polytechnique, Paris, France

A trader would like to maximize expected revenue from selling an inventory of stocks by a specified terminal time, in a market where expected returns are linear in the trading rate but with unknown but constant intercept (drift) and slope (price impact). Since the trading rate affects the learning data, this is intrinsically a problem of exploration and exploitation and we wish to understand this tradeoff under the optimal policy. To sidestep the challenges of solving the dynamic programming equation, which is high-dimensional and has no explicit solution even when the prior is multivariate Gaussian, we consider a high-noise asymptotic regime and use a Taylor Series expansion to extract the exploration component of the optimal policy. Exploration is shown to depend, in a complex but intuitive way, on the time horizon, inventory level, and level of parameter uncertainty.

Advances in Optimization for Logistics Network Design

Community Committee Choice Session

Session Chair: Lacy Greening, Georgia Institute of Technology, Atlanta, GA

1 Optimization-Based Learning for Tactical Load Plan Modification in Trucking Service Networks

Ritesh Ojha[1], Wenbo Chen[1], Hanyu Zhang[1], Reem Khir[2], Pascal Van Hentenryck[3], Alan Erera[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]Purdue University, West Lafayette, IN, [3]ISyE Georgia Tech, Atlanta, GA, [4]Georgia Tech, Atlanta, GA, Contact: riteshojha8@gatech.edu

A critical service network design challenge for package carriers is the so-called load planning problem. Load planning refers to decisions about how many trailers or container loads (perhaps of different types) to plan for dispatch over time between pairs of terminals. Such planned loads are the transportation capacity of the network. Another key component to the consolidation transportation plan are the decisions regarding which package volumes to assign into planned loads. This work considers dynamic optimization of load plans given fixed primary and alternate flow planning decisions. An extensive computational study on real-life instances, provided by our industry partner, including few of their largest terminals in their network, reports an average of 8-12\% potential improvement in trailer capacity utilization at the respective terminals.

2 The Service Network Design Problem with Fleet and Emissions Management

Mike Hewitt[1], Christian Truden[2], [1]Loyola University Chicago Quinlan School of Business, Glen Ellyn, IL,

[2]University of Klagenfurt, Klagenfurt, Austria. Contact: christian.truden@aau.at

While hydrogen fuel cell and battery-electric vehicles present opportunities to reduce emissions, effectively integrating their use into operations given range limitations, recharging (refueling) times, and sparse infrastructure requires careful planning. A recognition that the emissions associated with energy production can vary from one region to another is critical. This is also true with respect to the price of both energy and diesel fuel. In this work, we consider fleet management decisions regarding how many vehicles of each type (diesel, battery-electric, hydrogen) a carrier should acquire as well as in what regions they should operate. The impact of these fleet-level decisions on customer service is captured by explicitly modeling the routing of shipments and vehicles while recognizing the consumption of limited onboard resources.

3 Design Efficient Train Service Network with Cross-Network Synchronization

Peiheng Li, Gunnar Feldmann, Clark Cheng, Norfolk Southern Corporation, Atlanta, GA, Contact: peiheng.li2@nscorp.com

Train service network design is one of the fundamental decisions in railroad planning. It involves synchronization across large-scale physical, railcar blocking, and train crew networks to comply with various business rules. The problem itself is extremely complicated and the development is largely resorted to manual processes. At Norfolk Southern, we have developed a hierarchical approach, which considers it as a vehicle routing problem with pickup and delivery (VRPPD) and breaks the limitations of existing column generation methods in addressing business requirements and the need for cross-network synchronization. Numerical experiments against real-life operating plans have verified its effectiveness in delivering reliable service and driving productivity.

4 Solving Choice-Based Competitive Facility Location Problems Using Simulation and Submodularity

Robin Legault[1], Emma Frejinger[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Université de Montreal, Montreal, QC, Canada. Contact: legault@mit.edu

We introduce a novel framework for solving competitive facility location problems under any discrete choice model. Our approach approximates a deterministic equivalent reformulation of the problem by simulation. The problem is solved by a branch-and-cut method in which aggregated simulated customers are partitioned into two groups. The first is explicitly represented in the model, and the second is replaced by a single decision variable, which is bounded by submodular cuts. Our method reduces the computing time of the standard sample average approximation approach by orders of magnitude. When the entropy of the customers' behavior is low, it leads to near-optimal solutions in a fraction of the time required by model-specific algorithms.

5 Guided Large Neighborhood Search for Middle-Mile Consolidation Network Design

Lacy Greening, Alan Erera, Georgia Tech, Atlanta, GA

We study a middle-mile network design optimization problem with fixed origins and destinations to build load consolidation plans that minimize cost and satisfy customer shipment lead-time constraints. To solve real world instances, we develop a machine learning guided, integer programming based large neighborhood search approach.

On Facility Location Problems

Contributed Session

Session Chair: Paulo Moreira, Faculty of Sciences of the University of Lisbon, Lisbon, Portugal

1 A Branch and Price Algorithm for the Angular Set Covering Problem

Fredy Barrriga-Gallegos, Gabriel Gutiérrez-Jarpa, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile. Contact: fredy.barriga@pucv.cl

The Set Covering Problem (SCP) is a well-known location problem with many applications. Its main objective is to determine the minimum cost set of facilities from a finite and discrete set of options, covering all the demand points 360° around a given geographic area. We propose a mathematical formulation and a model for the angular covering problem, which considers establishing the coverage at specific angles guaranteeing covering angular zones where the demand points are located, and avoiding covering unnecessary space where there are no demand points. This covering structure has several applications, such as the location of surveillance security cameras. We propose a branch and price algorithm to solve large instances for the angular covering problem. We realize computational experiments to show the computational effectiveness of the solution method.

2 Location-Allocation of Cooling Shelters with the Varying Capacity and Demand Depending on the Temperature-Humidity Index

Sang Jin Kweon, Seokho Yoon, Yu Seon Yun, Yujin Song, Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of

During heat waves, the capacity and demand for cooling shelters can change depending on the temperature-humidity index. In this presentation, we explore the application of the temperature-humidity index to estimate both the capacity and demand for cooling shelters. Using these estimates, we propose a bi-objective integer linear programming model to allocate heat-vulnerable residents to cooling shelters. Our model is validated with a case study in Ulsan Metropolitan City, South Korea. We prioritize heat-vulnerable residents based on the temperature-humidity index, and assign them to cooling shelters with the objectives of maximizing coverage and minimizing the total operating cost. Our approach can improve the efficiency and effectiveness of cooling shelter allocation during heat waves.

3 Time Horizons for Multi-Period FLP, Under Uncertainty

Paulo Moreira[1,2], Francisco Saldanha-da-Gama[3], [1]Faculty of Sciences of the University of Lisbon, Lisbon, Portugal; [2]CMAFcIO - Center of Mathematics, Fundamental Applications and Operations Research), Lisbon, Portugal; [3]Sheffield University Management School, Sheffield, United Kingdom

The problem consists of deciding where to have facilities operating in each time period so that the demand of a set of customers can be satisfied. The objective is to minimize the total cost throughout the planning horizon, which is divided into the cost of operating the facilities and of supplying the customers. Additionally, a set of potential locations exists where new facilities can be installed during the planning horizon. However, it is assumed that is a phase-in/out problem. The work targets large (possibly infinite) planning horizons. A discount factor is assumed for the monetary values. Uncertainty is assumed for costs and demands. The resulting problem can be formulated as a multi-stage stochastic programming problem. Computational tests are reported on to assess the contribution provided by this work.

Air Traffic Management and Flight Delays

Community Committee Choice Session

Session Chair: Ke Liu, 1</sup

1 Data-Driven Aircraft Assignment to Minimize Delay Propagation

Vinayak V. Deshpande[1], Vidyadhar Kulkarni[2], Wei Liu[3], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, [3]Purdue University, West Lafayette, IN, Contact: liuweimsor@gmail.com

We propose a new approach to reduce the delay propagation by optimizing the assignment between incoming and outgoing flights flown by an airline at a given airport. Specifically, we provide a data-driven approach to estimate the arrival delay distribution, and then derive several assignment policies based on the estimated distribution. We show that the assignments derived from the data-driven approach can offer a verifiable improvement compared to the optimal assignment (FIFO) derived in the deterministic setting by using the real data of Delta Airlines at Atlanta airport.

2 Modeling Flight Interarrival Times

Ke Liu, the University of California Berkeley, Berkeley, CA

Runway capacity is a critical limiting factor in airport and air traffic network efficiency. Understanding the behavior of controlled interarrival time (CIT) and the operational conditions is important. This work presents an empirical study of CIT at landing runway threshold. A mathematical model is designed to fit the distribution of observed runway crossing time interval (RCTI) for arrival pairs by a conditional probability with uniform distribution for estimated time of arrival (ETA) and normal distribution for CIT. Behavior of CIT is further explained by variables relating to weather, runway and aircraft. This conditional probability model captures the situation when arrival demand is low and time gaps between arrivals are constrained by ETAs, and also ideally approximates the left-hand side of RCTI when short-term arrival demand exceeds capacity.

3 Benefits of Shifting Passenger Traffic from Air to High-speed Rail

Kaijing Ding, University of California Berkeley, Berkeley, CA

This study provides a method to quantify the benefit of shifting passenger traffic from air to high-speed rail (HSR) from the perspective of flight delay cost reduction. We first estimate the number of flight reductions for airport origin and destination pairs based on the HSR ridership forecast provided in the California High-Speed Rail 2020 Business Plan, and then distribute these flight reductions to quarter hours. After that, Lasso models are applied to estimate the impact of the reduced queuing delay of SFO, LAX and SAN on the arrival delay of national Core 29 airports. Finally, these delay reductions are monetized and we ultimately arrive at delay cost savings of $71-123 million in 2029 and $370-618 million in 2033.

AI, Quantum Computing, and Recommender Systems

Community Committee Choice Session

Session Chair: Xiang (Shawn) Wan, [1</sup]

1 Hierarchical Reinforcement Learning for Modeling User Novelty-Seeking Intent in Recommender Systems

Pan Li, New York University, Stern School of Business, New York, NY, Contact: pli2@stern.nyu.edu

We propose a novel hierarchical reinforcement learning-based method to model the hierarchical user novelty-seeking intent, and to adapt the recommendation policy accordingly based on the extracted user novelty-seeking propensity. We further incorporate diversity and novelty-related measurement in the reward function of the hierarchical RL (HRL) agent to encourage user exploration. We demonstrate the benefits of explicitly modeling hierarchical user novelty-seeking intent in recommendations through extensive experiments on simulated and real-world datasets. In particular, we demonstrate that the effectiveness of our proposed hierarchical RL-based method lies in its ability to capture such hierarchically-structured intent. As a result, the proposed model achieves superior performance on several public datasets, compared with state-of-art baselines.

2 Potential Energy Supremacy in Quantum Economy

Junyu Liu[1], Hansheng Jiang[2], Zuo-Jun Max Shen[3], [1]The University of Chicago, Chicago, IL, [2]University of California, Berkeley, Berkeley, CA, [3]University of California Berkeley, Berkeley, CA, Contact: junyuliucaltech@gmail.com

Energy cost is crucial in the modern computing industry. Governments prefer low energy consumption for computing providers' market development. This paper explores potential energy advantages of quantum computing over classical counterparts without considering computational complexity. By employing duopoly models with energy constraints for quantum and classical companies, we demonstrate that quantum firms may achieve higher profits within given energy limits and be more energy-efficient in the Nash equilibrium, regardless of computational efficiency assumptions for quantum and classical algorithms. Consequently, quantum computing could offer a more sustainable approach to the computing industry.

3 The Impact of Bifurcation on Platform Outcomes in a Knowledge Sharing Community

Xiaomeng Chen, [1</sup]

While some platforms remain one united community that includes all subcommunities, others bifurcate subcommunities into spin-off platforms. Such bifurcation breaks the community in the original platform and forces users to reallocate between the home platform and the spin-off platform. In this paper, we investigate the impact of bifurcation on platform outcomes. We exploit the introduction of spin-off platforms in an online platform incubator, where users can propose to start a new spin-off platform, to identify the effects of bifurcation using a DID approach. We find that the bifurcation decreases user contribution in the home subcommunity. However, the two bifurcation communities generate more total user contribution and attract more new users, compared to a single united community.

4 Asymmetric Impact of AI Matching on Influencer Marketing: Implications for Platform Revenue

Yi Liu[1], Z. Jessie Liu[2], [1]University of Wisconsin - Madison, Madison, WI, [2]Johns Hopkins University, Baltimore, MD

This paper explores the impact of using artificial intelligence (AI) to connect marketers with influencers. We develop a theoretical model to examine how AI accuracy affects the competition between influencers and the profitability of a social media platform. We find that improving AI accuracy may not always benefit the platform, which is due to the asymmetric nature of such matching technology: the matching outcome for influencers with a narrower audience is more sensitive to AI accuracy than that for those with a broader audience. Additionally, we find that adjusting commission rates in response to AI improvements could help the platform mitigate the negative impact, although it may not be eliminated entirely.

Machine Learning for Discrete and Global Optimization 2

Community Committee Choice Session

Session Chair: Rohit Kannan, Los Alamos National Laboratory, Los Alamos, NM

Session Chair: Can Li, 1</sup

1 Learning When and How to Decompose via Machine Learning

Ilias Mitrai, Prodromos Daoutidis, University of Minnesota, Minneapolis, MN

Decomposition-based solution algorithms have been widely used for the solution of large-scale optimization problems by exploiting the underlying structure. However, the efficiency of such algorithms over monolithic ones is not known a priori and the underlying structure is not always apparent. We present an automated framework that determines when and how to decompose an optimization problem. First, a graph classification approach is developed to determine a priori if a decomposition-based solution should be implemented over a monolithic one based on an appropriate graph representation of an optimization problem. Secondly, Bayesian inference and Stochastic Blockmodeling are used to “learn” the underlying structure of an optimization problem which can subsequently be used as the basis for the application of decomposition-based solution algorithms.

2 DNN-Based Learning Approaches to Accelerate Globally Optimal Solutions to the ACOPF Problem

Fatih Cengil[1], Harsha Nagarajan[2], Russell Bent[2], Sandra D. Eksioglu[3], Burak Eksioglu[3], [1]University of Arkansas, Fayetteville, AR, [2]Los Alamos National Laboratory, Los Alamos, NM, [3]University of Arkansas, Fayetteville, AR, Contact: mfcengil@uark.edu

We propose machine learning techniques to speed up the convergence to global solutions for the AC Optimal Power Flow (ACOPF) problem. The Optimality-Based Bound Tightening (OBBT) algorithm iteratively tightens variable domains and provides near-global optimum solutions for ACOPF problems, but it is computationally expensive. To accelerate OBBT, we propose two DNN-based learning maps between a load profile and a variable subset. Subsets are selected in static or iteration-specific dynamic ways, where tightening the variable bounds in the subset still contributes to improving the ACOPF problem’s relaxation. Both approaches are efficient in finding near-global optimal solutions, resulting in up to 14 times faster convergence on different-scale instances (up to 2,000 buses).

3 Learning to Select Convex Relaxations in a Branch and Bound Algorithm

Can Li, Purdue University, West Lafayette, IN

SDP type of relaxations provides tight bounds for Quadratic Unconstrained Binary Optimization(QUBO) but are more expensive to solve than most LP relaxations. We propose a branch and bound framework for solving QUBOs. By default, only the LP relaxation is solved at each node of the branch-and-bound algorithm. SDP relaxations are solved parsimoniously, i.e., we only wish to solve the SDP relaxations if there is a high chance that it can fathom a given node. To predict whether a node can be fathomed by SDP bound, we propose a method that combines machine learning with solving a convex quadratic program. Our proposed approach is shown to save the number of SDP solves and computational time in a number of maxcut instances we tested.

Fairness and Equity: Interpretation and Intervention

Community Committee Choice Session

Session Chair: Violet (Xinying) Chen, Stevens Institute of Technology, Hoboken, NJ
Session Chair: Wenting Li, 1</sup

4 Structural Properties of Fair Solutions

John Hooker, Ozgun Elci, Peter Zhang, Carnegie Mellon University, Pittsburgh, PA, Contact: jh38@andrew.cmu.edu

An optimization model can ensure a fair distribution of costs or benefits across stakeholders by incorporating an appropriate social welfare function (SWF). The choice of SWF has historically been guided by showing how it follows from certain axiomatic or bargaining arguments. We show how SWFs can be characterized by the structure of optimal solutions they actually deliver. We study utilitarian, maximin, leximax, proportional fairness, alpha fairness, Kalai-Smorodinsky, and threshold-based SWFs from this perspective. We also examine their behavior in hierarchical distribution networks, and their ability to incentivize efficiency improvements and sharing.

5 Fairness For Small And Medium Sized Enterprises (SMEs) Through Trade Credit Distribution

Wenting Li[1], Violet (Xinying) Chen[2], Rui Yin[1], [1]Arizona State University, Tempe, AZ, [2]Stevens Institute of Technology, Hoboken, NJ, Contact: wentingl@asu.edu

With over 95% of supply chain participants being small to medium-sized enterprises (SMEs), their development is pivotal for overall stability. We explore the SMEs' development with uneven trade credit distribution along supply chains. As SMEs usually lack bargaining power, they are forced to accept unfair payment terms, hampering their development. Our research prioritizes fair trade credit distribution to foster SME development. In a multi-period supply chain framework, we assess the impact of trade credit distribution on SMEs' development and supply chain performance. Our findings are useful for guiding long-term strategies for supply chain managers and policymakers to foster balanced and sustainable growth.

6 A Framework for Fair Decision-Making over Time with Time-Invariant Utilities

Guanyi Wang[1], Andrea Lodi[2], Sriram Sankaranarayanan[3], [1]National University of Singapore, Singapore, Singapore; [2]Cornell Tech, New York, NY, [3]IIM Ahmedabad, Ahmedabad, India. Contact: guanyi.w@nus.edu.sg

Fairness is a major concern in contemporary decision problems. Its objective is to maximize fairness while preserving the efficacy of the underlying decision-making (DM) problem. This paper examines repeated decisions on problems involving multiple stakeholders and a central decision-maker. Repetition provides additional opportunities to promote fairness while increasing complexity. This paper presents a general framework for the proposed fairness-over-time (FOT) DM problem. The framework includes an abstraction of the aggregation for utilities over time. We demonstrate that: under some conditions for the aggregation, a strong FOT-DM reformulation is amenable to branch-and-cut solvers. Finally, we propose a relaxation of this reformulation for computing high-quality approximate solutions via simultaneous row and column generation techniques.

7 Bridging Two Fairness Perspectives: Group Parity Metrics and Social Welfare Functions

Violet (Xinying) Chen[1], John Hooker[2], Derek Leben[2], [1]Stevens Institute of Technology, Hoboken, NJ, [2]Carnegie Mellon University, Pittsburgh, PA

Statistical parity metrics have been endorsed as a means of achieving group fairness, but they present both technical and philosophical issues. We explore whether a broader conception of social justice, based on a social welfare function (SWF), can address these issues. We propose two models to derive implications of the well-known alpha fairness SWF for demographic parity, equalized odds, and predictive rate parity. We find that alpha fairness can justify demographic parity and equalized odds under fairly weak conditions, while it provides no justification for predictive rate parity. Proportional fairness (Nash bargaining), a special case of alpha fairness, achieves demographic parity and equalized odds across all groups simultaneously under certain conditions.

Recent Advances in Cyber-Physical Security - Part II

Community Committee Choice Session

Session Chair: Dan Li, Clemson University, Clemson, SC
Session Chair: Akash Tiwari, Texas A&M University, College Station, TX

1 Integrating Incremental Learning and Blockchain to Better Protect Data Security in Cyber-Manufacturing

Boris Oskolkov, Oklahoma State University, Stillwater, OK,

Contact: boris.oskolkov@okstate.edu
The study aims to integrate incremental machine learning and blockchain technology to improve data security in cyber-manufacturing. The proposed approach is expected to make the data in a manufacturing system immutable and traceable, protecting manufacturers from a variety of data security threats, such as data tampering and data loss. As the blockchain is able to track the provenance of data, meaning that it can be traced back to its original source ensuring the authenticity of products and services. With the integration of machine learning, the authentication of the new coming data will also be contributed by the automatic data-driven quality check, further improving the efficiency and effectiveness of data security and protection.

2 Taxonomy-Driven Graph-Theoretic Approach for Manufacturing Cybersecurity Risk Modeling and Assessment

Md Habibor Rahman[1], Young-Jun Son[2], Mohammed Shafae[1], [1]The University of Arizona, Tucson, AZ, [2]Purdue University, West Lafayette, IN, Contact: habiborrahman@email.arizona.edu
This talk introduces a graph-theoretic cybersecurity risk modeling and assessment framework for smart manufacturing systems. Leveraging taxonomical classifications and attack graph formalism, first, it offers a cohesive and structured representation of threat attributes in manufacturing systems. Second, cyberattack propagation through the manufacturing value chain is analyzed, identifying which manufacturing assets are susceptible to compromise and calculating the cybersecurity risk associated with potential attack paths. Finally, the attack path with the maximum likelihood of success and minimum attack detection probability is identified. The proposed approach can aid practitioners in identifying the critical connections and manufacturing assets requiring prioritized security controls and deploying appropriate defense measures accordingly.

3 Security Assurance via PLC Fuzzing

Nicholas Heinrich-Barna, TX
Programmable Logic Controllers (PLC) Fuzzing applies conventional hardware and firmware fuzzing techniques to validate proper peripheral functionality within a PLC. By systematically testing and covering the design, PLC Fuzzing reduces potential attack vectors and strengthens system security, thus PLC Fuzzing ensures the safety and security of subsystems in industrial control systems. We demonstrate a peripheral fuzzing method that enhances the security of associated industrial control systems. Our evaluation involves using custom firmware on a Beagle Bone Black device and a Codesys runtime environment.

Data Analytics in Cybermanufacturing Systems

Community Committee Choice Session

Session Chair: Xiaoyu Chen, University of Louisville, Louisville, KY

Session Chair: Chenang Liu, Oklahoma State University, Stillwater

1 Point Cloud-Based Prediction of Mechanical Behavior for Additively Manufactured Mechanical Metamaterials

Zehao Ye[1], Chen Kan[1], Xin Liu[1], Bo Peng[2], [1]University of Texas-Arlington, Arlington, TX, [2]Dassault Systemes Simulia Corporation, West Lafayette, IN, Contact: zehao.ye@mavs.uta.edu
Mechanical metamaterials have been widely applied in industries such as aerospace, defense, and healthcare. Additive manufacturing (AM) offers advantages in producing mechanical metamaterials for its ability of fabricating complex geometries. However, geometric imperfections induced by AM processes can significantly compromise mechanical behaviors of metamaterials. Current approaches for mechanical behavior assessment rely on destructive tests and finite element modeling, which are costly and time-consuming. This project proposed a novel machine-learning framework to predict the mechanical behaviors of AM-fabricated metamaterials based on their as-built geometries represented by point clouds. Through a case study using auxetic mechanical metamaterials, the effectiveness of the proposed framework is experimentally validated.

2 Width Control of Direct Ink Writing via Offline Reinforcement Learning

Zebin Li[1], Wuyang Chen[2], Chi Zhou[1], Hongyue Sun[3], [1]University at Buffalo, SUNY, Buffalo, NY, [2]University of Georgia, Athen, GA, [3]University at Buffalo, Buffalo, NY, Contact: zebinli@buffalo.edu
The extrusion speed and the motion speed are two critical process parameters for direct ink writing (DIW). However, due to the potential issue of the material properties being inconsistent, the printing process can be unstable even under the constant extrusion speed and motion speed. Besides, the real-time control of the extrusion speed is difficult due to the system delay caused by the material properties (e.g., viscosity). Therefore, a RL-based method is proposed for real-

time motion speed control to realize better printing quality. Specifically, an offline-training-online-tuning framework is developed in which the trained control policy can adapt to a new material with limited efforts. The results suggest the effectiveness of real-time width control for better printing quality and the ability of adapting the control policy to other materials economically.

3 Diffusion Generative Model-Based Self-Supervised Learning for Smart Monitoring of Additive Manufacturing

Emmanuel Yangue, Chenang Liu, Oklahoma State University, Stillwater, OK, Contact: chenang.liu@okstate.edu

Despite the rapid adoption of deep learning models to additive manufacturing, quality assurance issues continue to be addressed for this technology, with the limited availability of sampling objects for advanced studies. Thus, this study leverages the emerging diffusion generative model, notably an improved denoising diffusion implicit models, for layer-wise image generation in AM. The proposed model demonstrates great potential for similarity image synthesis generation addressing sampling issues while maintaining diversity to explore possible new process variations.

4 Ful-Field Thermal History Sensing in Additive Manufacturing

Xiaoyu Chen[1], Chenang Liu[2], Li Yang[1], [1]University of Louisville, Louisville, KY, [2]Oklahoma State University, Stillwater, Contact: xiaoyu.chen@louisville.edu

Full-field thermal history sensing is a challenging yet important problem to characterize thermal cracking problem in multi-source laser powder bed fusion (LPBF) additive manufacturing system. Motivated by the limitations of the co-axial and off-axial IR imaging system, we propose a full-field sensing method to integrate both IR imaging systems for LPBF process. By formulating a sparse irregularly shaped matrix completion problem, a semidefinite programming method is developed to efficiently complete such matrix to provide real-time full-field thermal history sensing. A finite element simulation study is conducted to evaluate the proposed hybrid sensing method to demonstrate its effectiveness, efficiency, and generalizability.

Regression Modeling and Online Monitoring of Complex Data

Community Committee Choice Session

Session Chair: Kai Yang, Medical College of Wisconsin, Milwaukee, WI

1 Nonparametric Online Monitoring of Dynamic Networks

Yipeng Wang, University of Florida, Gainesville, FL, Contact: yipeng.wang1@ufl.edu

Online monitoring of a network sequence is important for detecting temporal structural changes of the system. To this end, there have been some discussions in the statistical process control (SPC) literature to first extract some features from the observed networks and then apply an SPC chart to monitor the extracted features sequentially over time. In this paper, we suggest using four specific features to describe the structure of an observed network, and their combination can reflect most network structural changes that we are interested in various applications. After the four features are extracted from the observed networks, we suggest using a multivariate nonparametric control chart to monitor the extracted features online. Numerical studies show that our proposed network monitoring method is more reliable and effective than some existing methods.

2 Joint Modeling of Multivariate Nonparametric Longitudinal Data and Survival Data - A Local Smoothing Approach

Lu You[1], Peihua Qiu[2], [1]University of South Florida, Tampa, FL, [2]University of Florida - Department of Biostatistics, Gainesville, FL, Contact: luyou@usf.edu

In many clinical studies, evaluating the association between longitudinal and survival outcomes is of primary concern. For analyzing data from such studies, joint modeling of longitudinal and survival data becomes an appealing approach. In some applications, there are multiple longitudinal outcomes whose longitudinal pattern is difficult to describe in a parametric form. In this paper, we develop a novel joint modeling method to fill the gap. In the new method, a local polynomial mixed-effects model is used for describing the nonparametric longitudinal pattern of the multiple longitudinal outcomes. Practical guidelines for choosing tuning parameters and for variable selection are provided. The new method is justified by some theoretical arguments and numerical studies.

3 Design Variable-Sampling Control Charts Using Covariate Information

Kai Yang[1], Peihua Qiu[2], [1]Medical College of Wisconsin, Milwaukee, WI, [2]University of Florida - Department of

Biostatistics, Gainesville, FL, Contact: kayang@mcw.edu
Statistical process control charts are widely used for monitoring sequential processes over time. A common practice in using a control chart is to first collect data of quality variables at equally spaced sampling times, and then make decisions about the process status based on the data. In some applications, however, the quality variables are associated with certain covariates, and it should improve the performance of a chart if the covariate information can be used properly. Intuitively, if the covariate information indicates that process shifts occur, then the next process observation should be collected sooner than usual to achieve quick shift detection. Motivated by this idea, we propose a variable-sampling control chart by using covariate information. It is a self-starting control chart that can well accommodate stationary short-range serial data correlation.

4 Spatio-Temporal Process Monitoring Using Exponentially Weighted Spatial Lasso

Peihua Qiu[1], Kai Yang[2], [1]University of Florida - Department of Biostatistics, Gainesville, FL, [2]Medical College of Wisconsin, Milwaukee, WI, Contact: pqiu@ufl.edu

In practice, if a spatio-temporal process has a distributional shift (e.g., mean shift) started at a specific time point, then the spatial locations with the shift are usually clustered in small regions. This kind of spatial feature of the shift has not been considered in the existing spatio-temporal process monitoring (STPM) literature yet. In this paper, we develop a new STPM method that takes into account the spatial feature of the shift in its construction. The new method combines the ideas of exponentially weighted moving average in the temporal domain for online process monitoring and spatial LASSO in the spatial domain for accommodating the spatial feature of a future shift. It can also accommodate the complicated spatio-temporal data structure well.

Multi-Objective Decision Making Under Uncertainty

Community Committee Choice Session

Session Chair: Jacqueline Dowling, California Institute of Technology, Pasadena, CA

Session Chair: Aleksander Grochowicz, 1</sup

Session Chair: Tyler Ruggles, Carnegie Science, Stanford, CA

1 Exploring Zero-Carbon Electricity System Planning Under Different Non-Carbon Co-Priorities in California

Brian Tarroja[1], Rebecca Peer[2], Emily Grubert[3], [1]University of California, Irvine, CA, [2]University of Canterbury, Christchurch, New Zealand; [3]University of Norte Dame, Norte Dame, IN, Contact: bjt@apep.uci.edu

Developing a zero-carbon electricity system is a critical enabler for transitioning away from fossil fuel dependence. Such systems are typically explored with the co-priority of minimizing monetary cost, but this approach can cause resulting systems to potentially have significant contributions to environmental impacts that are not adequately captured by cost inputs. Here, we explore what the composition of zero-carbon electricity systems in California can be when planned to minimize impacts other than cost, such as regional water consumption, land use, solid construction materials, and critical metals mass, and compare these to a system planned to minimize monetary cost. We highlight the importance of explicitly considering non-cost co-priorities in zero-carbon electricity planning.

2 Improving Trade-Offs Between Climate Policy Objectives via Robust and Self-Adaptive Decision-Making Approaches

Angelo Carlino[1], Paolo Gazzotti[2], Massimo Tavoni[3], Andrea Castelletti[2], [1]Carnegie Institution for Science, Stanford, CA, [2]Politecnico di Milano, Milano, Italy; [3]RFF-CMCC-EIEE, Milano, Italy. Contact: acarlino@carnegiescience.edu

Integrated assessment models represent how the global economy and climate are connected. Via cost-benefit or cost-effective analysis, emission trajectories balance the cost of reducing emissions with their economic damages or with given policy targets. Yet, uncertainty and trade-offs between economic, social, and climatic objectives challenge this traditional approach. To this aim, we design self-adaptive multi-objective climate policies and evaluate the improvement using the Dynamic Integrated Climate Economy (DICE) model. The conflicts between objectives are reduced by maintaining optionality and adjusting decisions as uncertainties realize over time. We extend the methodology to multiple agents in RICE, the regionalized version of the DICE model, to examine the differences between robust and self-adaptive decision-making.

3 Intersecting Near-Optimal Spaces for Policy Information

Aleksander Grochowicz[1], Koen van Greevenbroek[2], Fred Espen Benth[1], Marianne Zeyringer[3], [1]University of Oslo, Oslo, Norway; [2]UiT The Arctic University of Norway, Tromsø, Norway; [3]University of Oslo, Kjeller, Norway.

Contact: aleksgro@math.uio.no
We present the value of near-optimal solutions in quantifying uncertainties and depicting trade-offs between different decisions. By marginally deviating from the paradigm of cost optimality, we can find designs that are robust to perturbation and offer significant flexibility in investment decisons.
We explicitly describe the near-optimal space of an energy system optimisation model for Europe (with the open-source model PyPSA-Eur), formulated as an LP, thus visualizing the flexibility allowed by relaxing cost optimality.
With this methodology we show the importance of multi-decadal weather variability and how to obtain a robust solution in a highly parallelised manner. We also showcase regional trade-offs in an integrated system, identifying decisions that enable flexibility for others.

4 A Computationally Efficient Benders Decomposition for Energy Systems Planning Problems with Detailed Operations and Time-Coupling Constraints

Anna Jacobson[1], Filippo Pecci[1], Nestor Andres Sepulveda[2], Qingyu Xu[3], Jesse D. Jenkins[4], [1]Princeton University, Princeton, NJ, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Tsinghua University, Beijing, China; [4]ZERO Lab, Princeton University, Princeton, NJ, Contact: annafj@princeton.edu
We introduce a novel energy systems model (ESM) formulated with Benders decomposition. Our algorithm incorporates investment decisions and budgeting variables for policy constraints in a Benders master problem to decouple operational timesteps. Separated timesteps can be parallelized without need for a nested decomposition, allowing for inclusion of multiple Benders cuts per iteration. Runtime of our ESM scales linearly with temporal resolution, out-competing large scale monolithic mixed integer linear programming models. Several systems that successfully terminate under our algorithm are intractable under conventional schemes. Our model eases the need for abstraction in system representation in the temporal, spatial, and operational dimensions. This decreased abstraction mitigates structural uncertainty, increasing ESMs' policy relevance.

5 Coal Power Plant Decommissioning Strategy and Repurposing Opportunities in China

Ziting Huang, Johns Hopkins University, Baltimore, MD, Contact: zhuang51@jhu.edu
In China, over 100 GW existing coal power is to be retired in the next 30 years. The study aims to provide policy implications for coal power industry amid energy transition by optimizing retrofitting and decommissioning strategies at both plant and system levels.
Five strategies are identified for future coal power: (1) demolishing, (2) retiring for other use, (3) mothballing, (4) repurposing with renewable energy and storage, and (5) retrofitting with carbon capture systems. To achieve financial, social, and environmental goals, a multi-attribute rating analysis is first applied to optimize the decision at the plant level. Then, a least-cost capacity expansion model is performed to optimize the coal decommissioning scale or additional investment plan in the system. The study will also discuss the decision difference between government/ market-oriented systems.

Predictive and Prescriptive Modeling for the Energy Transition: Electricity, Buildings, Transportation, Industry, and More

Community Committee Choice Session

Session Chair: Erick Jones, University of Texas at Arlington, Arlington, TX

1 Accounting for Reliability Criteria in Long Term Planning of Power Systems

Raziye Aghapour[1], Erick Jones[2], [1]The University of Texas at Arlington, ARLINGTON, TX, [2]The University of Texas at Arlington, ARLINGTON, TX, Contact: rxa5674@mavs.uta.edu
The ever-increasing demand for electricity necessitates expanding power infrastructure to keep up with demand. Energy system planning is driven by the demand forecast, being prone to demand estimation error. Taking the effect of uncertainty in demand prediction into account, this research will model energy system planning as a stochastic problem. Supplying reliable power to customers is another crucial aspect of power system planning that will be considered via meeting predetermined power system reliability indices.

2 Risk-averse Three-stage Investment Optimization To Improve Power System Resilience To Winter Storms

Brent Austgen[1], Manuel Joseph Garcia[2], Bryan Arguello[3], Erhan Kutanoglu[4], John Hasenbein[5], [1]The University of Texas at Austin, Lowell, IN, [2]Sandia National Laboratories, Austin, TX, [3]Sandia National Labs, Albuquerque, NM,

[4]University of Texas-Austin, Austin, TX, [5]The University of Texas at Austin, Austin, TX

We present a three-stage scenario-based stochastic optimization model for determining power grid investments for winter storm resilience. First stage decisions pertain to generator winterization and mobile battery energy storage system (MBESS) acquisition, second stage to MBESS deployments, and third stage to operational response. We incorporate conditional value-at-risk (CVaR) as the risk measure to target high-impact, low-frequency events. Applying the model to a Texas-focused case study, we discuss not only how the optimal investments are affected by parameters like cost and risk aversion, but also how effectively the CVaR risk measure mitigates the severe outcomes in the tail of the loss distribution.

3 Disaggregating Errors in the Cumulative Experience and Learning Rate for Energy Technology Forecasts

Christian Hernandez-Negron[1], Erin Baker[2], [1]University of Massachusetts-Amherst, Amherst, MA, [2]Univ of Massachusetts-Amherst, Amherst, MA

As renewable technologies evolve, we investigate in more detail data underlying learning curves. Combining technological change analyses and modeling to analyze data on previous projections and actual trends, we decompose the error between these projections and the actual change in price, to determine how much came from increase in production and how much from learning per production. For the disaggregation, we use actual observed data, projections based on reliable reports, and forecasts based on an error using historical data. The decomposition analyses would tell us how much of a surprise in cost is due to higher or lower than expected capacity increases; or higher or lower than expected learning per unit capacity.

4 Sustainable Building Design Using Design and Analysis of Computer Experiments

Victoria C. P. Chen[1], Shirish Rao[2], Vishnu Sharma[1], Erick Jones[3], Jay Michael Rosenberger[2], [1]The University of Texas at Arlington, Arlington, TX, [2]University of Texas-Arlington, Arlington, TX, [3]University of Texas at Arlington, Arlington, TX, Contact: vchen@uta.edu

The construction industry is one of the largest consumers of natural resources, including water, materials, and energy. Towards the goal of more sustainable building design, we present a “tiny home” case study that demonstrates a design and analysis of computer experiments (DACE) approach for conducting a comprehensive study of potential building designs. Typical DACE methods are intended for purely numerical factor variables. Due to the high number of categorical factors (e.g., window type, roof color) and the nonlinear nature of relationships in building design, a new DACE framework appropriately integrates machine learning algorithms to address this complexity.

5 Energy Transition Supply Chains

Erick Jones, University of Texas at Arlington, Arlington, TX

Supply chains have traditionally focused on costs (e.g., acquisition and transportation), reliability, and delivery times. However, due to the pandemic, new geopolitical alignments, and new industrial policy (e.g., CHIPS Act and the Inflation Reduction Act) traditional supply chain models and metrics like Just-In-Time no longer suffice. The new supply chains, in addition to considering traditional supply chain metrics, must also balance geopolitical risk, sustainability, and workforce availability. These new metrics are especially important for critical supply chains identified by Executive Order 14017 which includes critical minerals like lithium and for the *Lithium based Battery Supply Chain.*We propose investigating how sustainable the new energy supply chain is.

CC-North 230

Learning-Augmented Decision-Making In Cyber-Physical Systems

Community Committee Choice Session

Session Chair: Tongxin Li, Caltech, Alhambra, CA

1 Learning-Augmented Control via Online Adaptive Policy Selection

Yiheng Lin, California Institute of Technology, Pasadena, CA

We present algorithms for a general class of online policy selection problem under time-varying dynamics and costs. In this setting, the decision maker seeks to minimize the total cost incurred over a finite horizon by selecting a parameter for a given policy class at each time step. We propose the Gradient-based Adaptive Policy Selection (GAPS) algorithm that achieves the optimal policy regret and is efficient to implement. Further, we establish a connection between online policy selection and a class of learning-augmented control problems. This connection, in turn, leads to novel algorithm designs for learning-augmented control with strong adaptive regret guarantees in time-varying environments.

2 Learning-Augmented Online Decision-Making with Anytime Constraints

Jianyi Yang, University of California, Riverside, Riverside, CA, Contact: jyang239@ucr.edu

Exploiting available statistical information, Machine Learning (ML) algorithms have been developed for online decision-making problems to improve the performance. However, to be deployed in real mission-critical systems, ML algorithms are required to have guaranteed performance at each decision round in in terms of some important metrics. This requirement can be modeled as an online decision-making problem with anytime constraints which is challenging due to the uncertainly in online settings. In this talk, I will present learning-augmented algorithms to provably guarantee the anytime constraints while achieving a good average performance for both settings with known and unknown dynamic models. In addition, I will present some application examples on sustainable AI workload scheduling and battery management in EV charging.

3 Online Peak-Aware Energy Scheduling with Untrusted Advice

Russell Lee, UMass Amherst, Amherst, MA, Contact: rclee@cs.umass.edu

This talk covers the online energy scheduling problem in a hybrid model where the cost of energy is proportional to both the volume and peak usage. Inspired by recent advances in learning-augmented online algorithms, we discuss deterministic and randomized algorithms for this problem such that the decision-making can be adjusted by a trust parameter. We then analyze the proposed algorithms using two performance metrics: *robustness* which measures the competitive ratio as a function of the trust parameter when the advice is inaccurate, and *consistency* for the competitive ratio when the advice is accurate. Our large-scale empirical evaluations using real traces of energy demand, prices, and renewable generations highlight that the proposed algorithms outperform worst-case optimized algorithms and fully data-driven algorithms.

4 Reinforcement Learning for Sustainability Applications: Challenges and Opportunities

Christopher Yeh, California Institute of Technology, CA

The lack of standardized benchmarks for reinforcement learning (RL) in sustainability applications has made it difficult to both track progress on specific domains and identify bottlenecks for researchers to focus their efforts on. We have built a suite of RL environments, called SustainGym, designed to test the performance of RL algorithms on realistic sustainability tasks. These multi-agent environments range from adaptive EV charging scheduling to carbon-aware data center job scheduling. We find that off-the-shelf standard RL algorithms tend to struggle in these environments, with traditional controllers often outperforming RL agents. Our findings provide important challenges to address before RL is ready for wide deployment.

Flexible and Efficient Power System Operations: New Models and Frameworks for Demand Response

Community Committee Choice Session

Session Chair: Bahareh Kargar, New Jersey Institute of Technology, Harrison, NJ

Session Chair: SangWoo Park, New Jersey Institute of Technology (NJIT), North Bergen, NJ

1 Offline Reinforcement Learning for Price-Based Demand Response Program Design

Ce Xu[1], Bo Liu[2], Yue Zhao[1], [1]Stony Brook University, Stony Brook, NY, [2]Amazon, Seattle, WA, Contact: ce.xu@stonybrook.edu

In this paper, price-based demand response (DR) program design by offline Reinforcement Learning (RL) with data collected from smart meters is studied. Offline RL does not need to interact with consumers in the real world and thus has great cost-effectiveness and safety advantages. A sequential decision-making process with a Markov Decision Process (MDP) framework is formulated. A novel data augmentation method based on bootstrapping is developed. Deep Q-network (DQN)-based offline RL and policy evaluation algorithms are developed to design high-performance DR pricing policies. The developed offline learning methods are evaluated on both a real-world data set and simulation environments, and are demonstrated to achieve excellent performance that is very close to the ideal performance bound provided by the state-of-the-art online RL algorithms.

2 Learning Heterogeneous Elasticity Values for Incentive Based Demand Response

Bahareh Kargar, SangWoo Park, New Jersey Institute of Technology, Newark, NJ, Contact: bk349@njit.edu

Residential electricity consumption constitutes over 38% of total U.S. electricity consumption, forming a large pool of flexibility that we can exploit. One of the reasons why DR has been unsuccessful in the residential sector is because there is a lack of understanding of consumer-specific behavior patterns. In this research, we establish a framework for understanding the heterogeneous elasticity of electricity consumption in the face of monetary rewards, and utilize that information for the dynamic pricing of rewards. We aim to predict the elasticity of electricity demand specific to each consumer and appliance given external factors such as time of day, temperature, building characteristics. Then, these elasticity information will be used to design a reward pricing mechanism that will dynamically change the amount of reward based on the current state of the system.

3 Online Learning for Incentive-Based Demand Response

Deepan Raj Prabakar Muthirayan, [1</sup]

In this presentation, we consider the problem of learning online to estimate the baseline and to optimize the operating costs over a period of time for Demand Response (DR) programs. We propose an online learning scheme that employs least-squares for estimation with a perturbation to the reward price (for the DR services or load curtailment) that is designed to balance the exploration and exploitation trade-off that arises with online learning. We show that, our proposed scheme is able to achieve a very low regret of O(log(T))^2 with respect to the optimal operating cost over T days of the DR program with full knowledge of the baseline, and is individually rational for the consumers to participate. Our scheme is significantly better than the averaging type approach, which only fetches O(T^(1/3)) regret.

4 A Two-Stage Mechanism for Demand Response Markets

Mardavij Roozbehani[1], Bharadwaj Satchidanandan[2], [1]Massachusetts Institue of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA

Demand response mechanisms incentivize electricity consumers to adjust their consumption during supply shortages. However, estimating customers' counterfactual consumption baselines is susceptible to errors. Moreover, customers' optimal responses depend on their private costs of curtailment, which are subject to strategic misreporting. The two-stage mechanism proposed here addresses these issues. In the day-ahead market, participating loads only provide a probabilistic description of their anticipated consumption and associated costs for the following day, thus, enabling day-ahead planning. In real-time, if summoned for demand response, they report their baselines and costs and receive credits for reductions below their reported baselines. The credit calculation mechanism guarantees incentive compatibility of truthful reporting in both stages.

5 Demand Response for a Novel Decentralized Power-To-Methanol Process

Max Kollmer[1], Markus Vogelbacher[1], Francisco Vidal-Vazquez[2], Jörg Matthes[1], [1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]Karlsruhe Institute of Technology, Karlsruhe, Germany. Contact: max.kollmer@kit.edu

Due to the increasing share of renewable energies, the role of demand response and production planning is becoming more important. Green methanol production is one promising process to use surplus renewable electricity to produce methanol through flexible operation. In this work, an optimization model for the flexibilization of a novel power to methanol process that uses decentralized CO_2 point sources is developed. Based on simulation data of a stationary power to methanol process, a MILP-model with buffer storages, an electrolyser and a power to methanol plant is constructed. The optimal operation is determined considering variable electricity costs, varying renewable electricity supply and various production constraints.

Advancements in Bridging the Gap between ML and OR

Community Committee Choice Session

Session Chair: Brandon Alston, Rice University, Houston, TX

1 Graph and Hopfield Neural Networks: Perspectives from the Machine Learning and Operations Research Communities

Haimonti Dutta, University at Buffalo, Buffalo, NY, Contact: haimonti@buffalo.edu

In Operations Research, the Hopfield Neural Network (HNN) has been used to solve optimization problems dynamically by characterizing the behavior of the network using an energy or Lyapunov function.
In Computer Science, Graph Neural Networks have been proposed, for processing data represented as graphs. GNN models use information diffusion and relaxation mechanisms for processing structured data.
So, how similar are Graph Neural Networks to Hopfield Neural Networks?
In this talk, we explore this possibility and discuss the

hypothesis that GNNs are more general than Hopfield Networks since they can be used for processing more general kinds of graphs and can adapt more general diffusion mechanisms.
Finally, we discuss an application -- finding care pathways for patients admitted to a hospital using a Graph Neural Network but using it to solve an optimization problem.

2 Learning Mdps from Features: Predict-Then-Optimize for Sequential Decision Problems by Reinforcement Learning

Kai Wang, Harvard University, Cambridge, MA, Contact: kaiwang@g.harvard.edu

In the predict-then-optimize framework, the objective is to train a predictive model, mapping from the environment features to parameters of an optimization problem to solve subsequently. Recent work on decision-focused learning shows that embedding the optimization problem in the training pipeline can improve decision quality and help generalize better to unseen tasks compared to training based on intermediate loss functions. We study the predict-then-optimize framework in the context of sequential decision problems (formulated as MDPs) via understanding the differentiability of MDPs. We use features and a set of trajectories to train a model to predict MDP parameters. Our method learns a model that generates predictions with better decision quality in sequential decision problems with applications in public health and wildlife conservation.

3 Optimal Multivariate Binary Decision Trees

Brandon Alston, Rice University, Houston, TX

Multivariate decision trees are powerful machine learning tools for classification and regression that attract many researchers and industry professionals. An optimal binary tree can be obtained by solving a biobjective optimization problem that seeking to maximize the number of correctly classified datapoints and minimize the number of branching vertices. We propose two cut-based mixed integer linear optimization (MILO) formulations for designing optimal binary classification trees (leaf vertices assign discrete classes). Our models leverage an on-the-fly subprocess testing for irreducible infeasible subsystems (IIS) which we make feasible through cutting planes that hold the form of packing constraints. We conduct experiments on publicly available datasets to show our models' ability to scale and robustness in out-of-sample test performance.

Operations of Online Marketplaces

Community Committee Choice Session

Session Chair: Sebastien Martin, Kellogg School of Management, Northwestern University, Evanston, IL

1 Trading Flexibility for Adoption: From Dynamic to Static Walking in Ridesharing

Sebastien Martin[1], Julia Y. Yan[2], [1]Kellogg School of Management, Northwestern University, Evanston, IL, [2]University of British Columbia, Vancouver, BC, Canada

On-demand ridesharing aims to fulfill riders' transportation needs anytime and anywhere. Although this is appealing for riders, overall system efficiency can improve substantially if riders can be flexible. We explore riders' flexibility in space via walking to better pickup locations. Ridesharing platforms traditionally use dynamic walking, which jointly optimizes rider-driver assignment with pickup locations. We instead propose static walking, which presents a fixed pickup location to the rider, then optimizes assignment. We study characteristics of networks that make static walking viable, propose algorithms for static walking, and apply our algorithms to Lyft data in Manhattan.

2 Implications of Worker Classification in On-Demand Economy

Ming Hu[1], Zhoupeng (Jack) Zhang[2], Jianfu Wang[3], [1]University of Toronto, Minneapolis, MN, [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada; [3]College of Business, City University of Hong Kong, Kowloon, Hong Kong. Contact: zhoupeng.zhang@rotman.utoronto.ca

How should gig workers be classified? We study this policy question focusing on the welfare of full-timers, who depend on gig jobs as primary income sources. We identify two issues with uniform regulations: when all workers (full- and part-timers) are reclassified as employees, a profit-maximizing company may *undercut* full-timers, which result in lower welfare; when all are reclassified as contractors+, which offers incomplete employee benefits but allows flexibility, workers can *overjoin* such that full-timers' welfare may not be enhanced due to extra congestion in the marketplace. We show that differentiated approaches such as to classify gig workers according to their labor input or to operationally prioritize full-timers can improve over uniform classifications. We empirically calibrate the model and apply our insights to the ride-hailing market in California.

3 Recent Developments in Reinforcement Learning for Ridesharing

Zhiwei (Tony) Qin, Lyft, San Francisco, CA

Online rideshare platforms allow idle vehicle vacancy to be more effectively utilized to meet the growing need of on-demand transportation, by connecting potential mobility requests to eligible drivers. In this presentation, we talk about recent developments in rideshare matching which shift toward online on-policy methods. We will also discuss learning the value functions for individual market participating units (both supply and demand) while making sure that they collectively approximate the system values well.

4 Complexity Conundrum: Balancing Efficiency and Innovation for Sustainable Success

Yudi Huang, Northwestern university, Evanston, IL, Contact: yudi.huang@kellogg.northwestern.edu

The proliferation of advanced analytical tools and processes in the tech industry has resulted in significant efficiency gains and profit improvements. However, this adoption has also led to greater system complexity, which may pose long-term maintenance and improvement challenges. This study proposes a dynamic model to quantify the magnitude of complexity-related losses and provide strategies to mitigate the hidden cost of complexity. Leveraging additional data, the model can evaluate a company's current position and suggest development strategies. The findings of this study highlight the importance of balancing efficiency gains with the long-term implications of increased system complexity in the tech industry.

Quadratic Optimization and Convexification

Community Committee Choice Session

Session Chair: Hao Hu, Clemson University, Clemson, SC

Session Chair: Boshi Yang, Clemson University, Clemson, SC

1 MILP Approximations for QCQP

Shiyi Jiang[1], Kai Pan[2], Boshi Yang[3], Jianqiang Cheng[4], [1]The Hong Kong Polytechnic University, Hong Kong, China; [2]The Hong Kong Polytechnic University, Hung Hom, Hong Kong; [3]Clemson University, Clemson, SC, [4]University of Arizona, Tucson, AZ

This talk discusses a new method to solve general quadratically constrained quadratic programs (QCQPs). We use an eigenvalue based decomposition to rewrite nonconvex quadratic functions as the difference of two convex ones. A new variable is introduced to partition each nonconvex quadratic constraint to an SOC constraint and the complement of an SOC constraint. We linearly approximate the former constraint and approximate the latter one by linear constraints and a complementarity constraint. We show that the optimal value of the linear program with complementarity constraint relaxation converges to that of the QCQP asymptotically. Numerical experiments are conducted to show the effectiveness of the reformulation.

2 Convexification of Bilinear Terms over Network Polytopes

Seyed Erfan Khademnia, Danial Davarnia, Iowa State University, Ames, IA, Contact: erfank@iastate.edu

The McCormick relaxation for bilinear constraint z=xy gives the convex hull over box domains. In network problems, the McCormick relaxation often leads to poor dual bounds. We study the convex hull of sets containing bilinear constraints $z_{ij}=x_i y_j$, where x_i is the network arc-flow variable, and y_j is in a simplex. For the case with a single y variable in the simplex, we introduce a systematic procedure to obtain the convex hull in the original space of variables and show that all facet-defining inequalities of the convex hull can be obtained explicitly by identifying a tree structure in the network. For the general case with multiple y variables in the simplex, we design a constructive procedure to obtain a class of facet-defining inequalities for the convex hull that is characterized by a special forest structure. Computational results are presented to evaluate both methods.

3 Solution of Disjoint Bilinear Programs Using Simplicial Branch-And-Bound

Hyun-Ju Oh[1], Mohit Tawarmalani[2], [1]Clemson Univerity, Clemson, SC, [2]Purdue University, West Lafayette, IN

In this paper, we propose a branch-and-bound algorithm for disjoint bilinear programs (DBPs). The feasible region of each sub-problem is derived by exploiting the reformulation-linearization technique and a variant of the double-description method. We demonstrate that our algorithm converges to an optimal solution of DBP finitely by carrying out the simplicial branch-and-bound scheme, which splits the feasible region of a variable into sub-simplices at the branching step. We also show that our algorithm outperforms competing methods on large-scale problems.

4 Solution Existence Of Quadratically Constrained Quadratic Programs

Alexander Joyce[1], Boshi Yang[2], [1]Florida Polytechnic University, Lakeland, FL, [2]Clemson University, Clemson, SC, Contact: ajoyce@floridapoly.edu

The Frank-Wolfe Theorem provides conditions for when a problem defined by a quadratic objective function over affine linear constraints has an optimal solution. Over time, this theorem has been extended to cover cases involving convex quadratic constraints. We discuss more current results through the lens of the asymptotic cone of a set defined by a single quadratic constraint. This discussion expands current results and provides sufficient conditions for when a quadratically constrained quadratic program with one quadratic constraint with an indefinite Hessian has an optimal solution.

Emerging Technologies in Transportation Systems I

Community Committee Choice Session

Session Chair: Si Liu, McMaster University, Hamilton, ON, Canada

1 DCA: Delayed Charging Attack on the Electric Shared Mobility System

Shuocheng Guo[1], Hanlin Chen[2], Mizanur Rahman[1], Xinwu Qian[3], [1]The University of Alabama, Tuscaloosa, AL, [2]Purdue University, West Lafayette, IN, [3]University of Alabama, Tuscaloosa, AL, Contact: sguo18@crimson.ua.edu

This study investigates the Delayed Charge Attack (DCA) on electric shared mobility systems (ESMS), which can delay charging services by exploiting vulnerabilities in shared electric vehicles (SEV), electric vehicle supply equipment (EVSE), and the grid, leading to a long-term degradation of the ESMS. We begin by the ESMS threat model with the assets, information flow, and access points, forming a linked sequence for a viable attack vector. Using a Susceptible-Infectious-Removed-Susceptible process, the DCA model is tested against various anomaly detection algorithms using real-world taxi trip data and EVSE locations in New York City. Results show that a 10-min delay leads to a 10.7% ($311.7) weekly revenue loss per driver and the DCA is robust against the AD. Increased repair costs of $36,000 are required to prevent at least 3.8% ($111.8) of weekly revenue loss.

2 Deep Reinforcement Learning Based Stealthy Attack Modeling in Mixed Traffic Flow

Yangjiao Chen, Chaojie Wang, Srinivas Peeta, Georgia Institute of Technology, Atlanta, GA, Contact: ychen3254@gatech.edu

This study leverages deep reinforcement learning (DRL) to understand the behavior and impact of stealthy attacks on traffic flow in a mixed traffic environment consisting of human-driven vehicles (HDVs), normal connected autonomous vehicles (CAVs), and compromised CAVs controlled by stealthy attackers. The results show that compromised CAVs can significantly disrupt traffic flow, weakening the efforts of normal CAVs to smoothen traffic flow.

3 Selective Two-Echelon Orienteering Problem Using UAM and Drones in Urban Logistics

DongKyun Kim, Hyungjoo Cha, Cheong Taesu, Korea University, Seoul, Korea, Republic of. Contact: dongkyun_kim@korea.ac.kr

Urban Air Mobility (UAM) has emerged as a potential solution to urban traffic congestion in logistics zones. This study proposes the Selective Two-Echelon Orienteering Problem using UAM (StOP-U), where UAM selectively visits stations in the first echelon and drones or customers complete last mile delivery in the second echelon according to station types. A mixed-integer linear programming (MILP) formulation is presented to solve the StOP-U problem. Due to the problem's complexity, a two-phase Variable Neighborhood Search (VNS) heuristic algorithm is also proposed. Computational analysis shows that the MILP outperforms the conventional traveling salesman problem (TSP), while the VNS heuristic algorithm generates near-optimal solutions for small-sized instances.

4 Exploring Private-Public Partnership for Innovative Last Mile Deliveries

Si Liu, Elkafi Hassini, McMaster University, Hamilton, ON, Canada. Contact: lius278@mcmaster.ca

We present a pioneering exploration of Private-Public Partnerships (PPPs) in the context of the platform that integrates smart parcel lockers with city bus systems. Implementing such a solution requires the resolution of complex issues, including allocating costs, benefits, and risks among the stakeholders. We propose a game-theoretic framework that models the strategic interactions between the public (city bus operators) and private entities (digital platform operators and e-commerce companies) involved in this PPP. The model, built on non-cooperative and cooperative game theory, analyses the potential outcomes under different partnership scenarios and strategic decisions.

It helps to identify the conditions under which a stable and mutually beneficial partnership can be established and how the benefits and costs can be fairly allocated.

COVID-19 Response

Community Committee Choice Session

Session Chair: Peter Frazier, Cornell / Uber, Ithaca, NY

Session Chair: Shane Henderson, Cornell University, Ithaca, NY

Session Chair: David B. Shmoys, Cornell University, Ithaca, NY

1 Responding to the COVID-19 Pandemic: The Central Role of Computing and AI

Madhav Marathe, University of Virginia, Charlottesville, VA

The COVID-19 pandemic serves as a grim reminder of our collective inability to control pandemics. Globalization, anti-microbial resistance, urbanization, climate change, social media and ecological pressures threaten to upend the progress we have made in fighting infectious diseases. In this talk, we will argue that pandemics is a complex systems problem that is intricately tied to the social, behavioral, political and economic issues that go beyond human health. We will describe how scalable computing, AI and data science played an important role in supporting COVID-19 pandemic response. Computational challenges and directions for future research will be discussed.

2 Designing Safe Classrooms at Cornell During the COVID-19 Pandemic

Peter Frazier, Cornell / Uber, Ithaca, NY

We describe a model of SARS-CoV-2 transmission in classrooms that accounts for masking, seating density, ventilation, vaccination rates, and the type of classroom activity. This model was used during the pandemic to safely increase the student density in classrooms at Cornell University to support in-person teaching with limited classroom capacity. We then use data from weekly mandatory testing for COVID-19 at Cornell to estimate the risk of transmitting SARS-CoV-2 in classrooms at Cornell during the Fall 2021 semester. By avoiding all classes with COVID-positive classmates, we estimate that a typical student would reduce their chance of testing positive for SARS-CoV-2 over that semester from 13.8% to 13.6%, a 0.2 percentage point decrease.

3 Analytics Saves Lives During the Covid-19 Crisis in Chile

Leonardo J. Basso, Instituto Sistemas Complejos de Ingenieria (ISCI) & Universidad de Chile, Santiago, Chile

During the COVID-19 crisis, the Chilean Ministries of Health and Science partnered with Instituto Sistemas Complejos de Ingeniería (ISCI) and telecom ENTEL, to develop innovations that placed OR and analytics at the battlefront during the pandemic. Innovations included tools that (1) provided data on the actual effects of lockdowns in different municipalities and over time; (2) helped allocate limited intensive care unit capacity; (3) significantly increased testing and provided on-the-ground strategies for active screening of asymptomatic cases; and (4) implemented a nationwide serology surveillance program that significantly influenced Chile’s decisions regarding booster doses. According to conservative estimates, the initiatives saved about 3,000 lives, roughly 5% of the total death toll in Chile, while saved resources amount to more than 300 million USD.

Applications of Optimization

Community Committee Choice Session

Session Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO

1 Modeling Heavy Machinery in an Underground Mine to Optimize Ventilation

Aaron Swift, Colorado School of Mines, Golden, CO

An underground mine ventilation system provides fresh ambient air, and dilutes dust and gases produced by equipment and blasting activity. It is also is one of the largest ongoing costs of an underground mining operation. We investigate impacts from the operation of an electric equipment fleet in order to determine optimal airflow.

2 Ventilation Considerations in Medium- and Short-Term Underground Mine Planning

John Ayaburi, Colorado School of Mines, Golden, CO

Underground mines may face schedule disruptions due to the accumulation of heat. Ventilation systems serve as the primary source of fresh air. We develop an integer program to determine the airspeed within a ventilation system that maximizes mine productivity in the medium term, accounting for equipment heat output. We correspondingly provide a mixed-integer quadratically constrained program that minimizes schedule deviation between medium- and short-term plans and determines the distribution of air across operating mine levels.

3 A Specialized Heuristic for Solving the Open-Pit Resource-Constrained Project Scheduling Problem

Nicholas F. Parham, Air Force, Las Vegas, NV

A critical capability for strategic mine planning is the ability to solve the resource-constrained project scheduling problem to optimality, and to do so quickly. However, generalized optimization techniques do not scale well. A specialized heuristic using value propagation allows near-optimal schedules to be found and remains scalable for practical use cases. We verify the heuristic with instances from MineLib, a public mining library, and validate it with active commercial instances.

4 Optimizing Buildings for Energy Efficiency

Chase Robinson, Colorado School of Mines, Golden, CO

Buildings are one of the most significant contributors to greenhouse gas emissions. The high emissions levels are due to the poor energy efficiency of the buildings. To improve energy efficiency, the way facilities produce and use energy must change. Renewable energies can be used along with better materials and construction methods to reduce emissions. At Southern University, a research house is being installed with solar panels, and an air-to-water filtration system is being used to supply the water. A thermal simulation was performed to research different building methods and materials to help improve thermal efficiency. A single-walled construction house was modeled, and a steady thermal simulation was performed using the model.

Diversity in Public Sector Service Operations

Community Committee Choice Session

Session Chair: Vanitha Virudachalam, Gies College of Business, UIUC, Champaign, IL

Session Chair: Dawson Kaaua, McDonough School of Business, Georgetown University, Washington

1 Block Power: Building Health, Wealth, and Power

Karthik Balasubramanian, Harvard Business School, Boston

Block Power partners with non-profit organizations who help their constituents build networks of family members, friends and neighbors to build health, wealth, and power in traditionally marginalized communities. As elections approach, these networks are activated to expand voter outreach and increase civic engagement.

2 Impact of Women in the Invention Team on Product Development Outcomes

Nagarajan Sethuraman[1], Deepak Jena[2], Rachna Shah[3], Shashikant Kumawat[2], [1]University of Kansas, Lawrence, KS, [2]Indian School of Business, Hyderabad, India; [3]University of Minnesota, Minneapolis, MN, Contact: nagarajan@ku.edu

Does having additional women participate in research and product development teams result in more successful products downstream? We examine this question in the context of the pharmaceutical industry which has suffered from historically low women participation in the patent invention teams, leading US congress to act.

3 Female Decision Makers in Public Health Supply Chains

Dwaipayan Roy[1], Amir Karimi[2], [1]University of Virginia Darden School of Business, Charlottesville, VA, [2]The University of Texas at San Antonio, San Antonio, TX

In resource constrained settings, such as low and middle income countries, reproductive health issues do not receive adequate priority from national governments. We examine the relationship between female decision makers in national governments and operational outcomes associated with reproductive health supply chains. Findings from this study contribute to the literature on public health supply chains, highlighting the role that the identity of decision makers play in these supply chains.

4 Going the Distance: The Impact of Commute on Gender Diversity in Public Service

Dawson Kaaua[1], Vanitha Virudachalam[2], [1]McDonough School of Business, Georgetown University, Washington, [2]Gies College of Business, UIUC, Champaign, IL

We analyze the extent to which high commute distances deter female political participation and whether this effect is mitigated by the availability of part-time work. Leveraging differences in distance to the state capitol among state house districts, we use a sharp regression discontinuity design to show that state house districts located further from the state capitol have a lower percentage of female candidates, but this effect disappears in part-time state legislatures. Then, we conduct a conjoint survey experiment administered to a pool of college students to understand how a variety of policies could help to close the gender gap in politics. We find that paid parental leave is the policy most likely to temper the differential effect of a longer commute distance on women entering politics.

Data Analytics and Optimization for Manufacture-Circulation Industrial System

Community Committee Choice Session

Session Chair: Lixin Tang, Shenyang, China

1 A Row Generation-Lagrangian Relaxation-Based Profit Sharing Method for Cooperative Game

Miao Chang[1,2], Shengnan Zhao[1,2], Lixin Tang[1], [1]National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China; [2]Key Laboratory of Data Analytics and Optimization for Smart Industry, Northeastern University, Ministry of Education, Shenyang, China

In manufacture-circulation industrial system, there are many industrial enterprises which collaborate to conduct the organized manufacturing. To facilitate the stability of the collaboration, it is crucial but challenging to enhance the profits of participants. In this work, we formulate the profit-sharing problem as a cooperative game model, and design multiple profit-sharing mechanisms to obtain profit-sharing schemes that satisfy the core. We then propose a row generation-Lagrangian relaxation algorithm to determine the core allocation of the profit-sharing game. The effectiveness of the proposed algorithm is demonstrated through numerical experiments, and the characteristics of different profit-sharing mechanisms are analyzed.

2 Interface Connection and Logistics Optimization Management of the Manufacture-Circulation Industrial System

Nengmin Wang, Qi Jiang, School of Management, Xi'an Jiaotong University, Xi'an, China. Contact: jiangqiq@foxmail.com

Interface connection and logistics optimization management are important to ensure smooth, high-quality, low-carbon logistics in Manufacture-Circulation Industrial System (MCIS). This project focuses on the heavy logistics manufacturing industry in China. (1) It studies the influence mechanisms of logistics on MCIS by exploring the evolution patterns when manufacture integrates with logistics. (2) It investigates the operation rules and management mechanisms of the interface connection in manufacturing enterprises. (3) It develops logistics decision model, extends, and innovates solution and optimization methods in MCIS according to the characteristics of complex dynamics and high uncertainty. (4) It researches into the way of improving logistics efficiency and provides policy suggestions to promote the integration of manufacture and logistics.

3 The Production Planning Problem of Steel Enterprise Driven by Manufacture Circulation

Gongshu Wang[1,2], Yang Yang[3], Lijie Su[4], Lixin Tang[1], [1]National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China; [2]Key Laboratory of Data Analytics and Optimization for Smart Industry (Northeastern University), Ministry of Education, Shenyang, China; [3]Liaoning Engineering Laboratory of Data Analytics and Optimization for Smart Industry, Shenyang, China; [4]Liaoning Key Laboratory of Manufacturing System and Logistics Optimization, Shenyang, China. Contact: wanggongshu@ise.neu.edu.cn

This talk presents a study of a steel production planning problem driven by manufacture circulation. The problem is unique in that it comprehensively considers batch production mode, product substitution, and demand uncertainty. For the deterministic scenario, we formulate the problem as a mixed integer programming model. For uncertain scenarios, we develop a two-level robust optimization model. We propose an enhanced Benders decomposition algorithm that incorporates a problem-specific method for generating valid inequalities to strengthen the master problem, and a hybrid strategy that combines approximate and exact methods to solve the non-convex slave problem. We have performed a large number of computational experiments on synthetic examples to verify the performance of the proposed method, and the results demonstrate its efficiency and effectiveness.

4 Relax-And-Fix Based Heuristics to Solve Production Planning Problem in Steel Industry

Yuming Zhao[1], Gongshu Wang[2], Lixin Tang[1], [1]National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Shenyang, China; [2]Key Laboratory of Data Analytics and Optimization for Smart Industry (Northeastern University), Ministry of Education, Shenyang, China

In this work we study production planning problem inspired by real-world steel industry continuous galvanizing process in aiming to improve production management and efficiency. A formulation of the model with setup carryover is introduced and a minimum cost network flow reformulation of the model is demonstrated. We regroup the items of different product families according to their available time window to improve the solving efficiency, and propose heuristic algorithms based on relax-and-fix method with different variable partition strategies to solve the different formulations. Experimental results of generated problem instances indicate the algorithm's efficiency in practical application.

Service Science Best Student Paper Award Competition (II)

Award Session

1 Waiting Online versus In-Person in Outpatient Clinics: An Empirical Study on Visit Incompletion

Jimmy Qin[1], Carri Chan[1], Jing Dong[2], Shunichi Homma[3], Siqin Ye[3], [1]Columbia Business School, New York, NY, [2]Columbia University, New York, NY, [3]Columbia University Irving Medical Center, New York, NY

To better manage telemedicine visits and effectively integrate them with in-person visits, we need to better understand patient behaviors under the two modalities of visits. Utilizing data from two large outpatient clinics, we take an empirical approach to study service incompletion for in-person versus telemedicine appointments. Our estimation results show that intra-day delay increases the telemedicine service incompletion rate by 7.40%, but it does not have a significant effect on the in-person service incompletion rate. We conduct counterfactual experiments to optimize the intra-day sequencing rule when having both telemedicine and in-person patients. Our analysis indicates that not correctly differentiating the types of incompletions due to intra-day delays from no-show can lead to highly suboptimal patient sequencing decisions.

2 Fair Markovian Search

Mohammad Reza Aminian[1], Vahideh Manshadi[2], Rad Niazadeh[1], [1]The University of Chicago, Booth School of Business, Chicago, IL, [2]Yale University, New Haven, CT

We study the problem of optimal search (with costly information acquisition) for the best alternative among a pool of candidates that belong to different societal groups. Due to baked-in biases in the prior data, group-unaware comparisons of candidates may lead to unfair treatment of certain groups. As such, a socially-aware decision-maker aims to achieve fairness by imposing constraints on ex-ante outcomes in various stages of the search. We start with the classic Pandora's box model of Weitzman (1979) under demographic parity constraints. Candidates belong to two demographic groups and we constrain the policy to equalize the probability of selection or the expected number of opportunities (inspected candidates) across these groups. For each case, we show that optimal fair policy retains the index-based structure of the optimal unfair policy, but potentially randomizes between two policies that are dual-based adjustments of the unfair problem - thus they are easy to compute and economically interpretable. Building on these constructs, we consider richer search processes, such as search with rejection and multi-stage search, that can be modeled by joint Markov scheduling (JMS) (Dumitriu et al., 2003; Gittins, 1979). Imposing general affine and convex ex-ante fairness constraints - that encompass various notions such as the 4/5 rule or minimum guaranteed welfare - across an arbitrary number of groups or even individuals, we give a primal-dual algorithm to find the almost fair and optimal policy. This algorithm, too, randomizes over index-based policies; this time, over a polynomial number of policies whose indices are dual-based adjustments to the Gittins indices of the unfair JMS. Our algorithmic developments, while involving many intricacies, rely on a simple yet powerful observation: there exists a relaxation to the Lagrange dual function of these constrained optimization problems that admit index-based policies akin to the original unconstrained ones.

3 A Data-driven Approach To Improve Artisans' Productivity In Distributed Supply Chains

Divya Singhvi[1], Somya Singhvi[2], Xinyu Zhang[3], [1]New York University, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA, [3]New York University Stern School of Business, New York, NY, Contact: xz1151@stern.nyu.edu

Despite their vital role in rural economy, artisanal supply chains continue to be plagued by low productivity and the highly fragmented nature of their upstream. This study presents research conducted in close collaboration with a leading exporter of handmade rugs in India, aimed at improving artisans' productivity in distributed supply chains. We provide robust empirical evidence that frequent supervisor visits can play a crucial role in improving artisans' productivity. Our analysis also suggests that this impact is heterogeneous, with visits to more complex rugs, and visits that are more consistent, leading to maximum productivity gains. To capitalize on these insights, we propose a novel predict-then-optimize framework for optimizing supervisor visits in the supply chain and we see significant productivity improvement from extensive numerical analysis.

4 Stopping The Revolving Door: MDP-based Decision Support For Community Corrections Placement

Xiaoquan Gao, Pengyi Shi, Nan Kong, Purdue University, West Lafayette, IN

We study the incarceration-diversion decision problem to reduce jail overcrowding and recidivism rates by leveraging community corrections. We build a large-scale Markov decision process (MDP) model to balance the tradeoffs among congestion, recidivism, and violation. The salient features of the criminal justice setting, including deterministic service times and occupancy-dependent costs, present significant theoretical and algorithmic challenges. We propose a unified approach with system coupling and policy deviation bounding to compare value functions. We establish the convexity of the value function, which provides a theoretical basis for developing an efficient algorithm based on a separation of time scales. We showcase the effectiveness of our algorithm in solving real-world problems through a case study using data from our community partner.

Harnessing Social Media Intelligence

Community Committee Choice Session

Session Chair: Xunyu Chen, University of Arizona, Tucson, AZ

Session Chair: Yeongin Kim, Virginia Commonwealth University, Glen Allen

1 The Effect of Emoji and Social Influence on Intervention for Misinformation on Social Media

Seonjun Kang, Victoria Yoon, Yeongin Kim, Virginia Commonwealth University, Richmond, VA, Contact: kangs10@vcu.edu

Misinformation has spread rapidly through social media and has recently become a concern. Therefore, social media platforms have intervened to prevent the spread of misinformation, such as labeling photos or videos of misleading articles (i.e., flag) and displaying links to fact-checking. Although the development of various interventions can reduce the consumption of misinformation, it has yet not fully effectively controlled the spread of misinformation. In particular, a factor that influences individual decisions, such as emojis accompanying articles on social media, has received little attention in the context of misinformation intervention. We study the effect of emojis on the article's believability and user engagement with the article. Drawing on emotions as social information theory, we build a research model and validate it using online experiments.

2 Meta-Voicing for Social Good: Unpacking the Influence of Social Media Engagement in Corporate Philanthropy Communication

Yan Shi[1], Ying Liu[1], Yi (Zoe) Zou[2], [1]University of Massachusetts Amherst, Amherst, MA, [2]University of Western Ontario, London, ON, Canada. Contact: yanshi@umass.edu

Social media has become a viable channel for firms to communicate corporate social responsibility. Nevertheless, little is known about how the online diffusion of a firm's philanthropic announcement unfolds over time and how such diffusion can influence consumer behavior. To address these questions, we drew on the attribution theory and utilized an online natural experiment that took place during the disaster relief period of 2021 Henan floods in China. Preliminary results reveal that both the intensity and content of meta-voicing responses towards a firm's charitable donation announcement can influence consumers' online livestreaming purchases of the firm's products. More importantly, the initial meta-voicing reactions towards a firm's philanthropic announcement can have both immediate and enduring impacts on purchase behavior.

3 Seeing is Believing? Utilizing Multi-Modal Features and Inter-Modal Inconsistency of Ceo Interviews to Predict Financial Risk

Cuibing Wu[1], Xunyu Chen[2], Julie Zhang[3], Xiaobai Li[1], [1]University of Massachusetts Lowell, Lowell, MA, [2]University of Arizona, Tucson, AZ, [3]University of Massachusetts, Lowell, Lowell, MA, Contact: cuibing_wu@student.uml.edu

Multimedia content of business executives holds a potential to influence financial markets. This study introduces a deep learning approach to forecasting stock volatility by analyzing CEO interviews circulated on YouTube. We extend existing research by incorporating not just the CEO's multi-modal features (i.e., verbal, vocal, and visual) but also the inter-modal inconsistency among these channels, which has been evidenced to shape audience perception, within a deep learning framework, as key factors affecting a firm's stock volatility. Our work contributes to communication, finance, and deep learning literature by demonstrating the impact of CEO interviews on financial markets, highlighting the predictive power of behavioral inconsistency, and proposing a hierarchical fusion framework that effectively leverages multi-modal signals.

Text Analytics for Social Good

Community Committee Choice Session

Session Chair: Ozgur Turetken, 1</sup

1 Social Media, Sentiments and Political Discourse

Hiba M. Noor[1], Mehmet Akgul[2], Ozgur Turetken[1], [1]Toronto Metropolitan University, Toronto, ON, Canada; [2]McMaster University, Hamilton, ON, Canada. Contact: akgulm@mcmaster.ca

Social media is widely used for online political discourse, and opinions shared on social media have different sentiments associated with them. Moreover, opinions expressed on social media affect the sentiments of those who are exposed to them. Therefore, understanding the factors related to the sentiments expressed in messages can help policymakers to take actions that align with voter needs and priorities. In this talk, we will discuss the application of sentiment analysis to tweets related to the political elections. We will provide how key drivers of the sentiments could be extracted from the tweets and discuss the relationship between tweet sentiments and tweet virality, i.e., how much a tweet spreads. In addition, we will provide how text clustering, along with tweet virality, could be applied in reflecting election outcomes.

2 Unpacking the Relation Between Media Sentiment and House Prices: A Topic Modelling Approach

Ernest N. Biktimirov, Tatyana Sokolyk, Anteneh Ayanso, Brock University, St Catharines, ON, Canada

This study uses a topic modelling approach to investigate the relation between news media sentiment and house price movements. By examining real estate related articles published in local newspapers of 16 major cities in Canada and Australia, we identify the specific topics discussed and report differences in their themes and media sentiment's predictive power between Canada and Australia. This analysis presents novel inferences of qualitative information related to the housing market. The findings indicate that more transparent housing markets have more efficient prices, suggesting that regulators should strive to improve information transparency in housing markets.

3 Combating Disinformation Warfare with Artificial Intelligence

Richard Frank, Barry Cartwright, Simon Fraser University, Burnaby, BC, Canada. Contact: rfrank@sfu.ca

This project aims to develop an AI tool that will permit the detection of disinformation attacks mounted on social media by hostile foreign actors. The process starts with the manual discovery of sources of dis-, mis-, and real-information on various social media platforms, after which the content is scraped to form the "truth" on which the machine-learning models are built. These, and additional, feeds are then continuously crawled for new content. The AI tool is comprised of 6 underlying machine-learning algorithms to avoid algorithmic bias, each of which, for each new post, "vote" as to whether the post is dis-, mis-, or real- information. Finally, the aggregated (weighted) votes are used to identify new dis-information attacks, which can be analyzed using keywords and topic detection to help understand the thrust and source of the attack.

4 Large Language Models and Conspiracy Theory

Yisheng Li, Toronto Metropolitan University, Torronta, ON, Canada

In the post-truth era, the rise of large language models (LLMs) like ChatGPT, an emerging general-purpose technology in artificial intelligence (AI), has significant implications for the mass production and diffusion of conspiracy theories. The repercussions include the decline of social capital and the erosion of democratic institutions. However, information systems (IS) research on this area is in its infancy. This study aims to identify outstanding research problems such as designing experiments to test the persuasiveness/sophistication of AI-generated conspiracy theories. Of particular analytical interest is to extract the linguistic/rhetoric features of AI-generated conspiracy theories by conducting sentiment analysis and topic modeling. We also discuss the challenges for content moderation and fact-checking. Our study enriches the understanding of potential harms incurred by LLMs and contributes to IS research on misinformation/disinformation.

Data Envelopment Analysis: Recent Advances in Methodologies and Applications

Contributed Session

Session Chair: Sonia Valeria Aviles-Sacoto, Universidad San Francisco de Quito, Quito, Ecuador

1 Counting Operations in Data Envelopment Analysis

Dulá H. José H[1], Gregory Koronakos[2], Dimitris Despotis[2], [1]University of Alabama, Tuscaloosa, AL, [2]University of Piraeus, Piraeus, Greece

Algorithms and computations are an important aspect of DEA. Current practices when introducing a computational procedure for DEA consist of describing the approach and comparing its performance based on execution times. The preponderant operation in DEA is solving linear programs; therefore, an operation count for DEA procedures can be limited to the "LP workload" based on the number and size of LPs solved. Operation counts provides a common ground for analyzing and comparing DEA procedures. They are independent of hardware, LP solvers, and platform. We discuss the use of machine-independent operations count to analyze and compare DEA procedures. We make the case for the use of operation counts in DEA procedures that claim substantial speedups as part of the analysis and comparison with competing approaches. We provide a taxonomy for DEA procedures.

2 A Study on the Improvement Targets of Data Envelopment Analysis Models

Xu Wang, Waseda University, Tokyo, Japan

DEA is a mathematical programming methodology for the relative efficiency evaluation of decision making units (DMUs) with multiple inputs and outputs. Besides the efficiency score, DEA model can provide an improvement target for each inefficient DMU to achieve efficiency, which is the attractive point of DEA. Thus, the idea of least-distance DEA has been proposed for finding the closest efficient target that is similar to the DMU under evaluation and can be achieved easily. We make a comparison between improvement targets provided by the conventional additive(ADD) model and least-distance DEA model using a time-series data set of 86 retail businesses in Japan. The results of numerical experiments suggests the superiority of the improvement target provided by the least-distance DEA model on the realization of efficiency for those inefficient DMUs.

3 Parallelizing DEA Procedures

Gregory Koronakos[1], José Dulá[2], [1]Department of Informatics, University of Piraeus, Piraeus, Greece; [2]The Culverhouse College of Business, University of Alabama, Alabama, AL

There has been an interest since the early days of DEA to explore the parallelization of its procedures. The traditional approach along with innovations that followed such as Reduced Basis Entry (Ali, 1993), Hierarchical Decomposition (Barr & Durchholz, 1997) and its variants are highly parallelizable. Others, such as BuildHull (Dula, 2011), less so. We show how to parallelize BuildHull to attain speedups for DEA computations that make it competitive setting new performance standards.

4 Shared Inputs and Multicriteria Grouping in DEA

Sonia V. Aviles-Sacoto[1], Estefania C. Aviles-Sacoto[2], Wade D. Cook[3], David Güemes-Castorena[4], [1]Universidad San Francisco de Quito, Quito, Ecuador; [2]Universidad Politécnica Salesiana, Cuenca, Ecuador; [3]York University, Toronto, ON, Canada; [4]Tec de Monterrey, Monterrey, Mexico. Contact: svaviless@usfq.edu.ec

DEA is a methodology for evaluating the efficiencies of DMUs, with each unit having its own set of inputs and outputs. However, in certain situations, the DMUs can share inputs or outputs. An example of this is one where a set of university departments, grouped according to the faculties to which they belong, share a faculty-level resource. Furthermore, it is assumed that the shared resource cannot be split up and allocated to the group members. Unlike previous studies, the situation herein can involve multiple criteria upon which DMUs can be grouped and as well can have multiple stages with different DMU groupings in one stage than in another. This paper analyzes a situation wherein a DEA-like methodology is developed to derive efficiency scores in a two-stage setting and in the presence of multiple criteria. We demonstrate the new methodology using the Mexican tourism sector

A Team-Based Approach for Design and Implementation of Artificial Intelligence Applications and Its Impact on Workforce Development

Houshang Darabi, University of Illinois-Chicago, Chicago, IL, Contact: hdarabi@uic.edu

A false assumption made by industry professionals is that artificial intelligence (AI) systems are software codes, and their development is solely dependent on people with programming skills in machine learning (ML) and data processing. This presentation outlines a team-based approach for design and implementation of AI applications. It shows that a successful AI project requires several skillsets and a framework through which ML model developers and application experts/users not familiar with coding and ML model development can communicate/advance the project. Real world examples of this approach in healthcare and occupational safety projects are presented. It is argued that the approach must be considered as the education core of any AI workforce development effort that is meant to train industry professionals who are not computer savvy.

Learning to Make Adherence-Aware Advice

Guanting Chen[1], Xiaocheng Li[2], Chunlin Sun[3], Hanzhao Wang[4], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Imperial College Business School, London, United Kingdom; [3]Stanford University, Stanford, CA, [4]Imperial College London, London, United Kingdom

As AI systems continue to contribute to human decision-making, it is frequently observed that human agents sometimes disregard the advice provided by AI. The probability that the human agent follows the AI's advice is called the agent's adherence level. Although the optimal advice is the best action for the agent when the adherence level is 1, when the adherence level is less than 1, it might become suboptimal for the AI system to provide the same advice. We propose a decision-making model that aims to provide optimal adherence-aware advice, accounting for the varying levels of adherence exhibited by human agents across different states and actions. In addition to the model, we introduce accountable and near-optimal reinforcement learning algorithms specifically designed to address adherence-aware advice.

Advanced Machine Learning for Complex Physical Systems

Community Committee Choice Session

Session Chair: Yinan Wang, Rensselaer Polytechnic Institute, Troy, NY

1 Physics-Informed Data-Driven Degradation and Prognostic for Hydropower System

Mucun Sun, Idaho National Laboratory, Idaho Falls, ID, Contact: Mucun.Sun@inl.gov

The hydropower system is a cyber-physical system, and the industry is experiencing high operation and maintenance (O&M) costs along with increasing unplanned outages, primarily due to aging equipment and new asset loading patterns. Current (O&M) practices in asset management are predominantly reactive rather than predictive and systematic. To address these challenges, a proposed physics-informed data-driven degradation model aims to simulate the health of components in various environments. Its purpose is to accurately characterize wear and fatigue in the pilot components of hydropower systems. Additionally, the model provides informed confidence in prognostic predictions concerning asset degradation and remaining life.

2 Detonate: Nonlinear Dynamic Evolution Modeling of Time-Dependent 3-Dimensional Point Cloud Profiles

Michael Biehler[1], Daniel Lin[2], Jianjun Shi[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Walton High School, Atlanta, GA, [3]ISyE Georgia Tech, Atlanta, GA

Modeling the evolution of a 3D profile over time as a function of heterogeneous input data and the previous time steps 3D shape is a challenging, yet fundamental problem in many applications. We introduce a novel methodology for the nonlinear modeling of dynamically evolving 3D shape profiles. Our model integrates heterogeneous, multimodal inputs that may affect the evolvement of the 3D shape profiles. We leverage the forward and backward temporal dynamics to preserve the underlying temporal physical structures. We leverage the theoretical Koopman framework to develop a deep learning-based framework for nonlinear, dynamic 3D modeling with consistent temporal dynamics. We evaluate our method on multiple high-dimensional and short-term dependent problems, and it achieves accurate estimates, while also being robust to noise.

3 ADs: Active Data-Sharing for Data Quality Assurance in Advanced Manufacturing System

Yue Zhao[1], Yuxuan Li[2], Chenang Liu[2], Yinan Wang[1], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Oklahoma State University, Stillwater, OK, Contact: zhaoy23@rpi.edu

The Data-sharing framework is enabled among multiple machines with similar functionality to augment the dataset for building ML models. It is needed to ensure only high-quality data to improve the performance of ML methods. There are two main challenges: (1) the labeling information usually cannot distinguish data points from different distributions; (2) it is hard to evaluate the "quality of information" in each data point. We proposed an Active Data-sharing (ADs) framework to ensure the quality of the shared data among multiple machines. It is designed as a self-supervised learning framework by integrating the architecture of contrastive learning and active learning. The results of our ADs framework are very promising that data-sharing is conducted between similar machines, and the ML methods can receive better performance with the high-quality augmented dataset.

4 Augmenting Generative Adversarial Network (GAN) to Enable Effective Longitudinal Data for Imbalanced Classification

Ziyang Zhang[1], Chenang Liu[2], [1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University, Stillwater, Contact: jan.zhang@okstate.edu

This study aims to extend the Generative Adversarial Networks (GAN) for longitudinal data augmentation in imbalanced classification. The proposed approach first extends the generator by involving a new filter layer with a longitudinal data-oriented distance metric, which can identify the qualified generated samples for discrimination. Afterwards, it also explores a collaboration mechanism among multiple discriminators for training, enabling more effective discrimination. This approach is validated on a Diabetic Retinopathy (DR) dataset which contains imbalanced and non-equally spaced longitudinal data.

1 Is AI a Panacea? An Investigation of the Impact of AI-Related Competitive Actions on Firm Performance

Yuanyuan Chen[1], Annie Tian[1], Danish Hasnain Saifee[2], [1]University of Alabama Culverhouse College of Commerce, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, Contact: ychen200@cba.ua.edu

Organizations are striving to take various competitive actions to embrace Artificial intelligence (AI) technology. Drawing on the Functional and Symbolic Framework (FSF) and related literature on competitive action repertoires and IT innovation, and assembling a large longitudinal dataset spanning 12 years, we examine the impact of four competitive repertoire characteristics-presence, total volume, novelty (new action types), and diversity-on a firm's financial performance and stock valuation. Our results show that while firms' engagement in AI-related competitive actions can increase a firm's symbolic value, which is reflected in higher stock market valuation, the impact on functional value is more mixed, reflected only in higher revenues but not in profitability.

2 Examining the Impact of Situational Factors on Performance in Crowdsourcing Competitions

Indika Dissanayake[1], Mahmut Yasar[2], Sridhar P. Nerur[3], Mahyar Sharif Vaghefi[2], [1]University of North Carolina at Greensboro, Greensboro, NC, [2]University of Texas at Arlington, Arlington, TX, [3]University of Texas-Arlington, Arlington, TX, Contact: i_dissan@uncg.edu

Organizations seek innovation and competitive advantage through crowdsourcing platforms, relying on the wisdom of the crowds. Solvers participate in contests hosted by seekers on these platforms for monetary incentives, learning opportunities, and reputation enhancement. While the collective intelligence of the crowds generates creative solutions, the impact of contest incentives, the number of solvers, and contest complexity on solution quality remain unclear. To address this gap, we explore the direct effects of the number of solvers and monetary prizes on performance while considering the moderating effects of task complexity. Additionally, we examine how these direct effects vary based on solver performance levels. This research has important implications for academia, platform designers, and seekers.

3 Do Digital Platforms Make Nonbinding Contracts More Enforceable? Evidence from the Amazon Freight Platform

Ali Shirzadibabakan, William J. Kettinger, He Li, Clemson University, Clemson, SC, Contact: ashirza@clemson.edu

This study examines how spot markets enabled by digital platforms improve the enforcement of nonbinding contracts. The simultaneous use of *nonbinding contracts* and *spot markets* is prevalent in industries with high uncertainties in supply and demand, making the enforcement of nonbinding contracts challenging. Leveraging the entry of the Amazon Freight platform, we demonstrate that a digital platform-enabled spot market reduces suppliers' refusals of nonbinding contracts by increasing supply capacity and reducing spot prices. Also, the platform-enabled spot market has a stronger impact on reducing refusals in markets with high demand volatility. This research contributes to understanding the role of digital platforms in enforcing nonbinding contracts and improving operational efficiency in uncertain industries.

4 Effects of Perceived Fairness of Work Assignment Algorithms on Crowdsourcing Performance

Hansol Lee, Texas Tech University, Lubbock, TX

Many crowdsourcing platforms have employed artificial intelligence (AI) based algorithms to assist the work assignment and worker allocation systems, in order to optimize worker resources and improve worker performance on tasks. However, as many of such algorithms are "black boxes" and platforms usually provide insufficient information about the algorithms' working mechanisms, workers may perceive unfairness with their work assignments, leading to a negative impact on their performance. In this study, we conduct an online experiment to investigate how a platform's information provision regarding the AI algorithmic decision making influences workers' performance by affecting workers' perceived fairness of the work assignment system.

Centralized and Decentralized Platforms

Community Committee Choice Session

Session Chair: Wael Jabr, Pennsylvania State University, University Park, PA

1 Leveraging The Digital Tracing Alert In Virus Fight: The Impact Of Covid-19 Cell Broadcast On Population Movement

Heeseung Andrew Lee, University of Texas at Dallas, Dallas, TX, Contact: andrewlee@utdallas.edu

Digital tracing alerts have emerged as effective means to share information with agility in responding to disaster outbreaks. We examine the extent to which instant digital tracing alerts and the information included in the alerts affect people's actions toward disaster management in the context of South Korea. We leverage 4,029,696 sub-district and hour level dataset, including population movement and digital tracing alert transmission information. Our results show that digital tracing alerts are effective in inducing population movement out of the infected area and decreasing the population density. Furthermore, the effectiveness of digital tracing alerts hinges on the inclusion of different private information of individuals on case confirmation.

2 Impact of Platform Privacy Governance on Mobile App Cross-Promotion Strategies: Evidence from Apple's App Tracking Transparency

Shivan Bhatt, He Li, William J. Kettinger, Pranith Abbaraju, Clemson University, Clemson, SC, Contact: hl3@clemson.edu

This research examines how platform privacy policy affects mobile apps' *cross-promotion*, i.e., an app advertises on another app. We exploit Apple's implementation of app tracking transparency on April 26, 2021—i.e., a privacy feature that requires apps to obtain permission to track users across apps and websites owned by other firms. We conduct a longitudinal analysis of the top downloaded game apps on iOS and Android platforms. We found that in response to new app tracking transparency, advertising apps decrease ad content creatives and ad platform integrations. After implementing the app tracking transparency policy, ad content creatives are negatively associated with app revenue, but more ad platforms generate higher app revenue. This research provides implications for mobile apps' cross-promotion strategies in the presence of stricter privacy policies.

3 Democratizing AI Innovation with Open Data: Evidence from Imagenet

Jing Tian, Penn State University, University Park, PA

The increasing concentration of AI innovation has raised concern that AI innovation may endow the leading firms with dominant market power that prevents others from harnessing the benefits and squeezes social welfare. Against this background, there is a growing number of open data initiatives in which data are purposefully collected, curated, and made freely available to the public. Leveraging the release of ImageNet as the empirical setting, our study investigates the concentration of AI innovations among platform and non-platform firms, as well as the role of open data in countering the data advantages of platform firms, thereby facilitating the democratization of AI innovation.

4 Examining the Impact of AI-Supported Recommendations on Judicial Fairness

Wael Jabr[1], Ian Ho[2], Yifan Zhang[3], [1]Pennsylvania State University, University Park, PA, [2]Pennsylvania State University, State College, PA, [3]Kennesaw State University, Kennesaw, GA, Contact: wjabr@psu.edu

The judicial system grants judges a great degree of subjectivity when making criminal sentencing decisions. While those sentences, in theory, should be based on crime severity, offenders' criminal history and their reoffending likelihood, judges, in practice, have little to no constraints on how they decide cases. To promote fairness, several state's judicial systems have adopted AI to support judges in their bailing and sentencing decisions. This research answers the following questions: (1) Do AI-supported recommendations affect individual judges' sentencing decisions? (2) If so, how do judges respond to those recommendations? (3) Do judges make "better" decisions with AI's support regarding overall recidivism and public safety? (4) How does such impact evolve over time? We answer these questions in the context sentencing in the United States.

Responsible AI

Community Committee Choice Session

Session Chair: Shweta Singh, University of Warwick, Coventry, United Kingdom

1 Hiring Biases and Responsible Artificial Intelligence

Shweta Singh, [1</sup]

In order to mitigate algorithmic AI biases, there has been ample research to develop 'de-biased' AI solutions. However, researchers also acknowledge that technological fixes of AI bias and a mathematical notion of AI fairness is hard to come by. Thus, we propose a unique and novel technique to understand biases from the AI models and argue to integrate this knowledge in our society, in order to have bias free community, society and humanity!

2 Selecting Social Influencers And Managing Influencer-brand Collaboration

Mengjie (Magie) Cheng, Shunyuan Zhang, Harvard Business School, Cambridge, MA, Contact: macheng@hbs.edu

The growth of the influencer marketing industry warrants an empirical examination of the effect of sponsored videos on an influencer's reputation. We collect user-generated YouTube videos created by prominent English-speaking influencers, extract a rich set of theory-driven video features, and use reweighting to construct comparable treatment and control influencer-video pairs. A difference-in-differences analysis on the matched sample finds a reputation-burning effect: posting a sponsored video, compared to posting an equivalent organic video, costs the influencer 0.17% of their reputation. The reputation-burning effect is stronger among influencers with larger audiences, and it s mitigated when there is high fit between the sponsored content and the influencer's "usual" content and when the promoted brand is less well-known.

3 When Systemic Biases Taint Algorithms: A Path to More Equitable Access in Healthcare

Ozgur Aksoy[1], Mehmet U.S. Ayvaci[1], Asunur Cezar[2], Srinivasan Raghunathan[1], [1]The University of Texas at Dallas, Richardson, TX, [2]Bogazici Universitesi, Istanbul, Turkey. Contact: ozgur@utdallas.edu

Predictive algorithms can sift through vast amounts of past data and assist in critical decisions in healthcare. For example, health insurers commonly use algorithms to identify beneficiaries likely to generate high costs and offer interventions to reduce the associated risks. Despite their potential for efficiency gains, such cost predictions can reflect systemic inequities in historical data, which we refer to as social bias. Explicitly measuring this social bias and adjusting the decision-making process can help mitigate the unintended consequences of social bias. In this research, we formulate a bias-aware algorithmic decision-making framework that factors in the origins of the social bias while also considering fairness outcomes. Besides analyzing this problem structurally, we use Medicare claims and U.S. Census data to validate our approach empirically.

1 Asset-Pricing Factors with Economic Targets

Sicong Li[1], Svetlana Bryzgalova[1], Victor DeMiguel[1], Markus Pelger[2], [1]London Business School, London, United Kingdom; [2]Stanford University, Stanford, CA

We propose a method to estimate latent asset-pricing factors that incorporates economically motivated targets for both cross-sectional and time-series properties of the factors. Cross-sectional targets may capture the shape of loadings (monotonicity of expected returns across characteristic-sorted portfolios) or the pricing span of exogenous state variables (macroeconomic innovations or intermediary-based risk factors). Time-series targets may capture overall expected returns or mispricing relative to a benchmark reduced-form model. Using a large-scale set of assets, we show that these targets nudge risk factors to better span the pricing kernel, leading to substantially higher Sharpe ratios and lower pricing errors than conventional approaches.

2 The Merton Model Re-visited: Design of Optimal Incentives for Traders in Copy Trading

Kai Sun[1], Mingwen Yang[2], Vijay S. Mookerjee[3], [1]University of Texas at Dallas, Richardson, TX, [2]University of Washington, Seattle, WA, [3]University of Texas- Dallas, Richardson, TX

Copy trading allows retail investors (followers) to automatically copy the trades of experts (traders) in real time after paying the following fees to the platform. By allowing others to replicate the trading, traders who get copied will earn following fees through the compensation contract with the platform. The compensation scheme is crucial in aligning the interests of all parties involved, including traders, followers, and the platform. We propose a model that compensates the trader in a way that his trading behavior will not be altered.

3 Randomized Policy Optimization For Optimal Stopping

Xinyi Guan, Velibor Misic, UCLA Anderson School of Management, Los Angeles, CA

Optimal stopping is the problem of determining when to stop a stochastic system in order to maximize reward, which is of practical importance in domains such as finance, operations management and healthcare. Existing methods for high-dimensional optimal stopping that are popular in practice produce deterministic linear policies -- policies that deterministically stop based on the sign of a weighted sum of basis functions -- but are not guaranteed to find the optimal policy within this policy class given a fixed basis function

architecture. In this paper, we propose a methodology for optimal stopping based on randomized linear policies, which choose to stop with a probability that is determined by a weighted sum of basis functions. We motivate these policies by establishing that under mild conditions, given a fixed basis function architecture, optimizing over randomized linear policies is equivalent to optimizing over deterministic linear policies. We formulate the problem of learning randomized linear policies from data as a smooth non-convex sample average approximation (SAA) problem. We theoretically prove the almost sure convergence of our randomized policy SAA problem and establish bounds on the out-of-sample performance of randomized policies obtained from our SAA problem based on Rademacher complexity. We also show that the SAA problem is in general NP-Hard, and consequently develop a practical heuristic for solving our randomized policy problem. Through numerical experiments on a benchmark family of option pricing problem instances, we show that our approach can substantially outperform state-of-the-art methods.

Market Design in the Field

Community Committee Choice Session

Session Chair: Apostolos Filippas, Fordham University, New York, NY

1 Treasury Auction Format

Aleksandrs Smilgins[1], Sasa Pekec[2], [1]Copenhagen Business School, Frederiksberg, Denmark; [2]Duke University, Durham, NC

The choice of auction format for government bond auctions varies by country, with uniform or discriminatory sealed-bid auctions with preapproved bidders (Primary Dealers) being the most prevalent. We compare bidding in Danish and Swedish government bond auctions, and how it relates to the auction pricing rule: Denmark uses uniform pricing, while Sweden uses discriminatory pricing.

2 Advertising as Coordination: Evidence from a Field Experiment

Apostolos Filippas, Fordham University, New York, NY

Paid advertising can increase market efficiency by directing buyers to sellers with greater capacity. We show this with a field experiment in a large marketplace, where all sellers could choose to buy advertising but buyers were randomized into seeing the advertising. Contrary to concerns that buyers might infer advertising sellers were adversely selected, treated buyers sought out advertising sellers. Consistent with this buyer preference, advertising sellers were better on every measurable dimension, particularly in their capacity to take on more work. This shift in buyer attention to higher-capacity sellers increased market transaction volume by around 2%. Costly advertising was necessary to facilitate this coordination, as mere statements about capacity had become uninformative.

3 Reducing Interference Bias in Online Marketplace Experiments Using Cluster Randomization

David Holtz[1], Felipe Lobel[2], Ruben Lobel[3], Inessa Liskovich[3], Sinan Aral[4], [1]UC Berkeley Haas School of Business, Berkeley, CA, [2]UC Berkeley, Berkeley, CA, [3]Airbnb, San Francisco, CA, [4]MIT Sloan School of Management, Cambridge, MA, Contact: dholtz@haas.berkeley.edu

Online marketplace designers frequently run randomized experiments to measure the impact of proposed product changes. However total average treatment effect (TATE) estimates obtained through individual-level randomized experiments may be biased due to SUTVA violations, a phenomenon we refer to as “interference bias.” The practice of randomizing treatment assignment at the level of “clusters” of similar individuals is an established experiment design technique for countering interference bias in social networks, but it is unclear ex ante if it will be effective in marketplace settings. In this paper, we use an “experiment over experiments” conducted on Airbnb to provide empirical evidence of interference bias in online market settings and assess the viability of cluster randomization as a tool for reducing interference bias in TATE estimates.

4 Dueling Contests and Platform’s Coordinating Role

Sanjiv Erat[1], Konstantinos Stouras[2], Casey Lichtendahl[3], [1]University of California-San Diego, La Jolla, CA, [2]University College Dublin, Dublin, Ireland; [3]Google, Data Science, Charlottesville, VA, Contact: serat@ucsd.edu

We study equilibria in prize allocations among competing contests. We extend our results to heterogeneous contests.

Bidding-based Markets

Contributed Session

Session Chair: Meixi Wu, National University of Singapore, Singapore, Singapore

1 Optimal Bidding Strategy for Sponsored Advertising on Ecommerce

Biyi Fang, Phaniram Sayapaneni, Xinzi Sun, Chaowen Zheng, Darren Xu, Kuang-chih Lee, Walmart, Sunnyvale, CA

Real-time bidding (RTB) is a widely used mechanism in online sponsored advertising, where advertisers compete to show their ads to relevant customers through real-time auctions. However, deriving the optimal bidding strategy can be challenging due to the complexity and volatility of the auction environment. In this talk, we will discuss two main bidding strategies that are driven by constrained optimization and reinforcement learning, to help maximize advertiser's objective(s) in 2nd price auction environment on Walmart eCommerce. We will discuss the algorithm and formulation in details, and share the challenges and insights when applying them in real-world scenario. At the end, our experiments demonstrate the effectiveness and efficiency of the proposed bidding strategies through auction simulation in terms of optimizing ad campaign performance.

2 Low Revenue in Display Ad Auctions: Algorithmic Collusion vs. Non-Quasilinear Preferences

Martin Bichler[1], Oberlechner Matthias[1], Laura Mathews[1], Alok Gupta[2], [1]Technical University of Munich, Garching B. München, Germany; [2]University of Minnesota, Minneapolis, MN, Contact: bichler@in.tum.de

Most display ad exchanges moved from second- to first-price auctions in recent years. The effect on revenue is difficult to evaluate empirically. Recent literature on algorithmic collusion finds that, in contrast to the second-price auction, first-price auctions can induce Q-learning agents to bid below the Nash equilibrium in a repeated complete-information version of the auction. We analyze a variety of online learning algorithms and show that they all converge to equilibrium in both, the complete and incomplete information model. We also compute equilibrium for ROI-optimizing agents and show that their revenue in the first-price auction is lower than in the second-price auction in equilibrium.

3 Course Selection Under Social Network Effects

Meixi Wu, Jussi Keppo, Zhenyu Hu, National University of Singapore, Singapore, Singapore. Contact: meixi@u.nus.edu

We consider a course selection model that matches a continuum of students to a finite number of courses. Students' valuations for the courses are subject to their individual level social network effects. We adopt a pseudo-market allocation mechanism for course selection that takes the students' reported valuations for the courses as input and then outputs the students' bid-price vector for each course and the corresponding allocations. We show the existence of equilibrium prices and allocations under any distribution of students' reported preferences for the courses, and show that one such equilibrium can be solved by a linear program. Simulations suggest that the welfare is non-increasing in the strength of the network effects.

Design and Optimization for Transit Systems

Contributed Session

Session Chair: Sanaz Kazemzadehazad, Illinois Institute of Technology, Chicago, IL

1 Smart Public Transportation: Designing To Improve Welfare

Pooria Choobchian[1], Ali Shamshiripour[2], Ali Mohammadi[3], Abolfazl (Kouros) Mohammadian[1], [1]University of Illinois Chicago, Chicago, IL, [2]University of Arizona, Tucson, AZ, [3]Independent Researcher, Tehran, Iran, Islamic Republic of

This paper proposes a smart, auction-based public transportation platform to address information asymmetry and sparse demand in suburban areas. The platform elicits potential demand and ensures profitability for the service provider. The auction is designed to be truthful, budget-balanced, customer sovereign, and individually rational. The service provided by the proposed platform provides an inclusive, on-demand public transportation access to residents who are underserved under the conventional, fixed-route public transportation.

2 Anticipatory Vehicle Repositioning and Routing in Autonomous Mobility-On-Demand Systems

Monika Filipovska, Haimanti Bala, University of Connecticut, Storrs, CT, Contact: monika.filipovska@uconn.edu

In the context of an autonomous mobility-on-demand (AMOD) system, this study focuses on the problem of effective vehicle repositioning in anticipation of future demand. A major challenge of AMOD operations is the integration of vehicle matching and repositioning decisions, as well as vehicles' routes as they perform the assigned tasks. We propose a hierarchical multi-scale approach for anticipatory vehicle repositioning that integrates routing guidance for the vehicles from the perspective of a single operator. The vehicles' routes during repositioning determine the times and locations at which vehicles are available to be matched and serve new arising demand, thus determining the effectiveness of the repositioning strategy.

3 Managing Capacity for Curb Spaces in Urban Transportation System

Armagan Bayram[1], Yuchi Guo[2], [1]University of Michigan Dearborn, Livonia, MI, [2]University of Michigan - Dearborn, Dearborn, MI, Contact: armagan@umich.edu

The management of curb spaces in the urban transportation system becomes increasingly challenging and it becomes more important to allocate the curb space effectively to improve the overall traffic system. In this study, the various uses of the curb space (such as parking, pick-up/drop-off, and loading/unloading) are taken into account as we first construct an open migration network to analyze the flow of the vehicles. Then, using a news-vendor model, the capacity needed for different users is allocated with the objective of maximizing cities' profits. We derive optimal capacity allocation policies and implement numerical experiments. With the model developed, capacity allocation decisions for various curb uses can be made more systematically and can result in improvements in the overall traffic system.

4 Capacity-Based Heuristic Optimization of Signal Timings and Vehicle Trajectories Within a Connected Vehicle Environment

Paul Rieger[1], Arturo Crespo[1], Andreas Oetting[2], [1]TU Darmstadt, Darmstadt, Germany; [2]TU Darmstadt, Darmstadt, Germany. Contact: rieger@verkehr.tu-darmstadt.de

The increasing volume of personal motorized vehicles (PMVs) in cities has become a serious issue leading to congestion, noise and air pollution. However, the current technological development of Vehicle-to-everything (V2X) communication allows the possibility to enhance traffic flow, especially at road intersections. With these new technological possibilities in mind, we suggest a heuristic to simultaneously optimize traffic signals and vehicle trajectories such that available capacities are efficiently utilized. Our method is based on state-of-the-art signal control enhanced by the V2X-enabled possibilities to simultaneously determine additional green times adapted trajectories of arriving vehicles.

5 Pandemic Aftermath: How Do Travel Patterns Change After Covid-19?

Sanaz Kazemzadehazad[1], Mohammad Miralinaghi[2], Ramin Shabanpour[3], Mohammad Hossein Pourgholamali Davarani[4], Samuel Labi[5], [1]Illinois Institute of Technology, chicago, IL, [2]Illinois Institute of Technology, Chicago, IL, [3]University of North Florida, Jacksonville, FL, [4]Purdue, West Lafayette, IN, [5]Purdue University, West Lafayette, IN, Contact: skazemzadehazad@hawk.iit.edu

The COVID-19 pandemic has changed many facets of human life, including travel behaviors. The repercussions of these changes have persisted into the post-COVID period. By considering both attitude (perception of risk) and mode utility factors (sociodemographic, car ownership, employment status, and travel distance and time), we developed a hybrid model using a stated preference survey to analyze how commuters' travel habits changed before and after the COVID pandemic. The results indicate that people are reluctant to use public transit, still prefer to work remotely and shop online, and if not possible, they choose their private car for long distances and active modes for short distances. This research can be used by transit agencies with a vested interest in reviving public transit ridership after future pandemics.

6 Dynamic Routing, Confirmation And Compensation For Combined Urban Transportation Of Passengers And Goods

Yilun wang, ?, ?, AL

Transporting goods with passengers on board has the potential to increase profits for Mobility-on-demand companies, while reducing travel experience to passengers due to detours caused by making deliveries along the way. To approach this, we studied offering compensation as incentives in dynamic and stochastic scenarios, where the requests arrive dynamically and the passenger's acceptance of detour is unknown. We design an anticipatory policy which is based on a new value function approximation (VFA) with slide memory and makes integrated routing, confirmation, and compensation decisions for CUT. The anticipatory policy shows significant effectiveness in the numerical experiments, which can improve the total profit by 20% than the mode that delivers goods without passengers on board alone. When compared to the benchmark policies, it achieves up to 17% more profits.

1 Natural Language Processing (NLP)-Based Neural Network Architecture to Process the G, E, and APSIM Inputs and Their Interactions for Yield Prediction

Zahra Khalilzadeh, Lizhi Wang, Iowa State University, Ames, IA, Contact: zahrakh@iastate.edu

This study proposes a Natural Language Processing (NLP)-based neural network architecture for yield prediction by processing the genotype(G), environment(E), and APSIM inputs along with their interactions. The proposed model utilizes a combination of NLP techniques and neural network architectures to process temporal and textual information and extract useful features for yield prediction. The study uses a publicly available dataset containing G, E, and APSIM inputs along with corresponding yield values to evaluate the proposed model. The experimental results demonstrate that the proposed approach achieves superior performance compared to existing state-of-the-art models. The proposed model not only captures the complex interactions between the input variables but also provides insights into the underlying factors influencing crop yield prediction.

2 Time Series Perturbation Based on Gradient of Deep Learning Models

Juheon Kwak, Dongil Kim, Ewha Womans University, Seoul, Korea, Republic of. Contact: juhun2005@ewhain.net

Perturbation refers to a tiny change designed to degrade the performance of deep learning models. Perturbation is usually made once by weights of trained model, which has drawbacks: time complexity is relatively high, and perturbation is limited to the last gradient of trained model. In this paper, we propose a new method can make the perturbation to time series with deep learning model. Prediction model is trained for original purpose, and an additional perturbation model is trained for attack of prediction model. The perturbation model uses original time series and gradient of prediction model as input data and label, and derives the changing perturbation to attack the prediction model. The experimental results showed that with 4 real-world dataset, the proposed method outperformed other benchmark methods in terms of performance degradation of the prediction model.

3 Generating Diverse Solutions for Vehicle Routing Problems via Reinforcement Learning

André Hottung, Kevin Tierney, Bielefeld University, Bielefeld, Germany

Deep reinforcement learning methods have shown significant promise at generating solutions to vehicle routing problems in a sequential decision process. At test time, these methods usually sample multiple solutions per instance from a trained model to search for high-quality solutions. However, it has been observed that trained models can suffer from overconfidence in their actions during the sequential construction process which can lead to low solution variety and hence an impaired search performance. We evaluate existing techniques that allow to increase solution diversity and their impact on the overall search performance. Furthermore, we present a novel approach that significantly increases the solution diversity and evaluate it on the vehicle routing problem and the vehicle routing problem with time windows.

4 Optimal Control of Dynamical Systems via Linearizable Deep Learning

Dzung Phan[1], Vinicius Lima[2], [1]IBM Research, Yorktown Heights, NY, [2]University of Pennsylvania, Philadelphia, PA, Contact: phandu@us.ibm.com

Deep learning models are frequently used to capture relations between inputs and outputs and to predict operation costs in dynamical systems. Computing optimal control policies based on the resulting regression models, however, is a challenging task because of the nonlinearity and nonconvexity of the models. We propose a linearizable approach to design optimal control policies based on deep learning models for handling both continuous and discrete action spaces. When using ReLU activation functions, one can construct an equivalent representation of recurrent neural networks by a set of mixed-integer linear constraints. The optimal control problem reduces to a mixed-integer linear program (MILP), which can be solved using MILP solvers. Numerical experiments on standard reinforcement learning benchmarks show the good performance of the proposed approach.

Games and Their Applications

Contributed Session

1 Computing an Equilibrium of Competition Among Sharing Platform Operators Modeled as an M-N Stackelberg Game

Jaeyeon Jo[1], Jihwan Yu[1], Jinkyoo Park[2], [1]KAIST, Daejeon, Korea, Republic of; [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of. Contact: robin512@kaist.ac.kr

The M-N Stackelberg game, consisting of multiple leaders and followers, is intricately intertwined with the hierarchical interaction between leaders and followers, as well as the simultaneous interaction among leaders and among followers. This game is essential for modeling competitive sharing platform markets with multiple platform operators. However, due to the intricate interactions between leaders and followers, finding optimal solutions for leaders is challenging. In this study, we propose a general methodology to find the Stackelberg equilibrium of the M-N Stackelberg game. We apply our algorithm to analyze the competition in sharing platform markets, such as sharing energy storage system platforms and car-sharing platforms.

2 Measuring Decentralized Network Efficiency : A Pre-Mortem Stackelberg Game

Minkeon Song[1], Dong-Joon Lim[2], [1]Sungkyunkwan University, Suwon, Korea, Republic of; [2]Sungkyunkwan University, Gyeonggi-do, Korea, Republic of. Contact: mksong0925@naver.com

In this research, we present the 'pre-mortem Stackelberg game model' as a non-cooperative game approach that can serve as an alternative to the conventional decentralized network DEA(Data Envelopment Analysis) model which suffers from infeasibility. We have identified the circumstances that give rise to the issue and recommended the use of non-radial slacks as a remedy. Our findings show that the proposed model provides an alternative efficiency measure for the follower and enables an optimal adjustment of intermediate products, for which feasible solutions do not exist under the conventional model. The proposed model provides equivalent efficiency measures to the traditional model when feasible solutions exist. It is expected to facilitate the use of non-cooperative games in network DEA when the VRS assumption is appropriate for performance evaluation.

3 Differential Game Theoretic Models for Designing Conservation Incentives

Behnam Momeni[1], Shima Mohebbi[2,1], [1]George Mason University, Fairfax, VA, [2]George Mason University, Fairfax, VA, Contact: bmomeni@gmu.edu

The efficient management of water resources is crucial for addressing a range of environmental challenges. This study applies differential game theoretic models to design incentive schemes for farmers, geographically distributed across a river network. Three main players considered are Non-Governmental Organizations (NGOs), upstream farmers, and downstream farmers while environmental and social feedback loops are captured. The proposed approach allows for analyzing the strategic behavior of farmers in their decision-making process related to water consumption and the NGOs in allocating incentives. The proposed model is parameterized for the Red River, the second-largest basin in the south-central United States, and demonstrates optimal incentive allocations balancing the economic and environmental efficiency among farmers.

5 Partition-Based Stability of Coalitional Games

Jian Yang, Rutgers University, Newark, NJ, Contact: jyang@business.rutgers.edu

We are concerned with the stability of a coalitional game. First, the concept of core can be weakened so that the blocking of changes is limited to only those with multilateral backings. This principle of consensual blocking along with others can be applied to partition-allocation pairs. Each such pair is made up of a partition of the grand coalition and a corresponding allocation vector whose components are individually rational and efficient for the various constituent coalitions of the given partition. The resulting stability concepts are compatible with core-related concepts. Probably more importantly, two of them are universal meaning that any game, no matter how ``poor'' it is, has its fair share of stable solutions. There is also a steepest ascent method to guide the convergence process to a stable partition-allocation pair from any starting partition.

Recent Advances in Stochastic Optimization

Contributed Session

Session Chair: Evgeny Shindin, IBM Research - Haifa, Haifa, Israel

1 Data Valuation from Data-Driven Optimization

Robert Mieth[1,2], Juan M. Morales[3], H. Vincent Poor[2], [1]Rutgers University, New Brunswick, NJ, [2]Princeton University, Princeton, NJ, [3]University of Malaga, Malaga, Spain

In this talk we show how Distributionally Robust Optimization (DRO) offers a natural framework to both (i) account for data quality in data-driven stochastic optimization and (ii) directly value data sets according to their contribution to the decision cost. For this purpose, we first discuss the usefulness of the Wasserstein metric to quantify data quality and then construct a novel Wasserstein DRO formulation that accommodates data from multiple sources with individual transport budgets. We illustrate the proposed framework using an application from power system operations, where we show how the resulting optimization problem implicitly computes the value of data given its quality and the context of the physics-constrained decision-making problem at hand.

2 Personalized Learning in Partially Observable Environments

Anas Abdelhakmi[1], Jussi Keppo[2], Hong Ming Tan[1], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: a.anas@u.nus.edu

Personalized Learning (PL) aims to improve learning outcomes by adapting to learners' unique needs. Existing work on PL typically faces a trade-off between adapting to partially observable environments and maintaining tractability. In this paper, we propose a data-driven approach to estimate learners' skill levels by utilizing multiple information sources such as instant skills' assessment and instructors' forward-looking views. We formulate the problem as a constrained Markov Decision Process and then propose a model-free Deep Reinforcement Learning algorithm to approximate the solution. We show that our approach can handle such environments by using real world data.

3 An Efficient Algorithm to Find Optimal Control for Robust Fluid Processing Networks

Evgeny Shindin, Roi Ben Gigi, Odellia Boni, IBM Research - Israel, Haifa, Israel

Multiclass Processing Networks are used in various applicative domains. The tractable way to find an optimal control for such a network is to approximate it by a fluid model resulting in a Separated Continuous Linear Programs (SCLP). To deal with uncertainty in the network models robust optimization (RO) approach for SCLP recently developed. However robust counterpart (RC) of SCLP often enlarge SCLP problem dimensions and reduces scalability and stability of Revised SCLP-simplex algorithm that developed to solve large SCLPs. To overcome this issue we examined RO theory for LP problems and developed new algorithm, that does not require to build full RC in order to find its optimal solution of uncertain SCLP problems.

Innovative Approaches to Analytics Knowledge Transfer

Contributed Session

Session Chair: Alessandro Hill, Cal Poly, San Luis Obispo, CA

1 Analytics Course Project

Marcy Jance, Indiana University East, Richmond, IN

A course assignment/project that can be used for learning and assessment purposes in a statistics or analytics class will be presented.

2 Effect of Gamification on Knowledge Transfer in Stack Overflow (SO)

Orcun Temizkan[1], Ram Kumar[2], [1]Ozyegin University, Istanbul, Turkey; [2]University of North Carolina, Charlotte, NC, Contact: orcun.temizkan@ozyegin.edu.tr

Stack Overflow (SO) is a popular Question and Answer community for software development. Gamification in SO takes the form of badges and bounties earned by users. Badges are designed to encourage participation. Users can get different levels of badges (gold, silver, bronze). Bounties are reputation points offered by users who want answers to questions. While these gamification mechanisms are popular, there is limited research on whether badges and bounties are effective and existing research is inconclusive. We develop and empirically test models of knowledge transfer that include the effects of gamification and explore the effectiveness of these two forms of gamification mechanisms on knowledge transfer in SO.

3 Expanding Students' Social Networks via Optimized Seating Assignments

Alessandro Hill[1], Steffen Peuker[2], David Hom[1], [1]California Polytechnic State University, San Luis Obispo, CA, [2]California Polytechnic State University, San Luis Obispo, CA

A strong and diverse peer network is important for students' educational, personal, and professional success. We present a novel method for assigning students to seats using social network analysis and optimization. We aim at augmenting students' ties through optimized seating, and suggest a processes for surveying existing connections and representing arbitrary classroom layouts. We show that the underlying difficult combinatorial problem, a variant of the assignment problem, can be formulated as an integer program and solved to optimality using mathematical optimization. We also account for classroom balancing and various student needs. In a case study including more than 240 students, we analyze potential and impact. Compared to self-selection, the new ties can clearly be increased. Student and instructor feedback support the usefulness of our approach.

Evaluating Quality of Care for Healthcare Systems

Contributed Session

Session Chair: Weifen Zhuang, Xiamen University, Xiamen, China

1 Exploring the Impact of Health It Features on Quality of Hospital Care

Raluca Cobzaru[1], Roy Welsch[1], Stan Finkelstein[1], Zach Shahn[2], Kenney Ng[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]CUNY School of Public Health, New York, NY, [3]IBM Research, Cambridge, MA, Contact: rcobzaru@mit.edu

As policies with staggered adoption - such as Medicaid expansion across states - have been gaining traction in the public health sector, so has the topic of difference-in-differences (DiD) methods which allow for time-varying treatment strategies. We utilize a novel adjustment framework for time-dependent covariates in the DiD setting to study the causal effect of implementing certain EHR system features (e.g. clinical decision support, care coordination across departments, automated drug interaction checks, etc.) on hospital performance metrics (e.g. 30-day mortality and readmission rates) over time. Our results help inform Health IT adoption policies and ease the operational burden on hospitals by identifying a sufficient set of EHR features associated with improved quality of care.

2 The Impact of Provider Coaching on Patient Satisfaction in Emergency Department

Sara Nourazari[1], Samuel Davis[2], Joshua Joseph[3], Leon Sanchez[2], [1]California State University, Long Beach, Long Beach, CA, [2]Harvard Medical School, Cambrdige, MA, [3]Harvard Medical School, Cambridge, MA, Contact: sara.nourazari@csulb.edu

Patient experience and satisfaction are crucial factors in healthcare, as they correlate with better health outcomes and financial incentives. Emergency departments (EDs) face unique challenges in achieving high patient satisfaction due to fragmented interactions and limited time for providers to build trust. This study aims to investigate the influence of professional coaching on patient experience and satisfaction in EDs, considering patient, provider, and visit characteristics. The research questions address the impact of these factors on patient satisfaction scores and the effectiveness of provider coaching. By understanding the role of professional coaching, this study aims to help healthcare providers improve patient experience, population health, and financial performance.

3 Evidence on the Validity of the Healthcare Quality Competency Framework

Xinyu Wei[1], Heng Xie[2], Richard (Xianghui) Peng[3], Victor R. Prybutok[4], [1]California State University, Chico, Chico, CA, [2]California State University, Sacramento, Sacramento, CA, [3]Penn State Erie, The Behrend College, Erie, PA, [4]University of North Texas, Denton, TX, Contact: xwei1@csuchico.edu

Assessment of healthcare quality is vital for enhancing patient outcomes and achieving organizational excellence. As such, assessment is of interest to healthcare professionals and scholars. This research investigates an industry framework of healthcare quality competencies to explore relevant measurements arising from the dynamic nature of today's healthcare quality landscape. We integrate healthcare quality practices and results to develop a research model and validate its effectiveness using survey data.

4 Impacts of Staff Collaborations on the Service Time for Inpatient Stays: An Analysis Using EHR Audit Logs and Dynamic Graphs

He Zhang[1], Gaurav Jetley[2], [1]University of South Florida,

Tampa, FL, [2]Colorado State University, Fort Collins, CO, Contact: hezhang@usf.edu

In this study, we investigate the impacts of collaboration between teams of care providers in healthcare organizations on the service time for inpatient stays. Using data from EHR audit logs, we first develop a temporal data mining algorithm to obtain a dynamic graph representing the strengths of collaboration between care providers, which is used with econometric models to find the impact of collaboration between care providers on the service time. We find a curvilinear impact (inverted-U) of staff collaborations on service time of inpatient stays. It suggests a learning curve; when care providers with little to no experience in working together collaborate, they initially have a negative impact on service time for inpatient stays. However, as the collaborations strengthen over time, they start to make a positive impact by decreasing the service time for inpatient stays.

5 Where is the Value of Information Sharing in the Regional Collaborative Emergency Care System-Evidence from a Regional Chest Pain Center

Weifen Zhuang[1], Yao Li[2], Jian Chen[3], Hong Chen[4], Changqing Zhong[5], [1]Xiamen University, Xiamen, China; [2]Southern University of Science and Technology, West Lafayette, IN, [3]Tsinghua University, Beijing, China; [4]Cheung Kong Graduate School of Business, Shanghai, China; [5]Hunan People's Privincial Hospital, Changsha, China. Contact: wfzhuang@xmu.edu.cn

Timely access to a specialized and systematic care is important for patients with time-sensitive and life-critical conditions. We empirically investigate effects of pre-hospital information sharing within a regional collaborative emergency care system, for inter-hospital transferred patients with the most severe type of heart attack, from a regional chest pain center. Our results show that pre-hospital information sharing not only significantly improves operational efficiency of the receiving hospital and the whole coordinated system by reducing 27.7% in-hospital delay and 12.1% system delay, but also exerts significant effect on reducing duplicate electrocardiogram tests by 17.6% and emergency department utilization by 30.7%. We further explore the underlying mechanism of operational efficiency improvements.

Advances in Time Series Modeling

Contributed Session

Session Chair: Yu An, Peking University, Beijing, China

1 Improving the Forecast Accuracy of Protected Data Using Time Series Features

Cameron Bale[1], Matthew Schneider[2], Jinwook Lee[2], [1]Drexel University, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, Contact: cdb327@drexel.edu

Existing data privacy methods degrade forecast accuracy to unusable levels. To overcome this problem, we investigate the similarity between time series features that are predictive of forecast accuracy. We develop a matrix-based privacy method called k-nearest time series + (k-nTS+) swapping tailored to maintain forecast accuracy. We apply our privacy method to a forecasting competition data set where the identities of the time series are hidden but an adversary seeks to identify them. Using only six time series features, we find that k-nTS+ swapping maintains forecast accuracy and preserves the distribution of time series features much better than competitor methods at similar privacy levels. The k-nTS+ protected time series are also more representative of the original data, potentially leading to increased trust between data owners and forecasters.

2 Predicting the Price of Gold in the Financial Markets Using Hybrid Models

Mohammadhossein Rashidi, University of Massachusetts, Amherst, MA, Contact: mrashidi@umass.edu

Forecasting accurate prices in financial markets is one of the most challenging issues for market participants and researchers. The use of time-series forecasting models such as ARIMA, technical analysis variables indicating trader behavior, and psychological factors can help to create a more accurate model. By combining these factors with a stepwise regression and neural network, a hybrid model can be created for predicting the price of gold in international financial markets. This hybrid model, called "ARIMA-Stepwise Regression-Neural Network," could be used to forecast stocks, commodities, currency pairs, and other financial market instruments. The hybrid model outperforms time-series, regression, and stepwise regression models in terms of accuracy. The study could help traders in financial markets make better decisions based on accurate price predictions.

1 Anomaly Detection in Time Series Using a Hybrid Deep Learning One Class Algorithm

Waldyn Martinez, Miami University, Oxford, OH, Contact: martinwg@miamioh.edu

Detecting anomalies in time series data is an important area of research with applications in a wide variety of fields including finance, transportation, health monitoring, etc. In this work we present a hybrid algorithm consisting of a Auto-Encoder architecture as a feature extractor and a one-class peeling (OCP) support vector machine (SVM) algorithm as a discriminator to detect potential novel and anomalous observations. We find that the proposed hybrid algorithm performs favorably against other competing deep learning, statistical and machine learning methodologies.

5 TCP-ARMA: A Tensor-Variate Time Series Forecasting Method

Yu An[1], Di Wang[2], Lili Chen[3], Xi Zhang[1], [1]Peking University, Beijing, China; [2]Shanghai Jiao Tong University, Shanghai, China; [3]Beijing Academy of Blockchain and Edge Computing, Beijing, China. Contact: yu.an@pku.edu.cn

Time series forecasting based on complex high-order historical tensor data poses significant challenges due to the high-dimensional nature of these data that exhibit complex structures. Traditional time series models, designed for scalar or vector data, are insufficient for handling such data, necessitating the development of novel techniques to tackle these challenges. To address this issue, we propose a TCP-ARMA model for time series forecasting, which integrates a smoothed mean and a tensor-variate ARMA model with a parameter reduction technique. To efficiently solve the optimization problem, a tailored BCD-PALM algorithm is designed. A real-world case study was employed to validate the proposed approach, and the results demonstrate its effectiveness in addressing the challenges associated with high-dimensional tensor data.

Global Supply Chains

Contributed Session

Session Chair: Carlos Paternina-Arboleda, San Diego State University, San Diego, CA

1 Benefits of Extreme Political Stability and Instability of Suppliers Countries for Focal Firms: The U-Shaped Relationship

Jafar Namdar[1], Sachin B. Modi[2], Arash Azadegan[3], Milad Baghersad[4], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Villanova University, Villanova, PA, [3]Rutgers University, newark, NJ, [4]Florida Atlantic University, fort lauderdale, FL

Using a large-scale panel dataset, we investigate the relationship between a firm's performance and its suppliers' exposure to political instability. The empirical evidence suggests a U-shaped relationship between a focal firm's performance and the political instability of its suppliers' countries, indicating that the firm experiences the highest benefits when its suppliers are located in highly stable or unstable political environments. Furthermore, we discovered that the relationship varies depending on the industry category of the firm.

2 Financial Hedging Incentive Contracts in Global Supply Chains:A Distributionally Robust Approach

Xiaoyi Li, Hui YU, Chongqing University, Chongqing, China. Contact: 20200201013@cqu.edu.cn

This paper considers global sourcing decisions under exchange rate and demand uncertainties,proposes financial hedging incentive contracts to explore the characteristics of exchange rate risk mitigation policies for global supply chains. The distributionally robust Stackelberg game model is designed to solve the problem. Our results show that in the distributionally robust setting, the correlation between the exchange rate and demand does not affect the retailer's order decision. Additionally, the variance of the exchange rate and demand fluctuation has an impact on the retailer's order decision, which mainly depends on the mean value of the exchange rate. Moreover, financial hedging incentive contracts make wholesale price constraints looser, increasing the scope for upstream and downstream cooperation and enabling higher order quantity.

3 Exchange Rates and International Trade: Insights from Spatial Price Equilibrium Modeling with Policy Instruments via Variational Inequalities

Anna B. Nagurney[1], Dana Hassani[1], Oleg Nivievskyi[2], Pavlo Martyshev[2], [1]University of Massachusetts Amherst, Amherst, MA, [2]Kyiv School of Economics, Kyiv, Ukraine. Contact: dhassani@umass.edu

This paper presents a multicommodity international trade spatial price equilibrium model with exchange rates and policy instruments. The model allows for multiple trade routes, different modes of transportation, and transport through distinct countries. We identify the governing equilibrium conditions as a variational inequality problem in product path flows. A case study inspired by the impacts of the war against Ukraine on agricultural trade flows and product prices is presented. The modeling and algorithmic framework allows for quantifying the effects of exchange rates, various trade policies, and the availability of routes on supply and demand market prices and the volume of trade flows with implications for food security.

4 Capacity Investment and Pricing Strategies Across International Markets Under Currency Exchange Rate and Tariff Uncertainty

Murat Erkoc[1], Huaqing Wang[2], Chunlin Wang[3], Yu Xia[4], [1]University of Miami, Coral Gables, FL, [2]Palm Beach Atlantic University, West Palm Beach, FL, [3]University of New Mexico, Albuquerque, NM, [4]College of William and Mary, Williamsburg, VA, Contact: cwang17@unm.edu

This paper analyzes capacity investment and pricing strategies for a multinational manufacturer to hedge against exchange rate and tariff uncertainties in the competitive global market. Because of long-lead times, the capacity investment must be done before the selling season begins when the exchange rate between the two countries is uncertain. We consider a duopoly competition in the foreign country. We model the exchange rate as a random variable. An analytic model is built to study the duopoly competition in a foreign market with both currency exchange rate and tariff rate as exogenous variables. We find the optimal capacity investment and pricing strategy given various exchange rate and different tariff policy statuses. Some penetrating managerial insights are generated. Case discussion and numerical tests confirm our findings.

5 Smart Information Systems for Real-Time AI-Driven Decision Support in Ports

Carlos D. Paternina-Arboleda[1], Jesus M. Velasquez-bermudez[2], Danilo Abril[3], [1]San Diego State University, San Diego, CA, [2]Hypothalamus Ai, Miami, FL, [3]Hyphotalamus Ai, Miami, FL, Contact: cpaternina@sdsu.edu

The ongoing issues in global supply chain disruptions have raised many concerns on ports productivity among which port congestion is a key issue. This article implements an integrated tactical-operational optimization framework which raises the capabilities of port information systems to deliver smarter decision-making processes in ports. To this end, we have developed a library of multiple smart models for the optimization of ports operations, independently engaged in parallel but mathematically coordinated to achieve Autonomous Real-Time Distributed Optimization, using a novel event-driven structure to enable future implementations using digital twins. The framework has been tested to benchmark different commercial solvers on several real instances for the port under study. The results show a strong improvement in Port's operational planning.

Monday, October 16, 12:45 PM - 2:00 PM

CC-North Exhibit Hall

Monday Poster Session

Poster Session

Session Chair: Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ

Session Chair: Bjorn Berg, University of Minnesota, Minneapolis, MN

Session Chair: Hrayer Aprahamian, Texas A&M University, College Station, TX

1 Are We Gaming Students Evaluations And Does It Matter?

Philip M. Goldfeder[1], James A. DiLellio[2]; [1]Northwestern University, USA, [2]Pepperdine University, USA

The utility and predictive reliability of Student Evaluations of Teaching (SET) are a controversial topic in higher education. At many schools they are a primary metric used in promotion and tenure decisions. The ideas that have been frequently researched are whether SET measure teaching effectiveness and if these evaluations can be gamed by inflating student grades. This paper will address the latter question by comparing grades and evaluations from a graduate level Data Science course taught by the same instructor over a 10-year period. Further questions investigated include what other metrics might be better correlated to student grades and any conclusions which can be drawn from this.

2 More Online Search By Investors, Less Blame On Managers?evidence From Insurance Markets

Hua Cheng[1], Luying Wang[2]; [1]University of Texas at Austin, USA, [2]Singapore Management University, Singapore

There has been limited investigation into the impact of online search on insurance markets such as Directors' and Officers' liability insurance (D&O insurance), which provides an ideal setting to examine information asymmetry. This study investigates how online search activities influence the purchase of D&O insurance among Chinese listed firms. Our analysis reveals that higher online search is associated with reduced purchases of D&O insurance, and these findings remain robust after addressing potential endogeneity concerns. Additionally, we found that the reduced D&O insurance purchases induced by online search on D&O insurance improve firm value.

3 How Empowering Leadership Affects Employee Creativity? Moderated-Mediation Analysis

Nosheen Amjad; Xian Jiaotong University, China
Results from 172 repondent from Pakistani firms confirm that empowering leadership postively affect perceived job autonomy. Moreover, job autonomy is found to mediate the association between empowering leadership and employee creativity. In addition, the study demonstrates that supervisors' creativity expectations moderates the relationship between job autonomy and employee creativity. Finally, the moderating effect of supervisor's creativity expectations in the conditional indirect association of empowering leadership with employee creativity through perceived job autonomy.

4 Long-term Mortality Prediction In Patients With Cirrhosis Using Machine Learning

Mohsen Mohammadi[1], Alexander Huang[1], Bima Hasjim[1], Praneet Polineni[1], Mitchell Paukner[1], Sydney Olson[1], Alexandra Harris[1], Julianna Doll[1], Therese Banea[1], Lisa VanWagner[2], Lihui Zhao[1], Sanjay Mehrotra[1], Daniela Ladner[1]; [1]Northwestern University, USA, [2]University of Texas Southwestern Medical Center, USA
MELD-Na is a strong predictor for 30-day mortality in patients with cirrhosis and high MELD-Na, but is less predictive of long-term outcomes. We assess the accuracy of machine-learning models that leverage additional laboratory data in predicting 1-year mortality and compare them to MELD-Na.

5 Explainable FinBERT: Extending Explanations In Sentiment Analysis Of Financial Texts Via Shapley

Yoshihiro Nishi, Hiroshi Takahashi; Keio University, Japan
Financial sentiment analysis can help investors make more efficient decisions. FinBERT has been pre-trained on a financial-specific dataset and is highly accurate in the sentiment analysis of financial documents. However, FinBERT has the disadvantage of sometimes requiring assistance to interpret or explain output results, which may make it difficult to use for critical decision-making. In this study, we propose Explainable FinBERT, which supplements the output results of FinBERT with those of SHAP and explicitly shows the impact of each word in the body of analyzed data on the results of financial sentiment analysis using FinBERT. A more detailed analysis will be conducted in the future.

6 How Does Selective Incivility Undermine Diversity In Supply Chains?

Iman Nosoohi; Dalhousie University, Canada
In this research, we introduce *selective incivility* as a behavioral risk to diversity in supply chains. We develop a conceptual model to describe how selective incivility may influence supply chain decision making, buyer-supplier relationship, and employee recruitment and retention in ways that undermine supply chain diversity.

7 Interpreting Characteristics Behaviors In Empirical Asset Pricing

Zequn Li, Ying Wu, Steve Y. Yang; Stevens Institute of Technology, USA
We propose a novel approach for interpreting machine learning models in measuring risk premium, which infers global model interpretations through local interpretable model-agnostic explanation (LIME). This method helps us understand the different behaviors in explaining the influence of the existing firm characteristics in asset pricing whether it was linear, independent, interacting, or insignificant. Our study advances the asset pricing literature by introducing a novel approach to interpreting the contribution of firm characteristics through local interpretations when using advanced machine learning methods in asset pricing.

8 Bringing Data Into Dynamic Models: Guidelines For Advanced Estimation Methods

Jose Lopez; MIT, USA
Dynamic, non-linear models require customized methods for formal estimation. Increasing data availability and computational power provide opportunities, though many audiences remain unfamiliar. Synthesizing across literatures, we develop a pragmatic workflow to guide decision making and identify promising approaches for addressing recurring problems. Additionally, we provide detailed examples through different models.

9 A Two-stage Approach To Minimize Number Of Material Movements In A Warehouse

Andrea Esposito[1], Ryme Kabak[2]; [1]MIT, USA, [2]Johnson & Johnson, USA
We propose a new approach that redefines the material categories and their placement within a fully automated warehouse. The strategy proposed is to forecast the movements of materials using deep learning, and then to optimize their storage. By doing so, we aim to streamline warehouse operations, improving efficiency and cost-effectiveness.

10 Analyzing Trends In Battery Electric Vehicles(Bev) And Hybrid Electric Vehicles (Hev) Through Patent Data With Structural Topic Modeling

Yong suk Hong[1], Hyunhong Choi[2]; [1]Kyunghee university, Korea, Republic of, [2]Kyung Hee University, Korea, Republic of

This research explores distinctions between Battery Electric Vehicles (BEV) and Hybrid Electric Vehicles (HEV) through patent data via Structural Topic Modeling (STM). Integrating time as covariate in STM, we established a trend analysis, highlighting the possible evolution in BEV and HEV related themes over time. From 1980 to 1990, the main focus in patent discussions was on HEV-related topic. Then, from 1990 to 2000, BEV topic took the lead. Between 2000 and 2010, there was a mix of common and HEV theme. Lastly, from 2010 to 2020, common topic prominently featured in latent topics

11 Analyzing Masking And Quarantine Interventions During The Covid-19 Emergency: Insights From Seir Models

Diego Hernandez; The University of Oklahoma, USA

The COVID-19 pandemic required diverse public health interventions, such as masking and quarantine, to mitigate virus transmission. This study employs SEIR models incorporating COVID-19 variants, vaccination rates, mortality rates, herd immunity, and the effects of masking/quarantine. By referencing initial reproduction numbers (Ro) for each variant, we assess the impact of interventions by comparing observed data with SEIR simulations. Our findings offer valuable insights into the effectiveness of these measures, aiding evidence-based decision-making and informing future public health strategies for similar epidemics.

12 DEMONETIZATION, FINANCIAL INCLUSION AND BANK EFFICIENCY

keyur thaker[1], Vinceint Charles[2], Abhay Pant[3]; [1]INDIAN INSTITUTE OF MANAGEMENT INDORE, India, [2]University of Bradford, United Kingdom, [3]Indian Institute of Technology Gawhati, India

The impact of Demonetization and Financial Inclusion on Indian Bank Efficiency using three measures namely, New Profit, New Cost, and New Technical, across Size and Ownership groups is examined. The impact across groups, using Repeated ANOVA is examined. Uniform impact across groups, events, and efficiency types was not found. The number of frontier banks increased. SBI, largest bank, with significant role had positive impact on cost and profit efficiency while foreign banks saw muted impact. The study unique to examine demonetization and Financial Inclusion impact on banking sector and two-stage estimation that combines DEA with repeated ANOVA.

13 Social Particles In The Open Medium: Open Collaboration In Github

Shiyang Lai; University of Chicago, USA

Drawing from sociophysics, this study posits a method to enhance structured and holistic modeling of online collaboration. By viewing individuals, teams, and collaborative surroundings as social atoms, molecules, and medium, this study employs tools and principles from physics to illustrate human interactions. This study proposes an analytical framework that adheres to the key principles of select traditional instruments from physics, while concurrently integrating more probabilistic and fluid elements to harmonize discrepancies between the two systems. This framework is tested on a dataset sourced from GitHub, including 416 thousands of users and their associated collaboration data.

14 Time Heals - A Trust Game Experiment Of Anger

Kamyar Kamyar[1], Marco Palma[2], Ian Krajbich[1]; [1]The Ohio State University, USA, [2]Texas A&M University, USA

Psychological literature has shown that emotions calm down as time passes. However, few studies have tried to apply this phenomenon to cases where economic decisions are involved. Do people remain angry at each other over time when treated unfairly in cases involving monetary stakes? To figure out, we have designed trust game experiments with monetary stakes. Specifically, we are studying the effect of time on anger in economic decision making.

15 An Empirical Study Of Daily Commuting And Employees' Work And Well-being

Vivien Lim, Thompson Teo; National University of Singapore, Singapore

This study examined the commute stress and enjoyment experienced by employees during their morning and evening commute. Data were collected from 174 employees who utilized public transportation in their morning (home to work) and evening (work to home) commute in Singapore. Results suggest that the morning and evening commutes are different in terms of the stress and enjoyment they engender, as well as in the extent to which different types of activities are carried out. The evening commute was related with higher levels of recovery. These findings hold some practical implications for commuters and public transportation service providers.

16 Content Promotion For Online Content Platforms With The Diffusion Effect

Yunduan Lin[1], Mengxin Wang[1], Zuo-Jun Max Shen[2], Heng Zhang[3], Renyu Zhang[4]; [1]University of California, Berkeley, USA, [2]University of California Berkeley, USA, [3]Arizona State University, USA, [4]The Chinese University of Hong Kong, China

In this paper, we tackle the candidate generation and promotion optimization (CGPO) problem in online content platforms, incorporating the diffusion effect neglected by traditional promotion policies. We introduce a diffusion model to characterize content adoption, leading to an NP-hard CGPO problem. To estimate model parameters from platform data, we propose Double Ordinary Least Squares (D-OLS) estimators. Our CGPO solution demonstrates submodularity, permitting an efficient approximation. In a video-sharing platform case study, our promotion policy increased total adoption by 49.90% over the existing policy, underlining diffusion's importance in online content promotion.

17 Cooperative Connected Automated Vehicle Control: Strategies For Speed Harmonization In Mixed Autonomy Traffic

Zhe Fu, Abdul Rahman Kreidieh, Alexandre Bayen; University of California, Berkeley, USA

We explore methods for generating traffic-regulating behaviors by automated driving systems through feedback control and imitation learning. We construct an expert policy that exploits knowledge of global states of traffic to homogenize the movement of vehicles towards their desirable uniform-flow equilibrium. We then demonstrate that imitation learning techniques can successfully capture such behaviors using only local observations and relatively few interactions with the environment. The proposed expert strategy that served as part of the "speed planner" was deployed on 103 automated vehicles in a massive traffic experiment conducted on Nashville's I-24 highway in November 2022.

18 Competitive Landscape Analysis On College, Academic Program And Student Levels

Krystie Dickson[1], Vladimir Zlatev[2]; [1]Boston University, USA, [2]Boston University Metropolitan College, USA

The Competitive Landscape Analysis Framework (CLA) was developed to gain insights into the performance of programs offered at Boston University Metropolitan College. The framework seeks to analyze data of competing universities by rating and ranking them to determine the competitive positioning of our programs based on various key differentiating factors.

19 Durability Design Of Conspicuous Products

Jiacheng Guo[1], Lai Wei[2]; [1]Princeton University, USA, [2]Boston College, USA

For conspicuous consumption good, durability not only have a direct impact on the second-hand market, but also affects consumers' utilities of status from it. The latter is due to a diluted exclusivity value of the product when there is an increase in sales, whether on the first-hand or second-hand market. In this context, we examine the ideal durability decisions for conspicuous goods, particularly in cases of competition between two products.

20 Study Of Influencing Factors Of Trust Formation In Digital Economy

Cong Cao, Yangbin Xu, Jinyang Zhou; Zhejiang University of Technology, China

This research study investigates online trust as a breakthrough point aiming at consumers in the digital economy; as such, it examines specific factors that influence consumers' online trust. Based on a literature review and existing research results in relevant fields, with the TPB as the theoretical underpinning, this study proposes a three-dimensional integrated trust model and identifies three factors that impact consumers' trust: personal attitude, online reviews and TTPs. The required experimental data were obtained using random sampling and online questionnaires. Moreover, the study investigated the mechanism and impact of different factors on consumers' trusting behaviours.

21 Pricing Strategies For Profitability And Market Opportunities: A Case Study

Xilin Zhang; Binghamton University, USA

This study analyzes the impact of pricing strategies on profitability across sectors. We evaluate cost-based, competition-based, and value-based pricing approaches and their influence on profitability and market opportunities. To maximize profit margins and sales, companies must carefully consider pricing approaches. We explore the benefits of value-based pricing, implementation barriers requiring change, and recommend its strategic adoption to leverage market advantages. Also, we analyze the benefits of cost-based and competition-based pricing in achieving specific goals. Our proposed pricing model integrates these approaches, offering flexibility for diverse objectives.

22 Crafting A Compelling Narrative: How Self-presentation Influences The Success Of Online Medical Crowdfunding Campaigns

Shuaishuai Yang; University College London, United Kingdom

Like in daily life, most people want to create a positive image by selectively providing information based on others' preferences. Online medical crowdfunding fundraisers also aim to manage donors' perceptions of their campaigns to achieve their fundraising goals. The fundraisers usually present their situations differently. Different pictures and writing styles will give donors different impressions of patients and their campaigns. Moreover, the impressions could significantly affect donors' intention to donate. Therefore, the objective of this research is to investigate the impact of various self-presentation styles on the efficacy of medical crowdfunding campaigns.

23 Modeling The Spread Of Circulating Vaccine-derived Poliovirus Type 2 Outbreaks And Interventions

Yuming Sun[1], Pinar Keskinocak[1], Lauren N. Steimle[1], Stephanie Kovacs[2], Steven Wassilak[2]; [1]ISyE Georgia Tech, USA, [2]CDC, USA

Despite the successes of the Global Polio Eradication Initiative, there are circulating vaccine-derived poliovirus outbreaks that require improved interventions. We built a compartmental model to simulate the spread of polio and evaluate interventions. We validated the model and tested the impact of interventions that varied in the number of vaccination rounds, the target regions, and the start dates. Results indicated to stop the outbreaks, stakeholders should conduct aggressive interventions with more rounds, shorter delays from detection to vaccination, and broader coverage compared to the current practice.

24 Breaking The Law, Or Breaking Even? The Factors Affecting SVoD Password Sharing Piracy In The Context Of Digital Piracy Neutralization

Jaehyun Lee[1], Yeolib Kim[2], Yoonhyuk Jung[3]; [1]Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of, Korea, Republic of, [2]Ulsan National Institute of Science and Technology (UNIST), Korea, Republic of, [3]Korea University, Korea, Republic of

Subscription Video on Demand (SVoD) platforms are experiencing a new type of digital piracy: password sharing. Our research analyzes piracy neutralization, password borrowing/lending, and moderating factors to explore password-sharing piracy preconditions. We conducted a survey on Amazon Mechanical Turk to identify the nature of password sharing. We found that piracy neutralization has a significant impact on password-sharing piracy. Moreover, privacy concern, fashion involvement, and network dynamics moderates the main effects. The study contributes to the digital piracy literature and offers practical insights for SVoD services to better understand password sharing.

25 Statistical Teleodynamics Analysis Of Emergent Equilibria In The Schelling Game

Jessica Shi; Columbia University, USA

The behavior of a Schelling type agent-based model is studied. The space is divided into blocks, and agents move between blocks to maximize their utility. The agent utility function is dependent on block density and parameters. At equilibrium, all agents have equal utility and the system could exhibit segregation in which agents cluster in certain blocks. We programmed the agent-based simulation with NetLogo. We identify the parameter ranges for non-monotone utility functions which are necessary for segregation, and we show the asymptotic behavior of the system given initial conditions and verify it through simulation. The model emulates socioeconomic segregation occurring in many urban areas.

26 Shared Parking And Charging Management In Multi-unit Dwellings

Ruolin Zhang, Eleftheria Kontou; University of Illinois at Urbana-Champaign, USA

In urban areas, the search for parking and charging results in vehicle cruising and congestion. However, private parking spaces and charging infrastructure in multi-unit dwellings (MUDs) could be available during daytime, when MUD residents drive their vehicles to work. We design a shared parking and charging system for MUD charging hubs and public users to provide accessible parking and charging services to the general public. A binary integer linear programming (BILP) model is formulated for the supply side. Counterfactual analysis is conducted to model users' charging behavior. Results from a numerical experiment in Chicago, Illinois using real-world data will be presented.

27 Keeping The Lights On: Optimizing Gas Allocation For Extreme Winter Energy Demands

Ashish Radhakrishnan; The Pennsylvania State University, USA

The growing interdependence of natural gas and electricity infrastructure in the U.S. has caused reliability concerns during extreme winter weather events such as the 2014 Polar Vortex and 2021 Winter Storm Uri. Lack of natural gas fuel supply was found to be a major contributor behind the power outages experienced during these events. The primary driver behind the fuel supply delivery risk is rooted in the way gas is currently allocated to the various end users. This study builds an optimization modeling framework that endogenously models the fuel supply delivery risk to allocate gas amongst various end users. The benefits of the optimal allocation are analyzed for the Northeastern part of U.S.

28 Waiting Together: How To Infer Response Time When Customers Wait In Groups

Yanting Li[1], Ricky Roet-Green[2]; [1]University of Rochester, Simon business school, USA, [2]Simon Business School, University of Rochester, USA

In this work, we relax two fundamental assumptions in the strategic queuing literature: (1) customers arrive one after the other and (2) the service provider serves customers one by one. We study customers' strategies under Bayesian updating in the case of uncertainty for the demand ratio where customers are either single or in a group. We find that providing group information to customers is not always beneficial regarding revenue maximization. When the demand ratio is at a specific range, it is better not to disclose any information to customers.

29 Dynamic Vehicle Yard Operations Under Uncertainty

Katja Meuche[1], Mathieu Dahan[1], Benoit Montreuil[2]; [1]Georgia Institute of Technology, USA, [2]Georgia Tech, USA

A vehicle yard is a set of parking lots between which groups of vehicles are moved. The movements are executed by multiple assigned teams of relocators who themselves are transported in vans. We propose a Markov decision process to determine the dynamic operations of the vehicle yard while accounting for travel time and vehicle demand uncertainty. We leverage the problem structure to propose two solution approaches based on a cost function approximation policy and an approximate dynamic programming policy. We compare their performance on a test instance to minimize relocator idle time and late vehicle movements.

30 Food Transportation Safety And Food Recalls

Bukola Bakare[1], Sarah Campbell-Sengupta[2]; [1]Western Carolina University, USA, [2]St. Cloud State University, USA

Contaminated food is the number one cause of food recalls in the United States. The CDC reported 7,659 illnesses, 2,044 hospitalizations, and 41 deaths from 2017-2020 foodborne outbreaks in produce alone. The USDA has continually strengthened sampling programs to understand relative risks in food contamination. Food safety inspections are done on local and imported produce. Thus, annual sampling in food transportation has had a significant impact. Safety regulations are closely monitored, yet, there is an unexplained gap between the number of food related recalls and food safety inspections. This study uses data from USDA and CDC to track food recalls and the implemented food security.

31 The Impact Of Construal Level On Planning Fallacy: Programmers' Construal Level And Their Estimations On Workload

Hongyu Gao[1], Mark Keil[1], Yi Yang[1], Jong Seok Lee[2]; [1]Georgia State University, USA, [2]University of Tennessee, Knoxville, USA

The planning fallacy has long been recognized as a prevalent phenomenon in IT project management. Construal Level Theory (CLT) suggests that individuals with distal or proximal psychological distance perceive things abstractly or concretely, respectively. This study aims to investigate the impact of construal level on the planning fallacy. Specifically, we propose that when individuals focus on the similarities between projects, they tend to underestimate the workload of the specific project. When individuals concentrate on a project's distinctive aspects, they are inclined to overestimate its workload. A preliminary study with professional programmers lends support to the hypotheses.

32 Stochastic Dominant Resource Allocation Fairness With A Cloud Computing Application

Jiaqi Lei, Sanjay Mehrotra; Northwestern University, USA

Allocation of limited resources across different operational areas requires consideration of fairness. In this paper, we introduce the concept of stochastic dominant resource fairness for multi-resource allocation. We demonstrate that the proposed model is amenable to approximation using Sample Average Approximation, which is second-order cone representable and satisfies key properties of Stochastic Pareto-efficiency, Stochastic sharing incentive, and Stochastic envy-freeness under suitable conditions. A cloud computing application with real-world data shows that consideration of stochasticity is important when the desired resources have greater variance.

33 Advertising Pricing: The Impact Of The Integration Of E-commerce On Social Media Platforms

Jiayu Fan, Subodha Kumar; Temple University, USA

Several multi-sided platforms, including TikTok and Instagram, have recently introduced in-app shopping capabilities, meanwhile, TikTok built connections with third-party suppliers or manufacturers. This integration with eCommerce is set to revolutionize the revenue ecosystem of these platforms, prompting changes in ad pricing strategies and revenue-sharing policies. Users can now conveniently browse products and make purchases directly within the app. In addition to generating revenue through advertisements, these platforms also earn commissions on each purchase. This poses new questions regarding the pricing of two distinct ad types: traditional ads and shoppable ads.

34 A Systematic Modeling Framework For Sustainable From-farm-to-fork Logistics Network Design And Planning

Chao Lei, Waiyanet Phuwadon; Shanghai Maritime University, China

The distribution of perishable goods throughout the world has been largely restricted to short distances because of their perishability; however, poor transportation planning has contributed to a substantial amount of supply chain costs. A sophisticated long-haul food network design is depicted as a challenging task in an optimization model. We present a mathematical model for "farm-to-fork" logistics networks involving the export of perishable products from regional farms to an overseas country. A case study based on the fresh food logistics system between Thailand and China is undertaken to demonstrate the relevance of the proposed approach to accelerating sustainable development.

45 Local Acceptance Of Hydrogen Power Plant Project: The Case Of South Korea.

Seungyeon Lee; Korea University, Korea, Republic of

This study aims to determine the willingness-to-accept (WTA) of local residents regarding the construction of a fuel cell power plant (FCPP) using the contingent valuation method (CVM) and the marginal-willingness-to-accept (MWTA) of the factors affecting acceptance using the discrete choice experiment (DCE) method. Combining the two methods, a simulation was conducted to determine the subsidy level based on FCPP attributes. The results showed that constructing a 5MW FCPP with a storage tank, supplying hot water to households, could secure acceptance with a WTA of 7.8 million KRW/year (USD 6,037/year). This study provides practical evidence for policymakers to promote H_2 economy expansion.

35 Quantifying The Impact Of Energy Storage In PJM Interconnection

Shailesh Wasti[1], Anthony Giacomoni[2], Sushant Varghese[1], Aravind Retna Kumar[1], Mort David Webster[1]; [1]Pennsylvania State University, USA, [2]PJM Interconnection, USA

In this study, we model the interaction of energy storage resources (ESRs) in the Day-Ahead and Real-Time Markets of PJM Interconnection to assess their impacts under system uncertainties such as real-time net-load variability and random outages. The results show integrating ESRs reduces the total online capacity of coal generators in the day-ahead market at the expense of worsening overall system reliability by increasing unserved energy and reserve capacity shortages. We propose a multi-interval real-time market and stochastic fast-start unit commitment as market enhancements and demonstrate that system reliability and bid production cost improve while reducing the coal capacity online.

36 Using Etl And Data Visualization Tools To Enhance Career Services For Analytics Master Program Student

Putranegara Riauwindu, Vladimir Zlatev; Boston University, USA

This poster proposes an ETL framework & Data Visualization method to provide tailored occupation information for analytics graduates, specifically for Boston University Metropolitan College (BU MET) Applied Business Analytics students. The data is extracted from various sources, manipulated using MS Power Query and Excel, and stored in MS SharePoint. Interactive visualizations are created in MS Power BI, resulting in two dashboards: Analytics Career Prospect and Job Market Consultation. These dashboards offer comprehensive information on occupations, salary, job posting trends, required skills, industries, and more. They serve as a convenient and efficient resource for career research.

37 Using Extract, Transform, And Load Framework And Data Visualization Tools To Enhance Career Services For Analytics Master's Program Student

Putranegara Riauwindu, Vladimir Zlatev; Boston University, USA

This poster proposes an ETL framework & Data Visualization method to provide tailored occupation information for analytics graduates, specifically for Boston University Metropolitan College (BU MET) Applied Business Analytics students. The data is extracted from various sources, manipulated using MS Power Query and Excel, and stored in MS SharePoint. Interactive visualizations are created in MS Power BI, resulting in two dashboards: Analytics Career Prospect and Job Market Consultation. These dashboards offer comprehensive information on occupations, salary, job posting trends, required skills, industries, and more. They serve as a convenient and efficient resource for career research.

38 The Nexus Of Crisis Perception: Unraveling The Link Between Covid-19 And Climate Change Concerns

Sabrina Tang[1], Dennis Cui[2]; [1]Northwood High, USA, [2]Wayzata High School, USA

Our study examines the relationship between individuals' perceptions of the COVID-19 pandemic and their subsequent attitudes towards climate change, and finds that concern about COVID-19 correlates with stronger attitudes towards climate change. Our findings shed light on the interconnectedness of crisis perception and highlight the potential for combating climate change.

39 Student Initiated Management Science-based Projects In An MBA Course

David G. Hollingworth, Tara Stiles-Rath; University of North Dakota, USA

MBA students typically have lower levels of training, experience, and comfort with quantitative methods. In addition, they are usually more interested in practical use, rather than technical detail. This poster describes the use of student-initiated Management Science-based projects in an MBA course to enhance student motivation and learning by solving problems that they identify as personally relevant. The projects facilitate higher impact learning by taking concepts out of the classroom and encouraging hands-on learning-by-doing. Key aspects of project are identified, a sampling of projects that students have initiated and completed, and a detailed example of a recent project is provided.

40 Spectral Bundle Methods For Primal And Dual Semidefinite Programs

Feng-Yi Liao[1], Yang Zheng[2], Lijun Ding[3]; [1]University of California, San Diego, USA, [2]University of California San Diego, USA, [3]University of Washington and University of Wisconsin - Madison, USA

We present an overview and comparison of Spectral Bundle Methods (SBMs) for solving both *primal* and *dual* semidefinite programs (SDPs). In particular, we introduce a new family of SBMs for solving SDPs in the *primal* form. The algorithm developments are parallel to those by Helmberg and Rendl, mirroring the elegant duality between primal and dual SDPs. The new family of SBMs achieves linear convergence rates for primal feasibility, dual feasibility, and duality gap when the algorithm captures the *rank of the dual solutions*. The original SBM by Helmberg and Rendl is well-suited for SDPs with low-rank primal solutions, while our new spectral bundle method works well for SDPs with low-rank dual solutions.

41 Robust Screening And Partitioning For Feature Selection

Ethan Houser, Sara Shashaani; North Carolina State University, USA

Feature selection (FS) is the process of eliminating irrelevant or redundant covariates in a dataset to construct interpretable prediction models. Solving FS with optimization is often done greedily and inefficiently. We propose a stochastic search with optimality guarantees for FS using a partitioning structure informed by an initial screening phase.

42 Link Prediction Models For Organ Illicit Networks

Hasini Balasuriya, Monica Gentili; University of Louisville, USA

Link prediction models are vital for analyzing complex networks by predicting missing or future connections and are particularly significant in understanding and combating illicit organ trafficking networks. This preliminary study compares different models experimentally to solve the static link prediction problem and employs multiple evaluation metrics to assess their accuracy. The findings contribute to enhancing our understanding of link prediction models' performance in this domain.

43 An Integrated RSM-ANN Technique To Predict The Optimal Pricing Strategy

Moddassir Khan Nayeem[1], Shahriar Tanvir Alam[2], Omar Abbaas[1]; [1]University of Texas at San Antonio, USA, [2]University of Southern California, USA

It is deemed pertinent to have knowledge of product demand and pricing strategies to achieve the economics of scale and profitability of a product. The price, salvage value, and cost of the product have a significant influence on the expected profit, overstock, and understock of an order. Therefore, in this study, the price, salvage value, and cost of a product along with the mean and standard deviation of demand are considered deciding factors in controlling the expected overstock and understock. This study combines the Response Surface Methodology (RSM) and Artificial Neural Network (ANN) to determine the combination of optimum deciding factors to find the maximum expected profit from an order.

44 Learning Fixed Points In Recurrent Neural Networks

Vicky Zhu[1], Robert Rosenbaum[2]; [1]Babson College, USA, [2]University of Notre Dame, USA

Fixed points of recurrent neural networks are commonly used to model neural responses to static or slowly changing inputs. These applications raise the question of how to train the weights in a recurrent neural network to minimize a loss function evaluated on fixed points. A natural approach is to use gradient descent on the Euclidean space of recurrent weights. However, this approach can lead to poor learning performance. Under a re-parameterization of the network, we derive two alternative learning rules that produce more robust learning dynamics and show that one of the learning rules can be interpreted as gradient descent under a non-Euclidean geometry on the space of recurrent weights.

45 A New Upper Bound Of The Euclidean Tsp Constant

Yue Yu, John Gunnar Carlsson; University of Southern California, USA

Let $X_1, X_2, \ldots, X_n$ be n independent and uniformly distributed random points in a compact planar region *R* of area 1. Let $TSP(X_1, \ldots, X_n)$ denote the length of the optimal Euclidean traveling salesman tour that traverses all these points. The classical Beardwood-Halton-Hammersley theorem (1959) proved the existence of a universal constant β_2 whose best bounds are $0.625 \leq \beta_2 \leq 0.92116$. Building upon an approach proposed by Steinerberger (2015), we present a computer-aided proof that improves its upper bound to $\beta_2 < 0.90304$.

46 A Machine Learning Embedded Dijkstra's Algorithm For Shortest-path Problems

Weiheng Zhong, Hadi Meidani; University of Illinois Urbana Champaign, USA

The shortest path computation in dynamic graphs is crucial in a variety of applications, including internet routing services and product recommendations. To achieve the efficiency requirements for these applications, machine-learning-based solutions are proposed. However, these methods cannot overcome the barrier of graph topology generalization. Hence, we proposed a novel class of methods for solving shortest-path problems by embedding machine-learned components into a Dijkstra-based algorithm. By combining a purely heuristic method and a purely data-driven model, our algorithm achieved satisfactory performance and could be directly applied to unseen graph topologies in multiple fields without re-training.

47 Projection-free Methods For Solving Nonconvex-concave Saddle Point Problems

Morteza Boroun, Erfan Yazdandoost Hamedani, Afrooz Jalilzadeh; The University of Arizona, USA

In this study, we investigate a class of constrained saddle point optimization problems where the objective function is nonconvex-(strongly) concave and smooth. This class of problems has wide applicability in machine learning, including robust multi-class classification and dictionary learning. Several methods have been developed for tackling this problem when the projection onto the constraint set is easy to compute, however, the availability of methods with projection-free oracles remains limited. To address this gap, we propose efficient single-loop projection-free methods reliant on first-order information.

48 Stochastic Sustainable Supply Chain Network Design For Reusable Products

Amir Hossein Sadeghi, Robert Handfield; North Carolina State University, USA

This project addresses the problem of supply chain network design for reusable products in a single-vendor, multi-product, multi-retailer, with a focus on economic and environmental sustainability. The objective is to efficiently manage product reuse and recovery, considering various constraints such as budget limitations, storage capacity, and the number of orders. To capture the uncertainty associated with these constraints, a stochastic formulation is adopted to provide a more realistic representation of the problem.

49 A Unified Machine Learning Framework For Optimization Under Uncertainty

Justin Dumouchelle; University of Toronto, Canada

Stochastic programming and robust optimization are powerful modeling frameworks for decision-making under uncertainty. Typically, algorithms in these domains are limited to a class of problems or are even problem specific. This work presents a unified machine-learning framework for computing high-quality solutions within various problems in both domains. By approximating the intractable aspects of these optimization problems with machine learning models, we can formulate easy-to-solve surrogate optimization problems that can be solved efficiently with off-the-shelf libraries.

50 Optimal Diagonal Preconditioning

Zhaonan Qu[1], Wenzhi Gao[1], Oliver Hinder[2], Yinyu Ye[1], Zhengyuan Zhou[3]; [1]Stanford University, USA, [2]University of Pittsburgh, USA, [3]Stern School of Business, New York University, USA

Preconditioning has long been a staple technique in optimization. In this paper, we study the problem of optimal diagonal preconditioning, that achieves maximal reduction in the condition number of any full-rank matrix. We first reformulate the problem as a quasi-convex optimization problem and provide a bisection and an interior point method. Next, we specialize to one-sided optimal diagonal preconditioning problems, and demonstrate that they can be formulated as standard dual SDP problems. Our findings suggest that optimal diagonal preconditioners can significantly improve upon existing heuristics-based diagonal preconditioners at reducing condition numbers.

51 Bayesian Feasibility Determination With Multiple Constraints

Tingnan Gong[1], Liu Di[2], Yao Xie[1], Seong-Hee Kim[1]; [1]Georgia Institute of Technology, USA, [2]Google, USA

We aim to efficiently determine a feasible region of a group of unknown black box functions that assign real numbers to discrete alternatives. Unlike existing binary classifications that primarily develop a classifier trained on a fixed number of data, we optimize the order of alternative sampling to achieve high accuracy in feasibility determination with few observations. To achieve this, we utilize the Gaussian process as the surrogate model and introduce a novel value-of-information acquisition function to perform adaptive sampling under multiple constraints. We thoroughly analyze the convergence of our proposed scheme and demonstrate its effectiveness through numerical experiments.

52 A Proactive/reactive Mass Screening Approach With Uncertain Symptomatic Cases

Jiayi Lin[1], Hrayer Aprahamian[1], George Golovko[2]; [1]Texas A&M University, USA, [2]The University of Texas Medical Branch, USA

This work employs population-level risk data to optimize the allocation of limited testing resources between proactive screening of specific groups and reactive screening of symptomatic cases, integrating individual and Dorfman group testing. By analyzing the optimization problem, efficient solutions are devised. A case study using geographically-based COVID-19 data in the US reveals up to 52% reduction in total misclassifications compared to conventional strategies, and provides valuable managerial insights regarding the allocation of proactive/reactive measures and budget across regions.

53 A Streamlined Heuristic For The Problem Of Min-Time Coverage In Constricted Environments

Young In Kim[1], Spiridon Reveliotis[2]; [1]Georgia Institute of Technology, USA, [2]ISyE Georgia Tech, USA

We consider the employment of networked robotic fleets for the support of inspection tasks taking place in constricted environments, like subterranean utility networks or pipelines, in an expedient manner. We provide a taxonomy regarding the formal positioning of this problem, analytical characterizations for some members of this taxonomy in the form of mixed integer programs, a formal analysis of the worst-case computational complexity, and additional structural results that eventually enable the development of an efficient heuristic for the considered variates of the addressed problem.

54 Optimizing Electric Vehicle Charging Station Locations: Exploring Grover's Quantum Searching Algorithm

Tina Radvand[1], Alireza Talebpour[2]; [1]University of Illinois at Urbana- Champaign, USA, [2]University of Illinois at Urbana-Champaign, USA

Electric Vehicles (EVs) offer sustainable solutions for environmental concerns. However, limited charging station infrastructure impedes their widespread adoption. Determining optimal charging station locations is an NP-hard combinatorial optimization problem. Recent quantum computing breakthroughs address the computational power needed.This poster presents a novel approach using Grover's Quantum Searching Algorithm to optimize charging stations for long-distance trips. Grover's algorithm exhibits exponential speedup for solving combinatorial optimization problems. Employing a 433-qubit Osprey processor, this research showcases its capabilities on a sample graph.

55 Facilitating The Movement Emergency Response Vehicles In A Transportation Network: A Two-level Routing Framework

Jamal Nahofti Kohneh, Pamela Murray-Tuite; Clemson University, USA

This study presents a two-level routing framework to facilitate the movement of emergency response vehicles (ERVs) in a transportation network. In the first level, the framework utilizes mixed-integer programming (MIP) models to generate optimized micro-paths for multiple ERVs in different road types. In the second level, a dynamic routing approach employs the traffic simulation tool SUMO to execute Dijkstra's algorithm, integrating the optimization results from the first level to assist ERVs in selecting the shortest travel-time path across the network. The findings demonstrate improved ERVs' travel time compared to static routing with lights and sirens.

56 Patient-Centric Early-Stage Clinical Trial Design

Hanwen Liu, Amin Khademi, Qi Luo; Clemson University, USA

We propose an innovative patient-centric design for early-stage clinical trials, wherein patients actively determine therapy times and dose selection by solving an optimal stopping problem. This approach balances the exploration of the dose-response curve and maximization of patients' utility. Our findings indicate that involving patients' preferences in the decision-making process of clinical trials not only boosts patient recruitment but also accelerates the drug development process.

57 Can Multiple Offers Achieve Higher Profits? Ride-Hailing Platform

Amir Zamani[1], Subodha Kumar[2]; [1]Fox Business School, USA, [2]Fox School of Business, Temple University, USA

This paper examines a novel feature on the driver's side of a ride-hailing application using a game-theoretic model that aims to determine the optimal pricing strategy for the platforms in scenarios involving price-sensitive riders. The feature entails sending two ride requests simultaneously to each driver, in contrast to the conventional practice of drivers receiving a single request. Through an evaluation of its impact and a comparison with the traditional approach, valuable insights can be gained regarding the benefits and drawbacks of this feature. We consider both the 1-offer and 2-offer settings and extend our model to incorporate the behavior of impatient riders.

58 Adaptive Strategies For Flooding Risk Management Under Climate Change: A Reinforcement Learning Application For Nyc

kairui feng, ning Lin, Oppenheimer Michael; Princeton University, USA

The escalating threat of storm-induced flooding, driven by climate change, rapid coastal development, and sea-level rise, highlights the urgent need for advancements in coastal flood risk management. This study introduces a reinforcement learning-based strategy for adaptive seawall design, allowing for regular adjustments based on observed data to better address the deep uncertainties associated with climate change impacts. Our findings reveal that implementing the dynamic, reinforcement learning strategy results in a substantial reduction in total life-cycle costs by 20% to 40% compared to conventional approaches.

59 Electric Stampede: A Robust Solution To The Challenging Task Of Us Power Grid Optimization

Hussein Sharadga[1], Javad Mohammadi[1], Constance Crozier[2], Kyri Baker[2]; [1]The University of Texas at Austin, USA, [2]University of Colorado, USA

Our team actively participates in the US Department of Energy's Power Grid Optimization Competition, solving the intricate challenge of optimizing the US power grid. This competition poses a significant challenge due to the complicated nature of the problem, involving millions of variables and constraints, including binary variables and nonconvex, nonlinear characteristics. To overcome these complexities, we employ techniques like constraint relaxation, linearization, and problem reformulation. By leveraging these methods, we efficiently solve complex problems while maintaining optimality and meeting time constraints. Our proposed model excels above all others for its robustness.

60 Pivotal Uncertainties To Resolve - Optimal Information Gathering In Supply Chain Design

Austin I. Saragih[1], Milena Janjevic[1], Matthias Winkenbach[1], Jarrod D. Goentzel[1], Gilberto Montibeller[2]; [1]Massachusetts Institute of Technology, USA, [2]Loughborough University, United Kingdom

In this paper, we formulate an optimal information gathering strategy (IGS) to identify which uncertainties in the supply chain network drive our decisions. Existing approaches consider uncertainties, but do not consider the benefit of resolving them. Based on stylized, numerical, and case study results, we show a significant value of optimal IGS. As a non-monotone non-submodular minimization problem, we solve the problem with an algorithm which achieves a constant approximation guarantee.

61 Impacts Of Natural Gas Ordinances On Long-term Energy Investment Decisions

Stephanie Wilcox[1], Ozge Kaplan[2], Ben Hobbs[1]; [1]Johns Hopkins University, USA, [2]U.S. Environmental Protection Agency, USA

Several cities in the U.S. have enacted GHG-limiting ordinances to reduce on-site building sector emissions. However, analyses of the ordinances' long-term impacts on natural gas and power system infrastructure investment are missing from the literature. In this study, we extend the U.S. EPA's City-Based Optimization Model for Energy Technology to model long-term minimum cost energy and building sector investment decisions of NYC's GHG-limiting ordinance. Our results show that the cost-optimal investment decisions depend heavily on the inclusion of necessary system upgrades such as natural gas main replacements and future costs of "clean" natural gas substitutes.

62 Multi-objective Ship Schedule Recovery With Voluntary Ship Speed Reduction Zones And Emission Control Areas

Zeinab Elmi, Bokang Li, Maxim A. Dulebenets; Florida A&M University-Florida State University, USA

In order to reduce ship emissions in the vicinity of ports, some ports provide dockage fee refunds for ships sailing below a particular speed threshold near these ports. Such programs are expected to substantially improve environmental sustainability but impose limitations on ship schedule recovery in response to disruptions where ship speeding-up is viewed as a common option. Furthermore, emission control areas within the vicinity of ports impose additional restrictions. This study presents a new multi-objective optimization model for ship schedule recovery that directly captures voluntary speed reduction programs and emission control areas in order to facilitate the analysis of tradeoffs.

63 Remanufacturing And Recycling Decisions For Critical Parts And Materials

K Jo Min, Samantha Bradley, Alexander Hoffmeister, Mohammad Ahnaf Sadat, John Jackman; Iowa State University, USA

We construct and analyze remanufacturing and recycling facility decisions when the price of high valued parts and materials follows a geometric Brownian motion process.

By stochastic optimal control, we find the optimal price thresholds and timings. Illustrative example is given in the case of Nickel.

64 Autonomous Drone Delivery Problem

Zahra Gharibi[1], Mojtaba Gharibi[2], Steven Waslander[3], Raouf Boutaba[4]; [1]California Satie University San Marcos, USA, [2]University of Texas at Austin, USA, [3]University of Toronto, Canada, [4]University of Waterloo, Canada

We introduce the Vehicle Scheduling Problem (VSP) to minimize late vehicles in a transportation network while meeting safety, deadline, and speed requirements. VSP is NP-hard for common job shop scheduling objectives, but we present a heuristic algorithm and MIP formulation. Our motivation is to create a framework for scheduling Unmanned Aerial Vehicles (UAVs) in the airspace, a problem not naturally addressed in existing scheduling literature.

65 Living Together For The Future!exploring The Willingness Of Functional Restricted Groups To Use New Public Infrastructure Under The Integration Of Virtual And Real Worlds

Zhenyang Shen[1], Cong Cao[2]; [1]Zhejiang University of Technology, China, [2]Zhejiang university of Technology, China

The United Nations will establish sustainable cities and communities as one of its sustainable development goals. With the advancement of digital technology, physical space gradually intersects and integrates with virtual space based on digital technology. Functional restricted groups have obstacles when using new public infrastructure in the field of virtual and real integration. Identify the various sources of factors that affect functional restricted groups' intention to use of new public infrastructure. Analyze and verify the impact of the above factors on functional restricted groups on the concept to use of new public infrastructure.

66 Adaptive Batching For Order Picking In Warehouses

Jelmer Pier Van der Gaast; Fudan University, China

In this research, a new order batching method used in the order picking process called adaptive order batching is presented. In adaptive order batching, incoming customer orders are dynamically batched, and a pick batch can be modified in real-time even when the pick tour has already started. We develop a mathematical model for adaptive batching that minimizes the order throughput time and show when adaptive order batching outperforms other conventional batching methods.

67 Creating Majority-minority Districts In Alabama: A Column Generation Heuristic

Julia R. Allen[1],[2], Wes Gurnee[1], David B. Shmoys[2]; [1]MIT, USA, [2]Cornell University, USA

Redistricting in the US plays a crucial role in determining political representation, but it often exacerbates existing inequalities. This study proposes a two-stage approach that can be scaled effectively to optimize for various fairness criteria. In the first, a randomized divide-and-conquer column generation heuristic generates many potential districts. In the second, a master selection problem determines which districts will be included in the final plan. This work focuses on Alabama due to a recent Supreme Court case mandating the creation of new districts, with specific emphasis on creating two majority-minority districts and preserving the cohesive Black Belt community.

68 Enhancing Supply Chain Resilience Through Inventory, Process And Volume Flexibility

Fangyuan Li, Stephan Biller; Purdue University, USA

Enhancing supply chain resilience has become a prevalent research topic following the widespread product shortages during the pandemic. Different mitigation strategies have been proposed using inventory, process, and volume flexibility. Inventory is effective in dealing with short-term fluctuations, process flexibility lessens product mix mismatches while volume flexibility can effectively handle long-term and systematic demand disparities. This study will investigate how to utilize the interplay of these three strategies to achieve supply chain resilience in an uncertain environment.

69 Simulation Is All You Need

Akshit Kumar[1], Omar Besbes[2], Yash Kanoria[1], Yilun Chen[3], Wenxin Zhang[2]; [1]Columbia Business School, USA, [2]Columbia University, USA, [3]CUHK Shenzhen, USA

Motivated by online matching markets and NRM problems with many types (e.g., fulfillment optimization), we study dynamic spatial matching (DSM) in which supply and demand live in d dimensional space and need to be matched with each other dynamically. If demand and supply have different spatial distributions, the matching constraint has bite and greedy matching fails. We introduce a unifying and practical algorithmic principle for NRM and DSM dubbed SOAR: Simulate, Optimize, Assign, Repeat, which repeatedly simulates the future to enable good matching decisions. For particularly challenging NRM and DSM models, SOAR with multiple simulated sample paths at each stage achieves near optimal regret.

70 Evacuation Planning Under Traffic Congestion And Network Disruption Uncertainty

Aura Jalal, Valérie Bélanger; HEC Montreal, Canada

This study addresses evacuation planning under traffic congestion and network disruption uncertainty. We propose mathematical formulations to decide the shelter location and the flow and route definition for evacuees in a multi-period planning horizon, aiming to minimize the expected evacuation time and risk.

71 Optimal Channel Selection Considering Price Competition And Information Sharing Under Demand Uncertainty

Nan Chen[1], Jianfeng Cai[1], Devika Kannan[2], Kannan Govindan[2]; [1]Northwestern Polytechnical University, China, [2]Southern Denmark University, Denmark

The rapid development of Internet technology has led to an increasingly significant role for e-commerce platforms in economic growth. To explore how the green supply chain operates on different marketing channels with demand uncertainty, we develop a model to analyze a manufacturer's channel selection decision among the traditional offline channel, E-commerce online channel (resell mode, agency mode), and further consider the traditional retailers and E-tailer whether or not to share the demand information with the manufacturer.

72 A Nationwide Analysis Of An Oilseed Supply Chain For Sustainable Aviation Fuel

Juliana Pin; North Carolina State University, USA

This research project evaluates the Sustainable Aviation Fuel (SAF) targets established by U.S. Administration, aiming for 3 billion gallons by 2030, 17 billion gallons by 2040, and 35 billion gallons by 2050. Using oilseeds like pennycress, carinata, and camelina as feedstocks, simulations demonstrate that their combined estimated production would be sufficient to meet the 2030 SAF target at a cost of $0.20 per pound. However, relying solely on oilseeds beyond 2030 has limitations, as increasing their market price only results in an increase of less than half a billion gallons in SAF production, revealing the need of alternative feedstocks to achieve the desired goals.

73 The Bilevel Optimization Of Decentralized Multiple Projects Scheduling With Flexible Resources Supply

Xinyu Lin; Renmin University of China, China

In project scheduling, the resource supply plan is as important as the task scheduling plan, and there is a mutual influence relation between them. However, in the existing studies, these two decisions are usually separated. The focus of decentralized multi-project scheduling is how to solve the resource conflicts among projects, which can be reduced by a good resource supply plan. The paper addressed the resource competition from both the demand supply side. With the prevailing of flexible employment mode, the paper considered two ways of flexible supply of global resources, internal supply and external supply, established a bilevel optimization model, and designed a new negotiation mechanism.

74 Robust Auction Design With Support Information

Jerry Anunrojwong, Santiago R. Balseiro, Omar Besbes; Columbia Business School, USA

The seller wants to sell an item to n i.i.d. buyers and only the support [a,b] is known; a/b quantifies relative support information (RSI). The seller either minimizes worst-case regret or maximizes worst-case approximation ratio. We show that i) with low RSI, second-price auctions (SPA) is optimal; ii) with high RSI, SPA is not optimal, and we introduce a new mechanism, the "pooling auction" (POOL), which is optimal; iii) with moderate RSI, a combination of SPA and POOL is optimal. Under POOL, whenever the highest value is above a threshold, the mechanism still allocates to the highest bidder (just like SPA), but otherwise the mechanism allocates to a uniformly random buyer, i.e., pools low types.

75 Win-curves In Real-time Bidding: A Micro-foundation

Shailender Joseph[1], Ganesh Janakiraman[2], Milind Dawande[3], Vijay S. Mookerjee[2]; [1]University of Texas at Dallas, USA, [2]University of Texas- Dallas, USA, [3]The University of Texas at Dallas, USA

In this work, we show the existence of a consistent win-curve in a dynamic model of economically rational bidders who participate in a first-price auction in a real-time bidding set-up. We show this with a minimal set of assumptions and provide ways to compute the win curve numerically.

76 Scheduling Multi-skill Technicians And Reassignable Tasks In A Cloud Computing Company

SHUANG JIN[1], JIAMING TAO[2], QIAN HU[1], MINGHUI LAI[3]; [1]Nanjing University, China, [2]Meituan, China, [3]Southeast University, China

We investigate a multi-skill technician and reassignable task scheduling problem in a cloud computing company. Multi-skill technicians are assigned to process tasks from customers in a horizon. The tasks are allowed to be reassigned to others multiple times, and one technician can process in parallel. We characterize the feasible solutions and introduce a weighted objective containing three metrics, processing efficiency, response delay, and workload balance. An effective two-stage hierarchical optimization method embedded in a greedy randomized adaptive search procedure framework is proposed. Computational experiments are conducted to evaluate the effectiveness of our algorithm.

77 An Iterative Approach To Optimizing Repair Part Inventory Policies Using Simheuristics

Ruthairut Wootisarn[1], Liying Zhang[2], Xueying Wang[1]; [1]Boston University, USA, [2]Bonston University, USA

Simheuristics is an approach that allows the modeler to use a simulation and a heuristic to solve a stochastic combinatorial optimization problem. MBTA, the transportation authority in Boston, maintains an inventory of over 3 million parts used for repairs that have intermittent demand and long supplier lead times. The simheuristics approach searches for an optimal amount of parts in inventory that minimize holding, delay, and setup costs. Initial reordered points and order-to-to levels (s, S) are provided by a simple deterministic model. The heuristic is based on the slope for the total cost equation for each potential policy change.

78 Dynamic Chance Constraints For Stochastic Capacitated Lot Sizing Problems

Azadeh Farsi[1], Jianqiang Cheng[1], Boshi Yang[2]; [1]University of Arizona, USA, [2]Clemson University, USA

The economic lot-sizing problem aims to find the most cost-effective production plan to meet uncertain future demands over a specified period. In this presentation, we focus on the dynamic capacitated lot-sizing problem, which ensures demand satisfaction by imposing individual and joint chance constraint cases respectively. We develop deterministic reformulations and approximations for the chance constraints, and develop a sequential convex approximation algorithm to solve the obtained mixed-integer nonlinear approximations. Numerical tests demonstrate that the proposed dynamic model is more cost-effective than the static model while meeting the demand satisfaction requirements.

79 Task Allocation And Path Planning For Multiple Tethered Autonomous Underwater Vehicles

Abhishek Patil, Jung Yun Bae, Myoungkuk Park; Michigan Technological University, USA

This work presents a heuristic approach to efficiently solve the task allocation and path planning problem for multiple Tethered Autonomous Underwater Vehicles (T-AUVs). The proposed heuristic ensures workload balance and accounts for the entanglement-free constraint imposed by vehicle tethers. By formulating the problem as an integer programming problem with a min-max objective and entanglement-free constraints, we address the complexity arising from nonlinearity. The heuristic produces a feasible solution within a reasonable computation time, enabling its practical application in real-time operations. Simulation-based validation further confirms its effectiveness.

80 Optimization Model For Technology Investment In Steel Industry: The Case Of Korea

Woojin Son; Korea university, Korea, Republic of

The industrial sector is the largest emission source in Korea where the steel industry takes up to 39% of the sectoral emission. The goal of this work is to provide a novel approach for decision-making in the implementation of greenhouse gas reduction technology in the steel industry.A solution model elaborates a bottom-up approach for cost optimization using GAMS. The yearly investment of newly developed steel production technologies is demonstrated for existing steel production facilities in Korea. The result indicates that the model provides an optimal investment decision with reduced cost and greenhouse gas emissions.

81 A Novel Approach To Hospital Selection For Stroke Patients With Ais And Lvo

Yu-Chun Cheng, Yu-Ching Lee; National Tsing Hua University, Taiwan

Timely treatment is vital for stroke patients, especially those with AIS and LVO. Past studies on hospital selection strategies have only focused on expected treatment time. We propose a new approach that factors in the risk of not receiving definitive treatment within the therapeutic time window. By comparing the likelihood of receiving definitive treatment under various strategies, we identify the one with the least risk. The optimal strategy varies with different therapeutic time window settings and the presence of LVO. With more data, this approach could offer better hospital recommendations for stroke patients.

82 Integrated Bioenergy Network Design Under Pricing Flexibility And Uncertainty In Supply And Demand

Leyla Sadat Tavassoli, Halit Üster; Southern Methodist University (SMU), USA

We study profit-maximizing strategic bioenergy network design in an integrated fashion by considering variability in biomass (supply) as a reaction to price set as well as uncertainty in biomass yield in addition to uncertainty in biofuel demand. A stochastic model that integrates network design and inventory decisions in a multiperiod planning horizon setting is presented along with an efficient solution approach based on decomposition. The model is tested on both randomly generated instances and a real case study with data from Midwest US using GIS.

83 Inventory Distribution Planning and Optimization for Flipkart's Large Supply Chain

Shobhit Bhatnagar, Gowtham Bellala, Apoorva Agrawal, Vikas Goel, Sai Anjani Kumar KVN; Flipkart, India

We study the problem of supplier inbound (IB) planning in different fulfillment centers (FCs) for a large e-commerce company in India. Inefficient planning of inbound quantities could lead to idle manpower at FCs and loss of in-stock and speed. We propose integer programming models that maximize the IB allocation across multiple FCs and product categories subject to various constraints such as storage space, manpower and other business requirements. The proposed solution resulted in an annual savings of over $1 Million.

84 Column Generation For Multistage Stochastic Mixed-integer Nonlinear Programs With Discrete State Variables

Tushar Rathi[1], Benjamin P. Riley[1], Angela Flores-Quiroz[2], Qi Zhang[1]; [1]University of Minnesota, Twin Cities, USA, [2]Universidad de Chile, Chile

Although stochastic programming provides a natural framework for modeling sequential optimization problems under uncertainty, efficient solution of large-scale multistage stochastic programs remains a challenge, particularly in the presence of discrete decisions and nonlinearities, as well as long planning horizons and a large number of scenarios. In this work, we propose an exact decomposition approach based on column generation that takes advantage of the specific structure of multistage stochastic mixed-integer nonlinear programs with discrete state variables. Several real-world case studies are used to demonstrate the effectiveness of the proposed decomposition algorithm.

85 A Model And Method For Optimization Problems With Decision-dependent Uncertainty

Zhichao Ma[1], Jeffrey T. Linderoth[2], Jim R. Luedtke[2]; [1]University of Wisconsin Madison, USA, [2]University of Wisconsin-Madison, USA

We focus on stochastic programs with endogenous uncertainty in which decisions can affect the time of realization of uncertainty. We provide a three-stage stochastic program with binary decision variables in the first stage that can determine the realization time of uncertainty, whether in the second stage or in the third stage. We develop methods to estimate the upper and lower bounds of this problem. Additionally, we present a branch and bound algorithm to efficiently solve the problem, which can significantly reduce computation time compared to the extensive form.

86 Investigating The Impact Of Telemedicine On Service Times

Yupu Sun[1], Ersin Korpeoglu[1], Lina (Dahye) Song[2]; [1]University College London, United Kingdom, [2]University College London School of Management, United Kingdom

More people than ever needed telemedicine in response to the COVID-19 pandemic. To understand how telemedicine works across different specialties, we investigate the impact of telemedicine on service times. We find that telemedicine adoption is related to longer psychology therapies while it is associated with shorter outpatient services, compared with in-person care.

87 Free-Flow Optimal Blocking Model

Mehmet Kolcu, Clark Clark Cheng, Gunnar Feldmann; Norfolk Southern Corp., USA

A railroad blocking problem (RBP) is a routing problem grouping the shipments to minimize the shipment cost by considering various factors, such as network constraints, and the available yard resources. RBP focus on handling and distance cost, making it a multi-objective problem. Our Free-Flow Model approach initially finds an optimal trade-off between handling and distance costs for the specific shipment set by using our Optimal Blocking Model tool. Then, it lets the traffic to flow freely. Free-Flow Model brings new blocking opportunities that we do not see in the existing model and improves the current plan's quality. It supports the business by running a zero-base plan to learn new opportunities.

88 A Nonlinear Wiener Process Based Degradation Model With Damage Resistance For Reliability Analysis

Yuhan Hu, Mengmeng Zhu; NC State University, USA

The degrees of damage caused by random shocks may affect system degradation differently. In this paper, we consider a damage-resistant system, which can resist shock damage to a certain level. Contemplating the system's damage resistance, we first propose a new shock classification based on shock magnitude, and discuss the damage resistance level accordingly. Further, considering system vulnerability after multiple significant shocks, we develop two-stage degradation models using a nonlinear Wiener process incorporating the new shock classification. Lastly, the closed-form system reliability functions are derived, and numerical examples are conducted to predict system reliability.

89 Quantifying The Benefits Of Customized Vaccination Strategies: A Network-based Optimization Approach

Su Li, Hrayer Aprahamian; Texas A&M University, USA

We study the problem of designing vaccine distribution strategies through a multi-period optimization-based framework that embeds important subject-specific risk and contact information into the decision making process. By analyzing the structure of the resulting optimization problem, we identify key structural properties and two heuristic schemes. We demonstrate the benefits of the considered framework through a case study on COVID-19 in Texas. Our results highlight the importance of considering risk and contact information as doing so substantially reduces the total expected number of fatalities over conventional compartmental-based approaches.

90 Capacity Planning For Services With Customers Having Time-dependent Priorities

Jae Yoon Hwang, Tianyu Xu, Xinran Yu; Boston University, USA

The increase in product or service complexity and time-dependent urgencies can cause difficulties in determining priorities among customer needs. This poster details a capacity planning framework that is based on a discrete-event simulation, programmed in Python, to determine how priorities should be set in real time for customers waiting in queue. These systems exist for nurse dispatching, transportation deployment, police response, repair technician and call center. Dynamic urgencies increase over time until the need is addressed. An example is presented from a hospital cardiac unit that compares four different nurse dispatching rules.

91 Supply Chain Risk Response Analysis Using Utility Functions

Hanyi Zheng, Jingyi Wu, Zhilin Liu, Yucheng Yao; Boston University, USA

In response to the increasing frequency and severity of climate-related disruptions, supply chain managers can no longer rely solely on accepting a risk or transferring the risk through insurance. Decision makers must consider two alternative approaches by investing in either risk mitigation or risk avoidance. This presentation explores the integration of the analytical hierarchy process method with a color-coded decision aid that quantifies their utility function, and is consistent with the decision tree of the four alternative decisions. The proposed methodology results in a ranking of the four options with weights representing their respective preferences.

92 Existence And Uniqueness Of Bayesian Nash Equilibrium Under Multinomial Logit Demand

Jian LIU; The Chinese University of Hong Kong, Hong Kong

This paper examines the pricing problem of an individual firm using the classical Multinomial Logit (MNL) model to estimate market demand. We assume that the marginal cost of each product offered by distinct firms is private information and construct a Bayesian Nash equilibrium (BNE) model to identify the optimal pricing strategy. We prove the existence and uniqueness of the equilibrium and propose a decomposition algorithm based on the Progressive Hedging algorithm to solve the BNE. Our algorithm improves the efficiency of finding the optimal solution.

93 Social Optimal Freight Routing Pricing Considering The Ordering Behavior Of Receivers

Oriana Calderon, José Holguín-Veras; Rensselaer Polytechnic Institute, USA

The ordering decisions of the receivers of supplies play a significant role in creating freight externalities. This research develops an analytical formulation, i.e., the Social Optimal Routing and Ordering Problem (SOROP) to compute the optimal charges to induce receivers to implement socially optimal inventory management procedures. The SOROP considers: (i) the profit-maximizing behavior of receivers in decisions concerning floorspace allocation, (ii) externality charges to account for the externalities produced by their ordering decisions, and (iii) the effect of these decisions on the routing and the corresponding cost structure.

94 Mip-based Scheduling For Welding T-beams In Shipbuilding

Yeonho Kang, Minseok Song, Duksang Lee; Pohang University of Science and Technology, Korea, Republic of

During the production of T-beams for ship manufacturing, a bottleneck arose during the welding process. To minimize waste time and delays, an optimization algorithm was utilized. By applying MIP models, the welding was efficiently completed within the designated working time, resulting in increased daily production, reduced weekend work, and meeting T-beam deadlines.

95 Earned Value Measurement In Project Buffers Management

Pawel Blaszczyk; University of Silesia, Poland

The aim of this research was the trial of modelling and optimizing the time-cost trade-offs in project planning problem. The base of the problem description contains both safe and reasonable amounts of time and cost estimations and the influence factors matrix. We assumed also the pricing opportunity of performance improving. Finally we try to combine that method with Earned Value Analysis (EVA) method - one of the most popular project audit method.

96 Optimal Dynamic Pricing In The Presence Of Strategic Consumers: A Game-theoretic View

Ziqi Zhang, Zelin Zhang, Guoqing Guo; Renmin University of China, China

The current research explores a monopolist's dynamic pricing decisions facing strategic consumers under limited capacity. While previous literature has proved the existence of a unique Nash equilibrium in a seller-consumer game, we challenge this finding and show there may exist multiple Nash equilibria under such pricing policies. We highlight the interdependency (implicit collusion) and mix strategies of customers' decision-making, resulting in the inefficiency of seller's pricing policy. To address this issue, we propose a maximum-matching dynamic pricing strategy that can lead to a unique pure Nash equilibrium while generating significant profits and examine it with a lab experiment.

97 Distributionally Ambiguous Multistage Stochastic Integer And Disjunctive Programs: Applications To Multistage Two-player Interdiction Games

Sumin Kang[1], Manish Bansal[2]; [1]Virginia Tech, USA, [2]Virginia Tech., USA

This paper studies the generalizations of multistage stochastic mixed-integer programs (MSIPs) with distributional ambiguity, namely distributionally risk-receptive and risk-averse multistage stochastic mixed-integer programs (denoted by DRR- and DRA-MSIPs). These frameworks have applications in non-cooperative games involving two players with uncertainty in the impact of the decisions made by a player. We present cutting plane-based and reformulation-based approaches for DRR- and DRA-MSIPs. We also introduce generalizations of MSIPs by considering multistage stochastic disjunctive programs with(out) distributional ambiguity and present algorithms for solving them.

98 Multi-stage Models For Dynamic Ride-sharing Pairing In Taxi Services: A Case Study In Chicago

Min-Ci Sun, Cheng Zhang, Luca Quadrifoglio, Dahye Lee; Texas A&M University, USA

Ridesharing has been regarded as an effective way to mitigate traffic congestion. This study intends to propose a practical and solvable model to reduce the total travel distance. We formulate the ride-sharing problem as multi-stage models to consider multiple riders in a match, and various permutations are examined to identify the best pick-up/ drop-off sequence. Furthermore, user-centric factors, including riders' waiting time and detour tolerance, are integrated. The multi-stage optimization model is verified by the taxi data from the city of Chicago, and the result indicates that the proposed model can effectively reduce the total travel distance.

Supply-Chain-Centric View of Working Capital, Hedging and Risk Management: Integrated Supply Chain Finance (iSCF) Tutorial

Tutorial Session

Session Chair: Hari Balasubramanian, University of Massachusetts, Amherst, Amherst, MA

1 Supply-Chain-Centric View of Working Capital, Hedging and Risk Management: Integrated Supply Chain Finance (iSCF) Tutorial

Panagiotis Kouvelis, Washington University in St. Louis, Clayton, MO

Integrated Supply Chain Finance (iSCF) is a portfolio of effective operating, financial and risk mitigating practices and techniques within supply chains, which reflect strategic concerns of participating firm agents (decision makers) within the chain, and optimize not only the management of the working capital for liquidity, but also make effective use of assets for firm profitability and risk control. The main theory and research areas within iSCF are: Financing Working Capital in Supply Chains; Financial Hedging in support of Supply Chain Operations; Integrated Risk Management (IRM) in Supply Chains; Supply Chain Contracts and Risk Management. This tutorial chapter will dedicate a section in each of the above topics, and it will elucidate the foundational models and the key results in each of these areas. It will conclude with thoughts on future research topics, and how emerging technologies may be shaping the future of iSCF decision making.

1 Littlefield 2.0 -- A New Version of the Online Game for Operations Management Courses

Samuel C. Wood, Responsive Learning Techologies, Los

Altos, CA, Contact: wood@responsive.net
After 24 years there is a new version of Littlefield! Littlefield is a competitive online simulation of either a factory or a medical laboratory that has been by more than half a million students in 500+ universities in 60+ countries to excite and engage students in operations management topics like process analysis and inventory control. This presentation will introduce a newly updated version 2 of the game that will go into production in 2024.

New Directions in the Online Allocation of Reusable Resources

Community Committee Choice Session

Session Chair: Will Ma, Columbia University, New York, NY
Session Chair: Wenxin Zhang, New York
Session Chair: Santiago Balseiro, Columbia University, Armonk, NY

1 Dynamic Pricing for Reusable Resources: The Power of Two Prices

Santiago Balseiro[1], Will Ma[2], Wenxin Zhang[3], [1]Columbia University, Armonk, NY, [2]Columbia University, New York, NY, [3]Columbia University, New York, NY, Contact: wz2574@columbia.edu
Motivated by real-world applications such as cloud computing services, we study pricing for reusable resources where system states include how many units are in use and for how long. As the system states grow exponentially, we propose a class of stock-dependent (SD) policies that adjust prices solely based on the number of available stocks. We introduce a convex optimization problem to obtain the optimal policy in this class. We provide a tight characterization of the regret of the optimal SD policy, where the local shape of the reward function is the key driver of performance. Our results demonstrate that the optimal SD policy can significantly outperform the fluid policy w.r.t. the convergence rate of regret. Interestingly, we show that a simple two-price policy that increases prices when the stock is below a certain threshold achieves the same regret as the optimal SD policy.

2 The Power of Static Pricing for Reusable Resources

Adam N. Elmachtoub[1], Jiaqi Shi[2], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY
We consider the problem of pricing a reusable resource service system. Potential customers arrive according to a Poisson process and purchase the service if their valuation exceeds the price. If no units are available, customers immediately leave. Serving a customer corresponds to using one unit for an exponential service time. The objective is to maximize the steady-state revenue rate.
Although an optimal policy is fully dynamic, we provide two main results that show a simple static policy is universally near-optimal for any service rate, arrival rate, and number of units in the system. When there is one class of customers who have a monotone hazard rate (MHR) valuation distribution, we prove that a static pricing policy guarantees 90.2% of the optimal policy. When there are multiple classes of customers, we prove that static pricing guarantees 78.9% of the optimal policy.

3 Online Reusable Resource Assortment Planning with Customer-Dependent Usage Durations

Tianming Huo, Wang Chi Cheung, National University of Singapore, Singapore, Singapore. Contact: e0007875@u.nus.edu
We consider an online setting, where a revenue-maximizing decision maker offers assortments of reusable resources to a sequence of online customers. Our setting allows each customer to have a different usage duration on a reusable resource, departing from existing research works that focus on customer-homogenous usage duration models. We first consider the linear revenue case, where the revenue earned is linear in a customer's usage duration. We propose a novel online algorithm featuring the notion of rejection durations, which serve to reserve capacities for future customers. When the capacities are sufficiently large, our online algorithms achieve a competitive ratio within a constant factor from the best possible one. Our framework can be generalized from the linear revenue case to the cases of affine or constant revenue.

4 Leveraging Reusability: Improved Competitive Ratio of Greedy for Reusable Resources

Jackie W. Baek[1], Shixin Wang[2], [1]NYU Stern School of Business, Berkeley, CA, [2]The Chinese University of Hong Kong, Hong Kong, China. Contact: shixinwang@

cuhk.edu.hk

We study online weighted bipartite matching of reusable resources with adversarial requests. Matched resources are used for random durations. We examine the greedy policy, previously known to be 1/2 competitive against a clairvoyant benchmark. We improve this result by introducing a parameter that quantifies the degree of reusability. If p is the smallest probability of a matched resource returning in one step, the greedy policy achieves a competitive ratio of 1/(2-p). For geometric usage distributions, we establish a (1+p)/2 ratio, shown to be tight. Our results are robust to greedy policy approximations. Our work demonstrates that reusability enhances performance of the online algorithm, with simple greedy policies sufficing in high reusability settings.

Sequential Learning Problems in Operations Management

Community Committee Choice Session

Session Chair: Dohyun Ahn, The Chinese University of Hong Kong

Session Chair: Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong

1 Online Resource Allocation for Reusable Resources with Many Customer Types

Xilin Zhang[1], Wang Chi Cheung[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: isecwc@nus.edu.sg

We consider reusable resource allocation under uncertainty. Customers with different types arrive sequentially. The decision maker (DM) selects allocations based on observed types. Each resource unit is occupied for a random duration and becomes available again. Our model covers applications such as admission control and assortment planning. The DM aims to maximize multiple rewards, satisfy resource constraints, and handle uncertain customer arrivals. We present a near-optimal algorithm that balances rewards, resources, and durations using a novel adaptation of the Multiplicative Weight Update algorithm. Importantly, the performance guarantee remains invariant even with increasing customer types, making our algorithm applicable to machine learning driven model that involves many customer types.

2 Recommendation Policies in the Presence of Social Learning

Wen Yun[1], Assaf Zeevi[2], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY

We study the interaction between recommendation policies and social learning whereby customers make purchase decisions using product reviews. A key feature is that demands keep evolving as reviews accumulate over time. A monopolist uses a recommender system to sell a single product with product reviews over a finite selling horizon. The monopolist seeks to maximize the expected total profit via a recommendation policy that determines the customer type and the amount to recommend. In the fluid approximation, we quantify effects on immediate revenues and future demands, and show how their relative importance varies with the extent of social learning. The gain of accounting for social learning, compared to benchmark policies oblivious of social learning, grows linearly or sublinearly in the selling horizon. Lastly, we propose asymptotically (near)-optimal policies.

3 Feature Misspecification in Sequential Learning Problems

Dohyun Ahn[1], Dongwook Shin[2], Assaf Zeevi[3], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]HKUST Business School, Clear Water Bay, Hong Kong; [3]Columbia University, New York, NY, Contact: dohyun.ahn@cuhk.edu.hk

We consider a class of sequential learning problems, where a decision maker must learn the unknown statistical characteristics of a finite set of systems using sequential sampling to ultimately select a subset of "good" systems. A salient feature of our problem is that system performance is governed by a set of features. The decision maker postulates the dependence on these features to be linear, but this model may not precisely represent the true underlying system structure. We show that this misspecification can lead to suboptimal performance, and propose a prospective sampling principle that eliminates the adverse effects of misspecification as the number of samples grows large. The proposed principle applies across a general class of widely used sampling policies, enjoys strong asymptotic performance guarantees, and exhibits effective finite-sample performance.

4 Information-Directed Selection for Pure Exploration

Wei You[1], Chao Qin[2], [1]Hong Kong University of Science

and Technology, Hong Kong, Hong Kong; [2]Columbia University, New York, NY, Contact: weiyou@ust.hk
In this study, we address pure exploration in stochastic bandits and propose an optimal algorithm framework based on problem complexity. Our conditions extend the top-two algorithm principle (Russo, 2020) for unstructured bandits and introduce an effective selection rule, information-directed selection (IDS). This selects top candidates based on information gain. We prove that integrating IDS with top-two Thompson sampling is optimal for Gaussian best-arm identification. We further illustrate instances where beta-tuning for the top-two algorithm and top-two algorithms for linear bandits are suboptimal, and propose simple algorithms to address these issues. Our IDS-integrated algorithms outperform those without adaptive selection, as shown in numerical experiments.

Submodularity in OR: New Approaches and Applications

Community Committee Choice Session

Session Chair: Rajan Udwani, UC Berkeley, Berkeley, CA

1 Coordinated Inventory Stocking and Assortment Personalization

Yicheng Bai[1], Omar El Housni[2], Paat Rusmevichientong[3], Huseyin Topaloglu[2], [1]Cornell University, New York, NY, [2]Cornell Tech, New York, NY, [3]USC Marshall School of Business, Los Angeles, CA, Contact: oe46@cornell.edu

We study a joint inventory stocking and assortment personalization problem. We have access to a set of products that can be used to stock a facility with limited capacity. At the beginning of the selling horizon, we decide how many units of each product to stock. Over the selling horizon, customers arrive into the system and depending on the remaining inventories and the arriving customer type preferences, we offer a personalized assortment of products. Our goal is to choose the stocking quantities at the beginning of the selling horizon and to find a policy to offer a personalized assortment to each customer so that we maximize the total expected revenue over the selling horizon. We develop an approximation framework that gives the first theoretical guarantees for this class of problems. Our framework builds on techniques from submodular optimization and dynamic programming.

2 Approximate Submodularity in Network Optimization

Levi DeValve, University of Chicago, Chicago, IL

Recent work on network design problems has identified an approximately submodular structural property, called cover modularity, that leads to algorithms with strong performance guarantees. This structural property has been shown to hold in a wide range of problems whose objectives can be expressed as the solution of a linear program. We review this work and identify further applications of cover modularity to an even wider range of problems, including applications in e-commerce fulfillment.

3 Fast Algorithm for Dynamic Assortment Planning for Multinomial Logit Choice Model

Shuo Sun, Rajan Udwani, Zuo-Jun Max Shen, UC Berkeley, Berkeley, CA, Contact: shuo_sun@berkeley.edu

In this work, we consider a dynamic assortment planning problem under the Multinomial Logit choice model (MNL). Customers arrive sequentially and each customer independently chooses at most one item. Items may stock out over time and our goal is to decide on the initial stocking quantities of each item subject to a constraint on the total inventory (such as a cardinality constraint or a capacity constraint), to maximize the total expected revenue. We propose a fast and scalable approximation algorithm with a constant-factor performance guarantee that improves upon the state-of-the-art algorithms in several variants of the problem.

4 MNL-Prophet: Sequential Assortment Selection Under Uncertainty

Vineet Goyal[1], Salal Humair[2], Orestis Papadigenopoulos[3], Assaf Zeevi[1], [1]Columbia University, New York, NY, [2]Amazon, Inc., Sammamish, WA, [3]Columbia University, New York, NY

We consider a stochastic variant of the assortment selection problem under the MNL choice model, where the parameters of each item (price and attraction) are drawn from some known distribution. The realized parameters of each item are observed sequentially in an arbitrary and unknown order. Upon observing each item, we must decide irrevocably whether to include it in the constructed assortment, or forfeit it forever. The above model applies in many real-life scenarios where retailers have to make deals with wholesalers without having accurate knowledge of the characteristics of other potential products, nor the ability to control the order those are observed. We provide simple optimal online selection policies for both unconstrained and cardinality-constrained versions of the above setting under the objective of maximizing the expected revenue.

Data, Platforms, and Algorithms

Community Committee Choice Session

Session Chair: Ali Makhdoumi, Duke University

Session Chair: Alireza Fallah, Massachusetts Institute of Technology, Cambridge, MA

1 Learning to Rank for Limited Attention Users

Arpit Agarwal[1], Rad Niazadeh[2], Prathamesh Patil[3], [1]Columbia University, New York, NY, [2]Chicago Booth School of Business, CHICAGO, IL, [3]University of Pennsylvania, Philadelphia, PA, Contact: pprath@seas.upenn.edu

Inspired by the challenge of incentivizing exploration in recommendation systems, we study the problem of Ranking with Limited-Attention Users. In our model, a platform displays a ranked list of items in an online fashion to a sequence of T arriving users. At each time, the user selects an item by first considering a prefix window, and then picking the most preferred item in that prefix. The user preferences are assumed to be known beforehand, but the payoffs are unknown and need to be learned. In this model, we study two settings: (a) adversarial prefix sizes and stochastic payoffs, and (b) stochastic prefix sizes and adversarial payoffs. We design combinatorial algorithms that achieve (a) an instance-dependent regret of O(log T) in the former, and (b) a worst-case regret of \sqrt{T} in the latter. We complement our algorithmic results with matching regret lower-bounds.

2 Artificial Intelligence Algorithms And Spontaneous Collusion

Martino Banchio, Giacomo Mantegazza, Graduate School of Business Stanford University, Stanford, CA

In this paper we characterize a new collusion scheme between Artificial Intelligence algorithms in market environments. The behavior we identify relies on a statistical linkage between independent AI algorithms, called spontaneous coupling, and it does not require monitoring one's opponent. Using a fluid approximation, we explain why coupling arises and how it prevents convergence to Nash equilibrium and even dominant strategies. We show that unequal learning speeds are responsible for coupling and the collusive behavior that ensues: with equal learning speed collusion disappears. Finally, we show how the collusive scheme we identify generates novel patterns of collusion in an online auction market, and we apply our findings to design strategy-proof mechanisms robust to the presence of players that use learning algorithms to determine their optimal strategy.

3 Incentivizing Compliance with Algorithmic Instruments

Daniel Ngo[1], Logan Stapleton[1], Vasilis Syrgkanis[2], Steven Wu[3], Keegan Harris[3], Anish Agarwal[4], [1]University of Minnesota, Minneapolis, MN, [2]Stanford University, Stanford, CA, [3]Carnegie Mellon University, Pittsburgh, PA, [4]Columbia University, New York City, NY, Contact: ngo00054@umn.edu

While existing work has studied compliance as static behavior, we propose a game-theoretic model to study compliance as dynamic behavior that changes over time. In rounds, a social planner interacts with a sequence of agents whose private type determines their prior preferences and baseline rewards. The planner gives each agent a recommendation that may alter their beliefs and action selection. We develop a novel recommendation mechanism that views the planner's recommendation as an instrumental variable that only affects an agent's action by mapping the history to a recommendation. While the initial agents may be completely non-compliant, our mechanism can incentivize compliance over time and enable the estimation of the treatment effect.

4 Bridging Central and Local Differential Privacy in Data Acquisition Mechanisms

Alireza Fallah[1], Ali Makhdoumi[2], Azarakhsh Malekian[3], Asuman Ozdaglar[4], [1]Simons Laufer Mathematical Sciences Institute/UC Berkeley, Berkeley, CA, [2]Duke University, Durham, NC, [3]University of Toronto Joseph L Rotman School of Management, Toronto, ON, Canada; [4]Massachusetts Institute of Technology, Cambridge, MA

We study the design of optimal data acquisition mechanisms for a platform interested in estimating the mean of a distribution by collecting data from privacy-conscious users. Users have heterogeneous sensitivities for two types of privacy losses corresponding to local and central privacy measures, and they are compensated in exchange for their data. The platform designs a mechanism to solicit users' preferences and then delivers both local and central privacy guarantees while minimizing the estimation error and the expected payment to users. We formulate the design of such mechanisms as a nonconvex optimization problem, and, using a primal-dual argument, we develop an algorithm to efficiently solve it in polynomial time.

Market Design for Electricity Markets

Community Committee Choice Session

Session Chair: Cheng Guo, Clemson University, Clemson, SC

1 Modeling, Equilibrium and Market Power for Electricity Capacity Markets

Cheng Guo[1], Christian Kroer[2], Daniel Bienstock[2], Yury Dvorkin[3], [1]Clemson University, Clemson, SC, [2]Columbia University, New York, NY, [3]New York University, Brooklyn, NY, Contact: cguo2@clemson.edu

The capacity market is a marketplace for trading generation capacity, and is viewed by its proponents as a mechanism to ensure power system reliability. It also provides an important revenue stream for generators. Based on current practice at NYISO, we propose optimization models for capacity markets and analyze outcomes. Our results show the influence of the capacity market on generator revenues, and the impact of market power. More specifically, we find that when there is no market power, the outcome of the capacity market does not affect electricity sales in the energy market. Also, with the capacity market, more generators become profitable, especially the generators with a lower net cost of new entry. In addition, it is possible for a generator to earn more revenue by exercising market power. We conduct case studies on NYISO datasets.

2 Auction Designs to Increase Incentive Compatibility and Reduce Self-Scheduling in Electricity Markets

Conleigh Byers[1], Brent Eldridge[2], [1]Harvard University, Cambridge, MA, [2]Pacific Northwest National Laboratory, Richland, WA

The system operator's scheduling problem in electricity markets is a non-convex mixed-integer program. We simulate bidder behavior to show that market power can be exercised by self-scheduling. Agents can learn to increase their profits via a reinforcement learning algorithm without explicit knowledge of the costs or strategies of other agents. Over a multi-period commitment window simulating the day-ahead market, we show that convex hull pricing can reduce producer incentives to deviate from the central dispatch decision. In a realistic test system, we find strategic bidding under conventional marginal pricing can increase total producer profits and decrease lost opportunity costs. While the cost to consumers with convex hull pricing is higher at the competitive solution, the cost to consumers is higher with the restricted convex model after strategic bidding.

3 Uncertainty-Informed Renewable Energy Scheduling: A Scalable Bilevel Framework

Dongwei Zhao[1], Vladimir Dvorkin[2], Stefanos Delikaraoglou[2], Alberto Lamadrid[3], Audun Botterud[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Lehigh University, Bethlehem, PA, Contact: zhaodw@mit.edu

This work proposes a bilevel framework for accommodating variable renewable energy sources (VRES) in electricity markets. The mechanism computes the optimal VRES day-ahead bids based on the bilevel model, which minimizes expected system costs across day-ahead and real-time stages. However, solving the bilevel problem is computationally challenging for large-scale systems. We introduce a novel technique based on strong duality and McCormick envelope, which relaxes the problem to a linear program, enabling large-scale applications. The framework is applied to the 1576-bus NYISO system and benchmarked against a myopic strategy, where VRES bid is at the mean value of probabilistic forecasts. The results show that, under high VRES levels, our framework can significantly reduce system costs, by optimizing VRES quantities efficiently in the day-ahead market.

Frontiers in Queueing (in Honor of Daryl Daley)

Community Committee Choice Session

Session Chair: Jalani Williams, Carnegie Mellon University, Pittsburgh, PA

Session Chair: Weina Wang, Carnegie Mellon University, Pittsburgh, PA

1 Stability and Functional Limit Theorems for Queues Fed by Scheduled Traffic

Peter W. Glynn, Stanford University, Stanford, CA, Contact: glynn@stanford.edu

A scheduled traffic model is one in which customer n is scheduled to arrive at time nh, but actually arrives at time nh + □_n, where the □_i's are iid. In this talk, we compare the behavior of these arrival models to renewal traffic. In particular, a queue fed by scheduled traffic can be stable even at the same time that the queue fed by the time-reversed scheduled traffic model is unstable. We also discuss functional limit theorems for scheduled traffic models as the ?_i's become successively more and more heavy-tailed, with limit processes that transition from fractional Brownian motion with H < 1/2 into the realm of Brownian motion as the tail gets heavier.

2 Uniform Bounds for Size Estimate Hedging

Douglas Down[1], Ziv Scully[2], [1]McMaster University, Hamilton, ON, Canada; [2]Cornell University, Ithaca, NY, Contact: downd@mcmaster.ca

The Size Estimate Hedging (SEH) policy, recently introduced by Down and Akbari-Moghaddam, is an index-based policy for scheduling in M/G/1 queues, where only service time estimates are available for scheduling decisions. Simulation results have suggested that it performs well for a wide range of service time distributions. To date, analytic results for SEH are lacking. In this work, we apply methodology developed by Scully et al. to derive performance bounds when jobs with true service time s have estimated size [bs,as]. Based on these bounds, SEH is compared with several policies that have been proposed for queues with service time estimates.

3 The Reset and Marc Techniques, with Application to Multiserver-Job Analysis

Isaac Grosof[1], Yige Hong[2], Mor Harchol-Balter[2], Alan Scheller-Wolf[3], [1]Georgia Tech, Atlanta, GA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Tepper School of Business, Pittsburgh, PA, Contact: isaacbg227@gmail.com

Multiserver-job (MSJ) systems, where jobs need to run concurrently across many servers, are increasingly common in practice. The default service ordering in many settings is First-Come First-Served (FCFS) service. Virtually all theoretical work on MSJ FCFS models focuses on the stability region, with almost nothing known about mean response time.
We derive the first explicit characterization of mean response time in the MSJ FCFS system. We characterize mean response time up to an additive constant, which becomes negligible as arrival rate approaches throughput.
We first use our novel RESET technique to reduce to a M/M/1 with Markovian Service Rate, with service process controlled by the saturated system, a simpler closed system which is more analytically tractable. We then use our novel MARC technique to characterize mean response time in that system.

4 The M/M/k with Deterministic Setup Times

Jalani Williams, Weina Wang, Mor Harchol-Balter, Carnegie Mellon University, Pittsburgh, PA

Capacity management, whether it involves servers in a data center, or human staff in a call center, or doctors in a hospital, is largely about balancing a resource-delay tradeoff. On the one hand, one would like to turn off servers when not in use (or send home staff that are idle) to save on resources. On the other hand, one wants to avoid the considerable setup time required to turn an off server back on. In this talk, we describe recent work focused on understanding the delay component of this tradeoff. In particular, we discuss new, tight bounds on the average delay in the M/M/k with Deterministic setup times.

Sequential Learning and Decision-Making

Community Committee Choice Session

Session Chair: Lin Fan, Stanford University, Stanford, CA

1 A Definition for Non-Stationary Bandits

Yueyang Liu[1], Benjamin Van Roy[1], Kuang Xu[2], [1]Stanford University, Stanford, CA, [2]Stanford Graduate School of Business, Stanford, CA, Contact: yueyl@stanford.edu

The subject of non-stationary bandit learning has attracted much recent attention, but lacks a formal definition. Non-stationary bandits have typically been characterized in the literature as those for which the reward distribution changes over time. We demonstrate that this informal definition is ambiguous. Further, a widely-used notion of regret---the dynamic regret---is motivated by this ambiguous definition and thus problematic. In particular, even for an optimal agent, dynamic regret can suggest poor performance.
The ambiguous definition also motivates a measure of the degree of non-stationarity experienced by a bandit, which often overestimates and can give rise to extremely loose regret bounds. This paper proposes a formal definition. This definition motivates a new regret measure, and a tighter regret analysis for non-stationary bandit learning.

2 Optimal Adaptive Experimental Design of Inference of Average Treatment Effect

Vikas Deep[1], Achal Bassamboo[1], Sandeep Juneja[2], [1]Northwestern University, Evanston, IL, [2]TIFR, MUMBAI, India. Contact: vikas.deep@kellogg.northwestern.edu

In this paper, our objective is to develop an adaptive experimentation policy with the objective of constructing a confidence interval (CI) of a pre-specified width $\

epsilon$, and with a coverage guarantee that the average treatment effect (ATE) lies in the CI with probability at least $1-\delta$. The novelty of our analysis is the derivation of asymptotic lower bound on the number of samples required by any adaptive policy and an optimal policy that matches lower bound. Existing literature talks about the optimal adaptive policy in the Best arm identification (BAI) problem. We observe that optimal policy in our set-up chooses assignment probabilities proportional to variance of the distribution of that particular arm. In contrast, in the case of the BAI problem, assignment probabilities decrease with an increment to variance of the distribution of that particular arm.

3 Smooth Non-Stationary Bandits

Su Jia[1], Qian Xie[1], Nathan Kallus[2], Peter Frazier[3], [1]Cornell, Ithaca, NY, [2]Cornell University, Long Island City, NY, [3]Cornell / Uber, Ithaca, NY

In many applications of online decision making, the environment is non-stationary and it is therefore crucial to use bandit algorithms that handle changes. Most existing approaches are designed to protect against non-smooth changes, constrained only by total variation or Lipschitzness over time, where they guarantee T^2/3 regret. However, in practice environments are often changing *smoothly*, so such algorithms may incur higher-than-necessary regret and do not leverage information on the rate of change. We study a non-stationary MAB problem where each arm's mean reward is a □-Holder function over time, i.e., (□ − 1)-times Lipschitz-continuously differentiable. We show the first separation between the smooth and non-smooth regimes by presenting a policy with an optimal T^3/5 regret for □ = 2. We complement this result by a T^{(□+1)/(2□+1)} lower bound for any □ ≥ 1.

4 The (Surprising) Rate Optimality of Greedy Procedures for Large-Scale Ranking and Selection

Zaile Li[1], Weiwei Fan[2], Jeff Hong[3], [1]Fudan University, Shanghai, China; [2]Tongji University, Shanghai, China; [3]Fudan University, Shanghai, China. Contact: zaileli21@m.fudan.edu.cn

Ranking and selection (R&S) aims to select the best alternative with the largest mean performance from a finite set of alternatives. Ideal large-scale R&S procedures should be rate optimal, i.e., the total sample size required for an asymptotically non-zero probability of correct selection (PCS) grows linearly in the number of alternatives. Surprisingly, we find that the naïve greedy procedure that keeps sampling the alternative with the largest running average appears rate optimal. We develop a boundary-crossing perspective and prove the greedy procedure's rate optimality. We further show that the derived PCS lower bound is asymptotically tight. Moreover, we propose explore-first greedy procedures to overcome the greedy procedure's inconsistency. Last, we conduct numerical studies to show our greedy procedures' performance in solving large-scale R&S problems.

5 Adaptivity and Confounding in Multi-Armed Bandit Experiments

Chao Qin, Columbia University

We explore a new model of bandit experiments where a potentially nonstationary sequence of contexts influences arms' performance. Context-unaware algorithms risk confounding while those that perform correct inference face information delays. Our main insight is that an algorithm we call deconfounted Thompson sampling strikes a delicate balance between adaptivity and robustness. Its adaptivity leads to optimal efficiency properties in easy stationary instances, but it displays surprising resilience in hard nonstationary ones which cause other adaptive algorithms to fail.

Queueing Control

Community Committee Choice Session

Session Chair: Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

1 Optimal Control of Supervisors Balancing Individual and Joint Responsibilities

Zhuoting Yu, Sigrun Andradottir, Hayriye Ayhan, ISyE Georgia Tech, Atlanta, GA, Contact: zhuoting@gatech.edu

We consider a two-stage service system with two types of servers, subordinates who perform the first-stage service and supervisors who have their own responsibilities in addition to working with the subordinates on the second-stage service. Rewards are earned when first or second-stage service is completed and when supervisors finish their own responsibilities. Costs are incurred when customers abandon without completing the second-stage service. Our problem is to determine how the supervisors should distribute their time between their joint work with the subordinates and their own responsibilities in order to maximize the long run average profit.

2 Parallel Server Systems Under Extended Heavy Traffic

Eyal Castiel, Georgia Tech, Atlanta, GA

The standard setting for studying parallel server systems (PSS) at the diffusion scale is based on the heavy traffic condition (HTC), which assumes that the underlying static allocation linear program (LP) is critical and has a unique solution. This solution determines the graph of basic activities, which identifies the set of activities (i.e., class-server pairs) that are operational. In this talk we explore the extended HTC, where the LP is merely assumed to be critical in a simple setting where we are able to describe an asymptotically optimal policy. The scaling limit for the control problem associated with the model is given by a so called workload control problem (WCP) in which a cost associated with a diffusion process is to be minimized by dynamically switching between control modes.

3 Expanding Service Capabilities Through an On-Demand Workforce

Xu Sun[1], Weiliang Liu[2], [1]University of Florida, Gainesville, FL, [2]National Univerisity of Singapore, Singapore, Singapore. Contact: weiliangliu@u.nus.edu

An on-demand workforce can greatly benefit a traditional call center by allowing it to adjust its service capacity on demand quickly. To operationalize this process, we develop a two-stage decision model in which the first stage seeks the optimal mix of permanent and on-call staff, and the second stage seeks a joint on-demand staffing and call scheduling policy to minimize the associated cost given a mix. In a suitable asymptotic regime, we characterize the system dynamics and derive an optimal joint staffing and call scheduling policy for the second-stage problem, which in turn is used to find an approximate solution to the first-stage problem. Interestingly, the call scheduling rule shows an unusual pattern due to the interplay between staffing and scheduling decisions. Extensive numerical studies show that our proposed approach can achieve significant cost savings.

4 Service Anatomy: Balancing Acute and Post-Acute Care

Noa Zychlinski[1], Itai Gurvich[2], [1]Technion - Israel Institute of Technology, Haifa, Israel; [2]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: noazy@technion.ac.il

Motivated by recent healthcare trends, we study the integration of Acute Care (AC) and Post-Acute Care (PAC). We develop an integrative modeling approach that captures the system's dynamics as it emerges through the evolution of individual patients' health conditions. Patients' outcomes depend, through their characteristics, on both AC and PAC efforts. The suggested modeling yields a tractable analysis while moving beyond common assumptions on service times being independent and fixed. We characterize the optimal AC-PAC effort integration and its dependencies according to (i) the extent to which AC and PAC complement/substitute for each other, (ii) the operational severity, which measures the ratio of PAC to AC marginal costs for the given health condition, and (iii) the relationship between the operational severity and the marginal AC cost within the patient group.

Variance Reduction

Community Committee Choice Session

Session Chair: Sara Shashaani, North Carolina State University, Raleigh, NC

Session Chair: Pranav Jain, North Carolina State University, RALEIGH, NC

1 Distributionally Robust Stratified Sampling for Stochastic Simulations with Multiple Uncertain Input Models

Seung Min Baik[1], Young Myoung Ko[1], Eunshin Byon[2], [1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]University of Michigan, Ann Arbor, MI, Contact: seungmin.baik@lstlab.org

This paper presents a robust version of stratified sampling for stochastic simulation with multiple uncertain input models. Traditional variance reduction techniques often assume a single, fixed input model, and thus pose a risk of having limited applicability under model uncertainties. Our distributionally robust (DR) stratified sampling approach minimizes the maximum of worst-case estimator variances among plausible input models, such as nonstationary wind conditions in wind turbine reliability assessment. We propose a bi-level optimization framework with various uncertainty set designs and use Bayesian optimization to solve the min-max problem. Numerical experiments and a wind turbine case study demonstrate the robustness of our method.

2 Simulation Optimization with Adaptive Stratification

Sara Shashaani[1], Pranav Jain[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, RALEIGH, NC

To increase the robustness and efficiency of a class of simulation optimization algorithms called ASTRO-DF (adaptive sampling trust-region optimization -- derivative-free), we use concomitant (auxiliary) variables in simulation to approximate the boundaries of the optimal strata at each visited solution during the optimization procedure.

3 A Stochastic Variance-Reduced Acceleratedprimal-Dual Method for Finite-Sum Saddle-Pointproblems

Afrooz Jalilzadeh[1], Erfan Yazdandoost Hamedani[2], [1]The University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ, Contact: afrooz@email.arizona.edu

In this paper, we propose a variance-reduced primal-dual algorithm with Bregman distance for solving convex-concave saddle-point problems with finite-sum structure and nonbilinear coupling function. This type of problems typically arises in machine learning and game theory. Based on some standard assumptions, the algorithm is proved to converge with oracle complexity of $O(\sqrt(n)/\epsilon)$ and $O(n/\sqrt{\epsilon}+1/\epsilon^{1.5})$ using constant and non-constant parameters, respectively where n is the number of function components. Compared with existing methods, our framework yields a significant improvement over the number of required primal-dual gradient samples to achieve -accuracy of the primal-dual gap. We tested our method for solving a distributionally robust optimization problem to show the effectiveness of the algorithm.

4 Cgpt: A Conditional Gaussian Process Tree for Grey-Box Bayesian Optimization

Mengrui (Mina) Jiang, Arizona State University, Tempe, AZ

In black-box optimization problems, Bayesian optimization algorithms are often applied to discover hidden structure and determine where to sample sequentially. However, information about system properties can be available, such as the trajectory of a dynamical system. We consider the case where the objective function can be encoded as a tree, each node performs input computation and the outcome directs the child branch. We propose the new Conditional Gaussian Process tree (CGPT) model for “tree functions” to embed the function structure and improving the prediction power of the Gaussian process. We utilize the intermediate information made available at the tree nodes, to formulate a novel likelihood for the CGPT parameter estimation under different levels of knowledge of the structure. Our study shows that CGPT always outperforms a single Gaussian process model.

5 Monte-Carlo Estimation of Covar

Nifei Lin[1], Jeff Hong[1], Weihuan Huang[2], [1]Fudan University, Shanghai, China; [2]Nanjing University, Nanjing, China. Contact: nflin19@fudan.edu.cn

CoVaR is one of the most important measures of financial systemic risks. It is defined as the risk of a financial portfolio conditional on another financial portfolio being at risk. In this paper we first develop a Monte-Carlo simulation-based batching estimator of CoVaR and study its consistency and asymptotic normality. We show that the best rate of convergence of the batching estimator can achieve $n^{-1/3}$, where n is the sample size. We then develop an importance-sampling inspired estimator under the delta-gamma approximations to the portfolio losses, and we show that the best rate of convergence of the estimator can achieve $n^{-1/2}$. Numerical experiments support our theoretical findings and show that both estimators work well.

Decision Models for Network Security and Resilience

Community Committee Choice Session

Session Chair: Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA

1 Strategic Network Inspection with Location-Specific Detection Capabilities

Bastián Bahamondes, Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA

We consider a network inspection game, in which a defender randomly positions a limited number of detectors in a network to detect attacks caused by an attacker, who randomly targets a subset of network components. Each detector location is associated with a probability of detecting attacks within its set of monitored network components. The objective of the defender (resp. attacker) is to minimize (resp. maximize) the expected number of undetected attacks. We formulate an integer program for the defender’s best response and use it within a multiplicative weights algorithm to compute approximate Nash equilibria. To handle the dimensionality of the attacker’s strategies, we add a projection step on the space of unidimensional marginal distributions. We compare the resulting inspection strategies with the optimal ones generated via a column generation approach.

2 Infrastructure Network Security With Imperfect Detection Technology

J. Haden Boone, Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, Contact: jboone31@gatech.edu

We consider a two-player zero-sum hide-and-seek game, in which a defender coordinates sensors according to a probability distribution to detect faults or strategic attacks on a critical infrastructure network. Detector performance is assumed to be imperfect, and is modeled with a probability that a fault in or attack on the network is successfully detected by a detector placed in its vicinity. This probability is determined from the detection technology utilized and the properties of the network, faults, or attacks. We analytically characterize Nash equilibria of the game in which the defender attempts to minimize the number of undetected attacks, and provide empirical evaluation of our methods on real networks.

3 Hyperconnected Relay-Based Network Design with Stochastic Demand

Onkar Kulkarni[1], Mathieu Dahan[2], Benoit Montreuil[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgia Tech, Atlanta, GA, Contact: onkar.kulkarni@gatech.edu

In this work, we study a bi-level stochastic program to design relay-based transportation network. In the first stage, we position the relay-hubs and size them and schedule trucks for transporting commodities upon realization of commodity demand uncertainty in the second stage. Due to commodity consolidation considerations, second stage consists of general integer decision variables which makes the problem challenging to solve. To alleviate the issue, we propose algorithm(s) based on Benders-decomposition to provide good quality solutions. In order to test our approach, we apply the developed methodology to design relay-hub network for a major car manufacturing company to be used for car deliveries.

4 Modeling a Military Campaign as a Stochastic Game Through Application of a Network Graph

Joseph McCarthy, Georgia Institute of Technology, Atlanta, GA, Contact: jmccarthy@gatech.edu

We model a military campaign as a zero-sum stochastic game which we solve through Shapley value iteration. We develop a heuristic to provide good value estimates that reduce solving time. To portray the campaign, we represent military objectives as nodes and integrate the military concept of lines of communication to express our operational state space as a directed acyclic graph, permitting expansive representations of armed conflict. We propose a parallel network graph that separates commanders who together create a combined, operational action.

5 Designing Resilient Short-Haul Logistics Networks Using K-Shortest Paths

Onkar Kulkarni[1], Mathieu Dahan[1], Benoit Montreuil[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Tech, Atlanta, GA, Contact: mathieu.dahan@isye.gatech.edu

We consider the problem of designing resilient short-haul logistics networks by selecting hub locations to minimize the total demand-weighted distance of the k-shortest paths between each origin-destination pair. We model this problem using a path-based integer-programing formulation and leverage its structure to devise two tailored scalable solution methodologies based on Benders decomposition and branch-and-price. To showcase the applicability of the developed model and solution methodologies, we design large-scale intercity parcel-delivery networks across Central China and compare their resilience to disruptions with respect to traditional cost-optimized logistics networks.

The Role of Transparency in Social Operations

Community Committee Choice Session

Session Chair: Lei Hua, University of Texas at Tyler, Tyler, TX

Session Chair: Karen Zheng, MA

1 Media Controversies and Supply Chain Labor Transparency in the Fashion Industry: The Need for a Fresh, Diverse Corporate Board

Veronica H. Villena[1], Li Cheng[2], [1]Arizona State University, Tempe, AZ, [2]Michigan State University, Leansing, MI, Contact: vhvillena@asu.edu

The fashion industry's labor scandals, with incidents such as the Rana Plaza and Boohoo, have drawn wide attention. Stakeholders have called for more transparency in the efforts of fashion brands to address their supply chains' labor issues. We draw attention to a less-studied institutional force: the media. Brands can react to media controversies—negative news coverage about the labor-related controversial activities in a firm's supply chain—differently; some take actions to ameliorate the consequences whereas others are defensive when their supply chain labor scandals are exposed. We investigate whether media exposure might prompt a fashion brand to publicly disclose data regarding its suppliers' working and labor conditions and, more importantly, *when* this pressure would be more effective depending on the board's composition.

2 Stories vs. Numbers: Enhancing Consumer Adoption of Socially Responsible Products

Lei Hua[1], Tim Kraft[2], Doug Thomas[3], Yanchong Zheng[4], [1]University of Texas at Tyler, Tyler, TX, [2]NC State - Poole College of Management, Raleigh, NC, [3]University of Virginia, Charlottesville, VA, [4]Massachusetts Institute of Technology, Cambridge, MA

Our study examines consumers' valuations of sustainability communication and the impact of different social responsibility topics and message formats on these valuations. Our research is based on collaboration with Goodio, a Helsinki-based craft chocolate maker that promotes positive social change. Our survey studies reveal that fair pricing information presented with fact-based messaging is more effective among U.S. participants, indicating a preference for educational attachment and information effects in societies with stronger 'masculine' characteristics, while Finnish participants are more receptive to story-based messaging, highlighting the importance of inducing emotional attachment in societies with stronger 'feminine' characteristics. Further studies establish causal evidence and generalize our findings to different products and prices.

3 Ex-Post Equilibrium Market Recommendations

Shai Vardi, Purdue University, West Lafayette, IN

New business models help sellers make better decisions by communicating information about market prices. However, sellers' inability to coordinate greatly reduces the efficacy of this information and can lead to market failures. We study the feasibility and benefits of providing equilibria as recommendations in economies where sellers face price uncertainty, information scarcity, and an inability to coordinate.

We describe a general model in which sellers wish to sell some good at one of several markets, and provide an algorithmic framework that a market planner can use to recommend ex-post equilibria to sellers. Using both synthetic data and real data on India's agricultural markets, we show that the recommended equilibria typically outperform other natural strategies in terms of seller welfare, geographic price dispersion, and market volume concentration.

Automation in Military Test & Evaluation

Community Committee Choice Session

Session Chair: Robert Newton, Penn State, University Park, PA

1 Build up Approach: Using RPAs as Scalable Autonomy Test Beds

Megan E. L. Burk[1], Aubrey Olson[2], [1]U.S. Air Force, Pentagon, VA, [2]U.S. Air Force, Edwards AFB, CA

The purpose of this presentation is to summarize a potential avenue to create an AI test bed developed by the team during the MIT/AIA Ideation course. The team surveyed the current efforts, engaged with the teams working on those efforts, and identified where a small group of motivated individuals could get a "5-yard win." The team proposed a possible AI/autonomy test bed, the benefits of this test bed, and required resources to accomplish the goal of a useful, accessible, and long-lasting AI-test bed.

2 Uncertainty Quantification: Artificial Intelligence and Machine Learning in Military Systems

Ayla Reed[1,2], [1]Maui High Performance Computing Center, Kihei, HI, [2]15th Space Surveillance Squadron, Kihei, HI

Instituting a military standard for quantified uncertainty metadata represents a solution to the problems inherent in using artificial intelligence/machine learning (AI/ML) for military advantage. By provisioning for metadata now, the Department of Defense can continue to determine the best policy for using AI/ML in parallel with capability development. This coordination will prevent delays in solving difficult technical problems associated with implementing AI/ML in warfighting systems. Uncertainty quantification can enable a practical digital implementation of the observe, orient, decide, and act loop, addressing ethical issues with employing AI/ML in war and optimizing investment in research and development.

3 Integrating Developmental Flight Testing and Crew Served Weapons Using Image Classification

James Mackey, Michael Zeihen, 413th Flight Test Squadron, Hurlburt Field, FL, Contact: james.mackey.14@us.af.mil

The MH-139A, fleet replacement for the UH-1N, is undergoing developmental testing to include integrating crew served weapons. Calculating safe trajectories and limitations on weapons use is time consuming and was not practical for the compressed testing timeline. Integrating high-speed camera photography with calibration measures and image classification techniques the data analysis team developed a rapid methodology to map rotor blade position during handling quality testing to determine blade location during typical engagement profiles. This approach enabled the team to rapidly model the safe employment envelope for the MH-139A crew served weapons and thereby compress the test schedule to meet delivery timelines.

Judgment and Algorithms

Community Committee Choice Session

Session Chair: Enno Siemsen, University of Wisconsin-Madison, Madison, WI

1 Automation or Collaboration? Comparing Integrated Learning Methods with Machine Learning in Demand Planning

Rebekah I. Brau[1], Finnegan McKinley[2], John Aloysius[2], Heilbronn Enno Siemsen[3], [1]Brigham Young University, Provo, UT, [2]University of Arkansas, Fayetteville, AR, [3]University of Wisconsin-Madison, Madison, WI, Contact: bekki_brau@byu.edu

Our research compares integrated forecasts (human judgment and algorithms) with machine learning forecasts without human input. We propose a novel method of integrating the three main components of demand forecasting analytics: technology (data, statistics, information technology), people, and processes. We test the individual components using field data and find that the novel method improves on each component. We also find that, overall, the novel approach is more accurate when compared to unsupervised machine learning.

2 Algorithm-Human-Algorithm: A New Classification Approach to Integrating Judgemental Adjustments

Christopher J. Chen[1], Nitish Jain[2], Varun Karamshetty[3], [1]Indiana University Kelley School of Business, Bloomington, IN, [2]London Business School, London, United Kingdom; [3]National University of Singapore, Singapore, Singapore. Contact: varun.karamshetty@nus.edu.sg

Firms often elicit judgemental adjustments to an algorithm-generated demand forecast. This process aims to utilize humans' private information that is inaccessible to the algorithm. However, humans are vulnerable to systematic biases when making such adjustments. Thus, it is challenging to integrate these adjustments with algorithm-generated forecasts to improve forecast accuracy. We propose a novel classification-based solution to address this challenge. First, we predict an adjustment's quality using predictors of humans' private information advantage (eg, product and store characteristics) and systematic biases (eg, recent forecast errors and adjustment characteristics). Next, we apply a simple heuristic--based on the predicted quality--to classify (accept/reject) each adjustment integration in the final forecast.

3 Forecast vs. Order Adjustments in Inventory Systems

Enno Siemsen[1], Eirini Spiliotopoulou[2], [1]University of Wisconsin-Madison, Madison, WI, [2]Tilburg University, GH Amsterdam, Netherlands. Contact: esiemsen@wisc.edu

Inventory order systems could allow human decision-makers to override forecasts, which are an input to the system, or to override order quantities, which are the system output. Which one works better? We test this question in the context of a behavioral experiment.

4 Expanding Knowledge Graphs with Humans in the Loop

Emaad Manzoor, NY

Curated knowledge graphs encode domain expertise and improve the performance of machine learning systems in several domains. As new concepts emerge in a domain, knowledge graphs must be expanded to preserve machine learning performance. Manually expanding knowledge graphs, however, is infeasible at scale. In this work, we propose a method for knowledge graph expansion with humans-in-the-loop. We show that our method is both accurate and provably "human-friendly", and validate human-friendliness with a controlled experiment. We further evaluate our method on a knowledge graph from Pinterest and show that it outperforms competing methods on both accuracy and human-friendliness. Upon deployment in production at Pinterest, our method reduced the time needed for knowledge graph expansion by ~400% and contributed to a subsequent increase in ad revenue of 20%.

5 Blame in Delegated Inventory Decision Making

Mirko Kremer[1], Doug Thomas[2], [1]Frankfurt School of Finance and Management gGmbh, Frankfurt Am Main, Germany; [2]University of Virginia, Charlottesville, VA, Contact: thomasd@darden.virginia.edu

Employees making inventory decisions are typically evaluated and compensated by managers rather than being owners of the firm. Additionally, employees often have access to more detailed information pertaining to their decision task as compared to the manager evaluating them. When such information asymmetry exists, managers can only imperfectly assess the quality of an employee's decision. In a controlled laboratory setting, we study how managers evaluate and compensate employees who are making an inventory order decision in the presence of demand uncertainty. We find evidence to support the notion that managers reward or punish the employee based on the outcome, even when the manager has sufficient information to evaluate the quality of the decision. Our findings have implications for managers mis-identifying good (and poor) performers in the workplace.

Fairness in Platforms and Recommendations

Community Committee Choice Session

Session Chair: Jackie W. Baek, UC Berkeley, Berkeley, CA

1 Online Platforms and the Fair Exposure Problem Under Homophily

Jakob Schoeffer[1], Alexander Ritchie[2], Keziah Naggita[3], Faidra Monachou[4], Jessie Finocchiaro[5], Marc Juarez[6], [1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]University of Michigan, Ann Arbor, MI, [3]TTIC, Chicago, IL, [4]Harvard University, Cambridge, MA, [5]Harvard University, Cambridge, MA, [6]University of Edinburgh, Edinburgh, United Kingdom. Contact: jef556@g.harvard.edu

In the wake of increasing political extremism, online platforms have been criticized for contributing to polarization. We study the *fair exposure problem*: given limited intervention power of the platform, how does one balance the spread of content among two groups of users. We develop a stylized framework that models intra- and inter-group content propagation, and we formulate the platform's decision as an optimization problem that aims at maximizing user engagement under fairness constraints that require each group see a mixture of their preferred and non-preferred content, encouraging information diversity. Fairness constraints only partially mitigate homogeneity in optimal policies: there exist optimal fairness-aware solutions which target one group with different types of content and the other group with only one type of content.

2 Game-Theoretic Perspective of Trust in Recommendation

Sarah Cen[1], Andrew Ilyas[2], Aleksander Madry[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT EECS, Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: shcen@mit.edu

Recommendation platforms—such as Netflix and Facebook—use various strategies in order to engage and retain users. These measures are meant to improve performance, but they can also erode their users' trust. In this work, we study the role of trust in recommendation. We show that, because recommendation platforms rely on users for data, trust is key to a platform's success. Our main contribution is a game-theoretic view of recommender systems and a corresponding formalization of trust. Precisely, if a user trusts their platform, then their optimal long-term strategy is to act greedily—and thus report their preferences truthfully—at all times. To illustrate the implications of this definition, we explore two simple examples of trust. We show that distrust can hurt the platform and that trust can be beneficial for both the user and platform.

3 Design and Engineering of Residential Crowdsourcing Systems

Nikhil Garg, Cornell Tech, New York, NY, Contact: ng343@cornell.edu

Modern city governance relies heavily on crowdsourcing (or "coproduction") to identify problems such as downed trees and power-lines. A major concern in these systems is that residents do not report problems at the same rates, leading to an inefficient and inequitable allocation of government resources. However, measuring such under-reporting is a difficult statistical task, as, almost by definition, we do not observe incidents that are not reported. Thus, distinguishing between low reporting rates and low ground-truth incident rates is challenging. First, joint with Zhi Liu, we develop a method to identify (heterogeneous) reporting rates, without using external (proxy) ground truth data. Second, I'll overview our work in redesigning inspection decisions to improve system efficiency and equity.

4 When Collaborative Filtering Is Not Collaborative: Unfairness Of PCA For Recommendations

David Liu[1], Jackie W. Baek[2], [1]Northeastern University, Boston, MA, [2]NYU Stern School of Business, Berkeley, CA, Contact: liu.davi@northeastern.edu

We study the fairness of dimensionality reduction methods for recommendations. We focus on the established method of principal component analysis (PCA). We identify two underlying mechanisms of PCA that induce unfairness at the item level. The first negatively impacts less popular items, due to the fact that less popular items rely on trailing latent components to recover their values. The second negatively impacts highly popular items, since the leading PCA components specialize in individual popular items instead of capturing similarities between items. We then develop a polynomial-time algorithm, Item-Preference PCA that addresses these unfairness issues. Our evaluations on real-world datasets show that Item-Preference PCA not only improves overall recommendation quality but also improves on both popular and less popular items.

Increasing Efficiency in Healthcare Delivery

Community Committee Choice Session

Session Chair: Feryal Erhun, University of Cambridge, Cambridge, United Kingdom

Session Chair: Zidong Liu, Cambridge Judge Business School, Cambridge, United Kingdom

Session Chair: Harshita Kajaria-Montag, University of Cambridge, Cambridge, United Kingdom

Session Chair: Houyuan Jiang, University of Cambridge,

Cambridge, United Kingdom

1 NHS Advice & Guidance: A Game Theoretical Consideration

Zidong Liu, Feryal Erhun, Houyuan Jiang, University of Cambridge, Cambridge, United Kingdom. Contact: zl424@jbs.cam.ac.uk

In the UK, general practitioners (GPs) are the primary point of contact for medical treatment, and specialist care usually require a GP referral. In recent years, the growing demand of secondary care resources has placed increased pressure on gatekeeping functions. To address this, the Advice & Guidance (A&G) service has been introduced as an optional and additional telemedicine gatekeeper, while the regulation and payment of this service remain unclear. Our study evaluates the system's performance under different contractual and regulatory arrangements and proposes a contract design to maximize the A&G's potential in reducing inefficiencies.

2 Incentivized Referral System with Co-Payment and Green Channels

Houyuan Jiang[1], Pengfei Guo[2], Qingxia Kong[3], Weifen Zhuang[4], [1]University of Cambridge, Cambridge, United Kingdom; [2]City University of Hong Kong, Hong Kong, Hong Kong; [3]Erasmus University, Rotterdam, Netherlands; [4]Xiamen University, Xiamen, China. Contact: h.jiang@jbs.cam.ac.uk

The Chinese government launched a major healthcare reform in 2009 to establish a tiered healthcare delivery system that can integrate and coordinate primary care and hospital care and deliver services effectively and efficiently. Incentive mechanisms are needed to leverage patients' preferences and re-direct patient flow from overcrowded large and urban hospitals to small community and rural clinics. We study two practical incentive mechanisms based on a co-payment approach and a specialist resource allocation approach. Our results show that a combination of both mechanisms can coordinate the system while the co-payment mechanism can only coordinate the system in some cases which are characterized by patients' medical conditions and their diagnosis abilities.

3 Patient Choice and Quality Competition Under Imperfect Quality Information

Zhan Pang[1], Linggang Qi[2], [1]Purdue University, West Lafayette, IN, [2]Soochow University, Suzhou, China. Contact: zpang@purdue.edu

Quality information imperfection is one of the most prominent characteristics of hospital markets. Employing the notion of rational expectations and the random utility theory, we characterize the choice behavior of quality- and delay-sensitive patients under imperfect quality information and hospital quality competition. We analyze the effects of imperfect quality information on both rational expectations equilibria and Nash equilibria. In particular, we show that more accurate quality information may not always lead to better quality under competition. We further discuss the policy implications of imperfect quality information and analyze how policy makers should coordinate the reimbursement and quality information strategies.

4 Estimating Heterogeneous Treatment Effects of Continuous Treatments with an Application to Diarrheal Infections

Zijun Gao, University of Cambridge, Cambridge, United Kingdom. Contact: gaozijun1995318@gmail.com

Diarrhea is a significant cause of child mortality and its occurrence is influenced by climatic factors. In this study, we examine the heterogeneous causal effect of precipitation shocks on diarrhea. In particular, we develop a method to estimate the effect curve of the continuous treatment precipitation shocks. Our method can incorporate effect modifiers, relies on mild model assumption, and leverages powerful machine learning algorithms. We apply the method to a survey data of low and middle-income countries combined with gridded climate data and find that precipitation shocks increase the susceptibility to diarrhea. We also identify specific social vulnerabilities, such as disposal practices and child feeding practices, that exacerbate the adverse effects of the precipitation shocks, which could be used to devise public health interventions.

Operations Research and Machine Learning for Maternal Health

Community Committee Choice Session

Session Chair: Lauren N. Steimle, Georgia Tech ISyE, Atlanta, GA

Session Chair: Meghan Meredith, Georgia Institute of Technology, Atlanta, GA

1 American Indians Travel Great Distances for Obstetrical Care: Examining Rural and Racial Disparities

Andreas Thorsen[1], Maggie Thorsen[2], Sean Harris[1], Janelle Palacios[3], Ronald McGarvey[4], [1]Montana State University, Bozeman, MT, [2]Montana State University, Bozeman, MT, [3]Kaiser-Oakland Medical Center, Oakland, CA, [4]IESEG, Paris, ., France. Contact: andreas.thorsen@montana.edu

Rural, American Indian/Alaska Native (AI/AN) people, a population at elevated risk for complex pregnancies, have limited access to risk-appropriate obstetric care. Obstetrical bypassing, seeking care at a non-local obstetric unit, is an important feature of perinatal regionalization that can alleviate some challenges faced by this rural population, at the cost of increased travel to give birth. Using data from Montana, we developed models to identify predictors of bypassing and predictors of factors associated with the distance people drove beyond their local obstetric unit to give birth. While bypassing may connect rural birthing people to more risk-appropriate care, rural and racial inequities in access persist, with rural, reservation-dwelling AI/AN birthing people experiencing greater likelihood of bypassing and traveling further when bypassing.

2 Scalable Decision-Focused Learning in Restless Multi-Armed Bandits with Application to Maternal and Child Health

Sanket Shah, Harvard University, Cambridge, MA, Contact: sanketshah@g.harvard.edu

We present the first algorithm for decision-focused learning in restless multi-armed bandit (RMAB) problems that scales to real-world problem sizes. Prior works often learn the model by maximizing the predictive accuracy instead of the final RMAB solution quality, causing a mismatch between training and evaluation objectives. In this paper, we propose a novel approach for decision-focused learning in RMAB that directly maximizes the downstream solution quality. We present three key contributions: (i) we establish differentiability of the Whittle index policy to support decision-focused learning; (ii) we significantly improve the scalability of decision-focused learning approaches in sequential problems, specifically RMAB problems; (iii) we apply our algorithm to a previously collected dataset of maternal and child health to demonstrate its performance.

3 Using Simulation Modeling to Improve Decision Making for Maternal Health

Karen T. Hicklin[1], Toni Reeves[2], [1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, Contact: khicklin@ufl.edu

Each year nearly 800 women die from pregnancy- or delivery-related complications in the United States. Non-Hispanic Black women are 2 times more likely to experience high-risk obstetric conditions and mortality compared to non-Hispanic white women, despite having similar rates of underlying health conditions. Discrete event simulation is used to model patient trajectories for prenatal care taking into account conditions that would make a pregnancy high-risk, such as advanced maternal age, eclampsia, diabetes, and/or high body mass index. Through this model we are able to identify opportunities for intervention that can reduce severe maternal morbidity and mortality and increase health equity.

4 An Adaptive Multilevel Neural Network for Early Detection of Preeclampsia

Rachel Bennett[1], Talayeh Razzaghi[2], [1]University of Oklahoma, Oklahoma City, OK, [2]University of Oklahoma, School of Industrial and Systems Eng, Norman, OK, Contact: rachel.l.bennett-1@ou.edu

The massive increase of healthcare data from electronic health records has been extremely beneficial to maternal complications diagnosis, allowing machine learning models such as neural networks to be applied to the tasks of disease early detection and treatment. With the increase in dataset size, however, comes a corresponding increase in computational complexity. Additionally, these datasets often suffer from class imbalance, leading to bias in the resulting models. To address these challenges, we develop an adaptive multilevel graph-based neural network and demonstrate its superiority over conventional neural networks.

5 Multi-Criteria Optimization to Balance Quality and Access for Risk-Appropriate Maternity Care

Meghan Meredith[1], Lauren N. Steimle[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Tech ISyE, Atlanta, GA, Contact: mmeredith8@gatech.edu

Among the factors contributing to the maternal mortality crisis in the United States is a lack of access to risk-appropriate obstetric care services. We present a multi-objective optimization model that seeks to design a hierarchical regionalization strategy to expand access considering travel distance, risk-appropriate care, and lower quality associated with low-volume obstetric hospitals. We present a case study that uses data on births and hospitals in Iowa to inform regionalized care and discuss the implications for healthcare policy.

Efficiency and Fairness in Operations Management

Community Committee Choice Session

Session Chair: Yichuan Ding, McGill University, Montreal, QC, Canada

Session Chair: Daniel Granot, University of British Columbia, Vancouver, BC, Canada

1 Achieving High Individual Service Levels Without Safety Stock? Optimal Rationing Policy of Pooled Resources

Jiashuo Jiang[1], Shixin Wang[2], Jiawei Zhang[3], [1]Hong Kong University of Science and Technology, New York, NY, [2]The Chinese University of Hong Kong, Hong Kong, China; [3]New York University, New York, NY, Contact: jzhang@stern.nyu.edu

We present a general framework to study the problem of allocating pooled resources when customers require individual and possibly different service levels. Our modeling framework generalizes and unifies many existing models in the literature and includes second-stage allocation costs. We propose a simple randomized rationing policy for any fixed feasible capacity level. Our main result is the optimality of this policy for very general service level constraints. The result follows from a semi-infinite linear programming formulation of the problem and its dual. As a corollary, we also prove the optimality of index policies for a large class of problems when the set of feasible fulfilled demands is a polymatroid.

2 Fairness in Accessibility of Public Service Facilities

Sheng Liu[1], Nooshin Salari[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Alberta, Edmonton, AB, Canada. Contact: snooshin@ualberta.ca

Our paper studies a fair stochastic facility location problem with congestion under the max-min principle. We analyze the price of fairness in a two-location problem and develop a tractable optimization framework for the general multi-location setting. Evaluating the fair solution against the utilitarian solution on Buffalo's demographic data reveals that implementing a fair solution can substantially improve fairness measures (up to 81%) with relatively limited impact on the overall service quality.

3 Tight Bounds for the Price of Fairness

Yifeng Cao[1], Daniel Granot[1], Yichuan Ding[2], [1]University of British Columbia, Vancouver, BC, Canada; [2]McGill University, Montreal, QC, Canada. Contact: yifeng.cao@sauder.ubc.ca

A central decision maker (CDM), who seeks an efficient allocation of scarce resources among a finite number, n, of players, often has to incorporate fairness criteria to avoid unfair outcomes. Indeed, the price of fairness (POF), a term coined in Bertsimas et al. (2011), refers to the efficiency loss due to the incorporation of fairness criteria into the allocation method. Quantifying the POF would help the CDM strike an appropriate balance between efficiency and fairness. In this paper we improve upon existing results in the literature, by providing tight bounds for the POF for the proportional fairness criterion for any n, when the maximum achievable utilities of the players are equal or are not equal, and we provide as well a tight bound for the max-min (Kalai - Smordinsky) fairness criterion, when the maximum achievable utilities of the players are not equal.

4 On Fairness and Efficiency in Nonprofit Operations: Dynamic Resource Allocations

Tong Wang, Yuanzheng Ma, Huan Zheng, Shanghai Jiao Tong University, Shanghai, China

We study a sequential resource allocation problem balancing fairness and efficiency for nonprofit operations. (Un)fairness is measured by the expected maximum demand shortfall among all communities, and (in)efficiency is measured by the expected remaining resources after allocation. We characterize the optimal allocation policy as a two-threshold policy in which the optimal allocation quantities are spoon-shaped in terms of the current maximum demand shortfall. We further show that the thresholds and optimal allocation quantity for each community are nondecreasing in resource levels, realized demand from the current community, and weight of the efficiency objective. Based on these results, we propose a simple heuristic policy and numerically show that it performs well and generates fair allocations in a stochastic majorization order. The numerical results show that adding a small weight to the fairness objective significantly improves the system's fairness at a small efficiency cost. Moreover, the optimal initial capacity level is increasing (decreasing) in demand variance if the efficiency weight is small (large). Our theoretical analysis can be extended to the fill rate--based fairness metric

Emerging Topics in Supply Chain Empirical Research

Community Committee Choice Session

Session Chair: Wenting Li, 1</sup

Session Chair: Zenan Zhou, 1</sup

1 The Impact of the Rivalry Behaviors Among the Vertical Partners on Their E-Commerce Performance

Woohyun Cho, Hao Su, University of New Orleans, New Orleans, LA, Contact: hsu3@uno.edu

We examine the impact of the relationship between the individual merchants' make or buy decisions and corresponding reactions of the online marketplace operator (i.e., Amazon.com) on the sales performance. Our study contributes to literature that significantly neglects the role of rivalry behaviors among the vertical partners on related outcomes.

2 Liquidity Shock and Behavior of Supply Chain Network

Mingyang Zhang, Wenting Li, Arizona State University, Tempe, AZ, Contact: mzhan235@asu.edu

We investigate the effects of the adoption of Basel III on the distribution of trade credit within the supply chain. The Basel III introduces a stricter risk framework, resulting in reduced financing provided by banks to firms. By considering the heterogeneous impact across firms in different supply-chain hierarchies and varying exposure to regulatory shock, we observe different effects on trade credit throughout the supply-chain network. Moreover, our hypothesis suggests that Basel III may indirectly undermine the financial stability of mid-stream firms.

3 The Impact of Shop and Scan Technology on Retail Store Visits: Assessing the Role of the Digital Divide

Brett Wang[1], Martin E. Dresner[1], Xiaodan Pan[2], Oliver Yao[3], Hyosoo Kevin Park[4], [1]University of Maryland, College Park, MD, [2]Concordia University, Montreal, QC, Canada; [3]Lehigh University, Bethlehem, PA, [4]University of Dayton, Dayton, OH, Contact: brett@umd.edu

Through a quasi-experiment, we examine the impact of an in-store product selection and purchase technology application on retail operations. Results reveal that the application leads to a reduction in shopper dwell time and an increase in new customers and total customer visits. Moreover, differential impacts of the technology are found, dependent on demographic characteristics of the retail market.

4 The Effect of the Chips Act on Stock Market Reaction: An Event Study Analysis

Zenan Zhou[1], Dale S. Rogers[1], Wenting Li[1], Molly Hughes[2], [1]Arizona State University, Tempe, AZ, [2]The Ohio State University, Columbus, OH, Contact: zzhou119@asu.edu

The United States Chips and Science Act (CHIPS Act) is designed to promote innovation, increase domestic production capabilities, and address supply chain vulnerabilities in the semiconductor industry. This empirical research employs an event study approach to investigate the impact of the CHIPS Act on the stock market reaction for semiconductor-related companies traded in China and the United States. To ensure validity and robustness, multiple statistical tests and various return models are employed. The study highlights the significance of the CHIPS Act, offers potential theoretical advancements by challenging conventional assumptions, and provides practical implications for investors, supply chain practitioners, and policymakers.

Healthcare Analytics and Operations

Community Committee Choice Session

Session Chair: Guihua Wang, The University of Texas at Dallas, RICHARDSON, TX

Session Chair: Minmin Zhang, The University of Texas at Dallas, Richardson, TX

1 Calibrate to Operate: Turning Patient Predictions into System-Wide Forecasts

Song-Hee Kim[1], William Overman[2], Jean Pauphilet[3], [1]Seoul National University, Gwanak-gu, Korea, Republic of; [2]Stanford, Stanford, CA, [3]London Business School, London, United Kingdom. Contact: wpo@stanford.edu

We investigate the usefulness of individual-level models for improving predictions on system-wide quantities in the healthcare industry. Using the prediction of occupancy in the emergency department as an example, we aim to predict short-term occupancy using patient-level predictions on length of stay. We identify and address various challenges in this process, including the construction of a credible benchmark, the choice of a suitable modeling technique, and the aggregation of patient-level predictions to obtain estimates on future occupancy. In particular, we observe, empirically and analytically, the emergence of a bias when naively summing patient-level predictions. We propose a simple calibration step to correct this bias and demonstrate the robustness of aggregating patient-level predictions to non-stationary processes.

2 Mitigating Nurse Shortage Via Inter-hospital Nurse Transfers: A Data-driven Multi-stage Distributionally Robust Optimization Approach

Wei Liu, Tianchun Li, Mengshi Lu, Pengyi Shi, Purdue University, West Lafayette, IN, Contact: mengshilu@purdue.edu

Motivated by the nurse shortage of our partner, IU Health, during the COVID-19 pandemic, we consider a nurse transfer plan by moving nurses from hospitals with surpluses to those with shortages. One key feature in our nurse transfer problem is that the nurses need to stay in the transferred hospital for a few days, known as secondment, before returning to their home location to avoid extended and possibly hazardous commutes. However, the introduction of the secondment further amplifies the pre-existing challenge incurred by the demand shift from the historical sample path, caused by the quick spread of COVID-19 and statewide distribution of hospitals. To overcome this challenge, we consider possible perturbations from historical data in advance by using a multi-stage distributionally robust optimization approach.

3 The Spillover Effect of Suspending Non-Essential Surgery: Evidence from Kidney Transplantation

Guihua Wang[1], Minmin Zhang[1], Tinglong Dai[2], [1]The University of Texas at Dallas, Richardson, TX, [2]Johns Hopkins University, Baltimore, MD

In this paper, we estimate the potential spillover effect of suspending non-essential surgery on patient access to essential health services, using deceased-donor kidney transplantation as the clinical setting. Through analyzing a dataset of all U.S. kidney transplantation procedures, we observe a steep reduction in the volume of deceased-donor kidney transplantation across nearly all states amid the initial months of the pandemic. However, states that suspended non-essential surgery experienced far steeper reductions than those without. Using a difference-in-differences approach, we estimate a state-level suspension of non-essential surgery led to a 23.6% reduction in the transplant volume. Our study reveals the spillover effect of state-level health policies on patient access to essential services such as deceased-donor kidney transplantation.

4 Examining the Impact of e-Consults on Access to Specialty Care: A Path Towards Improving Health Equity

Mengdi Tan, Apurva Jain, University of Washington, Seattle, WA, Contact: mengdit@uw.edu

This study investigates a eConsult system with a modified referral process, enabling primary care physicians (PCP) to deliver specialty care with support from specialists (SP) through remote consultations. The PCP has the option to independently treat the patient, refer them to a specialist, or seek guidance from a specialist. While consultations are assumed to offer cost-effective and timely benefits compared to referrals, the potential for treatment success may be lower. The analysis focuses on examining the impact on physicians' decisions, system performance, and the patients' experiences from diverse health and socio-economic backgrounds. The aim is to explore how eConsults can contribute to reducing health disparities among underserved patients by enhancing their access to specialty care.

5 The Effect of Must-Access Prescription Drug Monitoring Programs on Patient Volume and Outcomes

Beyza Celik[1], Guihua Wang[2], Behrooz Pourghannad[3], [1]University of Texas at Dallas, Dallas, TX, [2]The University of Texas at Dallas, RICHARDSON, TX, [3]Lundquist College of Business, University of Oregon, Eugene, OR, Contact: bxc190000@utdallas.edu

This study examines the effect of must-access Prescription Drug Monitoring Programs (PDMPs) on patient volume and outcomes. We first use the difference-in-differences approach to analyze the average effect of PDMPs. We then use an empirical machine learning approach to analyze the treatment effect heterogeneity across healthcare providers. Our analysis sheds light on the effects of must-access PDMPs, informing policymakers and stakeholders about their implications in addressing the opioid crisis and optimizing patient care.

Risk Management for Commodity and Energy Operations

Community Committee Choice Session

Session Chair: Sridhar Sridhar, 1</sup

Session Chair: Qi Wu, 1</sup

1 A Safe Reinforcement Learning Framework for Energy Real Options

Selvaprabu Nadarajah, University of Illinois at Chicago, Chicago, IL, Contact: selvan@uic.edu

Energy investments and operations require adapting decisions to future uncertainties (e.g., prices, climate, and supply intermittency). These decision flexibilities can be modeled as real options and optimized using reinforcement learning (RL). We propose a safe RL framework that manages the performance risks that arise when deploying RL policies.

2 Business Operations Redesign and Working-Condition Improvement in Agribusiness
Dongsheng Li[1], Saurabh Bansal[2], Karthik V. Natarajan[3], Phillip Coles[4], [1]Penn State University, State College, PA, [2]Penn State University, University Park, PA, [3]Carlson School of Management, University of Minnesota, Minneapolis, MN, [4]Lehigh University, Bethlehem, PA, Contact: dul596@psu.edu
We investigate how business operations can be redesigned to improve both a firm's performance and workers' working conditions in agribusiness. We provide a multi-dimensional decision support system based on the optimal strategies of our model. We further calibrate our model using industry data.

3 Agricultural Supply Chains in Emerging Markets: Competition and Cooperation Under Correlated Yields
Maqbool Dada, Johns Hopkins University, Baltimore, MD
We model the development of effective agricultural supply chains (agri-chains) in emerging economies for better utilization of land and intermediate processing resources for harvested export-oriented goods. We study decisions made by farmers, intermediate processors, and government officials in agri-chains. The structure and management of supply chains and government minimum guaranteed prices to farmers affect the performance of these chains and are in the domain of our study. We develop models of agricultural supply chains in which yields are correlated across regions, and, farmers sell to competing capacitated-processors.

4 Analysis on the Effect Environmental Cost on Financial Riskand Operational Decisions
Qi Wu, Peter Ritchken, Case Western Reserve University, Cleveland, OH, Contact: qxw132@case.edu
We aim to address the environmental challenge caused by abandoned mines. Mining firms incur significant financial risk due to the fluctuation in commodity price. When a mining firm faces financial difficulty, it may decide to abandon the mining land. According to Bureau of Land Management, there are over 50,000 abandoned mining sites in U.S., the majority of which need to be remediated. We consider and compare three payment schemes that government/environmental agency can adapt to make sure that mining firms commit to fulfill its environmental obligations. We study the effect of the three different environmental schemes on firms' production decision and financial risk. We provide insights and recommendations to policy makers in designing proper mechanism to address this environmental problem.

Information and Strategic Behavior in Queueing Systems

Community Committee Choice Session

Session Chair: Philipp Afèche, University of Toronto The Rotman School of Management, Toronto, ON, Canada

1 Advertising by Recruiting Influencers
Maya Jalloul[1], Vasiliki Kostami[2], [1]HEC Paris, Paris, France; [2]HEC Paris, Jouy-En-Josas, France
The growth of social media platforms allowed customers to rely on influencers and past consumers' experiences for their purchase decision. We address some of the firm's challenges of influencer marketing by considering different types of influencers and partnership schemes with them and address the effect of social learning in a two-period model. In the first period, the firm launches a new service experience of unknown quality and an influencer marketing campaign that relies on two types of influencers: sponsored advertising and public relations. We suggest the strategic partnerships a firm should establish with social media influencers to promote a new product depending on their credibility and popularity, on the market composition and the characteristics of the social media platform. We further instruct on capitalizing on social learning and optimal market choices.

2 Strategic use of Information in Healthcare
Jeunghyun Kim[1], Laurens G. Debo[2], Robert Shumsky[2], [1]Korea University Business School, Seoul, Korea, Republic of; [2]Dartmouth College, Hanover, NH, Contact: jeunghyunkim@korea.ac.kr
Maintaining costly effort to keep up with good health practices may be challenging at times. We explore how a care provider can strategically provide information to persuade a care receiver to sustain their effort over time, which is of benefit to both of them.

3 Behavior-Aware Queueing: When Strategic Customers Meet Strategic Servers
Yueyang Zhong[1], Raga Gopalakrishnan[2], Amy R. Ward[1], [1]The University of Chicago Booth School of Business,

Chicago, IL, [2]Smith School of Business at Queen's University, Kingston, ON, Canada

Traditional queueing theory assumes that customers do not balk and servers work at constant speeds. However, customers and servers in *service systems* are people, and the incentives created by managerial design decisions influence their behavior. First, we study strategic servers whose choice of work speed depends on (i) how many servers to staff and how much to pay them, and (ii) whether and when to turn away customers. We develop a queueing game model in which the work speeds emerge as solutions to a noncooperative game and asymptotically study the existence, uniqueness, and monotonicity properties of underloaded, critically loaded, and overloaded equilibria. Then, we extend our model to also include strategic customers' joining decisions, which endogenously induce a finite buffer. We conclude by discussing some managerial consequences of ignoring strategic behavior.

4 On The Design Of A Shared Waiting Room

Yanting Li[1], Ricky Roet-Green[2], [1]University of Rochester, Simon business school, Rochester, NY, [2]Simon Business School, University of Rochester, Rochester, NY, Contact: yanting.li@simon.rochester.edu

Many service facilities, such as food courts and clinics, provide multiple different services under one roof. These services often have a single waiting area for all customers. Unlike conventional line-up queueing, where customers can observe the queue in front of each server, customers in a shared waiting room cannot distinguish which server current customers are waiting for. In other words, customers do not have exact information about their actual queue length. However, in contrast to an unobservable queue setting, customers observe the number of customers in the system, and can use this information to infer their expected queue length. Based on such an estimation, customers decide whether to join the queue. We ask how the availability of designated queue-length information affects system performance in terms of throughput and social welfare.

Emerging Issues in Sustainable Supply Chains

Community Committee Choice Session

Session Chair: Andre Du Pin Calmon, Scheller College of Business, Georgia Institute of Technology, Atlanta, GA

Session Chair: Sytske Wijnsma, UC Berkeley, Berkeley, CA

1 Manufacturer's Intervention into Secondary Market: Implications for Firm's Pricing, Refurbishing Quality, Profit and Consumer Welfare

Hailong Cui[1], Greys Sosic[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Southern California, Los Angeles, CA, Contact: hailongc@umn.edu

We utilize an analytical model to study the manufacturer's trade-in programs. We focus on the firm's two operational levers, decisions on pricing andquality of refurbishing, and show that for most products it is optimal for the manufacturer to partially intervene into the secondary market.

2 Index-Based Yield Protection for Smallholder Farmers

Kehan Lu, Jing-Sheng Jeannette Song, Can Zhang, Duke University, Durham, NC, Contact: c.zhang@duke.edu

Government subsidies are common in the agricultural sector to protect farmers from unexpected losses. Two major categories of agricultural subsidies are price protection policies that subsidize farmers when the market price is low and yield protection policies that subsidize farmers when the crop yield is low. While both price and yield protection policies are widely implemented in developed countries, yield protection is typically difficult to implement in emerging economies due to the high cost of yield assessment for small farm sizes. To overcome this challenge, an innovative index-based approach for yield protection has emerged in recent years, under which farmers receive a subsidy payment when a pre-determined index (e.g., rainfall level) predicts that the yield level is low. This paper explores the design and value of such an index-based yield protection policy.

3 Reducing Lead and CO2 Emissions from a Deadly Circular Economy

Erica Plambeck[1], Qiong Wang[2], Amrita Kundu[3], [1]Stanford University, Stanford, CA, [2]University of Illinois at Urbana-Champaign, Urbana, IL, [3]McDonough School of Business, Georgetown University, Washington DC, WA, Contact: elp@stanford.edu

I will describe the deadly circular economy of lead acid batteries for electric vehicles in Bangladesh, and opportunities to reduce its lead and CO2 emissions through profitable business and operating model innovation.

4 Influence of Irrelevant Alternatives on Choices with Environmental Attributes

Mirel Yavuz[1], Charles J. Corbett[1], Guia Bianchi[2], Tayler Bergstrom[1], Aimee Drolet[1], Timothy F. Malloy[1], Deepak

Rajagopal[1], Rakesh Kumar Sarin[1], Francesco Testa[3], [1]University of California-Los Angeles, Los Angeles, CA, [2]European Commission, Sevilla, Spain; [3]Sant'Anna School of Advanced Studies, Pisa, Italy. Contact: charles.corbett@anderson.ucla.edu

Although several tools exist to collect environmental information, there is minimal guidance on making decisions based on such information. Decision-makers are subject to a wide range of context effects in other domains. We replicate an earlier study on choices involving non-environmental attributes and conduct an equivalent set of experiments involving trade-offs between environmental attributes. We show that context effects are frequently significant and substantial in the non-environmental as well as environmental settings; the choice frequency of an alternative can change by 30 percentage points after adding an irrelevant alternative. Our results highlight the importance of incorporating behavioral science into the broader environmental literature that involves trade-offs between environmental attributes.

Sustainable Operations Issues

Community Committee Choice Session

Session Chair: Helen Zhou, Singapore Management University, Singapore, Singapore

Session Chair: Natalie Ximin Huang, University of Minnesota, Minneapolis, MN

1 Effects of Ride-Hailing Platforms on Dual Distribution Channels

Gokce Esenduran, Jianing Li, Purdue University, West Lafayette, IN, Contact: li3193@purdue.edu

Automobile manufacturers in the U.S. typically distribute cars through dealers in the sales market and through rental agencies in the rental market. The emergence of ride-hailing platforms like Uber and Lyft has had a significant impact on both markets. When a platform exists, some customers may rely on using the platform's services instead of buying/renting a car, while others who buy a new or used car may provide rides on the platform. In this paper, constructing a detailed consumer utility model, we identify how the dealer and rental agency decisions, and thus the total ownership change after the ride-hailing platform's entrance. We also study extensions by allowing heterogeneity in the time car owners offer rides through the platform and by allowing the rental agency to sell used cars in the secondary market.

2 Storing Carbon in Supply Chains

Donghyun (Daniel) Choi[1], Andre Du Pin Calmon[2], Beril L. Toktay[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, Contact: donghyun.choi@scheller.gatech.edu

A nascent carbon mitigation practice involves the production of carbon-negative products using bio-based materials or carbon-capturing technologies. Motivated by a carpet manufacturing company that uses bio-based materials, we model the firm's sourcing and manufacturing decisions under different carbon accounting mechanisms and investigates how operating under these mechanisms can shape the firm's decisions.

3 Selling Agricultural Products via Livestream: Implications for Poverty Alleviation in Rural Economies

Xi Lin[1], Luyi Gui[1], Yixin Lu[2], [1]The Paul Merage School of Business, UC Irvine, Irvine, CA, [2]George Washington University, Washington, Contact: xlin32@uci.edu

Livestreaming has been increasingly used by farmers from remote rural areas to sell their agricultural products to consumers. In this paper, we study whether and under what circumstances selling through livestreaming can improve farmers' income compared to traditional approaches such as selling to wholesalers.

4 When To Regulate? The Case With Extended Producer Responsibility

Guiyun Feng[1], Natalie Ximin Huang[2], Bin LI[3], Yangfang (Helen) Zhou[4], [1]Singapore Management University, Singapore, Singapore; [2]University of Minnesota, Minneapolis, MN, [3]Wuhan University, Wuhan, China; [4]Singapore Management University, Singapore, Singapore. Contact: helenzhou@smu.edu.sg

We study the optimal timing decision of extended producer responsibility (EPR) regulation, which is an important lever, especially for emerging industries (e.g., electric vehicles). In those cases, delaying the regulation may allow the industries to advance further along the learning curve. Our study provides useful insight into the optimal design of EPR regulation.

Service and Product Innovations in Healthcare and Pharma

Community Committee Choice Session

Session Chair: Panos Markou, Darden School of Business

1 Does Transparency Hinder Technological Novelty? Evidence from Large Pharmaceutical Firms

Hanu Tyagi, Rachna Shah, University of Minnesota, Minneapolis, MN

Does transparency into a firm's new product development initiatives hinder technological novelty? In this paper, we examine the relationship in the context of the pharmaceutical industry. Using fine-grained data from approximately 10,000 clinical trials conducted between 2000 and 2014, we find that transparency pushes firms to increase the use of existing technologies that are less novel and less risky.

2 Preference Signaling in the Market for Medical Residents

Sasa Zorc, University of Virginia, Darden School of Business, Charlottesville, VA

The market for medical residents uses the celebrated Gale-Shapley algorithm for centralized matching, which guarantees stable and efficient matching. Despite this, inefficiency has crept into the market at the interview stage (so, prior to the application of the algorithm) as market congestion causes applicants to be interviewed only at a small fraction of institutions to which they apply. In an attempt to alleviate this problem, two medical specialties (urology and otolaryngology) introduced preference signals in 2022, which are centralized tokens that are given in limited quantities to candidates. Candidates can send these tokens to hiring institutions prior to interviews to signal interviews. In a retrospective cohort study, we empirically investigate the consequences of this intervention.

3 Behavioral Aspects in the Design of Procurement Auctions: The Capacity to Bid

Ivan Lugovoi[1], Jurgen Mihm[2], [1]Kühne Logistics University, Hamburg, Germany; [2]Insead, Fontainebleau, France. Contact: ivan.lugovoi@the-klu.org

Practical experience and academic research have shown that the design of a tender may have a substantial impact on its outcome. A recent focus on behavioral biases has complemented our understanding of rational aspects in auction design. But while extant work has focused mainly on individual behavioral biases, we focus on organizational biases afflicting entire organizations. Particularly, we are interested in understanding how a buyer should consider the bidders "capacity to bid". We conduct an empirical investigation of large-scale tenders of pharmaceutical products performed by German health insurance companie in order to study which tenderdesigns influence the number of participants. We thus hope to give tender designers practical advice based on rigorous analysis.

4 The Effect of Vote Timing Rules on New Product Evaluation Decisions: Advisory Committees at the Fda

Panos Markou[1], Tian Chan[2], [1]UVA Darden School of Business, Charlottesville, VA, [2]Emory University, Atlanta, GA

How should an expert committee vote to reach a collective recommendation on a complex issue? We examine how sequential versus simultaneous voting schemes shape the discussion, voting patterns, and ultimately the decision quality of the committee's recommendation. Combining multiple data sets based on FDA Advisory Committees' evaluations of new drugs and medical devices, we leverage a 2007 change from sequential to simultaneous voting to establish three key insights. We show that, relative to a sequential voting protocol, adoption of simultaneous voting by FDA Advisory Committees led to (1) a broader search for information in discussions, (2) a reduction in unanimous votes, and (3) an increase in the quality of recommendations made. We discuss academic and managerial implications.

The Role of Operations Research in Disaster Risk Reduction, Building Disaster Resilience and Effective Crisis Response

Panel Session

Session Chair: Fatma Salman, Koc University, Istanbul, Turkey

1 The Role of Operations Research in Disaster Risk Reduction, Building Disaster Resilience and Effective Crisis Response

Fatma Salman, Koc University, Istanbul, Turkey

Operations Research methods have been applied to problems arising in disaster management and humanitarian operations, especially with increasing interest by researchers over the past two decades. Moreover, the algorithms, tools, and insights developed by these studies have been instrumental in disaster and crisis management in practice and have found value among relief agencies and crisis managers. The role of OR in building disaster resilience and optimizing response operations will be discussed by panelists who are experts on disaster and crisis management and humanitarian operations management with anecdotes and findings from recent major disasters experienced worldwide, including the devastating earthquakes in Turkey, the wildfire in Hawaii, the global COVID-19 pandemic, and the Ukrainian war together with the resulting refugee crises and global supply chain disruptions.

Data-driven Operation of Emerging Mobility Systems

Community Committee Choice Session

Session Chair: Devansh Jalota, Stanford University, Stanford, CA
Session Chair: Karthik Gopalakrishnan, Stanford University, Cambridge, MA

1 Optimal Design of Best Response Dynamics in Multi-Agent Resource Assignment

Rohit Konda[1], Rahul Chandan[2], David Grimsman[3], Jason R. Marden[4], [1]University of California, Santa Barbara, Santa Barbara, CA, [2]Amazon.com, North Reading, MA, [3]Brigham Young University, Provo, UT, [4]University of California, Santa Barbara, Santa Barbara, CA

Game theory has emerged as a promising paradigm for the design of coordination algorithms in multi-agent systems. However, the emphasis of existing game-theoretic approaches is on the study of asymptotic (i.e., equilibrium) behaviour, whereas transient behaviour is often less explored. In this work, we adapt common game-theoretic techniques to study transient efficiency guarantees in the context of multi-agent resource assignment problems. Specifically, our main focus is on designing agent utility functions that induce optimal short-term, system-level behaviour under best response learning dynamics. Interestingly, we show that the performance guarantees under the induced transient learning dynamics are relatively close to the best achievable asymptotic performance guarantees.

2 Using Digital Infrastructure to Manage the Curbside in Real-Time

Shushman Choudhury, Lacuna Technologies, Palo Alto, CA, Contact: shushman.choudhury@lacuna.ai

As urban areas contend with increasing congestion, surging delivery demand, and diverse transportation modes, real-time optimization of limited curb space is crucial. This talk will explore how digital infrastructure, built upon sensors and algorithms, can enhance curb utilization via priority access, reservations, and other tactics. By analyzing two published case studies, we will explore the computational complexities inherent in designing algorithms for public right-of-way operations. Furthermore, the talk will highlight the advantages of managing the curb adaptively, including reduced traffic congestion and emissions, as well as increased safety and revenue opportunities.

3 Connected and Automated Vehicles in Mixed Traffic: Learning Human Driver Behavior for Effective On-Ramp Merging

Aditya Dave, University of Delaware, Newark, DE, Contact: adidave@udel.edu

Connected and automated vehicles (CAVs) are expected to improve safety and energy-efficiency of transportation systems. Since CAVs will penetrate the market gradually, it is critical to develop controls for CAVs in mixed-traffic scenarios involving human-driven vehicles (HDVs). This problem is challenging due to a dearth of well-understood models for CAV-HDV interactions. In this talk, we consider highway on-ramp merging scenarios requiring a CAV to merge with an HDV in a safe and energy-efficient manner. We present an approach to learn an approximate information state model for this goal. Then, we use it to generate trajectory predictions for the HDV and to control the CAV efficiently. We show in numerical simulations that our approach effectively predicts future trajectories of an HDV and generates safe control policies for a CAV during merging with the HDV.

4 Data-Driven Distributionally Robust Vehicle Routing for Heterogeneous Heavy-Duty Trucks
Ruiting Wang, University of California Berkeley, Berkeley, CA, Contact: rtwang@berkeley.edu
In this work, we study the routing of electric trucks through an application of distributionally robust optimization (DRO) for route planning and dispatch. This approach aims to minimize the cost of operation for the fleet, and considers the variability in energy consumption due to uncertain road conditions, traffic, weather, and driving behavior. Furthermore, we augment the distributionally robust energy-minimizing vehicle routing problem by learning the energy efficiency distribution over a horizon. We show that convergence to the true distribution is achieved while learning from samples taken from vehicles in operation on the network. Numerical experiments are conducted to validate this method and to compare it with the deterministic model.

CC-North 221C
Optimization for Sequential Decision-Making
Community Committee Choice Session
Session Chair: Sebastian Perez, [1</sup]
Session Chair: Alfredo Torrico, Cornell University, Ithaca, NY

1 Online Allocation with Priorities and Quotas
Matthew Eichhorn[1], Siddhartha Banerjee[1], David Kempe[2], [1]Cornell University, Ithaca, NY, [2]University of Southern California, Los Angeles, CA, Contact: meichhorn@cornell.edu
In online applications such as the rationing of medical care, the decision of who is treated is justified by various ethical, financial, and legal criteria. We build upon recent work on priority respecting allocations, adapting the model to an online setting. We highlight the fundamental trade-off between an allocation mechanism’s efficiency, its assurance that goods are allocated to the greatest extent, and its adherence to pre-defined notions of priority. In particular, in a setting with T online arrivals, we show that while insisting on zero priority violations leads to an $\Omega(T)$ loss in efficiency, one can design policies ensuring that the sum of the efficiency loss and priority violations is ⍰(1) under mild regularity conditions.

2 Response-Adaptive Clinical Trials with Many Treatments
David Brown, Cleo Yan, Duke University, Durham, NC, Contact: jingyi.yan@duke.edu
Clinical trials are traditionally designed to be non-adaptive. Although this design guarantees a well-performing treatment to be identified by the end of the trial with low bias, the process can be costly in terms of both time and resources. Response-adaptive design of clinical trials, on the other hand, enables the decision maker to alter the number of patients assigned to a treatment given its previous performances. Using an approach based on Lagrangian relaxations, we develop feasible policies and performance bounds. In a simplified two-period model, we bound the performance loss of the feasible Lagrangian policy and show that these policies are asymptotically optimal in a regime in which patients and treatments grow at the same rate.

3 Online ***K***-Median with Consistent Clusters
Benjamin Moseley[1], Heather Newman[1], Kirk Pruhs[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: hanewman@andrew.cmu.edu
We consider the online k-median clustering problem in which n points arrive online and must be irrevocably assigned to a cluster on arrival. As there are lower bound instances that show that an online algorithm cannot achieve a competitive ratio that is a function of n and k, we consider a beyond worst-case analysis model in which the algorithm is provided a priori with a predicted budget B that upper bounds the optimal objective value. We give an algorithm that achieves a competitive ratio that is exponential in the the number k of clusters, and show that the competitive ratio of every algorithm must be linear in k. To the best of our knowledge this is the first investigation in the literature that considers cluster consistency using competitive analysis.

4 A Simple Algorithm for Online Decision Making
Rui Chen[1], Oktay Gunluk[2], Andrea Lodi[1], Guanyi Wang[3], [1]Cornell Tech, New York, NY, [2]Cornell University, Ithaca, NY, [3]National University of Singapore, Singapore, Singapore. Contact: rc678@cornell.edu
Motivated by recent progress on online linear programming (OLP), we study the online decision making problem (ODMP) as a natural generalization of OLP. ODMP significantly broadens the modeling framework of OLP by allowing more general feasible regions (for local and long-term constraints) potentially involving both discreteness and nonlinearity in

each local decision making problem. We propose a Fenchel dual-based algorithm for ODMP that achieves sublinear long-term constraint violation and competitive difference in reward with respect to the optimal offline decisions. Experiments are conducted on an online knapsack problem with two different long-term fairness constraints.

CC-North 222A

Recent Advances in Nonsmooth Optimization

Community Committee Choice Session

Session Chair: Shaoning Han, University of Southern California, Los Angeles, CA

1 On the Tractable Resolution of Chance-Constrained Optimization Problems

Uday V. Shanbhag, Pennsylvania State University, University Park, PA, Contact: udaybag@psu.edu

We begin by considering the probability maximization where under suitable distributional assumptions, by leveraging properties of Minkowski functionals, the probability of interest can be expressed as the expectation of a Clarke-regular function with respect to an appropriately defined Gaussian density (or its variant). In fact, we may show that a suitably defined equivalent compositional representation is shown to be convex. We then derive rate and complexity guarantees for a regularized variance-reduced framework for computing approximate global maximizers of the original problem. We then extend our framework to a chance-constrained regime where distributional assumptions are weakened. Complexity guarantees for resolving this inclusion are provided for an inexact variance-reduced proximal-point scheme.

2 An Optimization Algorithm for Nonsmooth Problems with Weakly Concave Objective

Jingyi Wang, 1</sup

We present an optimization algorithm for a group of nonsmooth optimization problems that arise in solutions to parametric optimization problems and applications such as security-constrained AC optimal power flow problems. More specifically, the line search sequential quadratic programming method can be applied to constrained optimization problems with weakly concave objective. We present global convergence analysis and numerical examples in the form of two-stage optimization problems. Further, the algorithms can be extended to stochastic optimization where the exact function values and subgradients are unavailable. The algorithm is scalable and has been implemented and tested on supercomputers at national labs. The capabilities of the algorithm are demonstrated by solving a realistic optimal power flow problem as used in current power grid industry practice.

3 Adaptive Importance Sampling for Bayesian Hierarchical Models via Logarithmic Integral Optimization

Ziyu He[1], Junyi Liu[2], Jong-Shi Pang[3], [1]University of Southern California, Los Angeles, CA, [2]Tsinghua University, Beijing, China; [3]University of Southern California, Los Angeles, CA, Contact: ziyuhe@usc.edu

We explore Maximum a Posteriori inference of Bayesian Hierarchical Models (BHMs) with intractable normalizers, which are increasingly prevalent in contemporary applications and pose computational challenges when combined with nonconvexity and nondifferentiability. To address these, we propose the Adaptive Importance Sampling-based Surrogation method, which efficiently handles nonconvexity and nondifferentiability while improving the sampling approximation of the intractable normalizer through variance reduction. Our analysis ensures its almost sure subsequential convergence to a surrogation stationary point, a necessary candidate for a local minimizer. Extensive numerical experiments demonstrate the efficiency and stability of our algorithm in enabling advanced BHMs with intractable normalizers arising from enhanced modeling capability.

4 Variational Theory and Algorithms for a Class of Asymptotically Approachable Nonconvex Problems

Hanyang Li, Ying Cui, UC Berkeley, Berkeley, CA, Contact: hanyang_li@berkeley.edu

We investigate a class of composite nonconvex functions, where the outer function is the sum of univariate convex functions and the inner function is the limit of diﬀerence-of-convex functions. A notable feature of this class is that the inner function can be merely lower semicontinuous instead of continuous. It covers challenging applications, including bi-parameterized two-stage stochastic programs, value-at-risk for continuous distributions. We propose an asymptotic decomposition of the composite functions that epiconverges to the original function, leading to necessary optimality conditions for the minimization problems. We also design an algorithm provably convergent to the introduced optimality conditions. These results expand on the study of amenable functions by Poliquin and Rockafellar in 1992 and the prox-linear algorithm for their minimization.

First-Order Methods for Machine Learning

Community Committee Choice Session

Session Chair: Trang Tran, Cornell University, Ithaca, NY

Session Chair: Lam M. Nguyen, IBM Research, Thomas J. Watson Research Center, Yorktown Heights, NY

1 On the Convergence to a Global Solution of Shuffling-Type Gradient Algorithms

Lam M. Nguyen[1], Trang Tran[2], [1]IBM Research, Thomas J. Watson Research Center, Yorktown Heights, NY, [2]Cornell University, Ithaca, NY, Contact: lamnguyen.mltd@ibm.com

Stochastic gradient descent (SGD) algorithm is the method of choice in many machine learning tasks thanks to its scalability and efficiency in dealing with large-scale problems. In this paper, we focus on the shuffling version of SGD which matches the mainstream practical heuristics. We show the convergence to a global solution of shuffling SGD for a class of non-convex functions under over-parameterized settings. Our analysis employs more relaxed non-convex assumptions than previous literature. Nevertheless, we maintain the desired computational complexity as shuffling SGD has achieved in the general convex setting.

2 Stochastic Optimization Methods with Momentum

Trang Tran[1], Lam M. Nguyen[2], Katya Scheinberg[1], [1]Cornell University, Ithaca, NY, [2]IBM Research, Thomas J. Watson Research Center, Yorktown Heights, NY, Contact: htt27@cornell.edu

The empirical risk minimization problem (ERM) arises in most machine learning tasks, including logistic regression and some neural networks. Stochastic Gradient Descent (SGD) has been widely used to solve this problem thanks to its scalability and efficiency in dealing with large-scale tasks. Many variants of SGD involve momentum techniques which incorporate the past gradient information to the descent direction. Since the momentum methods offer encouraging practical performance, it is desirable to study their theoretical aspects and apply that knowledge to algorithm design. In this talk, we provide an overview of some of the stochastic momentum methods for the ERM problem and highlight some practical algorithms and/or settings where the momentum methods may have theoretical/heuristic advantages compared to plain SGD.

3 How to Escape Sharp Minima

Kwangjun Ahn, Massachusetts Institute of Technology, Cambridge, MA

Modern machine learning applications have seen a remarkable success of optimization algorithms that are designed to find flat minima. Motivated by this paradigm, this work formulates the algorithmic question of how to find flat minima. As an initial effort, we adopt the trace of hessian of the cost function as the measure of flatness and formally define the notion of approximate flat minima. We then design algorithms that find approximate flat minima efficiently. For general cost functions, we present a gradient-based algorithm that finds an approximate flat local minimum efficiently by using gradients computed from randomly perturbed iterates to estimate a direction that leads to flatter minima. For the setting where the cost function is an empirical risk over training data, we present a faster algorithm that is inspired by sharpness-aware minimization.

4 A Variance-Reduced and Stabilized Proximal Stochastic Gradient Method with Support Identification Guarantees for Structured Optimization

Yutong Dai[1], Guanyi Wang[2], Frank E. Curtis[3], Daniel Robinson[4], [1]Lehigh University, Bethlehem, PA, [2]National University of Singapore, Singapore, Singapore; [3]lehigh university, Bethlehem, PA, [4]Lehigh University, Bethlehem, PA, Contact: yud319@lehigh.edu

We propose, *S-PStorm,* a proximal stochastic gradient method with variance reduction and stabilization for structured sparse optimization. We prove an upper bound on the number of iterations required by *S-PStorm* before its iterates correctly identify with high probability an optimal support. Most algorithms with such a support identification property use variance reduction techniques that require either periodically evaluating an exact gradient or storing a set of stochastic gradients, while *S-PStorm* does not require either of these. Moreover, our support-identification result shows that, with high probability, an optimal support will be identified correctly in all iterations with the index above a threshold, while the few existing results prove that the optimal support is identified with high probability at each iteration with a sufficiently large index.

Recent Progress in Optimization Software III

Community Committee Choice Session

Session Chair: Hans Mittelmann, Arizona State University, Tempe, AZ

1 The Supporting Hyperplane Optimization Toolkit - Recent Advances

Andreas Lundell, Åbo Akademi University, Vaasa, Finland. Contact: andreas.lundell@abo.fi

The Supporting Hyperplane Optimization Toolkit (SHOT) is an open-source solver for mixed-integer nonlinear programming (MINLP) problems that combines a polyhedral outer approximation algorithm (Extended Supporting Hyperplane, ESH) with primal heuristics. SHOT has already been shown to work well for convex MINLP problems and can solve this problem class to global optimality. For most nonconvex problems, however, SHOT will only act as a heuristic method, without any guarantee to find the global optimal solution. In this presentation, some recent advances in solving nonconvex problems are described. Also, some recent benchmarks comparing SHOT to other MINLP solvers are provided.

2 Recent Progress in the Global Optimization of NLPs and MINLPs with BARON

Nick Sahinidis[1,2], [1]Georgia Institute of Technology, Atlanta, GA, [2]The Optimization Firm, Atlanta, GA

We review recent developments toward the global optimization of nonlinear and mixed-integer nonlinear programming problems with BARON. We discuss relaxation construction, preprocessing, branching, and tree management techniques. In addition to widely accepted benchmarks, we present results for a large test set. In all cases, we discuss historical progress and emphasize recent developments.

3 Highs: An Improved Interior Point Solver for the World

Julian Hall, University of Edinburgh, Edinburgh, United Kingdom. Contact: jajhall@ed.ac.uk

HiGHS is open-source optimization software for linear programming (LP), mixed-integer programming (MIP) and quadratic programming (QP). Independent benchmark results demonstrate HiGHS to be the world's best open-source linear optimization software, in particular when solving LPs by interior point. However, the interior point solver can still be totally uncompetitive with commercial solvers. This has been noticed particularly in the context of energy systems, and led to major funding for the development of a new interior point solver. This talk will discuss our work in the area, as well as providing an update on more general advances in HiGHS.

4 Latest Progress in Optimization Software

Hans Mittelmann, Arizona State University, Tempe, AZ

Algorithms for Robust Optimization

Community Committee Choice Session

Session Chair: Kartikey Sharma, Zuse Institute Berlin, Berlin, Germany

1 Frank Wolfe for Robust Combinatorial Optimization

Kartikey Sharma, Zuse Institute Berlin, Berlin, Germany

Robust Combinatorial Optimization (RCO) problems play a crucial role in many optimization applications. So far most research on RCO problems has focused on linear objective functions. In this project, we present a novel approach to solving nonlinear RCO problems with convex costs using the composite Frank-Wolfe (FW) algorithm. Our algorithm involves iteratively solving a linear RCO to compute the descent direction and then leveraging the convergence properties of the FW algorithm to solve the overall problem. The linear RCO is efficiently computed by solving a collection of nominal combinatorial optimization problems with modified objectives. We evaluate the performance of our algorithm through numerical experiments.

2 Decomposition Method for Two-Stage Distributionally Robust Optimization over 1-Wasserstein Balls

Geunyeong Byeon[1], Kibaek Kim[2], [1]Arizona State University, Tempe, AZ, [2]Argonne National Laboratory, Lemont, IL, Contact: geunyeong.byeon@asu.edu

We present optimality conditions for two-stage distributionally robust conic linear programming under constraint uncertainty over type-1 Wasserstein balls. Based on the optimality conditions, we propose binary representations of uncertain parameters that are supported on a hyperrectangle and develop a decomposition algorithm that achieves ⍰-optimality in a finite number of iterations. The proposed approach is validated through computational studies on electric power distribution systems.

3 First-Order Conditions for Optimization in the Wasserstein Space

Nicolas Lanzetti, Saverio Bolognani, Florian Dörfler, ETH Zürich, Zürich, Switzerland. Contact: lnicolas@ethz.ch

We consider the optimization of real-valued functionals over the probability space. This problem prompts us to tailor differential calculus to the space of probability measures. Specifically, we first explain the concept of "gradient with respect to a probability measure" (so-called Wasserstein gradient), which we then leverage to derive first-order optimality conditions. Remarkably, simple rationales such as "set the derivative to zero" and "the gradients of the objective function and the constraint align at optimality" carry over to the probability space. The generality of our methodology allows us to naturally deal with functionals, such as mean-variance, Kullback-Leibler divergence, and Wasserstein distance, which are traditionally difficult to study in a unified framework. We conclude with an application in distributionally robust optimization.

4 On the Convex Formulations of Robust Markov Decision Processes

Julien Grand-Clement[1], Marek Petrik[2], [1]HEC Paris, Paris, France; [2]University of New Hampshire, Durham, NH, Contact: mpetrik@cs.unh.edu

Robust Markov decision processes (MDPs) are used for applications of dynamic optimization in uncertain environments and have been studied extensively. Many of the main properties and algorithms of MDPs, such as value iteration and policy iteration, extend directly to RMDPs. Surprisingly, there is no known analog of the MDP convex optimization formulation for solving RMDPs. This work describes the first convex optimization formulation of RMDPs under the classical sa-rectangularity and s-rectangularity assumptions. We derive a convex formulation with a linear number of variables and constraints but large coefficients in the constraints by using entropic regularization and exponential change of variables. Our work opens a new research direction for RMDPs and can serve as a first step toward obtaining a tractable convex formulation of RMDPs.

Statistics and Robust Optimization

Community Committee Choice Session

Session Chair: Bart Paul Gerard Van Parys, Massachusetts Institute of Technology, Cambridge, MA

Session Chair: Amine Bennouna, MIT, Cambridge, MA

1 Optimal Holistic Robustness in Stochastic Optimization

Amine Bennouna, Bart Paul Gerard Van Parys, Massachusetts Institute of Technology, Cambridge, MA, Contact: amineben@mit.edu

We study the design of data-driven decision-making and machine learning methods that enjoy a guaranteed out-of-sample performance. We consider the setting where data points can be corrupted by noise or completely misspecified. Existing robust methods often overlook generalization issues and only protect against corruption, failing to provide guaranteed out-of-sample performance. We design a novel approach that offers a holistic solution that not only protects against corruption but also ensures strong generalization. This is achieved through a distributionally robust formulation with a novel combination of Kullback-Leibler and Levy-Prokhorov ambiguity. We prove our novel DRO approach optimal for learning under corruption and demonstrate its effectiveness in training neural networks, resulting in novel robust networks with state-of-the-art performance.

2 Smoothed ***F***-Divergence Distributionally Robust Optimization: Information-Theoretic Efficiency and Complexity Independence

Zhenyuan Liu[1], Bart Paul Gerard Van Parys[2], Henry Lam[1], [1]Columbia University, New York, NY, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: vanparys@mit.edu

In measuring model discrepancy against empirical data in DRO, divergence metrics are known impose the restriction of absolute continuity through as an indirect results of its definition involving likelihood ratios. On the other hand, distances such as Wasserstein operate via support point perturbations and do not impose continuity restrictions. However, neither satisfy the information-theoretic efficiency enjoyed by the KL-divergence; a special divergence metric. We study new computationally tractable distances by smoothing divergences with transport distances via a variational-representation-type optimization problem. We show that DRO based on such a distances may achieve the same large deviations asymptotic efficiency enjoyed by KL-divergence for general, possibly continuous, ground-truth distributions.

3 Generalization Power of Distributionally Robust Optimization: From Worst-Case Analysis to Minimal Hypothesis Class Dependence

Yibo Zeng, Henry Lam, Columbia University, New York,

NY, Contact: yz3587@columbia.edu

Established approaches to obtain generalization bounds in data-driven optimization mostly build on empirical risk minimization (ERM), which depend crucially on the hypothesis class complexity. We present an alternate route to obtain bounds for distributionally robust optimization (DRO). In contrast to the class complexity in ERM, our DRO bounds depend on the ambiguity set geometry and its compatibility with the true loss function. Notably, for distance-based DRO, our analysis implies generalization bounds whose dependence on the hypothesis class appears the minimal possible: The bound depends solely on the true loss function, independent of any other candidates in the hypothesis class. We discuss how our bounds reveal the strengths and weaknesses of DRO, and also how they amplify the benefits of DRO under distribution shift that ties to robustness.

4 Conditional Robust Optimization: A Framework for Decision Making Under Uncertainty

Abhilash Chenreddy, Erick Delage, HEC Montréal, Montreal, QC, Canada. Contact: abhilash.chenreddy@hec.ca

Conditional Robust Optimization (CRO) is a decision-making framework that blends the flexibility of robust optimization (RO) with the ability to incorporate additional information regarding the structure of uncertainty. This approach solves the RO problem, where the uncertainty set accounts for the most recent side information provided by a set of covariates. In this presentation, we will introduce two data-driven approaches to CRO: a sequential predict-then-optimize method and an integrated end-to-end method. We will demonstrate the application of both approaches and examine how each approach can incorporate additional information about the distribution of uncertainty into the optimization model. Finally, we will compare CRO with other contextual and non-contextual decision-making frameworks to emphasize their advantages and limiations.

Machine Learning/Reinforcement Learning in Vehicle Routing

Community Committee Choice Session

Session Chair: Xinwei Chen, Bucknell University, Lewisburg, PA

1 A Neural Separation Algorithm for the Rounded Capacity Inequalities

Hyeonah Kim[1], Jinkyoo Park[2], Changhyun Kwon[3], [1]KAIST, Daejeon, Korea, Republic of; [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of; [3]University of South Florida, Tampa, FL

The cutting plane method is a key technique for successful branch-and-cut and branch-price-and-cut algorithms that find the exact optimal solutions for various vehicle routing problems (VRPs). Among various cuts, the rounded capacity inequalities (RCIs) are the most fundamental. We design a learning-based separation heuristic algorithm with graph coarsening that learns the solutions of the exact separation problem with a graph neural network (GNN). We embed our separation algorithm within the cutting plane method to find a lower bound for the capacitated VRP (CVRP) with up to 1,000 customers. We compare the performance of our approach with CVRPSEP, a popular separation software package for various cuts used in solving VRPs.

2 Maximizing the Service Level over Time in Same-Day Delivery with Demand Evolution

Xinwei Chen[1], Marlin Wolf Ulmer[2], Barrett Thomas[3], Tong Wang[3], [1]Bucknell University, Lewisburg, PA, [2]Otto-von-Guericke Universität Magdeburg, Magdeburg, Germany; [3]University of Iowa, Iowa City, IA, Contact: xc003@bucknell.edu

The market for same-day delivery (SDD) is fast-growing, and the increasing demand brings challenges in delivering the service. Existing research focuses on improving service levels over a short period such as a day. However, the number of customer requests may evolve in the long run depending on the historical service level. For example, more customers are expected to be attracted if service levels increase in a neighborhood, and vice versa. In this talk, we consider the evolution of demand for SDD and develop a deep reinforcement learning approach to maximize the service level over time. We also compare different training strategies and discuss how our policies can help companies avoid significant customer churn and stay competitive in all neighborhoods.

3 Dynamic Time Slot Management with Uncertain Basket Sizes

Liana Van der Hagen[1], Niels Agatz[2], Remy Spliet[3], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Erasmus University Rotterdam, Rotterdam, Netherlands; [3]Erasmus Universiteit-Rotterdam, Rotterdam, Netherlands

In grocery home delivery, retailers usually let customers select a delivery time slot for receiving their groceries. The delivery capacity - the number of vehicles and drivers - is often fixed and inflexible in the short term. To effectively use their delivery capacity, e-grocers may dynamically close time slots for certain new customers given the already accepted customer orders. One complicating factor is that many online grocers allow customers to change their order basket at any time before the cut-off. Consequently, the e-grocer is uncertain about how much vehicle capacity should be reserved for each of the customers during the booking process. We study the challenges that arise with this order basket uncertainty, propose strategies to deal with it and assess if Machine Learning (ML) approaches are more reliable in these real-world settings.

4 Crowdsourced Delivery with Rental Electric Vehicles

Justin Goodson[1], Shu Zhang[2], Zhiwei Zhang[2], [1]Saint Louis University, Saint Louis, MO, [2]Chongqing University, Chongqing, China. Contact: goodson@slu.edu

We study a problem where crowdsourced drivers rent electric vehicles to deliver orders for an online retailer. Drivers' arrival times and work durations are uncertain. Vehicles' state of charge at the time of rental are also uncertain. We develop a cost function approximation to dynamically manage capacity. The approach seeks to balance the cost of hiring too many drivers against the cost of not having enough drivers.

Applications of Optimization

Contributed Session

Session Chair: Rachael May Alfant, Rice University, Houston, TX

1 Adaptive Linear Algebra

Theodoros Koukouvinos, MIT, Cambridge, MA

In this paper, we address two fundamental problems in linear algebra, linear systems and eigenvalues-eigenvectors (eigen-pairs), under adaptive optimization, by allowing the optimal solutions to be functions $f(\cdot)$ of uncertain parameters. Assuming $f(\cdot)$ is a linear function, we formulate both adaptive linear systems and adaptive eigen-pairs. We derive upper bounds for the optimal value and solve the problems to optimality using cutting planes. In the numerical experiments, we demonstrate the benefit of the adaptive linear systems and adaptive eigen-pairs over the nominal and robust ones in multi-period linear systems and multi-period eigen-pair problems. Moreover, we illustrate that the adaptive linear systems and adaptive eigen-pairs are more accurate than the nominal and robust ones on perturbations of ill-conditioned matrices.

2 Boole's Probability Bounding Problem and Linear Programming Aggregations

Joonhee Lee[1], Endre Boros[2], [1]Pace University, New York, NY, [2]Rutgers University, Piscataway, NJ

George Boole proposed the union bounding problem, a class of probabilistic satisfiability/optimization problems. In its most frequently studied case, we are given the probabilities of n events and the probabilities of their pairwise intersections and want to know how small/large can the probability of their union be. Hailperin (1965) provided a linear programming model for this problem which involves an exponential number of variables. We study methods that aggregate subsets of variables in Hailperin's model in various ways. We present one aggregation model with a polynomial number of variables that is equivalent to Hailperin's model.

3 Research Trends for Inventory Optimization with Product Substitution: From Model-Based to Data-Driven Approaches
Thais de Castro Moraes[1], Xue-Ming Yuan[1], Ek Peng Chew[2], [1]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: e0508687@u.nus.edu
Product substitution impacts different levels of the supply chain and contributes to the decisions in assortment planning, inventory optimization, and pricing. The increasing variety of products, level of consumer diversity and amount of historical data available has been instigating the development of new data-driven frameworks that account for different demand patterns and improve decisions flexibility due to substitution. We present a thorough review on the studies about product substitution with a focus on its effects on inventory optimization, evolving from the classical model-based approaches that rely on distributional assumptions, to fully data-driven decision-making methods. The studies are categorized based on the methodology to model and solve the inventory problem with the aim to identify knowledge gaps and suggest research directions.

4 A Stochastic Nonlinear Programming Approach to Pricing in the Cloud
Rachael M. Alfant, Sebastian Perez Salazar, Andrew J. Schaefer, Rice University, Houston, TX, Contact: rma10@rice.edu
There are three usage-payment plans that cloud computing providers often offer: reserved (long-term), on-demand (short-term), and spot (one-time). The spot market offers significantly discounted services by taking advantage of unused resources, which motivates the question of how to appropriately price spot market resources. This talk presents stochastic nonlinear programming formulations that optimize prices for the spot market under uncertain demand and available resources. We consider both static and dynamic pricing policies, and compare both in terms of revenue and interpretability. These formulations seek to maximize revenue for the cloud provider, and may also inform optimal pricing mechanisms for the on-demand and reserved markets.

Advanced Air Mobility
Community Committee Choice Session
Session Chair: Gokhan Inalhan, 1</sup
Session Chair: Michael Hardt, 1</sup

1 Congestion Management Protocols For Advanced Air Mobility
Christopher Chin, Massachusetts Institute of Technology, Cambridge, MA
The demand for advanced air mobility (AAM) operations is expected to be at a much larger scale than conventional aviation. Centralized optimization approaches to air traffic flow management assume that a central entity has complete knowledge of proposed flight trajectories in full. This assumption may not hold for AAM applications, where demand is expected to be more dynamic, and operators may be sensitive to sharing information. Therefore, we consider traffic management protocols that preserve operator privacy, while providing enough structure to mitigate efficiency loss. We demonstrate that our traffic management protocols can help balance efficiency and fairness.

2 A Comparative Study of Routing Options and Network Topologies for AAM Traffic Networks
Arinc Tutku Altun, Cranfield University, Bedford, United Kingdom
Future Advanced Air Mobility (AAM) is a concept that envisions to transform the current air transportation system into a more agile, flexible, and accessible system. Yet, the considered transformation and integrated system is not easy to achieve since it involves providing high level of safety as well as efficiency. For that purpose, we explored various metrics related to safety, efficiency, resiliency, social and environmental impact and analyzed different routing options

through the defined metrics over three vertiport networks. With these analysis, we aim to provide assistance for the integration process of the AAM.

3 An Airlift Scheduling Solution Based on Combination of Integer Programming and AI-Based Techniques
Michael Hardt, Boeing Research & Technology, Madrid, Spain. Contact: michael.w.hardt@boeing.com
We present a solution for an airlift scheduling pickup and delivery problem which contains probabilistic events in the route availability. A hierarchical approach is taken for which a high-level integer programming formulation provides a multi-agent solution in the planning horizon window and for the cargo to be delivered, while a lower level AI-based tree search solution performs a more detailed planning taking into consideration the uncertain elements in the distribution graph structure.

Recent Trends in Causality and Experimentation on Digital Platforms
Community Committee Choice Session
Session Chair: Ruoxuan Xiong, Emory University, DECATUR, GA
Session Chair: Jinglong Zhao, Boston University, Boston, MA

1 Design-based Estimation Theory for Complex Experiments
Haoge Chang, Microsoft Research, Cambridge, MA
This paper considers the estimation of treatment effects in randomized experiments with complex experimental designs, including cases with interference between units. We develop a design-based estimation theory for arbitrary experimental designs. Our theory facilitates the analysis of many design-estimator pairs that researchers commonly employ in practice and provide procedures to consistently estimate asymptotic variance bounds. We propose new classes of estimators with favorable asymptotic properties from a design-based point of view. In addition, we propose a scalar measure of experimental complexity which can be linked to the design-based variance of the estimators. We demonstrate the performance of our estimators using simulated datasets based on an actual network experiment studying the effect of social networks on insurance adoptions.

2 High-Dimensional Regression Adjustment in Completely Randomized Experiments

Dennis Shen, University of California-Berkeley, Berkeley, CA
Randomized experiments are a powerful tool for estimating causal effects. While the simple difference in means provides an unbiased estimator of the average treatment effect, it is often possible to improve the estimation by accounting for the impact of additional covariates on the outcome. Several regression adjustment methods have been proposed, but many of them have limitations in high-dimensional settings where the number of covariates is comparable to or even larger than the sample size. In this work, we propose and analyze regression adjustment via ordinary least squares interpolation in high-dimensional settings. We show that our method produces consistent estimates of the average treatment effect. Additionally, we conduct numerical experiments to support our theoretical findings and demonstrate the practical benefits of our approach.

3 Design and Analysis of Temporal Experiments in Ride-Hailing Platforms

Ruoxuan Xiong[1], Alex Chin[2], Sean Taylor[3], [1]Emory University, DECATUR, GA, [2]Lyft, New York, NY, [3]Motif Analytics, San Francisco, CA, Contact: ruoxuan.xiong@emory.edu
We study the design and analysis of temporal experiments. The motivating setting is a ride-hailing platform testing changes to marketplace algorithms, such as pricing, and estimating effects from observed outcomes at the city level. We propose an autoregressive specification for the outcomes, from which treatment effects can be efficiently estimated. Based on this specification, we propose a meta-analysis approach that leverages massive historical data to plan for a new experiment optimally.

Policing and the Opioid Crisis

Community Committee Choice Session

Session Chair: Veronica White, University of Wisconsin Madison, Madison, WI

1 Opioid Treatment Policies Using Discrete Event Simulation

Veronica White, Laura Albert, University of Wisconsin-Madison, Madison, WI, Contact: vmwhite@wisc.edu
The US opioid crisis has strained hospitals, treatment facilities, and law enforcement agencies due to inadequate resources and procedures to manage the crisis. Our study presents a discrete event simulation model that evaluates diverting individuals who use opioids to opioid use disorder treatment through three treatment policies: arrest diversion, overdose diversion, and re-entry case management. Using publicly available 2011 to 2019 data from Dane County, WI we estimate various opioid-related outcomes through 2032. Our analysis suggests that treatment policies alone may not reverse the opioid crisis in a community. However, high implementation of multiple treatment policies can reduce opioid-related crimes, hospital encounters, opioid use, and societal costs, suggesting communities need high levels of investment for effective treatment interventions.

2 Agent-Based Model of the Opioid Overdose Epidemic in a Rural Setting

Chelsea Spence[1], Mary Beth Kurz[2], Thomas Sharkey[2], Bryan Miller[1], [1]Clemson University, Seneca, SC, [2]Clemson University, Clemson, SC, Contact: cspenc2@g.clemson.edu
In 2021, 80,411 people died due to opioid overdoses in the United States. We report on progress in developing an agent-based model to simulate opioid use spread and overdose deaths in a rural community. The model is intended to support the evaluation of the effects of both harm reduction and drug control policies and changes in the opioids available. The model fills research gaps by including multiple types of opioids, including fentanyl, and can represent a heterogeneous population across rural regions.

3 Spatiotemporal Correlation of Drug Crime Data with Emergency Department Admissions - A Model for Geographically Estimating Underreported Crimes

Matthew Hudnall, University of Alabama, Tuscaloosa, AL
The ability of law enforcement to impact drug-related crime is directly related to the quality of information that the enforcement agencies have available to them. Research indicates that there is a high spatial correlation between criminal offenses and point-of-origin incidents in emergency medical service data. Given these considerations, we analyzed the potential in the utility of emergency room data and its ability to 1) identify the relative proportion of drug crimes unreported to the Alabama Law Enforcement Agency and 2) inform law enforcement and community partners as to levels of estimated unreported crimes to promote better community trust and engagement with law enforcement.

Bayesian Methods in OR

Community Committee Choice Session

Session Chair: Tevfik Aktekin, University of New Hampshire, Durham, NH

1 A Semi-Parametric Bayesian Model for Queueing Arrival Processes: An Application to Call Centers

Kaan Kuzu[1], Refik Soyer[2], Murat Tarimcilar[3], [1]University of Wisconsin-Milwaukee, Milwaukee, WI, [2]George Washington University, Washington, [3]The George Washington University, Washington, Contact: kuzu@uwm.edu

Nonhomogeneous Poisson process models are commonly used to forecast arrivals and require specification of intensity (arrival rate) functions that are typically defined in parametric form. Predictive accuracy of parametric models is highly sensitive to the choice of intensity function. We use a Bayesian framework by proposing a nonparametric form for the intensity function and introduce a robust semi-parametric model. The model is suitable for analyzing both time of arrival and interval censored count data and can capture both monotonic and non-monotonic intensity. We present three model extensions and implement them on two call center data sets. Our proposed model has robust performance for out-of-sample predictions, which can assist managers in determining appropriate staffing levels and effective workforce scheduling, resulting in more efficient operations.

2 Adversarial Outlier Detection: A Bayesian Decision Theoretic Approach

Tahir Ekin, Texas State University, San Marcos, TX

Outlier detection methods typically assume clean and legitimate data streams. However, adversaries may attempt to influence data which in turn may impact outlier designations. This paper presents a Bayesian decision theoretic approach for outlier detection in adversarial environments. Proposed adversarial risk analysis based framework allows incomplete information and adversarial perturbations on the data inputs. We solve the adversary's poisoning decision problem where he manipulates batch data inputted into outlier detection methods. We discuss potential defender strategies to improve the security of existing frameworks.

3 Information Concepts in Reliability Modeling

Refik Soyer, George Washington University, Washington, DC, Contact: soyer@gwu.edu

In this talk we present use of information theoretic methods in reliability analysis and discuss how models and inferences are developed and decisions are made in this framework. We present a range of Bayesian information measures for reliability analysis and discuss their use in failure model selection, prior specification, prediction, assessment of reliability importance and optimal design of life tests.

4 Zero-Inflated Poisson State Space Models: Application to Consumer Goods Demand

Tevfik Aktekin, University of New Hampshire, Durham, NH, Contact: tevfik.aktekin@unh.edu

In this study, we extend the literature on Poisson time series state space models when the count data has an excess number of zeros. In doing so, we implement an updating scheme that is analytically tractable under certain conditions. We term the model "Zero-inflated Poisson-Gamma State Space (ZIP-PGSS)". We introduce efficient sequential Markov chain Monte Carlo methods for model learning, updating, monitoring, and predicting. For illustration, the study uses weekly consumer goods demand data for sixty nine distinct household items for several households across several years. Several consumer good categories typically exhibit abundance of zero counts that cannot be analyzed/predicted using traditional supervised learning methods. The performance of the model are compared against these traditional predictive analytics tools as benchmarks.

1 Controllable Generation for Cimate Modelling

Moulik Choraria, University of Illinois Urbana-Champaign, IL

Recent years have seen increased interest in modeling future climate trends, from the point of view of accurately predicting and mitigating downstream impacts. However, high-resolution climate data for future climates needs to be simulated, which for multiple possible climate scenarios, becomes prohibitively expensive via traditional methods. Generative models leveraging the expressivity of neural networks have achieved immense success in modeling complex distributions. Herein, we demonstrate realistic simulation of climate scenarios via the GAN (Generative Adversarial Network) framework. We condition the model by quantifying the degree of "extremeness" of the observed sample, which allows the user to controllably sample from different parts of the distribution. Quantitative and qualitive evaluation demonstrate the efficacy of the proposed methods.

2 No-Show Prediction in Clinical Appointments Using Graph Neural Networks Based on Non-Euclidean Patient Data

Dyutimoy Nirupam Das, Paul Griffin, Soundar Kumara, The Pennsylvania State University, University Park, PA, Contact: dnd5258@psu.edu

Patient no-shows or cancellations have a negative impact on both provider efficiency and patient health outcomes. Previous approaches for estimating no-shows have trained machine learning models using Euclidian data consisting of features derived from socioeconomic factors and appointment details. However, we propose a novel approach that leverages non-Euclidean data derived from a network representation of the patient's journey through the healthcare system. The suggested network is effective in capturing patient preferences and physician referrals. A graph neural networks-based model is used to identify behavioral patterns from retrospective data and predict no-show behavior. Further, we study the network to infer congestion and vulnerable nodes in the physician referral network.

3 Eblime: Enhanced Bayesian Local Interpretable Model-Agnostic Explanations

Yuhao Zhong[1], Anirban Bhattacharya[2], Satish Bukkapatnam[3], [1]Texas A&M University, COLLEGE STATION, TX, [2]Texas A&M University, COLLEGE STATION, TX, [3]Texas A&M University, College Station, TX, Contact: hirobin_zhong@tamu.edu

We propose EBLIME to explain black-box machine learning models and obtain the distribution of feature importance using Bayesian ridge regression models. We provide mathematical expressions of the Bayesian framework and theoretical outcomes including the significance of ridge parameter. Case studies were conducted on benchmark datasets and a real-world industrial application of locating internal defects in manufactured products. Compared to the state-of-the-art methods, EBLIME yields more intuitive and accurate results, with better uncertainty quantification in terms of deriving the posterior distribution, credible intervals, and rankings of the feature importance.

4 Efficient Optimization of Cellular Automata Corrosion Simulation Parameters Using Neural Networks and Global Search Algorithms

Maha Yazbeck, Balavignesh Vemparala Narayana Murthy, Theodore T. Allen, Soheil Soghrati, Ohio State University, Columbus, OH, Contact: yazbeck.4@buckeyemail.osu.edu

This work presents an optimal design of experiment for data collection from a cellular automata corrosion simulation, to enable a neural network to learn the mapping between input parameters and image metrics. Global search minimization algorithms used the neural network predictions to provide optimized parameters to fit simulated corrosion patterns to real images. The approach enables efficient and accurate parameter optimization for agent-based simulations.

1 Energy Justice Implication of Large-Scale Electric Vehicle Adoption: A New England Case Study

Jie Xu[1], Richard Kornitsky[2], Ke Ma[2], Saba Siddiki[3], Victor Wang[4], Feng Qiu[5], [1]George Mason University, Fairfax, VA, [2]ISO-NE, Holyoke, MA, [3]Syracuse University, Syracuse, NY, [4]George C. Marshall High School, Falls Church, VA, [5]Argonne National Laboratory, Lemont, IL, Contact: jxu13@gmu.edu

Large-scale adoptions of electric vehicles (EVs) is hailed as an effective measure for reducing greenhouse gas emissions and fighting climate change. However, increasing charging loads coinciding with greater uptake of EVs will place additional pressure on the current and future electric grid. To better understand the implications of transportation electrification on the electric grid, here we conducted an in-depth study of large-scale EV grid integration using the ISO New England (ISO-NE) network as a case study. Using the regional system planning (RSP) model of ISO-NE, we investigated the changes in wholesale electricity price in 13 RSP areas in a baseline scenario that represents the current system projected into 2040, and a deep decarbonization scenario set forth in the technical report of Massachusetts 2050 decarbonization roadmap study.

2 Equitable Deployment of Weatherization and Distributed Generation Interventions

Miguel Heleno[1], Alexandre Moreira[2], [1]Lawrence Berkeley National Laboratory, Berkeley, CA, [2]Lawrence Berkeley National Laboratory, Oakland, CA

This talk presents an optimization model for equitable deployment of distributed energy resources and energy efficiency policy interventions. This model can be used to support policy decisions around just energy infrastructure investment by state and local authorities. The model adds sociodemographics to traditional energy planning models and formulates energy insecurity explicitly as an objective.

3 Approximating Time Domain in Equitable Deployment of Energy Storage

Alexandre Moreira, Miguel Heleno, Paul Lesur, Lawrence Berkeley National Laboratory, Oakland, CA

4 A Literature Review of Energy Justice

Weihang Ren[1], Feng Qiu[2], Yongpei Guan[1], [1]University of Florida, Gainesville, FL, [2]Argonne National Laboratory, Lemont, IL

Power Systems Planning and Optimization

Community Committee Choice Session

Session Chair: Anil Kaya, Karlsruhe Institute of Technology, Karlsruhe, Germany

1 Data-Driven Multistage Distributionally Robust Optimization for Economic Dispatch Problem

Zhiming Zhong, Neng Fan, University of Arizona, Tucson, AZ, Contact: zhongz@arizona.edu

This paper investigates data-driven multistage distributionally robust optimization (MDRO) for economic dispatch. A data-driven dynamic ambiguity set based on spatial-temporal autoregressive technique is introduced to model the uncertain netload. The conditional distributions of regression coefficients and Gaussian noise are derived explicitly, their joint confidence regions are incorporated into the ambiguity set. The proposed MDRO model enables the ambiguity set to be updated dynamically as the planning horizon rolls forward. Adaptive dispatch decisions are made to guarantee secure operation despite imperfect knowledge of future realizations. The case study demonstrates that the proposed MDRO approach effectively captures the spatial-temporal correlation, enabling less conservative decisions without compromising system reliability.

2 Dynamic Pricing in an Energy Community Providing Capacity Limitation Services

Bennevis Crowley, Technical University of Denmark, Lyngby, Denmark

A mathematical framework using bi-level optimization is proposed in which dynamic energy prices are used to coordinate prosumers in an energy community that subscribes to a limit on its maximum power import from the external grid in exchange for tariff reductions from the distribution system operator. In the upper-level problem, an energy community manager minimizes the total operational cost of the community while setting energy prices. In the lower-level problem, each community member optimizes their energy usage to minimize their daily cost based on the set prices. The proposed bi-level model is reformulated into a mixed integer quadratic problem and applied to a 15-node radial distribution grid case study in which different degrees of freedom are applied to the pricing constraints and the performance compared to other coordination methods.

3 Generation and Storage Capacity Expansion Problem Considering Cost Recovery of New Units

Miguel Carrion[1], Rafael Zárate-Miñano[2], [1]Universidad de Castilla - La Mancha, Toledo, Spain; [2]Universidad de Castilla - La Mancha, Almadén, Spain. Contact: miguel.carrion@uclm.es

The design of future power systems is one of the most challenging problems that power system planners are currently facing to supply the demand at minimum cost, considering the minimum percentage of demand supplied by low-emission energies. However, the increasing capacity of renewable units with almost zero operation costs significantly reduces pool prices at certain hours. Thus, the economic income of new generation units may be much smaller than expected if the installation rate of new renewable units is maintained or increased. In this study, we propose a bi-level programming approach to formulate the generation and storage capacity expansion problem, in which the cost recovery of new units is enforced. Different financial support mechanisms for the new units are considered, and a realistic case study is conducted and analyzed.

4 A Polyhedral Study on Unit Commitment with a Single Type of Binary Variables

Bin Tian, Kai Pan, Chung-Lun Li, The Hong Kong Polytechnic University, Kowloon, Hong Kong. Contact: bin12.tian@connect.polyu.hk

Previous studies for the Unit Commitment (UC) problem have primarily focused on formulations using two or three groups of binary variables, as it is believed to be challenging to derive strong valid inequalities using a single group of binary variables, and the improvement of compactness is often accompanied by a compromise in tightness. This paper presents a compact UC formulation using a single group of binary variables, which reduces the size of the search tree. To enhance the tightness of the formulation, two-period UC polytope and multi-period strong valid inequalities are developed. Conditions under which these strong valid inequalities are facet-defining for the multi-period UC polytope are provided. The effectiveness of the proposed compact formulation and strong valid inequalities is demonstrated through numerical experiments.

5 Integrated Stochastic Model with Electricity Market Simulation for Long-Term Generation Expansion Planning

Anil Kaya[1], Steffen Rebennack[2], Aboubakr Achraf El Ghazi[3], Ulrich Frey[3], [1]Karlsruhe Institute of Technology, Karlsruhe, Germany; [2]Karlsruhe Institute of Technology (KIT), Karlsruhe, Germany; [3]German Aerospace Center, Stuttgart, Germany. Contact: anil.kaya@kit.edu

Our study introduces a long-term stochastic power generation expansion model under uncertainty. Our aim is to minimize the total cost (investment and operational) during the planning horizon. The model is a two-stage stochastic mixed-integer linear program solved using Benders decomposition. The master problem determines investment and retirement decisions deterministically, while the sub-problem optimizes operational decisions through stochastic dual dynamic programming. Our model is coupled with an agent-based electricity market simulation (AMIRIS) to evaluate portfolio decisions and their market impact. Using Benders decomposition, optimality cuts incorporate AMIRIS feedback. With two optimality cuts, our multi-objective master problem is solved via a weighted sum approach. German power system case study shows our approach’s efficiency.

Planning for Reliable and Secure Electricity Markets

Community Committee Choice Session

Session Chair: Golbon Zakeri, University of Massachusetts - Amherst, Amherst, MA

Session Chair: Arash Khojaste, University of Massachusetts - Amherst, Amherst, MA

1 Reliability in Electricity Markets

Arash Khojaste[1], Golbon Zakeri[2], Geoffrey Pritchard[3], [1]University of Massachusetts Amherst, Amherst, MA, [2]University of Massachusetts - Amherst, Amherst, MA, [3]University of Auckland, Auckland, New Zealand. Contact: AKHOJASTE@UMASS.EDU

There are various sources of uncertainty when it comes to renewable energy. These variations range from seasonal to diurnal. Therefore, some fleets of generation-firming sources are needed to ensure grid reliability. This study focuses on addressing uncertainties in wind power generation by employing Markov decision processes. We construct Markov decision processes that accommodate periodic variations in residual demand (i.e., demand after wind power generation). These processes serve as a framework for decision-making in renewable energy systems. We use a technique for constructing such processes that allows for periodic variations both in the values taken by the process and in the serial dependence structure. Additionally, we develop an investment model aimed at determining the optimal quantity and sources of backup power for renewable energy.

2 The Value of Coordination in Interdependent Urban Energy Systems with Operational Flexibility Under Uncertainty

Sebastian Maier[1], Afzal Siddiqui[2], [1]University College London (UCL), London, United Kingdom; [2]Stockholm University, Kista, Sweden. Contact: s.maier@ucl.ac.uk

Coordinated decision making policies between operators of district heating networks (DHNs) can play a key role in the effective decarbonisation of interdependent urban energy systems under uncertainty; however, the value of coordination has been little studied. We consider two independently operated DHNs - one consists of a combined heat and power plant and a thermal storage; the other one has also a heat pump - that interact through markets (gas & electricity) and a DHN. We model the operators’ decision problems as multi-stage stochastic mixed-integer linear programs, where the interactions represent box-constraints, and investigate the value of coordination using ideas from adjustable robust optimization and generalized Nash equilibria in repeated games. We conclude with a numerical example illustrating the benefit of the proposed approach using real data.

3 Guiding Investment Decisions for Electricity Markets Under Risk and Uncertainty

Golbon Zakeri[1], Arash Khojaste[2], Geoffrey Pritchard[3], [1]University of Massachusetts - Amherst, Amherst, MA, [2]UMass Amherst, Amherst, MA, [3]University of Auckland, Auckland, New Zealand. Contact: gzakeri@umass.edu

We will present an investment model under uncertainty and risk to enable smooth integration of renewable sources of generation within electricity markets. We model renewable generation from offshore wind using quantile Fourier regression and (time inhomogeneous) Markov chains. We use Markov decision processes (MDPs) to model risk adjusted, (near) optimal operations of a grid given a mix of generation. This process is embedded within an investment model to ensure resilience of the grid.

Computational and Methodological Advances for Optimization Problems Under Uncertainty

Community Committee Choice Session

Session Chair: Matheus Ota, University of Waterloo, Waterloo, ON, Canada

Session Chair: Andre Augusto Cire, University of Toronto Scarborough, Rotman School of Management, Toronto, ON, Canada

1 Computational Study of Cutting Plane Algorithms for Multi-Stage Stochastic Programming Models

Akul Bansal, Simge Kucukyavuz, Northwestern University, Evanston, IL

We report a computational study of cutting plane algorithms for multi-stage stochastic programming models on multiple classes of real-world problems and consider the following cuts: (i) Benders cuts, (ii) integer L-shaped cuts, (iii) strengthened Benders cuts, and (iv) Lagrangian cuts. We enhance the performance of these cuts by using a mixture of these cuts. Specifically, we alternate between the relaxed and exact computation of subproblems, utilizing a Benders cut from the relaxation and either of (ii)-(iv) from the exact computation. Our preliminary results show that this approach leads to improvement in the solve times.

2 Accelerating Benders Decomposition for Solving a Sequence of Sample Average Approximation Problems

Kothari Harshit, James R. Luedtke, University of Wisconsin-Madison, Madison, WI

Sample average approximation (SAA) is a technique to get good approximate solutions to stochastic programs (SP). When applying SAA, it is often useful to solve multiple SAA problems to obtain a confidence interval on the true optimal value of the SP and also get a better solution. We study techniques to accelerate the solution of this sequence of SAA problems, when solving them via Benders decomposition. We exploit similarities in the problem structure, as the problems just differ in the realizations of the random samples. Our extensive computational experiments of large scale problems provide empirical evidence of the improved efficiency of our algorithm. In addition, we also present theoretical results that provide insight into the algorithm's performance.

3 A Two-Stage Chance-Constrained Stochastic Program for Disaster Housing Assistance Logistics Planning

Sheng-Yin Chen, Yongjia Song, Clemson University, Clemson, SC, Contact: shengyc@clemson.edu

We propose and study two-stage chance-constrained stochastic programming models to achieve the balance between logistics operational cost and its resiliency towards extreme disastrous situations. This consideration is reflected in utilizing two operational modalities, one for the ordinary modality and the other for the emergency modality, and the emergency modality is only allowed to be activated for a limited number of scenarios among all that may arise, according to the underlying uncertainty associated with a linear regression model for characterizing the disaster housing demand based on a selected number of independent variables from historical data. Preliminary numerical results based on a case study on Hurricane Ian have shown the effectiveness of the proposed approach and provided managerial insights in disaster housing logistics planning.

4 Recent Advances in Pyros: The Pyomo Solver for Two-Stage Nonconvex Robust Optimization

Jason Sherman[1], Natalie Isenberg[1], John Siirola[2], Chrysanthos E. Gounaris[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Sandia National Laboratories, Albuquerque, NM

In this work, we present recent algorithmic and implementation advances of the two-stage robust optimization (RO) solver PyROS, and a benchmarking study which demonstrates the utility of PyROS for two-stage RO problems. Our advances include extensions of the scope of PyROS to models with uncertain variable bounds, improvements to the initializations of the subproblems used by the underlying cutting set algorithm, and extensions of the uncertainty set interfaces. The benchmarking study is performed on a library of over 8,500 instances, with variations in the nonlinearities, degree-of-freedom partitioning, uncertainty sets, and polynomial decision rule approximations. Overall, our results highlight the effectiveness of PyROS for obtaining robust solutions to optimization problems with uncertain equality constraints.

Innovative Platform Operations

Community Committee Choice Session

Session Chair: Ming Hu, University of Toronto, Minneapolis, MN

Session Chair: Zhoupeng (Jack) Zhang, Rotman School of Management, University of Toronto, Toronto, ON, Canada

1 Riding Through Rallies: Will You Tip More?

Ming Hu[1], Zhoupeng (Jack) Zhang[2], Wanjiang Deng[3], [1]University of Toronto, Minneapolis, MN, [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada; [3]National University of Singapore, Singapore, Singapore. Contact: wanjiang.deng@u.nus.edu

Do customers treat gig workers in a more prosocial manner during social movements? In this research, we study the impacts of 2020 Chicago George Floyd protests on passengers' tipping in the ridehailing marketplace. While we find significant increases in tips after protests, such positive impacts do not last long or improve drivers' incomes very much. Moreover, the protests have no impacts on tips in the taxi market, yet the tipping standard for taxi is also much higher than that for ridehailing. Potential mechanisms in the ridehailing marketplace are a weakened social norm of tipping on platforms like Uber and passengers' empathy during protests. Interestingly, the empathy effect may have not only benefited Black drivers but also spilled over to non-Black drivers.

2 What is the Impact of Labor Productivity on the Optimal Staffing Level?

Terry Taylor, University of California at Berkeley, CA

An analysis of canonical operations models reveals that the answer exhibits a surprising, simple structure.

3 Minimum Wage Regulation in Ride-Hailing Platforms: Unintended Consequences in Spatially-Dispersed Markets

Harish Guda[1], Ashish Kabra[2], [1]Arizona State University, Tempe, AZ, [2]University of Maryland-College Park, College Park, MD, Contact: hguda@asu.edu

Ride-hailing platforms experienced tremendous growth in the recent past. As these platforms matured, a large population of drivers have reported dissatisfaction with their earnings. Motivated by their low wages, several large cities have proposed regulations to improve the effective driver pay, the most popular of which is a utilization-adjusted minimum wage. We analyze the implications of such a minimum wage in a spatially-dispersed market. Our model captures two key features. First, most large cities comprise a dense core zone, surrounded by peripheral zone. Second, the demand patterns between these zones exhibit large imbalances. We find that the effect of such a minimum wage leads to a disproportionate effect on the cross-zone demand, in comparison to the within-core-zone demand.

4 Market Thickness and Delivery Efficiency in Food Delivery Platforms

Wenchang Zhang[1], Ruomeng Cui[2], Zhanzhi Zheng[3], [1]Indiana University, Bloomington, IN, [2]Emory University, Decatur, GA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: wenczhan@iu.edu

In food delivery platforms, market thickness entails the restaurant density within a geographic area (i.e., a regional market) on the platform. We study the implications of the market thickness and restaurant performances in food delivery platforms. First, we find that higher market thickness leads to shorter order wait times (i.e., faster deliveries), suggesting an improvement in delivery efficiency. Second, increasing market thickness is estimated to boost restaurants' sales and revenues but reduce consumers' spending per order on the platform. Third, exploiting market thickness' heterogeneous effects, we tease out the cause of the delivery efficiency improvement and attribute it to drivers' delivery pooling.

1 Algorithmic Barriers from Intricate Geometry in Random Computational Problems

Eren C. Kizildag, Columbia University, New York, NY, Contact: eck2170@columbia.edu

Many computational problems that involve randomness exhibit a statistical-to-computational gap (SCG): the best known polynomial-time algorithm performs strictly worse than the corresponding existential guarantee. In this talk, we focus on the SCG of the symmetric binary perceptron (SBP), a random constraint satisfaction problem as well as a toy model of a single-layer neural network. We establish that the solution space of the SBP exhibits intricate geometrical features, known as the multi Overlap Gap Property (m-OGP). By leveraging the m-OGP, we obtain nearly sharp hardness guarantees against the class of stable and online algorithms, which capture the best known polynomial-time algorithms for the SBP. Our results mark the first instance of intricate geometry yielding nearly tight algorithmic hardness guarantees against classes beyond stable algorithms.

2 Universality of Approximate Message Passing Algorithms and Tensor Networks

Zhou Fan[1], Tianhao Wang[2], [1]Yale, [2]Yale, New Haven, CT

We develop several new results on AMP universality. For AMP algorithms tailored to independent Gaussian entries, we show that their state evolutions hold over broadly defined generalized Wigner and white noise ensembles, including matrices with heavy-tailed entries and heterogeneous entrywise variances that may arise in data applications. For AMP algorithms tailored to rotational invariance in law, we show that their state evolutions hold over matrix ensembles whose eigenvector bases satisfy only sign and permutation invariances, including sensing matrices composed of subsampled Hadamard or Fourier transforms and diagonal operators. We establish these results via a simplified moment-method proof, reducing AMP universality to the study of products of random matrices and diagonal tensors along a tensor network.

Emerging Technologies in Transportation Systems II

Community Committee Choice Session

Session Chair: Daniel Vignon, New York University, Brooklyn, NY

1 A Metaheuristic Approach for the Capacitated Truck Multi-Drone Pollution Routing Problem with Simultaneous Delivery and Pickup

Arash Alizadeh, Sharan Srinivas, James Noble, University of Missouri, Columbia, MO

This research deals with a new variant of the capacitated pollution routing involving a truck and drone fleet for last-mile parcel delivery and pickup. An adaptive large neighborhood search (ALNS) algorithm with novel destroy and repair operators that employ problem-specific characteristics to explore the search space is proposed. The results from our extensive computational experiments on small and large instances demonstrate the effectiveness of the proposed ALNS algorithm. Furthermore, the proposed variant achieves up to a 40% reduction in logistics costs compared to traditional truck-only logistics system. Finally, several managerial implications are provided based on the sensitivity analysis of key problem parameters.

2 Real-Time Signal and Trajectory Optimization Within Mixed-Autonomy Environments with White Phase

ali Hajbabaie[1], Ramin Niroumand[1], Leila Hajibabai[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, Raleigh, NC

This study uses connected automated vehicles (CAVs) as mobile controllers during a portion of the cycle called the “white” phase. During the white phase, CAVs form platoons of connected human-driven vehicles (CHVs) and navigate them through the intersection through conflicting movements simultaneously. An efficient shooting heuristic is developed to optimize the trajectories of CAVs while the trajectories of CHVs are estimated using a customized car-following model with a given set of signal timing plans in the lower level. The upper level enumerates all the feasible signal timing plans and selects the one with the best objective function to be implemented. In addition, a platooning logic is presented to operate platoons of vehicles containing one or more vehicle groups at a time during white phases to improve the quality of the solutions.

3 Cost-Effective Approaches for the Joint Electric Bus Charger Installation and Fleet Management

Yen-Chu Wu[1], Xiaotong Guo[1], Jinhua Zhao[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: yenchuwu@mit.edu

Many transit agencies across the US are working towards a zero-emission electric bus fleet in order to reduce petroleum use and carbon emissions. To identify the most cost-effective approach for charger installation while best using the purchased electric buses, this study proposes a Mixed Integer Programming (MIP) model based on a generalized multi-commodity network flow problem. The goal is to minimize total expenditure on electric bus procurement and in-garage charger installation while maintaining the current trip schedule and achieving a target percentage of electrified mileage. The results recommend optimal electric bus fleet size, installations of different levels of chargers, as well as efficient in-garage charging schedules.

4 Safety and Liability Under Infrastructure-Assisted Automated Driving

Daniel Vignon[1], Yafeng Yin[2], [1]New York University, New York, NY, [2]University of Michigan, Ann Arbor, MI, Contact: daniel.vignon@nyu.edu

We investigate safety and liability under infrastructure-assisted automated driving. In our model, automakers and infrastructure support service providers (ISSPs) make technology choices which impact both road safety and their exposure to accident risk. We show that, regardless of market structure, automakers and ISSPs fully bear the cost of accidents related to their technology. However, under the Nash game, this feature does not ensure social efficiency. An appropriate liability rule can alleviate that issue. Moreover, despite a shift of liability from customers to producers, the former do not necessarily experience lower ownership costs. The insurance provided by automakers and producers impacts retail prices, potentially nullifying welfare gains from increased safety.

Cliques and Their Relaxations

Community Committee Choice Session

Session Chair: Jack Zhang, 1</sup

1 The K-Core Interdiction Problem

Arlei Silva[1], Samuel Kroger[2], Illya V. Hicks[2], [1]Rice University, Houston, TX, [2]Rice University, Houston, TX, Contact: al110@rice.edu

Paramount to understanding and designing networks is identifying cohesive structures. The k-core - the maximal subgraph such that every vertex has a degree at least k - is one of the prominent ways to identify these structures. In this paper, we study the k-core Interdiction (KCI)} problem in which we try to reduce the size of the k-core by removing some budget b of edges or vertices from the graph. The KCI problem identifies the most crucial connections in a network to preserve the underlying k-core structure. We present the first exact method of solving the vertex and edge-based k-core interdiction problem by constructing an IP formulation. We compare the computational performance of the IP formulation to existing heuristic methods. Finally, we explore two applications epidemic propagation and the robustness of power grids. All code is made available on GitHub.

2 Interdicting Dense Clusters in Networks

Haonan Zhong[1], Foad Mahdavi Pajouh[2], Sergiy Butenko[3], Oleg A. Prokopyev[4], [1]Kunming University of Science and Technology, Kunming, China; [2]Stevens Institute of Technology, Hoboken, NJ, [3]Texas A&M University, College Station, TX, [4]University of Pittsburgh, Pittsburgh, PA, Contact: fmahdav1@stevens.edu

Given a graph with weights on its vertices and blocking costs on its vertices and edges, we aim to find a minimum-cost subset of vertices and edges to block such that the weight of any dense cluster in the interdicted graph is at most equal to some predefined threshold. Dense clusters are modeled using the concept of a quasi-clique. This problem has important applications in settings where we are trying to bound functional “tightly knit” groups of components in adversarial social and communication networks. We address the computational complexity of this problem and develop several exact algorithms for its solution. The computational performance of our exact algorithms is studied on a test bed of randomly-generated and real-life networks.

3 MIP Formulations for Partitioning a Graph into Low-Diameter Clusters

Lucas Silveira[1], Jack Zhang[2], Hamidreza Validi[3], Logan Smith[4], Austin Buchanan[5], Illya V. Hicks[4], [1]Military Institute of Engineering, Rio de Janeiro, Brazil; [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Texas Tech University, Lubbock, TX, [4]Rice University, Houston, TX, [5]Oklahoma State University, Stillwater, OK

In this paper, we study the problem of partitioning the vertices of a graph into s-clubs (the s-clustering problem) from the lens of Operations Research. An s-club is a subset of vertices for which the diameter of its included subgraph is at most s. We propose mixed integer programming (MIP) formulations with length-bounded constraints and compare them with the existing ones theoretically and computationally. We propose approximation algorithms for the s-club partitioning problem. Further, we develop fixing procedures to improve the performance of our MIP formulations. We test our MIP formulations on a large set of benchmark instances. Our computational experiments show the superiority of our approach when s is 2 or 3. Our code and data are available on GitHub.

4 Exact Solution Methods For A Class Of Fractional Mixed-integer Programs

Yehor Blokhin, Texas A&M University, College Station, TX, Contact: blokhin23@tamu.edu

We present a class of fractional knapsack mixed-integer problems with applications in service systems design and facility location problems with congestion. We explore two linearization approaches. The first one is based on Charnes and Cooper transformation. The second method utilizes a piecewise linearization.

Breaking the Chain: Leveraging Operations Research to Control and Mitigate Infectious Outbreaks

Community Committee Choice Session

Session Chair: Hrayer Aprahamian, Texas A&M University, College Station, TX
Session Chair: Su Li, Texas A&M University, College Station, TX

1 An Optimization-Based Framework to Minimize the Spread of Diseases in Social Networks with Heterogeneous Nodes

Su Li, Hrayer Aprahamian, Texas A&M University, College Station, TX, Contact: dclisu@tamu.edu

We present an optimization framework that identifies social separation policies to control the spread of diseases in networks. The framework considers subject-specific risk, social structure, and the economic consequences of restrictions. We first analyze a simplified variation consisting of a single period and a specific social structure to establish key properties and construct a tailored globally-convergent scheme. We extend this scheme to heuristically solve the general model with multiple periods and any social structure. It is evaluated using COVID-19 data and shows significant reductions in disease spread compared to existing algorithms. The optimized policies continue to perform well in realistic settings, emphasizing the importance of considering subject-specific information in policy design and providing tailored data-driven insights.

2 Robust Screening Policies in a Pandemic

Marwan S. Shams Eddin[1,2], Hadi El-Amine[1], Hrayer Aprahamian[3], [1]George Mason University, Fairfax, VA, [2]American Airlines, Euless, TX, [3]Texas A&M University, College Station, TX

Emerging pandemics cause severe strains on the healthcare systems. In this paper, we introduce a testing intervention to control the disease progression. We address several aspects of the problem including, testing inaccuracies, adherence to testing, and dependency between the disease prevalence and testing strategies. We consider uncertainty in the disease dynamics and model via stochastic and robust approaches. We develop Markov-decision process formulations and apply DP algorithms to obtain exact screening policies. We exploit the structure of the problem which enables us to drastically improve the computational time. We consider a simulation-based case study in which we generate different instances of pandemics in a average and antagonistic environments. Our results show that early testing has the potential in drastically reducing total healthcare costs.

3 Vaccine Prioritization in a Social Network Against a Pandemic Outbreak

Yang Zhang[1], Dong Liang[2], Ming Hu[3], [1]University of Kent, Canterbury, United Kingdom; [2]Tsinghua University, Beijing, China; [3]University of Toronto, Minneapolis, MN, Contact: yangzhang.buz@gmail.com

We investigate the vaccination over a social network to curb a pandemic (e.g. COVID-19). Under limited vaccine supply, the planner has to prioritize different social groups in the order of receiving the vaccine. The conventional wisdom suggests a vulnerability-first allocation: the vaccination should begin with those who suffer most from the infection and then reach out to those suffering less. However, given the contagious nature of the disease, the planner may also consider the role of different social groups in transmitting the virus (characterized by their centrality in the social network). We show that the optimal vaccination policy combines *vulnerability* and *transmissivity*, and follows the *Bonacich priority* which linearly depends on a variant of Bonacich centrality of the social network. We calibrate our model using NYC data.

4 Covid-19: Agent-Based Simulation-Optimization to Vaccine Center Location Vaccine Allocation Problem

Xuecheng Yin[1], Esra Buyuktahtakin Toy[2], Sabah Bushaj[3], Yue Yuan[4], [1]Yale University, New Haven, CT, [2]Virginia Tech, Blacksburgh, VA, [3]State University of New York at Plattsburgh, Plattsburgh, NY, [4]Altfest Personal Wealth Managemen, New York, NY, Contact: sunnysunnyyuan@qq.com

This paper presents an agent-based simulation-optimization modeling and algorithmic framework to determine the optimal vaccine center location and vaccine allocation strategies under budget constraints during an epidemic outbreak. Both simulation and optimization models incorporate population health dynamics, while their integrated utilization focuses on the COVID19 vaccine allocation challenges. We calibrate, validate, and test our simulation-optimization vaccine allocation model using the COVID-19 data and vaccine distribution case study in New Jersey. The integrated epidemiological MIP and agent based approach balances the proportion of vaccines distributed to a county with that county's population in proportion to all counties under different budgets.

5 Quantifying and Realizing the Benefits of Targeting for Pandemic Response

Sergio Camelo[1], Dragos Florin Ciocan[2], Dan Andrei Iancu[1], Xavier Warnes[1], Spyros Zoumpoulis[2], [1]Stanford University, Stanford, CA, [2]INSEAD, Fontainebleau, France

To respond to pandemics such as COVID-19, policy makers have relied on interventions that target specific population groups or activities. Rigorously quantifying the benefits of targeting is critical for effective and equitable pandemic control. We propose a flexible framework that leverages publicly available data and a novel optimization algorithm to compute optimized interventions that can target two dimensions of heterogeneity: age groups and the specific activities that individuals normally engage in. We showcase a complete implementation focused on the Ile-de-France region of France and use this case study to quantify the benefits of dual targeting and to propose practically implementable policies.

DEIC/MIF Panel: Broad and DEI-Specific Funding Opportunities at NSF

Panel Session

1 Moderator

Diana Gineth Ramirez-Rios, University at Buffalo, Buffalo, NY

This panel aims at bringing together NSF program managers and faculty getting funds from NSF to discuss broad funding opportunities at NSF and specific initiatives promoted across Diversity, Equity, and Inclusion. According to NSF's latest report in "Diversity and STEM," the representation of minority groups in STEM employment and Science and Engineering education in the U.S. is still quite low. The panel will discuss their experience with DEI efforts within the different NSF programs, the specific DEI funding opportunities, and the ways to become more active in DEI within the different research fields.

Session Chair: Clara Novoa, Texas State University, San Marcos, TX

Session Chair: Sofía Pérez-Guzmán, Georgia Institute of Technology, Atlanta, GA

1 Food Bank Responsiveness During Disasters

Faith Idoko[1], Chrysafis Vogiatzis[2], Lauren Berrings Davis[3], [1]North Carolina Agricultural and Technical State University, Greensboro, NC, [2]University of Illinois at Urbana-Champaign, Urbana-Champaign, IL, [3]North Carolina A&T State University, Greensboro, NC, Contact: faithidoko13@gmail.com

The unpredictable nature of disasters often leads to disruptions in food supply which affects the role of food banks. The increase in food insecure people due to a disaster causes a surge in demand to food banks. Prepositioning relief items to mitigate the effect of disasters has proven to be viable. In this work, we incorporate this concept in building a resilient network system for a non-profit organization. The state of the network, such as road and facility availability post disaster is crucial in managing the flow within the network. Pop-up delivery options such as mobile pantries or self-accessible food lockers are also considered to strengthen the relief response. A mixed integer linear programming model is used to propose a robust network for food banks while accounting for the distribution of food items.

2 A Good Teacher is Worth $420000. What Would It Cost Us, Though?

Hemanshu Das[1], Edward H. Kaplan[1], Edieal J. Pinker[2], [1]Yale University, New Haven, CT, [2]Yale School of Management, New Haven, CT, Contact: hemanshu.das@yale.edu

The study aims to examine the cost-benefit analysis of improving teacher mix in K-12 education through teacher evaluation policies. Through a flow model, we determined the relationship between teacher retention (due to evaluation policies) and changes in the required school budget. We connect our model to the existing literature in education policy to estimate the societal gains in terms

of incremental student lifetime incomes. Using parameters from two exemplars of teacher evaluation programs in DC and Chicago. Our findings suggest that while the cost of improving the teacher mix may be substantial, the long-term benefits in terms of increased student earnings justify the investment. The study highlights the importance of considering both the financial and educational impacts of policies aimed at improving teacher quality.

3 Does Leader Disability Status Influence the Operational Performance of Teams with Workers with Disabilities? an Empirical Study in the Apparel Industry

Dustin Cole[1], Sriram Narayanan[2], Shawnee Vickery[2], [1]Auburn University, Auburn, AL, [2]Michigan State University, East Lansing, MI

This research examines the impact of leader disability status on the operational performance of teams that have workers with disabilities. We hypothesize a beneficial moderating effect of leader-worker disability status similarity on team performance. Hypotheses are tested using Prais-Winsten regression applied to micro-data gathered over multiple years from an apparel manufacturing facility. The results show that the presence of a line leader with a disability has a beneficial impact on workgroup performance, measured in labor hours and operator caused defects to produce a garment, when there is an increasing number of workers with a disability. The quantitative analysis is complemented with semi-structured interviews of 50 individuals across three large organizations that employ individuals with disabilities to explore possible mechanisms.

4 Forming a Humanitarian Coalition when Time is Short

Iman Parsa[1], Mahyar Eftekhar[2], Scott Webster[2], Luk N. Van Wassenhove[3], [1]INSEAD, Fontainebleau, France; [2]Arizona State University, Tempe, AZ, [3]INSEAD, Fontainebleau Cedex, France. Contact: iman.parsa@insead.edu

Creating a higher social impact in humanitarian operations requires coordination among actors, as emphasized in the UN sustainable development goals. Yet, a lack of well-coordinated response remains a problem. We develop a sylized non-cooperative game theoretical model to analyze horizontal coordination among humanitarian organizations in the immediate response to a large-scale sudden onset disaster. Our analysis highlights the important role of time pressure and the structural barriers to higher levels of coordination.

5 Graph Partitioning & Assignment to Heterogeneous Resources: Applications in Disaster Debris Collection

Buse Eylul Oruc[1], Pinar Keskinocak[2], Mohit Singh[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: buseeyluloruc@gmail.com

Disaster debris collection operations require municipalities to partition the affected area into zones and assign them to multiple contractors of varying capacities. Collecting debris from the affected area as quickly as possible is desirable, while contractors' capacities affect the collection time (i.e., resource-dependent processing time). Additionally, the assigned zones must be contiguous for contractors to operate effectively. We formulate this problem as integer and mixed-integer programs, introduce approximation algorithms with provable bounds for some cases, and provide several heuristics. We present the results of an extensive computational study, including a case study focusing on a realistic hurricane scenario for Florida.

1 Dynamic Budget Allocation for Public Health Procurement: A Multi-Product Inventory Model with Partial Backlogging

Iva Rashkova[1], Jérémie Gallien[2], [1]Washington University in St Louis, St Louis, MO, [2]London Business School, London, United Kingdom

Motivated by Global Fund grant recipients, we study the periodic inventory procurement of multiple health products subject to a common uncertain fund disbursement schedule. The objective is to minimize expected health costs in the presence of random demand, procurement lead times and inventory dynamics driven by alternative distribution channels. We derive near-optimal heuristics for the dynamic allocation of funds and characterize their theoretical and computational performance. We illustrate how to estimate the model parameters and evaluate the benefit of modifying grants' funding patterns.

2 Leapfrogging for Last-Mile Delivery in Health Care: Drone Delivery for Blood Products in Rwanda

Harriet Jeon[1], Claudio Lucarelli[1], Jean Baptiste Mazarati[2], Donatien Ngabo[3], Hummy Song[1], [1]The Wharton School, University of Pennsylvania, Philadelphia, PA, [2]University of Global Health Equity, Kigali, Rwanda; [3]Ministry of Health, Kigali, Rwanda

The access to and quality of health care, especially in hard-to-reach areas, are challenges for many countries. Traditional solutions improve geographic connectivity through incremental and costly infrastructure investments. Radical technological innovations may allow leapfrogging to directly improve access to quality medical care. Using data from Rwandan public hospitals, we examine whether adopting drone delivery technology improves operational and health outcomes. We find that adopting drone delivery leads to a substantial reduction in on-hand inventory, wastage, and inpatient mortality for patients with post-partum hemorrhage (PPH). Additional analyses suggest that the drone delivery system exhibits a leapfrogging effect.

3 Food Subsidies at the Base-of-the-Pyramid: Take-Up, Substitution Effects and Nutrition

Alp Sungu, Ali Aouad, Kamalini Ramdas, London Business School, London, United Kingdom. Contact: asungu@london.edu

We investigate the impact of consumer food subsidy programs on poor consumers' nutrient purchases and data-driven pathways to improve the efficacy of such programs. We conduct an experiment in an urban settlement in Mumbai, India. First, we open a subsidy store to mimic governments' food subsidy programs. Second, we equip local grocery stores with point of sale scanner devices and start a loyalty card program to track individuals' shopping baskets. By randomly assigning households to a subsidy program, we examine how government-like subsidies affect food shopping behaviour. Next, we exogenously vary the subsidized food. Based on estimates of the take-up rates, we uncover a tradeoff between the nutrient richness of different staples and their attractiveness to customers.

4 Planning Bike Lanes with Data: Ridership, Congestion, and Path Selection

Sheng Liu[1], Auyon Siddiq[2], Jingwei Zhang[3], [1]University of Toronto, Toronto, ON, Canada; [2]University of California-Los Angrles, Los Angeles, CA, [3]UCLA, Los Angeles, CA, Contact: jingwei.zhang.phd@anderson.ucla.edu

We study the bike lane planning problem considering its conflicting effects in reducing and increasing traffic congestion. In an extensive case study in Chicago, we estimate adding 25 miles of prescribed bike lanes can lift cycling mode share from 3.6% to 6.1%, with at most an 9.4% increase in driving times.

5 Treatment Planning of Victims with Heterogeneous Time-Sensitivities in Mass Casualty Incidents

Yunting Shi[1], Nan Liu[2], Guohua Wan[1], [1]Shanghai Jiao Tong University, Shanghai, China; [2]Boston College, Chestnut Hill, MA, Contact: sherryshi@sjtu.edu.cn

Mass casualty incidents (MCIs) lead to a sudden jump in patient demand, making it inevitable to ration medical resources. Informed by a unique timestamps dataset collected during a large-scale earthquake, we develop data-driven approaches to aid treatment planning for MCIs . A distinguishing feature of our modeling framework is to simultaneously consider victim health deterioration and wait-dependent service times in making decisions. We identify conditions under which victims with a less critical initial condition have higher or lower priority than their counterparts in an optimal schedule—the priority order depends on victim deterioration trajectories and the resource (i.e., treatment time) availability.

Social Media Analytics in E-commerce and Digital Platforms

Community Committee Choice Session

Session Chair: Keumseok Kang, KAIST

Session Chair: JaeHong Park, Kyunghee University, Seoul, Korea, Republic of

1 Should be a First Mover, Fast Follower, or Just Stay?: Re-Categorization of Digital Products on Online Platforms

Mingi Song, Gunwoong Lee, Korea University, Seoul, Korea, Republic of. Contact: smgnc3@korea.ac.kr

Product categorization has been considered to reduce search costs for buyers and enhance the discoverability of a product for sellers. Thus, many e-commerce platforms often alter product categories to improve the matching between buyers and sellers. This study examines how digital goods suppliers can leverage platform-driven product re-categorizations to succeed in mobile app software markets. In November 2015, a leading mobile app store market introduced a new category that allowed app developers to move to this new category. Using a quasi-experiment design, we find that migrated apps exhibited improved sales compared to non-movers, and early-movers showed higher performances than those who followed. Our key findings provide important implications for the product search literature and offer practical insights for online platform participants and designers.

2 Customer Choice in Group-Buying: Empirical Study with Discrete Choice

YongJun Kwon, JaeHong Park, Kyung Hee University, Seoul, Korea, Republic of. Contact: yjun209@khu.ac.kr

The group-buying is known as a business activity that a group of customers purchase the same products or services at a discounted price at platforms. To get discounts, customers have to meet the predefined number of customers with a limited time. In particular, social e-commerce platforms have now adopted another form of group-buying strategy: group-buying with just two people to facilitate the group-buying deals. Since the deal can only be completed when the second participant joins (here, we call her co-purchaser), the participation of co-purchasers is essential to complete a deal on group-buying platforms. Therefore, the success of the deal is determined by the customers' choice to be a co-purchaser. To understand the customers' choice patterns, we use a discrete choice model to analyze the factors influencing consumers' decisions to become co-purchasers.

3 Population Level Analysis of Urban Social Media Data

Ann-Kathrin Meyer, Tobias Brandt, University of Münster, Münster, Germany. Contact: ann-kathrin.meyer@ercis.uni-muenster.de

Large-scale urban social media data can provide substantial insights into the real-time development of cities around the globe, illuminating phenomena such as gentrification, urban decay, and resilience to major adverse events. We explore methodological challenges associated with the analysis of this type of data, leveraging a data set of 150 million tweets from various major cities before, during, and after the Covid-19 pandemic. We identify four critical challenges potentially biasing analyses if not sufficiently considered: event-induced population shift, bots, between-city variation in baselines, and issues surrounding the collection and persistence of social media data. We provide effect estimates and suggest solution approaches.

4 Self-disclosure in Online Social Networks: An Empirical Study of Location-based Check-ins and Health-conscious Impression Management

Mahyar Sharif Vaghefi[1], Derek L. Nazareth[2], Sridhar P. Nerur[3], Kay-Yut Chen[4], [1]University of Texas at Arlington, Arlington, TX, [2]University of Wisconsin, Milwaukee, WI, [3]University of Texas-Arlington, Arlington, TX, [4]University of Texas at Arlington, Mansfield, TX, Contact: mahyar.sharifvaghefi@uta.edu

This study investigates self-disclosure dynamics and impression management in location-based online social networks. Using theories of social and hyperpersonal information processing, we develop a model to understand how peer influence, geographical proximity, and exposure to brand content affect self-disclosure. Using Twitter and Foursquare location-based data, we find that friends' health-related disclosures and their proximity significantly impact self-disclosure. Individuals tend to avoid unhealthy

impressions if they are surrounded by health-conscious peers. The influence of promotional content from health-related brands and social media pages is also explored. Our research expands our knowledge of online impression management, providing key insights with practical and theoretical applications.

5 The Impact of Network Neutrality Violation on the Streaming Platform Ecosystem: Evidence from Twitch TV

Dongwon Shin, Gunwoong Lee, Korea University, Seoul, Korea, Republic of. Contact: petter1286@korea.ac.kr

The widespread use of media streaming services has resulted in a surge in network traffic, triggering debates on network usage fees between internet service providers (ISPs) and content providers (CPs). As a response to network usage fees imposed by ISPs, CPs can opt to provide discriminatory service quality to mitigate costs. In 2022, a leading Korean ISP charged discriminatory fees to Twitch TV, due to its excessive network traffic. In response, Twitch implemented a service quality reduction policy for Korean viewers. Our study exploits this event and examines the impact of the policy on the streaming platform ecosystem. Our results indicate that the implementation of the policy led to a remarkable decline in the number of viewers. This study contributes to the literature on network neutrality violation by offering empirical evidence.

Introduction to Manufacturing Systems Integration Program at NSF

Panel Session

Session Chair: Janis Terpenny, Penn State University, University Park, PA

1 New NSF Program Focused on Digitalization, Integration and Smart/Intelligent Manufacturing

Janis Terpenny, National Science Foundation, Alexandria, VA

This session provides participants with the opportunity to learn about the newest core program in the NSF CMMI Division: Manufacturing Systems Integration (MSI). The MSI program focuses on fundamental research addressing the opportunities and challenges digital technologies present for the next industrial revolution, with particular emphasis on the digital integration of design and manufacturing within the larger life cycle ecosystem. MSI proposals might address underlying principles and advances such as: :

- Digital representation, protocols, and/or processes for integration and collaboration in manufacturing systems (machines and/or humans)
- Intelligent self-organizing production systems

- Ease of use, interoperability and seamless integration of technologies, machines, and humans
- Service-oriented architectures and systems
- Data sets that are compatible and usable across platforms
- Reliable and secure communications within and across the manufacturing value chain
- Integration of distributed manufacturing systems across time and space, including incorporating both legacy and leading-edge equipment and technologies
- Methods for assessing the impact and value of externalities throughout the life cycle within the digital environment

1 Feature Engineering Versus Green AI: Applications of Machine Learning Models to Support Analysis and Decisions on This Trade-Off

Marcos Machado[1], Amin Asadi[1], Renato W. de Souza[2], [1]University of Twente, Enschede, Netherlands; [2]IFCE, Boa Viagem, Brazil. Contact: m.r.machado@utwente.nl

This paper contrasts the processing time and accuracy of individual and hybrid Machine Learning (ML) models obtained when predicting customer loyalty in financial settings. We use frameworks that account for feature engineering and green AI philosophy aspects separately within the individual and hybrid proposed approaches. Our findings indicate that using a lower number of features results in a slightly smaller accuracy than models incorporating features. Besides, we explicitly illustrate the tradeoff between the higher accuracy and computational time of the hybrid ML models against the lower accuracy and computational time of the individual models when assessing customers' loyalty levels. Thus, our results provide managers with information regarding the model to be deployed based on their firms' specifications.

2 Deep Learning-Based Sentiment Analysis in Online Retail Stores

Roohollah Jahanmahin[1], Sara Masoud[2], [1]wayne state university, DETROIT, MI, [2]Wayne State University, Detroit, MI, Contact: hi3334@wayne.edu

This research focuses on the importance of sentiment analysis in online retail stores. Machine learning approaches have been used for sentiment analysis, but with the advancement of deep learning approaches, significant improvements have been made in text classification and sentiment analysis. The study evaluates and compares five machine learning classification models and three deep neural networks models such as a convolutional neural network, and bi-directional long short-term memory neural network with Bert-based embedding layers and Fasttext. The results show that deep learning models outperform other machine learning models in classifying sentiments in three classes of positive, neutral, and negative.

3 A Data-Driven Optimization Framework for Automating Product Design

Jongmin Han, Seokho Kang, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: hjm9702@gmail.com

Manual product design can be time-consuming and labor-intensive, often requiring repetitive trial-and-error experiments. We present a data-driven optimization framework for automating the design of the target product. The framework formulates an optimization problem where the decision variables are product design parameters, the constraints are the control ranges of the parameters, and the objective function is the product performance determined by the parameters. The objective function is approximated by a neural network trained using data collected from previous experiments. The optimal design parameters are then derived by solving the optimization problem. The proposed framework can significantly reduce the time and cost required for the product development process. A case study is presented to demonstrate the effectiveness of the proposed framework.

4 Product Misrepresentation in Dietary Supplements - Sentiment Analysis of Customer Reviews

Stanislav Mamonov, Liam Horton, Ben Besthof, Montclair State University, Montclair, NJ, Contact: stanislav.mamonov@montclair.edu

Dietary supplements are defined as products that supplement diet and provide nutrients that may be lacking or insufficient in a person's regular diet. Dietary supplements are considered food products and they are exempt from FDA review. Regulatory intervention can occur post-market introduction. To assess the substance of dietary supplement consumer complaints, we collect a dataset of the bestselling dietary supplements on a leading e-commerce platform and we develop sentiment analysis models for each product. We leverage sentiment analysis models to identify linguistic cues associated with negative sentiment. Analysis of linguistic cues reveals that product misrepresentation and adverse health conditions account for the vast majority of negative reviews. We discuss the implication of our results for market participants, including regulators.

5 Unfolding Tweedie Regression Model for Insurance Premium Pricing: A Diagnostic Tool Leading to Actionable Insights

ZEWEI LIN[1], Dungang Liu[1], Daniel Bauer[2], [1]University of Cincinnati, Cincinnati, OH, [2]University of Wisconsin-Madison, Madison, WI, Contact: linzw@mail.uc.edu

The viability of an insurance company depends on its ability to accurately estimate the cost of the financial protection. Tweedie compound Poisson regression model is used to capture the loss in insurance. However, the model diagnostic results have not been widely discussed in the literature. Traditional goodness-of-fit measurement focuses on prediction performance. They do not reveal why the working model is good/bad and how to make adjustments to improve the model. To this end, we propose a new diagnostic framework for Tweedie models. Through analysis of real data sets, we demonstrate that our diagnostic tools can generate insights on 1. What components of the Tweedie model may be misspecified; and 2. How to refine the model or segment data to achieve a better fit. It can help lower the data literacy requirement and increase the model transparency for policy maker.

Structural Learning for Heterogeneous Data

Community Committee Choice Session

Session Chair: Chen Zhang, Tsinghua University, Japan
Session Chair: Hao Yan, Arizona State University, Tempe, AZ
Session Chair: Ziyue Li, University of Cologne, Kowloon, Hong Kong

1 Multimodal Regression and Mode Recognition via an Integrated Deep Neural Network

Di Wang, Shanghai Jiao Tong University

Existing deep learning approaches in manufacturing are often used to directly predict the variables of interest (VoI) such as the system status from a set of sensor measurements by supervised learning. However, in various complex manufacturing systems, components are operated under multiple modes that are not well known beforehand. This study develops a novel deep learning method for multimodal regression and mode recognition to predict the VoI under multiple modes and recognize the specific mode of a component from its sensor measurements. Specifically, we establish a deep neural network (DNN)-based regression- and classification-integrated framework. We innovatively develop an Expectation-Maximum (EM)-based backpropagation algorithm for model training, where the modes of components are set as latent variables.

2 Bayesian Multi-Objective Optimization for Stochastic Simulations

Mei Han, Jiangchen Li, Nanjing University of Aeronautics and Astronautics, Nanjing, China. Contact: meihan2@nuaa.edu.cn

Multi-objective stochastic simulation optimization is important in designing engineering systems. To identify optimal solutions via simulations, Bayesian optimization has been popular in machine learning. However, existing studies are limited and can give undesired performances. In this work, we propose a novel framework for Bayesian optimization of multiple stochastic responses. Stochastic kriging metamodels are constructed considering heterogeneous noise. Quantiles of metamodels are employed to define the Pareto dominance. Acquisition functions are then proposed by integrating the hypervolume-based and probability-of-improvement-based acquisition functions with typical acquisition functions from stochastic optimization. This not only enhances the convergence and diversity of non-dominated solutions but also handles heterogeneous noise.

3 Multi-Size Industrial Anomaly Segmentation Using Incomplete Image
Hao Xu[1], Juan Du[1,2], Andi Wang[3], [1]The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, China; [2]The Hong Kong University of Science and Technology, HongKong, China; [3]Arizona State University, Mesa, AZ
Unsupervised anomaly detection is essential for product inspection and root cause analysis in industrial manufacturing processes. However, due to the randomness ofthe industrial manufacturing environment and products with complex representations. Existing approaches are easily affected by unpredictable or multi-size anomalies. To tackle this problem, we propose anomaly segmentation method by only inputting normal information of the original image. We use the structure of the vision transformer to reconstruct a normal prior image only using the normal patches of the image. Then the anomaly segmentation result is obtained by comparing the normal prior image with the original image. We demonstrate the superiority of our approach through relevant simulation experiments and case studies. relevant parameters affecting the model performance are also discussed.

1 Content Creator Versus Brand Advertiser? the Effect of Inserting Advertisements in Videos on Influencers
Tengteng Ma[1], Yingda Lu[2], Yuheng Hu[2], Xi Chen[3], Yuxin Chen[4], [1]University of Illinois at Chicago, Chicago, IL, [2]University of Illinois-Chicago, Chicago, IL, [3]Zhejiang University, Zhejiang, China; [4]New York University - Shanghai, Shanghai, China
Influencer advertising is important in online marketing due to the rise of social influencers and their impact., but it's unclear how inserted ads affect the influencers themselves. We studied how inserted ads in videos impact an influencer's reputation using live comment sentiment and video feedback. Our result suggests that inserting advertisements have a negative impact on both instantaneous and longer-term viewer engagement; advertisements with influencers' face showing moderate the negative effect of advertisements on viewers' instantaneous response, while the different impact between advertisements with/out influencers showing their faces is not significant in the longer term. Our study provides insights into how influencer endorsement can be effectively moderated to maintain viewer engagement and protect an influencer's reputation.

2 A Machine Learning-Based Framework Towards Assessment of Labelers' Biases
Wanxue Dong[1], Maria De-Arteaga[2], Maytal Saar-Tsechansky[3], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [2]University of Texas at Austin, Austin, TX, [3]University of Texas at Austin, Austin, TX, Contact: wanxue.dong@utexas.edu
Across key domains, human expert assessments and crowd annotations are essential for labeling data to train machine learning models, and constitute a pathway through which biases are learned by algorithms. In this research, we propose a machine learning-based framework to produce a relative assessment of the extent of bias contained in labels produced by different sources, when gold standard labels are costly or difficult to acquire and thus available for only a small set of instances. We provide theoretical guarantees and show empirically that our method outperforms the commonly used alternative to assess biases reflected in human assessments. The proposed approach lays the groundwork towards increased transparency in labelers' biases and offers an important building block towards mitigating algorithmic bias stemming from biased labels.

3 Responding to Supply Chain Uncertainty: Evidence from a Cutting-Edge NLP Technique-Based Measure
J. Frank Li[1], Wenting Li[2], Xuan Wei[3], Wenjian Xu[4], [1]Stanford University, Palo Alto, CA, [2]Lund University, Lund, Sweden; [3]University of Arizona, Tucson, AZ, [4]Shanghai Jiaotong University, Shanghai, China. Contact: jfli@stanford.edu
Managing supply chain uncertainty is essential for firms' production and operations strategies. Recently, the concern about supply chain has intensified due to massive disruptions caused by global pandemics, trade war, political unrest, and natural disasters, etc. Relying on cutting-edge NLP techniques (prompt-based zero-shot learning), we develop a new index to quantify supply chain uncertainty from corporate 10-K/Q filings. Our measure tracks intuitive variations over time and correlates with

other well-known uncertainty measures. Using firm-level data, we find that supply chain uncertainty is associated with higher human capital skill demand related to supply chain management, which facilitates a smoother navigation through uncertainty shocks.

4 Beyond Star Ratings: A Deep Learning Investigation of Online Doctor Reviews and Service Quality

Bin Zhang[1], Yongcheng Zhan[2], Jiang Wu[3], Haijing Hao[4], [1]Texas A&M University, College Station, TX, [2]California Polytechnic State University, San Luis Obispo, CA, [3]Wuhan University, Wuhan, China; [4]Bentley University, Waltham, MA, Contact: binzhang@tamu.edu

This study introduces a deep learning method for text mining online doctor reviews to extract sentiment scores, which are used to estimate a healthcare service quality model investigating the impact of online doctor reviews on consultation demand. Using data from China's largest online health platforms, our model demonstrates significant effects of sentiment scores on online consultation demand. The developed algorithm outperforms four common text mining methods and can be applied to various online platforms. Our results identify factors influencing healthcare service quality and consultation demand, guiding healthcare professionals to improve their services.

1 Machine Learning Measures of Social Proximity for Business Partnership Management

Ruiyun Xu, Miami University, Oxford, OH

We develop a new and generalized measure of social proximity, which denotes the closeness between two organizations or individuals in terms of social relations or sociodemographic attributes, using graph embedding approach. We assess the proposed measure across three distinct settings in the venture capital context. Our empirical findings reveal that this machine learning-based measure not only correlates with existing measures, but also offers two novel features: (1) delivering a more granular and precise evaluation of social proximity through simultaneous consideration of diverse connectivity patterns between actors, and (2) demonstrating flexibility in quantifying social proximity within a single relation or across multiple relations. This measure also exhibits superior predictive power on the investment decisions made by venture capitalists.

2 CEO Political Orientation And Software Innovation

Inmung Choi, Texas Tech University, Lubbock, TX, Contact: Inmyung.Choi@ttu.edu

This study conceptualizes CEO political orientation and examines how CEOs' values and beliefs reflected on CEO political orientation are associated with their firms' software innovation, drawing upon upper echelon theory. Specifically, we suggest that liberal CEOs are more likely to support software innovation because they are more open to newness and changes compared to conservative CEOs. Then, by considering CEO political orientation and top management team (TMT) political orientation together, we find that liberal CEOs' tendency to spur software innovation is more pronounced when they work with liberal top managers than conservative top managers. Our findings underscore the need to consider CEO political orientation as a critical characteristic of CEOs in IS research for examining its influence on IT-related strategic decision makings.

3 Leveraging Memory Cues on a Healthcare Crowdsourcing Platform for Engaging Crowds and Experts: An NLP Approach

Yiwen Gao[1], Sezgin Ayabakan[2], Sunil Wattal[2], [1]Colorado State University, Fort Collins, CO, [2]Temple University, Philadelphia, PA

Online healthcare crowdsourcing platform involves two types of participants: experts with medical field-related training and crowds with similar disease experiences. However, there is a lack of understanding about how different types of participants, i.e., crowds and experts, contribute and the factors leading to their engagement on healthcare crowdsourcing platforms. In this research, we examine (1) the differential impact of the participation levels of experts and crowds on case solutions and (2) the contextual communication factors, i.e., structural and emotional memory cues, leading to their participation in crowdsourcing platforms. By analyzing data from CrowdMed, this study seeks to shed light on the roles of experts and crowds in online healthcare crowdsourcing platforms and explain the differences between them using the episodic memory perspective.

4 The Role of AI Assistants in Livestream Selling: Evidence from a Randomized Field Experiment

Lingli Wang[1], Yumei He[2], Ni Huang[3], De Liu[4], Xunhua Guo[5], Yan Sun[6], Guoqing Chen[5], [1]Beijing University of Posts and Telecommunications, Beijing, China; [2]Tulane University, New Orleans, LA, [3]University of Miami, Gilbert, AZ, [4]University of Minnesota, Minneapolis, MN, [5]Tsinghua University, Beijing, China; [6]Alibaba Damo Academy, Hangzhou, China. Contact: yhe17@tulane.edu

Live-stream selling transforms online shopping, allowing streamers to present products while interacting with consumers. In collaboration with Alibaba, our study addresses how livestream selling platforms mitigate the tension between streamers' constrained service capacity and individual service demands with algorithm-based assistants (termed "AI assistants"). By analyzing data from 132,199 consumers, we find that the introduction of the AI assistant increases sales by 2.61% and reduces product returns by 62.86%. The AI assistant extends awareness and consideration stages, improves probability of placing an order in the evaluation stage, and reduces the likelihood of product return. Further, interacting with the AI assistant reduces consumers' expressions of affection and positive emotions, which we claim as mechanism.

1 Financial Inclusion and Comparative Efficiency Across Lenders in Credit Scoring: The Role of AI

Yidi Liu[1], Xin Li[2], Zhiqiang (Eric) Zheng[3], [1]The Chinese University of Hong Kong, Shenzhen (CUHK-Shenzhen), Shenzhen, China; [2]City University of Hong Kong, Kowloon Tong, Hong Kong; [3]University of Texas at Dallas, Richardson, TX, Contact: Yidi.Liu.PhD@gmail.com

Artificial Intelligence (AI) has proven to have remarkable credit-scoring capabilities in assessing borrowers' creditworthiness, enabling efficient credit underwriting and precise credit score identification. However, in practice, conservative lending practices and inadequate use of AI in consumer lending often result in the financial exclusion of disadvantaged groups, such as females, low-income households, rural populations, and youth. This research aims to examine the effects of AI-powered credit scoring on financial inclusion, particularly among underprivileged populations, while also considering the efficiency of credit risk control across multiple lenders. By providing cross-lender evidence, this study sheds light on the potential of AI to promote greater financial inclusiveness while maintaining efficiency in lending practices.

2 Proof-Of-Merit: Harnessing the Computing Power Used by Blockchain Consensus Mechanisms for Complex Transaction Generation

Haozhao Zhang[1], Zhe Zhang[2], Zhiqiang (Eric) Zheng[3], Varghese S. Jacob[4], [1]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]University of Texas Dallas, Irvine, CA, [3]University of Texas at Dallas, Richardson, TX, [4]University of Texas-Dallas, Richardson, TX

We propose a new blockchain consensus mechanism that integrates transaction generation with transaction recording, wherein the transaction to be recorded needs to be first generated by solving a complex problem. We call it the Proof-of-Merit (PoM) mechanism - this approach decentralizes the transaction-generation process and selects proposed solutions to the problem based on their merit. We illustrate the PoM mechanism in the context of ridesharing, where a group of solvers provide solutions to the problem of matching riders with drivers. Moreover, we define two objectives - efficiency and equity - to evaluate PoM. We introduce a parameter called the Decentralized Control Parameter (DCP) that governs the intrinsic tradeoffs between efficiency and equity. We demonstrate PoM's as well as DCP performance and nuanced properties using agent-based simulation.

3 How Free Market Entry Affects Creation and Engagement: Evidence from Non-Fungible Tokens

Ioannis Filippos Kanellopoulos[1], Dominik Gutt[1], Murat Tunc[2], Ting Li[1], [1]Erasmus University Rotterdam, Rotterdam, Netherlands; [2]Tilburg University, Tilburg, Netherlands. Contact: kanellopoulos@rsm.nl

Market entry costs present a threat for online marketplaces that wish to attract new users. In this work, we use data from an NFT marketplace to investigate how a new policy to deal with these costs affects the generated content and the engagement with that content. Studying creation, we find that the policy gives rise to a creation-effort trade-off, as creators introduce more work in the market but exert less effort when creating it. Studying engagement, we find that it decreases, while most affected are the creators whose engagement before the new policy was close to the median range. We also find that this decrease is driven by

effort and attention, while a larger follower count does not shield creators from this decrease. Moreover, we find no evidence that the reduced costs are passed to the first-time buyers. Finally, we discuss our contributions to the literature and management.

4 Market Punishment of Strategic Generosity: An Empirical Examination of NFT Charity Auctions

Chen Liang[1], Murat M. Tunc[2], Gordon Burtch[3], [1]University of Connecticut, Storrs, CT, [2]Tilburg University, Tilburg, Netherlands; [3]Boston University, Boston, MA, Contact: m.m.tunc@tilburguniversity.edu

NFT charity auctions, which involve the sale of artistic works as non-fungible tokens with proceeds donated to a philanthropic cause, have been an important development in crypto donations. Due to the potential for rapid increases in the value of charity NFTs, donors may be perceived as motivated by financial incentives. We explore how social image may translate into quantifiable economic penalties for donors in the context of a large NFT charity auction. We examine the consequences of charity NFT purchase and subsequent relisting, finding that donors who engage in such behavior experience a systematic penalty in terms of the prices in the later sale of other NFTs in their portfolio. Moreover, we demonstrate that these effects accrue to donors who re-listed their charity NFTs for sale shortly after purchase, and to those who are more socially embedded in the NFT community.

Machine Learning and Stochstic Control

Community Committee Choice Session

Session Chair: Xianhua Peng, Peking University, Shenzhen, China

1 Reinforcement Learning for Continuous-Time Optimal Execution: Actor-Critic Algorithm and Error Analysis

Boyu Wang, Xuefeng Gao, Lingfei Li, Chinese University of Hong Kong, Hong Kong SAR, China

We propose an actor-critic RL algorithm for the optimal execution problem. We consider the Almgren-Chriss model in continuous time and formulate a relaxed control problem for execution under an entropy regularized mean-quadratic variation objective. We obtain in closed form the optimal value function and the optimal feedback policy, which is Gaussian. We then use these results to parametrize our value function and control policy. In addition to policy evaluation and policy gradient update, we introduce a recalibration step which turns out to be critical for convergence. We develop a finite-time error analysis of our algorithm and show that it converges linearly. We test our algorithm in three different types of market simulators. Empirical results demonstrate the advantages of our algorithm over the classical control method and a deep learning based RL algorithm.

2 Dynamic Portfolio Selection and Asset Pricing Under Neo-Additive Probability Weighting

Xuedong He[1], Yu Sun[2], [1]The Chinese University of Hong Kong, Shatin, MN, Hong Kong; [2]The Hong Kong Polytechnic University, Kowloon, Hong Kong. Contact: yu-hkpolyu.sun@polyu.edu.hk

We study a dynamic portfolio selection problem in which an agent trades a stock and a risk-free asset with the objective of maximizing the rank-dependent utility of her wealth at the end of the investment horizon. Due to time inconsistency, we consider three types of agents, pre-committed, sophisticated, and naive agents, who differ from each other in whether they are aware of the time inconsistency and whether they have self-control. Assuming a neo-additive probability weighting function, we solve the strategies of these agents. We find that the pre-committed agent takes a loss-exit strategy, leading to a positively skewed wealth in the end. We also study equilibrium asset pricing and find that with pre-committed agents, the stock return exhibits a reversal effect, and the initial stock price is lower than in the case when the market consists of sophisticated agents only.

3 Reinforcement Learning for Financial Index Tracking

Xianhua Peng[1], Chenyin Gong[2], Xuedong He[3], [1]Peking University, Shenzhen, China; [2]Hong Kong University of Science and Technology, Hong Kong, China; [3]The Chinese University of Hong Kong, Shatin, MN, Hong Kong

We propose a novel reinforcement learning based approach for financial index tracking under both return-based tracking error and value-based tracking error. The approach better captures the joint market dynamics of a large number of stocks through learning from a much longer time period of data than existing approaches. We also propose to solve the portfolio rebalancing equation using a Banach fixed point iteration, which allows to accurately take into account the transaction cost specified as nonlinear functions of transaction volume that is used in practice. To effectively train the reinforcement learning agent, we develop a training strategy that addresses data limitation issues. Empirical results demonstrate that the proposed approach outperforms existing methods in terms of tracking accuracy and generates relatively low transaction costs.

4 Deep Learning the SABR Model Implied Volatility

Jaehyuk Choi[1], Jeonggyu Huh[2], [1]Peking University, Shenzhen, China; [2]Chonnam National University, Gwangju, Korea, Republic of. Contact: jaehyuk@phbs.pku.edu.cn

The stochastic-alpha-beta-rho (SABR) model is a standard volatility smile model for pricing European options. The asymptotic implied volatility approximation is quick to use but prone to errors and arbitrage. Pricing based on the Monte-Carlo simulation is accurate but slow to use. We fill this gap by training a neural network to learn the SABR implied volatility obtained from simulations. The efficiency and accuracy of the neural network approach are significantly enhanced by several innovations: (i) the reduction of parameter dimensions, (ii) the adoption of the asymptotic behavior of the implied volatility to the objective function, and (iii) a novel simulation scheme under the CEV model.

5 Probabilistic Forecasting of Multivariate Irregularly Sampled Sequences

Yijun LI, Cheuk Hang LEUNG, Qi Wu, City University of Hong Kong, Kowloon Tong, Hong Kong. Contact: yijunli5-c@my.cityu.edu.hk

Multivariate sequential data becomes asynchronous whenever components are not aligned. If temporal irregularity is endogenous rather than a result of insufficient observation, it shall play a defining role in characterizing the dependence dynamics. Recurrent architectures, e.g. RNN, GRU, LSTM, become insufficient as they share hidden states among components and often rely on biased imputation to handle multivariate asynchrony. We present an end-to-end solution that overcomes these limitations by letting the observation times dictate when, how, and which hidden state to update, and representing the data distribution via the normalization flow. We carefully explore the likelihood structure to ensure that the complete exploitation of the heterogeneous and asynchronous characteristics of the data is not compromised while capturing the dependence structure.

Applied Market Design

Community Committee Choice Session

Session Chair: Daniela Saban, Stanford University, Palo Alto, CA

Session Chair: Gabriel Weintraub, Stanford Graduate School of Business, Stanford, CA

1 Redesigning VolunteerMatch's Search Algorithm: Toward More Equitable Access to Volunteers

Vahideh Manshadi[1], Scott Rodilitz[2], Daniela Saban[3], Akshaya Suresh[1], [1]Yale University, New Haven, CT, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]Stanford University, Palo Alto, CA, Contact: vahideh.manshadi@yale.edu

In collaboration with VolunteerMatch—the world's largest online platform for connecting volunteers with nonprofits—we designed and implemented a novel recommendation algorithm called SmartSort to improve equity in access to volunteers. Based on promising experimental results in three large metro areas, each showing a statistically significant 8-9% increase in our metric for equity, VolunteerMatch has deployed SmartSort nationwide. We expect it to provide an additional 30,000 volunteer sign-ups annually to opportunities with limited access to volunteers.

2 Competing Platforms and Transport Equilibrium

Nicola Rosaia, 1</sup

This paper studies platform competition in the app-based transportation industry. I present a model of competing platforms in transport equilibrium, characterize analytically the profit-maximizing allocations and prices, and estimate it using high-frequency data on the operations of the two main platforms in New York City. The model identifies two key sources of inefficiency: platform market power and missed network economies due to platform competition. These factors contribute to an inefficient use of drivers, resulting in higher traffic per ride than the social optimum. I find that a substantial share of the traffic externalities that ride-sharing services create can be traced back to these inefficiencies, and explore the implications for merger analysis and for the optimal design of congestion pricing policies.

3 Designing Incentive Mechanisms to Reduce Public Spending: A Field Experiment in Government Procurement

Marcelo Olivares, Universidad de Chile / Instituto Sistemas Complejos de Ingenieria, Santiago, Chile

This paper explores incentive mechanisms to align public officials' goals and reduce inefficiencies in public spending. Large-scale field experiments in Chile, in collaboration with Chilecompra and the Ministry of Finance, assessed interventions improving incentive alignment in public procurement. Monthly reports on purchasing performance were provided to managers and officers, reducing overspending and increasing efficiency. After five months, significant reductions in overspending were observed among officers whose performance was known by top-level executives, amounting to 33% of the control group mean. This represents potential savings of 20 million dollars per year. The study highlights the efficacy of information-based monitoring interventions and the role of incentive alignment in driving procurement behavior change.

4 Redesigning Framework Agreement Auctions in Chile Reduces Government Spending

Daniela Saban, Stanford University, Palo Alto, CA

Framework agreements (FAs) mechanisms by which a central procurement agency selects an assortment of products, typically through auctions, and then affiliated organizations can purchase from the selected assortment as needs arise. In Chile's central procurement agency (ChileCompra), FAs accounted for 23% of the procurement expenditures during 2018-19. We collaborated with ChileCompra to redesign FAs to enhance competition. These changes were implemented through an experimental design in the new Food FA to measure its impact, showing that inducing more intense competition in the auction stage reduced transaction prices by 8%.

Operational Planning of Emerging Vehicle Technologies

Contributed Session

Session Chair: Yining Liu, University of Illinois at Urbana-Champaign, Urbana, IL

1 How Sustainable are Shared e-Scooters? Insights from a Real-World Application and Managerial Implications

Ja'far Mohammad Mandouri[1], Murat Kucukvar[2], Nuri Onat[1], [1]Qatar University, Doha, Qatar; [2]Daniels College of Business, Denver, CO

E-scooters are emerging technologies as a shared economy application in cities. In this research, we investigate environmental, economic, and social impacts of shared e-scooters and provide key managerial and policy insights for sustainable applications of e-scooter mobility solutions in cities. We develop a novel a novel life cycle sustainability assessment model and a set of utilization scenarios derived from a real-world application in city of Doha, Qatar. We quantified life-cycle sustainability impacts encompassing from regional and global value chains of each life cycle phase of e-scooters. The results highlight that the utilization of e-scooters has a paramount importance for successful application of shared e-scooters.

2 A Simulation-Based Approach for Rebalancing Micro-Mobility Systems with Incentives

Mehr Sadat Salami[1], Leila Hajibabai[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, Raleigh, NC, Contact: msalami@ncsu.edu

This study presents a simulation-based technique for rebalancing an e-scooter-sharing system by incentivizing customers. The offers are made when destinations are chosen that balance the number of scooters in all zones at any time, maximizing profits for the company, or when scooters are dropped off at destinations that are in the vicinity of charging areas, minimizing the collection efforts. The effects of varying parameters, including incentive offer, discomfort coefficient, demand, and optimization time, on profits are analyzed and the best configuration is presented.

3 Inventory Management at Points-Of-Sale of Recreational Off-Road Vehicles

Mathieu Sylvestre, IVADO Labs, Montreal, QC, Canada

Inventory management of recreational off-road vehicles is challenging due to many factors, including low retail volumes at points of sale and strong seasonality in demand. In this presentation we discuss how we leverage numerous data sources to generate recommended inventory position targets for different products at all points of sale in a large manufacturer's network in North America.

4 Planning Charging Stations and Incentive Mechanisms for Shared Dockless e-Scooter Services

Yining Liu[1], Yanfeng Ouyang[2], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Urbana, IL, Contact: yiningl5@illinois.edu

This talk focuses on planning charging stations for shared e-scooter services, where customers are rewarded with incentives for returning e-scooters at nearby charging stations. A queuing network model is developed to describe customer assignment, customer usage, e-scooter battery consumption, and recharging operations. Closed-form formulas for expected agency cost and passenger travel time are derived. A meta-heuristic method is integrated with a nonlinear programming model to optimize the number of deployed e-scooters, the density and capacity of charging stations, the priority for assigning e-scooters at different battery levels, the rebalancing headway, and the incentive mechanism.

Financial Portfolio Selection and Risk Analysis

Contributed Session

Session Chair: Alex Bernstein, University of California, Santa Barbara, CA

1 The Dodd-Frank Act and Hedge Fund Operational Risk

William N. Goetzmann[1], Bing Liang[2], Jue Wang[2], [1]Yale University, New Haven, CT, [2]University of Massachusetts Amherst, Amherst, MA, Contact: juewang@umass.edu

In this paper, we examine the impact of the post-Dodd-Frank change in 2011 on hedge fund disclosure. Our LASSO-selected indicators for operational risk are effective in identifying potential negative outcomes for hedge funds in the future. We also construct a more comprehensive uni-dimensional ADV-based Ω-score to predict future appraisal ratio, style-adjusted return, leverage, and adverse liquidation events in the 11-year panel sample. Our analysis indicates that the amended Form ADV Filing improves the ability to forecast future adverse operational events compared to the pre-Dodd-Frank era. Additionally, our ADV-based Ω-score has a negative association with future fund flows, suggesting that investors take into account the operational risk exposure of hedge funds when making investment decisions.

2 How Bad is Myopia for a Mean-Variance Investor?

Jinye Du, Moris Simon Strub, Zhongfei Li, Southern University of Science and Technology, Shenzhen, China. Contact: 12131291@mail.sustech.edu.cn

The mean-variance framework is widely used in portfolio selection but often overlooks the investment horizon. Current investment practices rely on myopic mean-variance approaches that neglect long-term considerations. Existing algorithms solve single-period mean-variance problems and extend the solution over time. This paper contributes to the existing research by incorporating a time dimension. We compare the out-of-sample performance of the dynamic mean-variance strategy with myopic strategies and three 1/N-type strategies. The results demonstrate that the dynamic mean-variance strategy outperforms the myopic approach in out-of-sample scenarios. Additionally, we highlight the benefits of optimization in a dynamic context compared to naive diversification.

3 Valuation Premium Effectof Targets' Operations Capability in M&As

Mehdi Nezami[1], Sara Rezaee Vessal[2], Ali Shantia[3], [1]Bradly University, Chicago, IL, [2]ESSEC Business School, Cergy-Pontoise, France; [3]Toulouse Business School, Toulouse, France. Contact: a.shantia@tbs-education.fr

Valuation of target firms in mergers and acquisitions (M&As) has far-reaching implications for shareholder wealth. This study investigates the effect of a target's operations capability on the valuation premiums, above its market value, that it receives from the acquiring firm. We find that target firms' operations capability has a positive and economically significant effect on their M&A valuation premiums. However, this effect becomes weaker with increasing market overlap between the target and acquiring firms. These findings offer corporate executives a comprehensive perspective on the role of operations capability in enhancing shareholder wealth---beyond its effect on stock market value---in the context of a major strategic decision: corporate M&As.

4 Robustness of the Higher Moment Risk Measure

Fabio Gómez[1], Spiridon Penev[2], Qihe Tang[1], [1]University of New South Wales, Sydney, Australia; [2]University of New South Wales, Sydney, Australia. Contact: qihe.tang@unsw.edu.au

The higher moment (HM) risk measure generalizes expected shortfall by incorporating an additional parameter interpreted as risk aversion. This work examines various robustness issues related to the HM risk measure. We prove that the HM risk measure is robust against optimization in a sense recently proposed by Embrechts, Schied, and Wang (2022, Operations Research). Based on the HM risk measure, we consider the distributionally robust optimization problem for linear portfolios and revisit the topics of risk parity and capital allocation under ambiguity, where ambiguity is quantified using the Wasserstein distance.

5 Analytical Solutions to the Constrained Markowitz Problem via Fixed Point Theory

Alex Bernstein[1], Alexander Shkolnik[2], [1]University of California, Santa Barbara, Santa Barbara, CA, [2]University of California, Santa Barbara, Santa Barbara, CA, Contact: abernstein@ucsb.edu

Harry Markowitz transformed finance by framing portfolio construction as a mean-variance tradeoff. Building on a special case solved (or rather, guessed) previously, we develop an analytical formula for the solution to the Markowitz problem with no short sales. Our results make use of fixed point theory to characterize the solution in a way that reveals its geometric properties.

On Recommendation Systems

Contributed Session

Session Chair: Dirk Daniel Sierag, Stitch Fix, San Francisco, CA

1 Budget Bot: A Hotel Recommendation Tool Powered by Generative AI and Mixed-Integer Programming

Han Dong, Elliot Wilens, Zhenzhen Zhu, Yunhong Liao, Michele Meyers, Marriott International, Bethesda, MD

Selecting hotel accommodations is a key component of planning a memorable road trip, and identifying options that match each traveler's preferences can be time-consuming. This presentation will cover a hotel recommendation tool that integrates generative AI and mixed-integer programming (MIP) to optimize hotel selections for multi-day and multi-hotel trips. The generative AI component captures the trip information and hotel preferences as inputs to the MIP model. The optimization model identifies the best combination of hotels that meet the traveler's requirements. This integration of generative AI and MIP creates an efficient and effective decision-making process for travelers.

2 AI: Automated Itinerary (For Road Trips)

Kyle Murphy, Anirudha Kulkarni, Zelin Jiang, David Todd, Marriott, Bethesda, MD, Contact: kyle.murphy@marriott.com

When planning a road trip, travelers typically plan routes, book hotels, and find local attractions using different online platforms. This presentation will discuss a tool that integrates Google Maps, Chat GPT, and hotel property location data to do all three things in one place. The tool starts with a list of user-specified required stops and uses a heuristic to generate a list of recommended additional stops. Then it leverages ChatGPT prompts to generate relevant, fun, and safe recommendations for a unique user-experience at each additional stop. Once a travel itinerary is planned, location data is used to recommend hotels along the way.

3 The Effect of Friend Recommendation Algorithms on Information Cocoon Formation: Evidence from a Field Experiment

Lin Wang, Communication University of China, Beijing, China. Contact: carolinewang@cuc.edu.cn

Along with the proliferation of social media, polarization has become a critical issue; widely implemented algorithms have changed the way users access information on platforms, facilitating the formation of information cocoons. However, recent research has focused on the existence and impact of information cocoons on social media platforms while ignoring the mechanisms that may drive their formation. Specifically, whether the widely adopted friend recommendation algorithms intensify or alleviate the information cocoon issue is unclear. Furthermore, the heterogeneous effects of friend recommendations on information cocoon formation remain unrevealed. Collaborating with one of the most popular short-video social networking apps, we implemented a large-scale randomized field experiment with further causal forest analysis to address the above questions.

4 Client Time Series Model: A Multi-Target Recommender System Based on Temporally Masked Encoders

Dirk Daniel Sierag, Stitch Fix, San Francisco, CA

Stitch Fix is an online personal styling and shopping service on multiple platforms. For example, a client can request a stylist to curate a personalized 'Fix', an assortment of 5 items; or they can make direct purchases in their own personalized shop in our 'Freestyle' experience. In order to provide the client with the most personalized experience across all platforms, we developed the Client Time Series Model (CTSM): a scalable and efficient recommender system based on Temporally-Masked Encoders (TME) that learns one client embedding across all platforms, yet is able to provide distinctive recommendations depending on the platform. An A/B test showed that our model outperformed the baseline model by 5.8% in terms of expected revenue.

Community Committee Choice Session

Session Chair: Ben Grannan, Queens University of Charlotte, Fort Mill, SC

1 Unsupervised Data Mining to Identify Golfer Performance by Course Profile on the PGA Tour

Ben Grannan, Queens University of Charlotte, Fort Mill, SC

This study develops an analytical approach to understand how different profiles of golfers perform on specific types of golf courses. A golfer's profile could be identified as a long-hitter, strong iron player or elite putter, or a combination of those strengths. A golf course can defend itself with length, necessity of shot-making and precision, or complexity of the putting areas. Anecdotally, "any type of player can win at the RBC Harbor Towne" but "great putting is a requirement at Augusta National." In a similar manner, the longest drivers on the PGA Tour do not win each week, but there may be some destinations on tour where the bombers aggregate towards the top of the leaderboard more than expected. Through data analysis this study seeks to understand who plays well where on tour and which tournaments are unlikely to yield success to specific groups of golfers.

2 Which Algorithm to Select in Sports Timetabling?

David Van Bulck, Dries Goossens, Ghent University, Gent, Belgium

In a round-robin sports timetable, each team competes against every other team a predetermined number of times. Over the years, a variety of sports timetabling algorithms have been proposed, including integer programming, meta-heuristics, and satisfiability solvers. The International Timetabling Competition on Sports (ITC2021) suggests that the performance of sports timetabling algorithms heavily depends on the specific constraints involved. This presentation demonstrates the use of machine learning techniques to predict the most suitable algorithm for a given sports competition. It also explores what properties are most important in making these predictions, and illustrates how the predictions can contribute to improve existing solvers.

3 Scheduling Women's Soccer in Belgium

Dries Goossens[1], Frits C. Spieksma[2], [1]Ghent University, Gent, Belgium; [2]Eindhoven University of Technology, EINDHOVEN, Netherlands. Contact: dries.goossens@ugent.be

The scheduling of women soccer leagues has hardly received attention in the literature. Perhaps due to lower interest by the general public (and hooligans), it has not been perceived as very challenging or important. However, the success of the women's national team prompted a TV channel to live broadcast a weekly match from the highest division of the Belgian women's soccer league. This triggered a number of scheduling constraints which require a more sophisticated approach. For instance, the TV channel wanted to broadcast a home game for each team at least once in the season. Moreover, as most teams lacked a suitable venue, live broadcasting was only possible when better infrastructure (typically from the men's teams) was available. We discuss the development of a tailor-made scheduling algorithm and its use in practice for the 2022-23 season.

4 Round-Robin Scheduling with Regard to Rest Differences: A Novel Branch-And-Price Method and Heuristic Approach

Tonguc Yavuz[1], Tankut Atan[2], Burak Cavdaroglu[3], [1]İstanbul Bilgi University, İstanbul, Turkey; [2]Bahçeşehir University, İstanbul, Turkey; [3]Teesside University, Middlesbrough, United Kingdom. Contact: tonguc.yavuz@bilgi.edu.tr

Fairness in rest durations is critical in round-robin sports scheduling. Our study introduces a novel branch-and-price (B&P) method to minimize rest differences, offering significant improvements in computation time and objective function value over conventional methods. Additionally, a new heuristic for basic solution identification consistently outperforms traditional integer programming solutions. These advancements present a promising path towards improved fairness in round-robin scheduling, with potential applications extending beyond sports. Future research will explore the wider applicability of these innovative methods.

Learning and Optimization

Contributed Session

Session Chair: Xiaotong Sun, University of Arkansas, Springdale, AR

1 Decision-Focused Surrogate Modeling for Mixed-Integer Optimization

Shivi Dixit, Rishabh Gupta, Qi Zhang, University of Minnesota, Twin Cities, Minneapolis, MN, Contact: dixit064@umn.edu

Many real-world operational decision-making problems are modeled as mixed-integer programs (MIPs) and involve solving multiple similar instances over time, which vary based on problem-specific input parameters. Due to their computational complexity, solving these MIPs in real time is often challenging. In this work, we propose a data-driven decision-focused surrogate modeling approach that constructs fast surrogate optimization models, e.g. in the form of convex quadratic programs, which generate solutions that closely approximate those obtained from the original MIPs.

2 Nested Learn to Branch-And-Price for Large-Scale Network Optimization Problems

Babak Aslani, Shima Mohebbi, George Mason University, Fairfax, VA, Contact: baslani@gmu.edu

While the Branch-and-Price algorithm is an effective solution approach for combinatorial optimization problems, high computational time and memory usage are still the main challenges for real-life problems. To address this gap, we propose a nested learning-based framework to use the information during the optimization process and accelerate the Branch-and-Price procedure. In specific, we use a learning component to select the most promising columns for the column selection step and embed a learning procedure to predict the upper bound for solving the pricing problem stage. We apply the proposed framework to a set of benchmark problems and a city-scale network flow problem for a case study in Tampa, FL. We compare the performance of the proposed framework with state-of-the-art methods to validate the applicability of the approach.

3 Experimental Design and Two Stage Stochastic Programming Analysis for Cyber Resilience

Tu Feng[1], Theodore T. Allen[2], Antonio Conejo[1], [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH, Contact: feng.1039@osu.edu

Resilience relates to the ability to prepare for and recover from disruptions which implies that concepts from two stage stochastic programming are relevant. Yet, in many cases experimentation and empirical modeling are needed to enable optimal resilience. We offer perhaps the first results that relate optimal experimentation to optimal resilience.

4 Adaptive Boosting with Sensitivity to Interaction Among Regressors

Xiaotong Sun, Justin Chimka, University of Arkansas, Fayetteville, AR, Contact: xs018@uark.edu

We will motivate the need for and introduce a new ensemble learning algorithm used for classification or regression where there is significant interaction among regressors. During rounds of training, we delete regressors that are insignificant and participate in no significant interaction or determine natural clusters of observations with respect to significant interaction among regressors.

Sequential Decision Problems and Applications

Contributed Session

Session Chair: Pavankumar Murali, IBM Research, Yorktown Heights, NY

1 Decomposition Strategies in Markov Decision Processes: Implications for Accuracy and Efficiency in Stochastic Logistics Networks

Ali Tolooie, Mercer University, Macon, GA, Contact: tolooie_a@mercer.edu

This study investigates the impact of varying decomposition strategies on Markov Decision Processes (MDPs) within stochastic logistics networks. We focus on constructing a theoretical framework that could guide the decomposition of MDPs considering stochastic rates inherent in the problem, while considering the tradeoff between the accuracy and efficiency of the decomposition. Moreover, we explore the characterization of optimal policies within these decomposed subsystems and discuss the extension of these policies to the original, higher-dimensional problem. Our goal is to enhance understanding and application of decomposition-based algorithms in complex logistics networks.

2 A Family of s-Rectangular Robust MDPs: Relative Conservativeness, Asymptotic Analyses, and Finite-Sample Properties

Siva Ramani, Archis Ghate, University of Washington, Seattle, WA

We study a family of distance-based s-rectangular robust MDPs (s-RMDPs), where in each state, the ambiguity set equals a sublevel set of the norm of a vector of distances from reference pmfs. This construction allows us to perform a rigorous analysis of the relative conservativeness behavior of (s,a)-RMDPs versus s-RMDPs from our family. We also study data-driven versions of our s-RMDPs. We prove that the optimal values of the RMDP converge to the true optimal, asymptotically with sample sizes. The robust optimal value also provides a probabilistic lower bound on the out-of-sample value of a robust optimal policy. This finite-sample result indicates that (s,a)-RMDPs are the least conservative among all s-RMDPs within our family.

3 Integrating Stochastic Approximation Algorithm into Markov Decision Process for Hotel Dynamic Pricing Optimization

Aysajan Eziz, Ivey Business School, Western University, London, ON, Canada. Contact: aeziz@ivey.ca

This research article presents a novel approach for dynamic pricing in the hotel industry by integrating a stochastic approximation algorithm (SAA) into a Markov decision process (MDP) formulation. The model optimizes booking prices for multi-day stays, taking into account room availability and demand fluctuations. The SAA helps find optimal pricing strategies, yielding higher revenues and minimizing losses during high-demand periods, as validated by computational experiments. While primarily focused on the hotel industry, the findings can be applied to other sectors with capacity constraints and variable demand, like transportation and e-commerce, providing valuable insights for dynamic pricing and revenue management.

4 Mining Sequential Decision-Making Behavior Based on Latent States

Chen Wang, Yuanyuan Lei, Tsinghua University, Beijing, China. Contact: chenwang@tsinghua.edu.cn

We propose an influence diagram model representing sequential decision-making behavior with underlying latent states. The model utilizes a generalized reward function to capture stationary decision rules, whether normative or descriptive. We then transform the influence diagram into a hidden Markov chain with neural networks for estimation. Case studies on the click data of online shopping from 100K customers and the pilot landing operations of about 5000 flights show surprisingly good predictability and explainable latent states.

5 Sequential Decision Making (SDM) with Long Term Reward Estimates

Pavankumar Murali[1], Dharmashankar Subramanian[2], Nianjun Zhou[3], [1]IBM Research, Yorktown Heights, NY, [2]IBM TJ Watson Research Center, Rye Brook, NY, [3]IBM, Chappaqua, NY

We study optimal control problems, wherein actions to be taken at a time step are dependent on a dynamical system's behavior such as realized demand or process behavior in a plant. Traditional SDM methods may not account for long-term effects of decisions or changing conditions. In our framework, we extend our objective function with two parts - the first part is the rewards within the time horizon for optimal policy, and we also include a modifier to the objective. The modifier term is the expected remaining reward after the recommended policies. Therefore, we can capture the holistic reward of the scenario, allowing us to ensure that the recommended policies benefit not only the period of the recommendation but also that the system is brought into a good system state for better future rewards. We benchmark the performance of our model on a use-case from a processing plant.

1 Innovation on Firm Performance and Moderating Role of State Ownership and Corporate Governance: Empirical Evidence China

Rushatey Feroz, Xi'an Jiaotong University, Xi'an, China. Contact: rushateyferoze@gmail.com

Although various aspects of innovation and firm performance have been studied, previous research has overlooked the overall impact of innovation on firm performance. Therefore, this study aims to determine the significance of innovation on the performance of Chinese firms. This study uses data from Chinese firms listed on the Shenzhen and Shanghai stock exchanges from 2007 to 2018. The result signifies that innovation has a positive impact on firm performance. State ownership and corporate governance both positively moderate this effect. The study also found that when corporate governance is high and state-owned support is low, the relationship between innovation and firm performance is stronger. Conversely, when corporate governance is low and state-owned support is high, the relationship between innovation and firm performance is weaker.

2 How Does Competition Affect AI Investment in Firms? Evidence From a Quasi-Natural Experiment in the United States

Taekyun Kim[1], Gangmin Park[2], Sukwoong Choi[3], [1]KAIST College of Business, Daejeon, Korea, Republic of; [2]Software Policy & Research Institute, Seoul, Korea, Republic of; [3]University at Albany, SUNY, Albany, NY

While previous research has predominantly focused on micro-level factors such as organizational structure and technological readiness, we propose that a macro-level competition policy (the US-China trade war) can also significantly influence AI investment. We suggest that tariffs on Chinese goods lessen production competition for US companies, boosting their likelihood to invest in AI and spur innovation. We empirically reveal a significant increase in AI investment among firms protected by the trade war, which in turn contributes to AI-relevant innovation. We further examine the mechanisms driving this investment, including slack resources, value chain complexity, and prior technological knowledge. We underscore the unforeseen positive repercussions of protectionism on US firms' AI endeavors and subsequent innovation.

3 How Employee Training Drives Firm Production Repurposing in Covid-19 Pandemic

Huan He, Yuxiao Ye, Baofeng Huo, Tianjin University, Tianjin, China. Contact: hohuan@tju.edu.cn

In the COVID-19 pandemic, we found some firms successfully repurpose production (i.e., adjusting firm production/services partially/fully) to adapt to the pandemic, which motivates us to study what factors drives firm production repurposing in COVID-19 pandemic. Drawing upon the ability, motivation and opportunity (AMO) framework, we study how to leverage human capital (by employee training) to enhance firm adaptation (i.e., production repurposing) in the pandemic. The results indicate that employee training prior to the pandemic develops human capital and firm capability to initiate production repurposing during the pandemic. Government wage subsidy and less labor shortage will enhance firm motivation and opportunity respectively in production repurposing, thus amplifying the positive impact of employee training prior to the pandemic.

Prediction and Data Mining in Healthcare

Contributed Session

Session Chair: Ajit Appari[1,2], [1]Boston University, Boston, MA, [2]Northeastern University, Boston, MA

1 Mitigating Underreported Error in Food Frequency Questionnaire Data Using a Supervised Machine Learning Method and Error Adjustment Algorithm

Anjolaoluwa A. Popoola[1], Jennifer K. Frediani[2], Terryl J. Hartman[2], Kamran Paynabar[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]ISyE Georgia Tech, Atlanta, GA, Contact: apopoola3@gatech.edu

Food frequency questionnaires (FFQ) are one of the most useful tools for understanding diet-disease relationships. However, they are susceptible to bias and misclassification. In this paper, a machine learning method is proposed to adjust for measurement error found in misreported data by using a random forest classifier and an algorithm that adjusts the measurement error. We show this method by addressing underreporting in selected FFQ responses. We have high model accuracies ranging from 78% to 92% in participant collected data and 88% in simulated data. This shows that our proposed method of using a RF classifier and error adjustment algorithm is efficient to correct most of the underreported entries in the FFQ dataset and could be used independent of diet-disease models. This could help nutrition experts to use dietary data estimated by FFQs with less measurement error.

2 Developing an Ensemble Model to Predict Safe Ambulatory Surgery

Clark Howell[1], Hamed Zaribafzadeh[1], Ursula Rogers[1], John Rollman[1], Dan Buckland[2], Peter Allen[1], Bruce Rogers[1], [1]Duke University, Durham, NC, [2]Duke University, Durham, NC, Contact: clark.howell@duke.edu

Health systems are seeking to perform more ambulatory surgeries to improve quality and patient satisfaction while decreasing cost and inpatient bed utilization. However, there is no reliable and generalizable model that predicts which patients and which surgeries are appropriate for ambulatory venues. Our aim is to create an ensemble model of distinct machine learning models that predict accepted metrics for safe ambulatory surgery. Ambulatory cases should be less than 5 hours (AUC 0.94), a patient must stay less than 23 hours (AUC 0.96), and the patient must be discharged home rather than to a facility (AUC 0.89). The ensemble of these models robustly predicts these three criteria (AUC 0.96) and ambulatory patient class (AUC 0.96).

3 A Modified Feature Selection Method to Build Interpretable and Trustable Machine Learning Model for Diabetic Retinopathy Disease Prediction

Enrico Laoh, Tieming Liu, Oklahoma State University, Stillwater, OK, Contact: elaoh@okstate.edu

The use of AI to help physicians make medical predictions is extensively explored nowadays. However, medical domain knowledge not provided in the data set plays a pivotal role in prescribing medical decisions. Current research direction predominantly focuses on extracting insights from data which is limited compared to well-established medical domain knowledge. Addressing this gap, our study aims to develop an approach to gather medical domain knowledge from well-published medical corpus available in the PubMed library and use it to select ML model variables for predicting diabetic retinopathy patient's condition. Moreover, this method also can preserve the model's interpretability which facilitates the limitation of user capability. This approach will help to make a robust and trustable AI-driven decision to support physicians in making better predictions.

4 Classification of Cognitive Groups in Aging Using dMRI

Mohammad Fili[1], Parvin Mohammadiarvajeh[1], Guiping Hu[1], Auriel A. Willette[1,2], [1]Iowa State University, Ames, IA, [2]University of Iowa, Iowa City, IA

"Positive-Agers" are middle-aged individuals who defy age-related cognitive decline and display superior cognitive abilities. This study develops a two-step approach to identify and differentiate "Positive-Agers" from "Cognitive-Decliners." First, a cognitive scoring procedure based on multiple cognitive tests was employed. Second, diffusion Magnetic Resonance Imaging (dMRI) and demographic data were used to distinguish between the two groups. This research contributes to the understanding of cognitive differentiation by exploring its relationship with dMRI attributes and cognitive tests.

5 Composite Risk Prediction of All-Types Hospital-Acquired Conditions Using Machine Learning for Pediatric Patients

Ajit Appari[1,2], [1]Boston University, Boston, MA, [2]Northeastern University, Boston, MA, Contact: aappari.work@gmail.com

Hospital-acquired conditions (HACs) are mostly preventable risk to the safety of hospitalized children, especially with multiple chronic conditions (MCC), that can result in elevated mortality & morbidity, longer hospitalization, and higher cost of care. Unlike past research focusing on specific HACs, my study develops composite risk prediction model for all types HACs among chronically ill children. I used administrative data on 710,320 pediatric hospitalizations (age: 1days-17years; includes 515,470 neonates & 33,375 infants) during 2015Q4-2016Q4 at all hospitals in Texas. I developed Poisson regression (with random effects) model for predicting HACs count with predictors including MCC patterns {estimated using Bernoulli Mixture model clustering}, patient factors, hospital factors, and physician factors controlling for admission type and time factors.

1 Personality Classification with Reddit Data Using Natural Language Processing

Sungmin Lim, Juheon Kwak, Dongil Kim, Ewha Womans University, Seoul, Korea, Republic of. Contact: 8962468@ewhain.net

Recently, Myers-Brix Type Indicators (MBTIs) are the key keywords that identify and infer personal characteristics of community users. In addition, the MBTIs have been increasingly used in business fields for a personalized management of employees. In this paper, we propose an MBTI classification method with natural language processing (NLP) models. The MBTI_reddit, consisting of real-world reddit data of various users, was used for train. The experiment showed that the proposed method outperformed the conventional machine learning methods for real-world dataset.

2 The Consequences of the Economic Crisis on the Number of Deaths Resulting from Accidents

Mayssam Tarighi Shaayesteh, University of North Texas, Denton, TX, Contact: mayssamshaayesteh@gmail.com

This paper delves into a comprehensive examination of the impact of the annual inflation rate on traffic fatalities. By analyzing a rich dataset encompassing the years 1975 to 2020 in the United States, the study explores the intricate relationship between the total number of traffic-related deaths and the average annual inflation rate over this period. The aim is to uncover patterns and trends that could shed light on the potential forecasting of yearly fatalities.

3 The Sound of Silence: Effect of Disclosing User Location on Users' Social Engagement

Jingwei Dai[1], Emaad Manzoor[2], Michael D. Smith[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Cornell University, Madison, WI, Contact: jingwei.dai6@gmail.com

This research explores how disclosing user location will affect platform users' social engagement and content quality and credibility. We leverage a natural experiment that took place on Zhihu, China's largest knowledge-sharing platform. We use difference-in-difference methods to identify the policy shock's impact, and the regression results indicate that disclosing user location led to a significant decrease in user activeness in terms of posting answers. However, when location information was relevant to the answer content and displayed, it resulted in an increase in answer upvote counts and commenting activity. We also conducted NLP analysis to analyze the answer texts via text mining.

Insights Into Food Supply Chain and Food Insecurity

Contributed Session

Session Chair: Rashik Intisar Siddiquee, North Carolina State University, Raleigh, NC

1 A Coordinated Network Allocation Model for Food Bank Operations

Naurin Zoha[1], Julie Simmons Ivy[2], Negash Medhin[3], [1]North Carolina State University, Raleigh, NC, [2]University of Michigan, Ann Arbor, MI, [3]North Carolina State University, Raleigh, NC, Contact: nzoha@ncsu.edu

Food banks and their partner agencies operate to mitigate food insecurity. However, during the onset of COVID-19, a lot of these agencies shutdown causing a huge disruption in the network. This paper proposes a coordinated network infrastructure that permits trans-shipments between the agencies to absorb this disruption. Here, some agencies work as super-agencies to store food. In case of any agency closure, other agencies within a predetermined radius become helping agencies to receive food from the super-agencies and serve the food insecure population who were supposed to be served by the closed agency. The study has two main objectives: i) Develop a deterministic linear programming model minimizing unmet demand, inventory cost and shipping cost of the food bank, ii) Develop structural properties and policy insights to aid in food banks' decision making.

2 Weighting Approach for Evaluating Organizations within the Food Rescue Landscape

Abdullah Al Nadim[1], Rashik Siddiquee[1], Naurin Zoha[1], Naimur Rahman Chowdhury[1], Ricky Owusu[2], Mo Ogunmola[3], Julie Simmons Ivy[4], Lauren Berrings Davis[2], Shona D. Morgan[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina A&T State University, Greensboro, NC, [3]North Carolina A&T State University, Greensboro, NC, [4]University of Michigan, Ann Arbor, MI, Contact: anadim@ncsu.edu

In the US, 13.5 million households were food insecure at some point during 2021 and a plethora of non-profit organizations play a crucial role in hunger relief through their programs. This study analyzes over 50 companies within the food rescue landscape and categorizes them based on their potential for partnership with hunger relief organizations. We developed a framework for effective partner selection considering categories such as Fund Development, Logistics, Relationship Building, Adaptability etc. Through a systematic method of attribution weighting, our technique generates results that provide decision-making insights, assisting hunger relief organizations in selecting partners and maximizing their impact on reducing food insecurity.

3 A New Produce Ordering Policy

Mark Velednitsky, Afresh, Bothell, WA

In this work, we propose a new policy for managing the inventory of perishable items in grocery stores. Existing models capture either highly perishable items (ex. newsvendor) or relatively shelf-stable items (ex. EOQ). Our new model consumes a distributional forecast as well as item shelf life estimates. Relative to our incumbent policy, the new policy is show in real-world experiments to reduce food waste by approximately 10% without increasing stock-out rates, driving a 2% increase in profitability. We offer insights into the factors driving this improvement, such as a better characterization of uncertainty, a sales-aligned safety stock, and better shelf life estimates.

4 Food Rescue Landscape Analysis Framework to Characterize For-Profit and Nonprofit Organizations

Rashik Intisar Siddiquee[1], Naimur Rahman Chowdhury[1], Abdullah Al Nadim[1], Naurin Zoha[1], Ricky Owusu[2], Motunrayo Ogunmola[2], Julie Simmons Ivy[3], Lauren Berrings Davis[2], Shona D. Morgan[4], [1]North Carolina State University, Raleigh, NC, [2]North Carolina A&T State University, Greensboro, NC, [3]University of Michigan, Ann Arbor, MI, [4]North Carolina A&T State University, Greensboro, NC, Contact: rsiddiq2@ncsu.edu

The broader area of food rescue and food waste reduction has seen the entry of many companies with varied operating and profit models. This study develops a framework for evaluating these companies' performance regarding attributes, including technology management, logistics, relationship building, and fundraising. These attributes are compared relative to perceived strengths and opportunities of existing nonprofit hunger relief infrastructure. A SWOT analysis is performed to compare service operations of the for-profit and nonprofit organizations. Potential partnership opportunities among these companies are explored.

5 Discretion in Automated Supermarket Replenishment: Censorship Bias and Self-Inflicted Stockouts

Bengu Ozdemir, Antti Tenhiala, IE Business School, Madrid, Spain. Contact: bengu.ozdemir@student.ie.edu

Retail store managers can use their discretion to adjust order proposals of automatic store replenishment (ASR) systems to incorporate their private knowledge. Apart from occasionally improving ordering decisions with human insights that is not available to the ASR system, store managers are suspect to biases. We examine the prevalence and performance implications of censorship bias, which explains a paradox where retailers order less than ASR proposals after a stockout. Accounting for the endogeneity of ordering decisions, we show that censorship bias is equally prevalent and detrimental as the well-known anchoring bias of ordering behavior. By out-of-sample analysis, we show that ASR systems can be improved to block deviations susceptible to censorship bias.

10 Pivotal Uncertainties To Resolve - Optimal Information Gathering In Supply Chain Design

Austin Saragih; Massachusetts Institute of Technology, USA

This paper addresses a critical supply chain management problem of designing networks amid uncertainties. It proposes a non-monotone non-submodular minimization approach, utilizing the value of information analysis, to optimize the trade-off between cost reduction achieved by resolving uncertainties through information gathering and the expenses incurred in the process. Results demonstrate the significant value of the proposed information-gathering strategy, with managerial implications for enhancing overall objectives in similar stochastic programming problems.

We propose an adjusted Wasserstein distributionally robust estimator---based on a nonlinear transformation of the Wasserstein distributionally robust estimator in statistical learning.This transformation will improve the statistical performance of WDRO because the adjusted

WDRO estimator is asymptotically unbiased and has an asymptotically smaller mean squared error.The adjusted WDRO will not sacrifice the out-of-sample performance guarantee of WDRO. Sufficient conditions for the existence of the adjusted WDRO estimator are presented. Numerical experiments demonstrate the favorable practical performance of the adjusted estimator over the classic one.

23 Tensor-based Feedback Control For Local Structured High-dimensional Streaming Data Under Limited Control Capability
Zihan Zhang, Kamran Paynabar, Jianjun Shi; ISyE Georgia Tech, USA
This study introduces a tensor-based feedback control model for structured high-dimensional (LSHD) streaming data, addressing limitations of conventional control models. Unlike traditional models that often overlook local correlation structures, our approach leverages kernel distributions to capture local response auto-correlations and incorporates the practical knowledge of control actions. We propose a dynamic control strategy that determines optimal control locations to boost efficiency under resource constraints. The model effectiveness is confirmed through simulations and case studies.

2 Automated Risk Analysis of Machine Learning Models: A Novel Approach
Daniel H. Fylstra, Frontline Systems Inc., Incline Village, NV, Contact: daniel@solver.com
See a new approach to risk analysis of machine learning models in action in this tutorial session. We’ll explain why the traditional machine learning approach - training a model on a data set, validating it on another data set, and testing it (or comparing it to other models) on a third data set isn’t “risk analysis” - and isn’t sufficient to assess or quantify the risk that the model will perform differently than expected when

deployed for production use, with disappointing or even costly business consequences. We'll discuss the complexity and time required to apply conventional risk analysis during machine learning model development. And we'll demonstrate a new, patent-pending approach that automates and integrates simulation-based risk analysis into the machine learning development process. As a side benefit, we'll show a new, fully automated approach to synthetic data generation, with many potential uses, and a novel use of such synthetic data in risk analysis. As time permits, we'll demonstrate use of these methods in our cloud platform RASON®, in Excel with Analytic Solver®, and in your choice of programming languages with Solver SDK®.

New Pricing Models for Online Economies

Community Committee Choice Session

Session Chair: Michael L. Hamilton, University of Pittsburgh, Pittsburgh, PA

Session Chair: Sekar Shreyas, University of Toronto, Toronto, ON, Canada

1 Pricing Strategies for Online Dating Platforms

Titing Cui, Michael L. Hamilton, University of Pittsburgh, Pittsburgh, PA

Dating apps have become the most common way for romantic partners to meet. These dating apps generate revenue through subscription-based pricing, which is a common monetization strategy for mobile apps. However, in the context of online dating, different subscription-period lengths can lead to very different outcomes for the platform and its users. In this study, we analyze the profit and welfare trade-offs associated with different length subscription pricing strategies for online dating platforms. Using a novel model, we find that short subscription periods are robust, guaranteeing 26.9\% of the optimal profit. However, when operating costs are low, a switch to long period pricing can both increase profits and improve user welfare.

2 List Now or Later? an Equilibrium Analysis of Asset-Sharing Platforms

Neha Sharma, Kellogg School of Management, Evanston, IL

Many sharing platforms facilitate on-demand service to their guests and allow guests to reserve assets ahead of service. On such platforms, ``hosts" inform the platform beforehand about their asset's availability by creating a ``listing", and by doing so, the hosts commit to the assets' availability in the future. In practice, many platforms use dynamic pricing, and the hosts earn a share of the revenue generated. Using data from a large car-sharing platform, we find empirical evidence to support our assumption that hosts' are strategic about their listings. Our analysis highlights the limitations of revenue-share contracts on asset-sharing platforms. Finally, we find revenue share based on the time of listing is optimal.

3 Incentives For Exploration At Market Equilibrium

Vijay Kamble, University of Illinois Chicago, Chicago, IL

Online marketplaces face an exploration problem: qualities of new supply units are unknown and must be discovered through customer feedback so that higher quality supply gets prioritized for matching. However, customers are unwilling to participate in exploratory matches. This paper sheds light on the role of congestion and the resulting market equilibrium prices in creating incentives for such exploratory behavior among myopic customers. The intuition is that since customers prefer established higher-quality supply units, these units demand higher equilibrium prices due to congestion compared to newer units, effectively incentivizing customers to explore. This paper presents a comprehensive analysis of the extent to which this intuition holds and exogenous incentives for exploration are necessary for such markets.

4 Help and Haggle: Social Commerce Through Randomized, All-Or-Nothing Discounts

Luyi Yang[1], Chen Jin[2], Zhen Shao[3], [1]University of California, Berkeley, Berkeley, CA, [2]National University of Singapore, Singapore, Singapore; [3]University of Science & Technology of China, Hefei, China. Contact: disjinc@nus.edu.sg

This paper studies a novel social commerce practice known as "help-and-haggle," whereby an online consumer can ask friends to help her "haggle" over the price of a product. Each time a friend agrees to help, the price is cut by a random amount, and if the consumer cuts the product price down to zero within a time limit, she will get the product for free; otherwise, the product reverts to the original price. Help-and-haggle enables the firm to promote its product and boost its social reach as consumers effectively refer their friends to the firm. We model the consumer's dynamic referral behavior in help-and-haggle and provide prescriptive guidance on how the firm should randomize price cuts.

CC-North 121B
RMP for Cultural Markets
Community Committee Choice Session
Session Chair: Abhishek Deshmane, IESE Business School, Barcelona

1 Multi-Player Game Design: Boost Engagement in Contests Through Intervention
Yifu Li[1], Lifei Sheng[2], Xuying Zhao[3], [1]University of Science and Technology of China, Hefei, China; [2]University of Houston Clear Lake, Houston, TX, [3]Texas A&M University, College Station, TX, Contact: sheng@uhcl.edu
In multi-player video games, it is important for game designers to boost players' engagement in contests. Some "handicapping policies" that intend to create an evenly-matched competition based on players' performance can improve players' engagement. We derive the players' equilibrium efforts and analyze the optimal intervention schemes. Our analysis reveals that a bang-bang solution can be optimal when players are strategic.

2 Ups and Downs in Audience Experience Management
Hongqiao Chen[1], Ming Hu[2], Jingchen Liu[3], Yaniv Ravid[4], [1]Nanjing University, Nan Jing Shi, China; [2]University of Toronto, Minneapolis, MN, [3]Nanjing University, Nanjing, China; [4]University of Toronto, Toronto, ON, Canada
Within the framework of prospect theory, we consider a service provider who wishes to maximize an audience's experienced utility under three different settings. First, we study how to release a piece of good news vs. bad news, where the provider may incrementally reveal the news over a preemptive period. Second, we consider how to organize an event such as a concert with performances of known valuations, where the provider needs to arrange the sequence of all performances. Lastly, we investigate the problem of simultaneous vs. sequential release of a series such as songs or TV episodes, where the provider does not know a priori the audience's exact valuation of each item. Across all of the settings, we show that the audience's sensitivity to losses relative to a reference point is a critical factor that governs how to design and manage the audience's evolving experience dynamics.

3 Beyond Cookies: Evidence About Team Environment and Engagement Retention from Girl Scouts Cookie Program
Tom Tan[1], Bradley R. Staats[2], [1]Southern Methodist University, Dallas, TX, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: ttan@cox.smu.edu
We collaborate with the Girl Scouts of USA to examine team-based factors of Girl Scouts' engagement retention in their Cookie Program. We find that a small troop size and more evenly distributed sales performance within the troop are positively associated with the propensity to stay. In addition, a troop having a high adult-to-girl ratio and a significant scout level (i.e., an age measure) heterogeneity are conducive to scout retention. However, we find that racial diversity has no significant effect on turnover. Finally, conducting troop-based booth sales is related to scouts' deciding to stay. Our study carries implications for developing more innovative and cost-effective approaches to keeping participants engaged in the volunteering and fundraising activities in an NPO setting.

4 Offering Memories to Sell Goods? Pricing and Welfare Implications of Experiential Retail
Nevin Mutlu[1], Hadi El-Amine[2], Ozge Sahin[3], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]George Mason University, Fairfax, VA, [3]Johns Hopkins University, Baltimore, MD
In an environment where consumers' rising valuation of Instagrammable memories drives their spending from products to experiences, retailers offer experiences to attract consumers back to their stores. In this work, we study under which settings consumers can benefit from these experiences and raise retailers' profits via a novel consumer choice model. Being the first to study this new retail format, our results highlight that there is no one-size-fits-all strategy. We show that experiences affect main product sales in non-obvious ways, especially in competitive markets. In a (post)-pandemic world where retailers try to attract consumers back to stores, we offer insights that can guide retailers in the process.

5 Intertemporal Spillovers in Consumer Experiences: Empirical Evidence and Service Design Implications
Abhishek Deshmane[1], Victor Martinez de Albeniz[1], Guillaume Roels[2], [1]IESE Business School, Barcelona, Spain; [2]INSEAD, Fontainebleau, France. Contact: guillaume.roels@insead.edu
This study examines intertemporal spillover effects in experiential consumption, where the evaluation of future activities can be influenced positively (assimilation) or negatively (contrast) by previous ones. We develop a model that disentangles these spillovers from underlying experience

quality and test it with retrospective data in four contexts. Results show that both types of spillovers are salient, especially when activities are similar and experienced closely in time. Positive spillovers have implications for experience design, suggesting scheduling the best activity in the middle and saving it as a "wild card" under uncertainty. New insights for service experience design based on counterfactual analyses are provided.

Network Revenue Management and Supply Chain Interface

Community Committee Choice Session

Session Chair: Levi DeValve, University of Chicago, Chicago, IL

1 Efficient Algorithms for Minimizing Compositions of Convex Functions and Random Functions and Its Applications in Network Revenue Management

Xin Chen[1], Niao He[2], Yifan Hu[3], Zikun Ye[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Illinois Urbana-Champaign, Urbana, IL, [3]EPFL, Lausanne, Switzerland; [4]University of Illinois Urbana Champaign, Urbana, IL

We study a class of nonconvex stochastic optimization, where the objective function is a composition of a convex function and a random function. Leveraging an (implicit) convex reformulation via a variable transformation, we develop stochastic gradient-based algorithms and establish their sample and gradient complexities for achieving a global optimal solution. Interestingly, our proposed Mirror Stochastic Gradient method operates in the original decision space using gradient estimators of the original objective and achieves sample and gradient complexities matching the lower bounds for solving stochastic convex optimization problems. Our methodology applies to the air-cargo network revenue management problem using booking limit control and provides superior performance over the state-of-the-art bid-price-based control policies.

2 The Golden Geese Problem

Weizhong Zhang[1], R. Ravi[1], Alan Scheller-Wolf[2], Karan Singh[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Tepper School of Business, Pittsburgh, PA, Contact: weizhong@andrew.cmu.edu

In the task of sequential short-form content recommendations such as YouTube shorts, the engine must carefully balance the need to prioritize items that provide high revenue, which may lead to termination (such as ads) and the need to serve lower revenue but a potentially more engaging content (such as short videos). We formalize this via an episodic reward aggregation model, a strict generalization of previously studied cascading bandit models.

With known parameters, we give an efficient, optimal dynamic program to sequence the items. Without such prior info, we propose an efficient UCB-style algorithm and furnish both instance-dependent and worst-case regret guarantees, which are tight in terms of their dependence on the horizon and the size of the item set. We demonstrate our proposal's efficacy in synthetic experiments and two real-world data sets.

3 Combining a Smart Pricing Policy with a Simple Replenishment Policy: Managing Uncertainties in the Presence of Stochastic Purchase Returns

Alys Liang[1], Stefanus Jasin[2], Joline Uichanco[3], [1]Michigan Ross, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Michigan, Ross School of Business, Ann Arbor, MI, Contact: jiaxinl@umich.edu

Regarded as the 'ticking time bomb' in the industry, returns have cost US retailers hundreds of billions of dollars. Undesirable as returns are, they cannot be entirely eliminated and lenient return policies are essential to maintain customer loyalty. Motivated by the reality, we ask: How can a retailer offering lenient return policy improves business efficiency? We model a single store/warehouse setting with lost sales, positive lead time, periodic review, and Binomial (Poisson) demand. Within a grace period, a purchase might be returned at a full refund and restocked after inspection. We develop an easy-to-implement heuristic policy that combines a 'smart' adaptive pricing policy with a very simple replenishment policy, under which the uncertainties in both demands and returns are effectively turned, leading to significant improvements in business performance.

4 Dynamic Control in On-Demand Inventory Sharing Networks

Hansheng Jiang, University of Toronto, Toronto, ON, Canada

We address the operational challenge inherent in one-way on-demand sharing services comprising a fixed number of units dispersed across multiple network locations. In such a system, customers can rent units without prior reservations and return them to any location within the network. The service provider must periodically reposition units to equilibrate supply and demand, minimizing costs related to repositioning labor and lost sales. Beyond direct repositioning measures, supplementary control mechanisms like pricing and wage adjustments may also alleviate supply-demand imbalances. This presentation delves into an adaptive inventory control problem aimed at devising a comprehensive solution that incorporates both pricing and repositioning tactics in managing one-way on-demand sharing networks.

Policy Evaluation and Long-term Treatment Effects

Community Committee Choice Session

Session Chair: Daniel Russo, Columbia University, New York, NY

Session Chair: David Cheikhi, Columbia University, New York, NY

1 On the Statistical Benefits of Temporal Difference Learning

David Cheikhi, Daniel Russo, Columbia University, New York, NY

Given a dataset on actions and long-term rewards, a direct estimation approach fits value functions that minimize prediction error on the training data. Temporal difference learning (TD) instead fit value functions by minimizing inconsistency between estimates made at successive time-steps. For finite state Markov chains, we provide a crisp asymptotic theory of the statistical advantages of TD. First, we show that an intuitive inverse trajectory pooling coefficient completely characterizes the reduction in mean-squared error of value estimates. Depending on problem structure, the gain could be enormous or nonexistent. Next, we prove that there can be dramatic improvements in estimates of the difference in value-to-go for two states: TD's errors are bounded in terms of a novel measure - the trajectory crossing time - which can be much smaller than the time horizon.

2 The Many Faces of TD: Approximation, Estimation, and Acceleration

Ashwin Pananjady, Georgia Tech, Atlanta, GA, Contact: apm7@gatech.edu

Temporal difference (TD) learning is the de facto algorithm for policy evaluation, and a linear parametrization is often used to approximately compute the original value function. In infinite horizon, discounted Markov reward processes, it is designed to estimate a certain projected fixed point and converges to this point while satisfying certain deterministic (optimization) and stochastic (statistical) error bounds. We ask whether (a) the fixed point of TD best approximates the original value function, (b) the statistical error of the algorithm is locally optimal, and (c) the optimization rate of the algorithm can be improved. This talk will present answers to these questions, introducing variants of TD that attain improved (and/or optimal) approximation, estimation, and acceleration.

3 Correcting for Interference in Experiments: A Case Study at Douyin

Andrew T. Zheng, Massachusetts Institute of Technology, Boston, MA

Interference is a ubiquitous problem in experiments on two-sided content marketplaces, such as Douyin. In many cases, creators are the natural unit of experimentation, but creators interfere with each other through competition for viewers' time and attention. Estimators ignoring interference incur bias on the order of the treatment effect; but unbiased estimators are impractically high variance. We introduce a novel estimator, based on ``Differences-in-Qs'' (DQ) techniques, which is sample efficient and achieves bias second-order in the treatment effect. In doing so, we develop a generalized theory of Taylor expansions for policy evaluation, extending to all major MDP formulations. Finally we implement our estimator on Douyin's experimentation platform, and in the process develop DQ into a truly ``plug-and-play'' estimator for interference in the real-world.

4 Estimating the Long-Term Effects of Novel Treatments

Keith Battocchi[1], Eleanor Dillon[1], Maggie Hei[2], Greg Lewis[3], Miruna Oprescu[4], Vasilis Syrgkanis[5], [1]Microsoft, Cambridge, MA, [2]ByteDance, Bejing, China; [3]Amazon, Cambridge, MA, [4]Cornell University, New York, NY, [5]Stanford University, Stanford, CA

Policy makers often need to estimate the long-term effects of novel treatments, while only having historical data of older treatment options. We propose a surrogate-based approach using a long-term dataset where only past treatments were administered and a short-term dataset where novel treatments have been administered. Our approach generalizes previous surrogate-style methods, allowing for continuous treatments and serially-correlated treatment policies while maintaining consistency and root-n asymptotically normal estimates under a Markovian assumption on the data and the observational policy. Using a semi-synthetic dataset on customer incentives from a major corporation, we evaluate the performance of our method and discuss solutions to practical challenges when deploying our methodology.

Advances in Revenue Management

Community Committee Choice Session

Session Chair: Tarek Abdallah, Northwestern University, Kellogg School of Management, Chicago, IL

Session Chair: Ashwin Venkataraman, University of Texas at Dallas, Richardson, TX

1 An Ensemble Learning Approach for Estimating the Mixture of the MNL Choice Models

Mohammad Amin Farzaneh[1], Tarek Abdallah[2], Ashwin Venkataraman[1], [1]University of Texas at Dallas, Richardson, TX, [2]Northwestern University, Kellogg School of Management, Chicago, IL, Contact: mxf180000@utdallas.edu

Estimating mixture models, such as the mixture of multinomial logit (MNL) models, is often challenging due to slow convergence and sensitivity to initialization when using the Expectation-Maximization (EM) algorithm. We investigate ensemble learning approaches as alternative estimation methods for the mixture of MNL models. Through empirical experiments, we compare the performance of ensemble learning techniques such as bagging and boosting with the EM algorithm. Our findings demonstrate that ensemble learning approaches offer improved estimation accuracy.

2 Joint Estimation of Arrival Rate and Customer Preference Parameters Under the Nested Logit Model

Xinchang Wang, Weikun Xu, Washington State University, Pullman, WA, Contact: weikun.xu@wsu.edu

This work aims to jointly estimate the arrival rate of customers to a market and the nested logit model that forecasts the probability of customers choosing a specific product from a set of alternatives. The goal is to determine the arrival rate, customer preference parameters, and nest dissimilarity parameters that maximize the likelihood of the observed transactional data. The problem is challenging since the likelihood function may be non-concave. We provide sufficient and necessary conditions under which the model parameters are identifiable. We develop a sequential minorization-maximization algorithm to solve the problem, by which the problem boils down to solving a series of convex optimization models. The algorithm is highly scalable, making it well-suited to problems with large-scale data. The algorithm is tested using real flight ticket booking data.

3 A Unified Analysis for Assortment Planning with Marginal Distributions

Zeyu Sun[1], Xiaobo Li[1], Selin Ahipasaoglu[2], [1]National University of Singapore, Singapore, Singapore; [2]SUTD, Singapore, Singapore

We study assortment planning under the marginal distribution model (MDM), a semiparametric choice model that only requires information about the marginal noise. We demonstrate that some multi-purchase choice models such as the multiple-discrete-choice (MDC) model and the threshold utility model (TUM) also fall into the framework of MDM. For assortment problems within the MDM framework, we identify a general condition under which a strictly profit-nested assortment is optimal. While the problem is NP-hard, we show that the best strictly profit-nested assortment is a 1/2-approximate solution for all MDMs. Additionally, we present a simple example of an MDM for which the 1/2-approximate bound is tight. Additionally, we present an arbitrary-close approximation algorithm for MDM, and an improved version for a class of choice models that includes MDC as a special case.

4 Heavy Tailedness and the Single Item Dynamic Pricing Problem

Tarek Abdallah, Northwestern University, Kellogg School of Management, Chicago, IL

We consider the single item dynamic pricing problem in an asymptotic regime where the selling horizon tends to infinity. Our main results provide the asymptotics of the optimal expected revenue, selling price and purchasing probability in the extreme value regime for valuations that have a heavy tail. We show that the optimal policy is of a generalized run out rate form that is different from those obtained from the fluid regime. Through extensive numerical simulations we demonstrate that when expected demand is high relative to inventory levels our proposed extreme value regime pricing policies are capable of outperforming other commonly used policies designed for the traditional fluid regime.

Simulation-based Stochastic Optimization

Community Committee Choice Session

Session Chair: Wei Xie, Northeastern University, Boston, MA

Session Chair: Ilya O. Ryzhov, University of Maryland, College Park, MD

1 Nested Elimination: A Simple Algorithm for Best-Item Identification from Choice-Based Feedback

Junwen Yang[1], Yifan Feng[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore

We study a ranking and selection problem from choice-based feedback. In this problem, a company sequentially presents display sets to customers and collects their choices, aiming to identify the most preferred item with minimal samples and high confidence. We introduce Nested Elimination (NE), a novel elimination-based algorithm inspired by the nested structure implied by the information-theoretic lower bound. Boasting a simple structure and ease of implementation, NE offers robust theoretical guarantees concerning sample complexity. Numerical experiments using synthetic and real data support our theoretical results.

2 Adaptive Experimentation at Scale: A Computational Framework

Hongseok Namkoong, Ethan Che, Columbia University, New York, NY, Contact: namkoong@gsb.columbia.edu

Bandit algorithms can provide substantial statistical power but are difficult to implement and maintain in practical problem instances involving large batches, delayed feedback, and a small number of opportunities to reallocate sampling effort. We design near-optimal, easy-to-deploy adaptive experimentation algorithms that can flexibly deal with any batch size. Our main observation is that normal approximations universal in statistics can guide the design of scalable adaptive experimentation methods. Our method significantly improves statistical power over standard adaptive policies (e.g., Thompson sampling). Overall, we expand the scope of adaptive experimentation to settings that are difficult for standard adaptive policies, including problems with a small number of reallocation epochs, low signal-to-noise ratio, and unknown reward distributions.

3 Semidiscrete Optimal Transport with Unknown Costs

Yinchu Zhu[1], Ilya O. Ryzhov[2], [1]Brandeis University, Waltham, MA, [2]University of Maryland, College Park, MD, Contact: iryzhov@rhsmith.umd.edu

In semidiscrete optimal transport, we design a joint distribution for two random variables (one continuous, one discrete) with fixed marginals, in a way that minimizes an expected cost function. We formulate a novel variant of this problem in which the cost function is unknown, but can be learned through stochastic simulation. This problem presents a novel combination of contextual ranking and selection and stochastic approximation. We propose a computationally efficient solution procedure, again combining elements of both methodologies, that achieves near-optimal convergence rates and performs well in numerical experiments.

4 Reinforcement Learning Based Process Control with Digital Twin Model Calibration

Hua Zheng[1], Wei Xie[1], Ilya O. Ryzhov[2], [1]Northeastern University, Boston, MA, [2]University of Maryland, College Park, MD, Contact: zheng.hua1@northeastern.edu

To support biopharmaceutical manufacturing automation, we present a novel reinforcement learning framework that integrates digital twin calibration and optimal control of the physical system. The objective is to maximize the expected accumulated reward while enhancing the fidelity of the digital twin model. Through local polynomial regression, we incorporate crucial information from the physical system into the action-value function, enabling a sample-efficient calibration of the digital twin model. The effectiveness and resilience of the proposed framework are shown with both empirical analysis and theoretical study.

1 Deep Reinforcement Learning for Large Scale Inventory Management

Xiaotian Liu, Yijie Peng, Peking University, Beijing, China. Contact: xiaotianliu01@gmail.com

This work introduces a simulation-driven machine learning framework exploiting both Deep Learning (DL) and Reinforcement Learning (RL) for large-scale inventory management. On data generated by simulation of the decision processes, a DL model is first trained by imitating the well-performing policy, after which an RL procedure is applied to fine-tune the DL model for further improvement. We formulate a multi-echelon multi-product problem with a practical warehouse network structure and shared storage resource as a representative of hard inventory problems without existing well-performing policies. RL model is trained based on feedback from the simulation of the decision processes. Our numerical results on real data from JD.com show that our method significantly outperforms a combination of several heuristics adapted to this problem.

2 Integrating Single Observation Adaptive Search with Probabilistic Branch and Bound for Noisy Black-Box Optimization

Pariyakorn Maneekul, Zelda B. Zabinsky, University of Washington, Seattle, WA, Contact: parim@uw.edu

We address noisy black-box optimization using single observations, as opposed to multiple replications, within Probabilistic Branch and Bound (PBnB). The single observation method estimates stochastic objective function values from neighboring solutions. This study integrates single observation adaptive search with PBnB and enhances the statistical estimation with a local quadratic regression. Additionally, a regularization technique is applied to the quadratic regression to accommodate problems in high dimensions. Numerical experiments on benchmark problems are presented to compare the performance of PBnB with multiple replications, single observations, and enhanced single observation method with statistical models.

3 Pricing Catastrophe Bonds --- A Probabilistic Machine Learning Approach

Hong Li[1], Xiaowei Chen[2], Yufan Lu[2], Rui Zhou[3], [1]University of Guelph, Guelph, ON, Canada; [2]Nankai University, Tianjin, China; [3]University of Melbourne, Melbourne, Australia. Contact: lihong@uoguelph.ca

This paper proposes a probabilistic machine learning method to price catastrophe bonds in the primary market. The proposed method combines machine-learning-based predictive models with conformal predictions, generating generate distribution-free probabilistic predictions of bond spreads. Using primary market bond data, the proposed method is found to be more robust and yields more accurate predictions of the bond spreads than traditional methods such as linear regression. Furthermore, the proposed method generates more informative prediction intervals than learning regression and identify important nonlinear relationships between different risk factors and bond spreads, suggesting that linear regression could mis-estimate the bond spreads. Overall, this paper demonstrates that machine learning methods could improve pricing of catastrophe bonds.

4 Mortality And Longevity Capital Risk Management: A Simulation Approach Using Surrogate Models

Shuai Yang[1], Kenneth Q. Zhou[2], [1]Aon PathWise Solutions Group, Toronto, ON, Canada; [2]Arizona State University, Tempe, AZ, Contact: kenneth.zhou@asu.edu

In the insurance industry, life insurers are required by regulators to meet capital requirements to avoid insolvency caused by, for example, sudden mortality changes due to the COVID-19 pandemic. To prevent any large movements in this required capital, insurance companies are incentivized to establish hedging strategies to mitigate their underlying risk exposures. However, the development and implementation of a risk mitigation solution for reducing solvency capital requirements are often challenged by computational burdens due to the large number of simulation. In this paper, we investigate a surrogate-based approach for solving this simulation problem. Our finding provides a numerical justification to the market-making of the mortality-linked securities in the context of mortality and longevity capital risk management.

5 Truncated Likelihood Ratio Method

Guangxin Jiang[1], Liang YIjuan[2], [1]Harbin Institute of Technology, Harbin, China; [2]Southwest University, Chongqing, China

In many decision-making problems, historical data obtained from repeated experiments is often available. However, when applying the likelihood ratio method to reuse this data, the distribution of new data may significantly differ from the distributions of the historical data, leading to a high variance for the likelihood ratio and a poorly performing estimator. In this talk, we introduce a truncated likelihood ratio method to control the variance of the likelihood ratio. We establish the optimal relationship between the truncated threshold and the sample size using Renyi divergence and Bernstein inequality in two settings: bounded performance function and unbounded performance function with existing higher-order moments. Our numerical examples demonstrate the effectiveness of the truncated likelihood ratio method.

Simulation Applications in Operations Planning

Community Committee Choice Session

Session Chair: Canan Corlu, Boston University, Boston, MA

1 Optimizing Resource Allocation in Service Systems via Simulation: A Bayesian Formulation

Weiwei Chen[1], Gao Siyang[2], Wenjie CHEN[3], Jianzhong Du[4], [1]Rutgers University, Piscataway, NJ, [2]City University of Hong Kong, Kowloon, NA, Hong Kong; [3]City University of Hong Kong, Hong Kong SAR, Hong Kong; [4]City University of Hong Kong, Hong Kong, Hong Kong. Contact: wchen@business.rutgers.edu

This paper studies a class of resource allocation problems, where the performance measures are probabilistic and evaluated via simulation. An optimal computing budget allocation (OCBA) formulation is proposed to select the optimal solution subject to random noises in simulation. The OCBA formulation minimizes the expected opportunity cost that penalizes based on the quality of the selected solution. Further, the formulation takes a Bayesian approach to consider the prior knowledge and potential performance correlations on candidate solutions. Then, the asymptotic optimality conditions of the formulation are derived, and an iterative algorithm is developed. Numerical experiments and a case study in a hospital emergency department demonstrate the effectiveness of the proposed algorithm for solving the resource allocation problem via simulation.

2 Pandemic Management: Minimizing Vaccine Waste and Group Wait Time with Line Jumpers

Chun-Miin (Jimmy) Chen, Bucknell University, Lewisburg, PA, Contact: cmc052@bucknell.edu

During the initial rollout of COVID-19 vaccines, individuals from the non-priority groups, or line jumpers, managed to get vaccinated before their turn by taking advantage of any leftover vaccine doses. Some argue that all vaccine doses should be strictly reserved for requesters from the priority groups, while others argue that vaccinating jumpers with leftover doses could reduce leftover doses that may expire. We define a heuristic policy that specifies a limit on the number of jumpers allowed. Moreover, we formulate an objective function of the average total wait time of requesters and vaccines to evaluate the optimal parameter values for the policy. Using the sample average approximation method, we suggest policy proposals by which the sites can minimize the objective function value.

3 Repair Kit Simheuristic Inventory Modeling

John Maleyeff, Ruthairut Wootisam, Boston University, Boston, MA, Contact: maleyeff@bu.edu

A simheuristic model creates repair kit inventory policies for intermittent demand repairs, where every part must be available for the repair to take place. The approach starts by applying a deterministic optimization model to calculate initial values for reorder points and order-to-to levels (s,S) for each part. This model is applied independently to each part within the repair kit. A simulation of the entire repair kit estimates the total annual cost associated with the (s,S) policy. The simheuristic algorithm uses a stochastic method to calculate slopes for the total cost equation based on unit changes (up or down) to each part's reorder points and order-up-to level. A modified branch-and-bound algorithm creates near optimal solutions in the presence of uncertainty.

4 Queueing Inspired Feature Engineering to Improve and Simplify Patient Flow Simulation Metamodels

Mark W. Isken, Osman T. Aydas, Yazan F. Roumani, Oakland University, Rochester, MI, Contact: aydas@oakland.edu

This study merges the application of discrete-event simulation with alternative metamodeling techniques for modeling patient flow in healthcare. We consider two cases: A tandem queueing system of obstetric hospital units and a transient analysis of an outpatient clinic. We use several metamodels including various types of linear models, random forests and neural networks. We evaluate the performance improvement of metamodel estimations when empowered with supplementary queueing theory knowledge. We consider three knowledge levels: no queueing inspired features, simple queueing features and sophisticated queueing approximations. Our results show that queueing related inputs improve the accuracy for the metamodels, independent of the model type. Moreover, the queueing related inputs improve model explainability and can lead to more parsimonious models.

DAS Awards Session

Award Session

Session Chair: Yael Grushka-Cockayne, Darden School of Business, Charlottesville VA, VA

1 DAS Ramsey Award 2023

Emanuele Borgonovo, Bocconi University, Milano, Italy

This session will introduce the 2023 Ramsey Awardee of the Decision Analysis Society. The Frank P. Ramsey medal is awarded for distinguished contributions in decision analysis. Distinguished contributions can be internal, such as theoretical or procedural advances in decision analysis, or external, such as developing or spreading decision analysis in new fields.

2 Decision Analysis Practice Award 2023

K. Nadia Papamichail, The University of Manchester, Manchester, United Kingdom

We will introduce the 2023 Decision Analysis Practice Award Finalists and Winners. The Decision Analysis Practice Award is sponsored jointly by the Decision Analysis Society and the Society of Decision Professionals. It is given annually to an outstanding decision analysis application that has made a significant difference in a critical decision.

3 Award Presenter

Aurelien Baillon, Erasmus University Rotterdam, Rotterdam, Netherlands

4 Best Paper Award

Sasa Zorc, University of Virginia, Darden School of Business, Charlottesville, VA

The Award is given annually to the best decision analysis paper by a student author, as judged by an award selection committee. For this award, decision analysis is defined as a prescriptive approach to provide insight for decision making based on axioms that are logically consistent with the axioms of von Neumann and Morgenstern and of Savage. Key constructs of decision analysis are the utility to quantify one's risk preferences and the probability to quantify the state of one's knowledge. The intent of the award is to recognize the best publication in decision analysis, by a student. This includes, but is not limited to, theoretical and methodological contributions to decision analysis, descriptions of applications, and experimental studies.

Emerging Topics in Socially Responsible Operations

Community Committee Choice Session

Session Chair: Can Zhang, Duke University, Durham, NC

1 Improving Group Testing in a Pandemic

Tong Wang, Kamalini Ramdas, S. Alex Yang, London Business School, London, United Kingdom

During a pandemic, we rely on accurate tests to identify positive cases and reduce infection, yet large-scale tests can be costly to run and subject to capacity constraints. Group testing can efficiently test populations and significantly save testing capacities. In a group test, samples are first pooled and tested. If the result is negative, every individual in the group is healthy. Otherwise, individual tests are conducted to detect the infected individuals. The appropriate group size depends on the underlying risk level of individuals. In this study, we examine different approaches that health policymakers or health administrators can use to improve group formation for the pooling stage of the testing procedure, particularly in the presence of heterogeneous and unobservable risk levels among individuals.

2 A Framework for Designing Policy for Incentivizing Sustainable Crop Cultivation

Sanchita Das, Masha Shunko, University of Washington, Seattle, WA

We propose a data driven framework to study the gap between the optimal crop production preferences of the government and smallholder farmers in the context of India. We characterize the gap analytically and design incentives for coordinating the two optima. Parallelly, we build a forecasting pipeline for yield of crops and use causal models/trees to determine pathways to bridge the gap. This study is generalizable and can provide a useful framework to design policy towards facilitating a financially viable shift to sustainable crop production at scale.

3 Ethics in the AI Supply Chain: A Study on Experiences and Fairness in Crowdwork
Martin Gonzalez Cabello, Auyon Siddiq, Charles J. Corbett, University of California, Los Angeles, Los Angeles, CA, Contact: martin.gonzalez.cabello.phd@anderson.ucla.edu
This paper explores the role of human labor in the Artificial Intelligence (AI) industry, with a specific focus on crowdwork and data labelling. We conducted a survey on the personal experiences of crowdworkers, examining the correlation between these experiences and how they perceive fairness of the platforms. Our research uncovers a wide spectrum of crowdwork experiences and analyzes various factors to ascertain their impact on workers' fairness perception. We also explore how these experiences and fairness perceptions vary across different platforms. The paper concludes with prescriptions for improving crowdworker welfare and suggestions for future research, emphasizing the potential influence on AI development and the crowdwork industry.

4 Sustainable Sourcing of Agricultural Products: Fixed vs. Flexible Premiums
Vishal Agrawal[1], Can Zhang[2], [1]Georgetown University, Washington, DC, [2]Duke University, Durham, NC, Contact: va64@georgetown.edu
Sustainability certification programs, such as Fairtrade, have gained increasing popularity for the sourcing of agricultural products. In order to help smallholder farmers achieve a living income and to promote sustainable agricultural practices, an important lever these certification programs use is a premium that manufacturing firms pay to certified farmers. This paper analyzes and compares the effectiveness of two different premium strategies that have been considered by different certifiers in practice: fixed premium, under which farmers receive a fixed premium level that is independent of the market price, and flexible premium, under which farmers receive a higher premium level when the market price is lower.

OR and Analytics in Healthcare: From Predicitons to Decisions

Flash Session

Session Chair: Afrooz Moatari-Kazerouni, Widener University, Chester, PA

1 ML-CTG: Machine Learning for Cardiotocography-Based Fetal Health Classification
Maryam Ahmadi[1], Minoo Ahmadi[2], [1]Clark University, WORCESTER, MA, [2]University of Southern California, Los Angeles, CA
In pursuit of the UN Sustainable Development Goals to reduce child and maternal mortality, this study leverages Cardiotocography (CTG) for fetal health assessment, aiming to develop accurate classification models with a focus on

prioritizing recall as the key metric. We evaluate several methods, including Decision Trees, K-Nearest Neighbors, Gaussian Naive Bayes, Logistic Regression, Random Forest, and Voting Classifier. The Pruned Decision Tree performs the best, achieving 96% accuracy with recall scores of 100% (Pathological), 96% (Normal), and 94% (Suspect). Our findings emphasize the significance of the Abnormal Short-Term Variability (ASTV) indicator in fetal health. This study contributes to global efforts to reduce mortality, providing valuable guidance for healthcare practitioners.

2 Digital Phenotyping-Based Depression Detection in the Context of Comorbidity

Zhijun Yan[1], Fei Peng[1], Dongsong Zhang[2], [1]Beijing Institute of Technology, Beijing, China; [2]The University of North Carolina at Charlotte, Charlotte, NC

Depression and is a growing health and societal concern that has become increasingly prevalent and burdensome, especially for the patients with other comorbidities. Digital phenotyping (DP) has emerged as a such promising tool that is widely used to detect depression. However, existing DP-based detection of depression doesn't consider the uncertainty caused by similar symptoms between depression and its comorbidities. In this study, we propose a deep learning model that can fuse and analyze different sensor data based on the evidence theory to address the uncertainty in depression detection. We evaluate the proposed model against state-of-the-art models on the sensor data. Our work contributes to the remote monitoring and self-management of mental health.

3 Analysis of U.S. Medical Device Recalls

Shuyu Lai, Westwood High School, Austin, TX

We investigate the medical device registration and recall data accessed from FDA. We find that medical device recalls in the U.S. increased significantly during 2001-2004, 2007-2010 and 2012-2017, and decreased from 2018 and during the pandemic. Class II recalls (that may cause temporary or medically reversible adverse health consequences, or the probability of serious adverse health consequences is remote) were the most among the three classes of recalls, but there is no significant correlation between the classes of recalls and the classes of devices. We also find that the proportion of foreign manufacturers among all that request US device approvals has significantly increased, while there is no significant correlation between this trend and the recalls.

4 Data-Driven Modeling to Project Omicron Scenarios in the U.S. While Tracking Population-Level Immunity

Kaiming N. Bi, UT austin, Austin, TX, Contact: kaiming.bi@austin.utexas.edu

As new COVID-19 variants emerge, rapid risk assessments are vital for estimating the epidemiological impact, designing mitigation strategies, and communicating with the public. Here, we introduce a COVID-19 transmission model that tracks the changing levels of population-wide immunity resulting from infections and vaccines. The model accurately predicted the timing and magnitude of the waves following the emergence of the BA.1, BA.4 and BA.5 variants. As of October, 2022, we estimate that population immunity against the BA.4/BA.5 variants totalled 36.52% with 22.57%, 5.35%, and 8.6% attributable to infections by prior variants, primary series vaccination, and booster vaccination, respectively.

5 When are Predictions Useful? A New Method for Evaluating Interval-Form Epidemic Forecasts

Maximilian Marshall, Felix Parker, Lauren Gardner, Johns Hopkins University, Baltimore, MD, Contact: mmarsh29@jh.edu

We introduce the Weighted Contextual Interval Score (WCIS), a new method for evaluating interval-form forecasts. Developed in response to the challenges of predicting turbulent COVID-19 outcomes, the score provides a pragmatic characterization of the utility of pandemic predictions. Currently used evaluation techniques generally fall into two groups: those that generate an individually interpretable metric, and those that generate a comparable and aggregable metric. The WCIS harmonizes these attributes, resulting in a normalized score that is nevertheless intuitively representative of the in-situ quality of individual forecasts. We also discuss why contextual interpretation of epidemic forecasts is necessary in a broader sense, and why this is important to consider as the community refines and develops prediction methods for future challenges.

6 An Examination of Disruptive Healthcare Technologies for Emergency Departments

Afrooz Moatari-Kazerouni, Shea'lyn Hubbs, Amin Keramati, Widener University, Chester, PA, Contact: amoatarikazerouni@widener.edu

This research presents a comprehensive review of disruptive technologies, including Blockchain, IoT, and RFID, for emergency department at hospitals. With the increasing demand for efficient and effective healthcare services, the adoption of technologies has become a critical consideration for healthcare institutions. This study focuses on exploring the role of these emerging healthcare technologies, to transform emergency department operations, through the Business Process Reengineering (BPR) approach. Findings indicate that these technologies have the potential to enhance the quality of care, reduce costs, and improve patient outcomes. The results highlight the need for further research and collaboration between healthcare providers and technology developers to fully realize the benefits of disruptive technologies in emergency departments.

2023 BOM Best Working Paper Award

Award Session

Session Chair: Rafael Escamilla, Tilburg University, Tilburg, Netherlands

1 Measuring Strategic Behavior by Gig Economy Workers: Multihoming and Repositioning

Gad Allon, Daniel Chen, Ken Moon, University of Pennsylvania, Philadelphia, PA

Gig economy workers make strategic decisions about where and when to work. These decisions are central to gig economy operations and are important policy targets both to firms that operate ridehail and delivery platforms and to regulators that oversee labor markets. We collaborate with a driver analytics company to empirically measure two types of strategic behavior: multihoming, an online change between platforms, and repositioning, a physical change between locations. Using a comprehensive dataset that tracks worker activity across platforms, we estimate a structural model to analyze how workers optimize their earnings and respond to earnings-based incentives to switch platforms or locations. We show that workers are highly heterogeneous in their preferences and find multihoming especially costly, both in absolute terms and relative to the cost of repositioning. Through counterfactual simulations, we show that firms and regulators can substantially improve system efficiency by enabling workers to freely multihome: workers' hourly earnings increase by 2.0% and service levels increase by 53.1%. In contrast, the existing equilibrium is similar to a system without multihoming, in which hourly earnings increase by 1.3% but service capacity decreases by 4.1%. Additionally, we show that policies to limit traffic congestion by increasing travel costs should include incentives to ensure that workers remain able to efficiently reposition. An increase to repositioning costs by $1 per mile increases hourly earnings by 2.3% but substantially decreases service capacity by 29.6%.

2 Improving Human-Algorithm Collaboration: Causes and Mitigation of Over- and Under-Adherence

Jordan D. Tong[1], Kris Ferreira[2], Maya Balakrishnan[2], [1]University of Wisconsin Madison, Madison, WI, [2]Harvard University, Boston, MA

Even if algorithms make better predictions than humans on average, humans may sometimes have "private" information which an algorithm does not have access to that can improve performance. How can we help humans effectively use and adjust recommendations made by algorithms in such situations? When deciding whether and how to override an algorithm's recommendations, we hypothesize that people are biased towards following a naïve advice weighting (NAW) heuristic: they take a weighted average between their own prediction and the algorithm's, with a constant weight across prediction instances, regardless of whether they have valuable private information. This leads to humans over-adhering to the algorithm's predictions when their private information is valuable and under-adhering when it is not. In a lab experiment where participants are tasked with making demand predictions for 20 products while having access to an algorithm's recommendations, we confirm this bias towards NAW and find that it leads to a 20-61% increase in prediction error. In a follow-up experiment, we find that feature transparency - even when the underlying algorithm is a black box - helps users more effectively discriminate when and how to deviate from algorithms, resulting in a 25% reduction in prediction error.

3 Competition in Optimal Stopping: Behavioral Insights

Ignacio Rios, Pramit Ghosh, The University of Texas at Dallas, Richardson, TX

: Problem definition: We study settings in which a clearinghouse organizes a market where agents sequentially search among different options under competition. We focus on the effect of two market design choices that are motivated in the context of kidney transplants: (i) transparency, i.e., whether agents know their priority relative to the other agents searching; and (ii) the mechanism to collect decisions, i.e., whether all agents make their decisions simultaneously or sequentially.Methodologies/results: We introduce a model of sequential search under competition, whereby agents are exogenously prioritized and must decide when to stop their search to maximize the chosen option's value. For each configuration, we characterize the optimal policy, which defines a sequence of thresholds that determine when each agent should accept an option depending on the information available. We find that, although the mechanism does not affect the optimal policy, providing information about agents' priorities reduces the overall welfare and fairness. We design and conduct a lab experiment that replicates our theoretical model to test these predictions. We find that agents significantly deviate from their corresponding optimal policies. Moreover, we find that the mechanism has a significant effect on their decisions, due primarily to two drivers: (i) saliency of competition and (ii) frustration. Finally, we find that the benefits of opaqueness do not translate to practice, mainly because agents do not incorporate relevant information about the amount of competition.Managerial implications: Our results show that the mechanism to collect agents' decisions matters, as it may affect the saliency of competition and induce frustration. Moreover, our results show that welfare and fairness could increase if agents have only partial information about their ranking, but these benefits do not translate to practice due to information friction.Thus, clearinghouses should accompany these changes with information policies and guidance to alleviate these effects.

4 Customers' Multihoming Behavior in Ride-hailing: Empirical Evidence Using a Structural Model

Maxime Cohen[1], Dmitry Mitrofanov[2], Sandeep Chitla[3], Srikanth Jagabathula[3], [1]McGill University, Kirkland, QC, Canada; [2]Boston College, Newton, MA, [3]New York University, New York, NY

Are customers loyal to a ride-hailing platform or they see this service as a commodity and multihome (i.e., check several platforms before booking a ride)? Using a large panel dataset on ride-hailing transactions, we investigate to what extent customers multihome. Our dataset offers a unique opportunity to study this question as we observe the repeated choices of riders for both Uber and Lyft. Our dataset comprises more than 1.4 million rides completed by 160 thousand riders in NYC in 2018. We develop a comprehensive structural model that incorporates both operational (price and waiting time) and behavioral factors (e.g.,platform stickiness) to explain riders' choices. Our model also accounts for the dynamic interactions between customers and platforms by assuming that riders update their beliefs on price and waiting time in a Bayesian fashion. Finally, the riders' propensity to multihome is modeled by incorporating the consideration set formation of customers into our framework. We find that riders' choices are not fully explained by operational factors, hence indicating that customers view the platforms as differentiated service providers. While 65% of riders took rides with a single platform, our model shows that even the remaining 35%, who used both Uber and Lyft at least once, considered both platforms 43% of the time. It is crucial for ride-hailing platforms to capture this single (or multi)-homing behavior while designing promotions. Specifically, personalized promotions may be ineffective if the platform is not part of the customer's consideration set. Our results show that targeting customers earlier in their lifecycle can enhance the platform's market share by 77.56% more than their current promotional strategy. We also find that targeting customers with low search friction results in a 24.78% higher increase in market share than targeting customers with high search friction

Fairness in Operations Research

Community Committee Choice Session

Session Chair: Swati Gupta, ISyE Georgia Tech, Atlanta, GA

1 Fair Fares for Vehicle Sharing Systems

Adam Elmachtoub[1], Hyemi Kim[2], [1]Columbia University, New York, NY, [2]Columbia University, New York, NY, Contact: hk3181@columbia.edu

Vehicle sharing systems show inequalities in fares and accessibility correlated to demographic factors of riders' neighborhoods. This paper proposes a framework for embedding fairness considerations in vehicle sharing systems from the consumer perspective. We consider two notions of fairness that measure how similar the prices are and how similar the access is at each location, where access is a product of vehicle availability and ride affordability. Under a stylized model, we analyze the impact of these fairness criteria on consumer surplus and social welfare. We find that achieving both price and access fairness simultaneously is impossible in practice. With price fairness, we characterize four regimes corresponding to different effects on social welfare and consumer surplus. Surprisingly, we show that imposing access fairness always makes all parties worse off.

2 Scalable Constant-Factor Approximation Algorithms for Socially Fair K-Clustering

Mehrdad Ghadiri[1], Mohit Singh[2], Santosh Vempala[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, ATLANTA, GA

Given a set of points and a metric, the socially fair k-clustering asks for a set of k-centers that minimizes the maximum average clustering cost across demographic

groups. We discuss constant factor approximation algorithms for this problem. Given m demographic groups, using an iterative rounding approach, we show how to obtain a constant factor approximate solution in polynomial time with at most k+m centers. We also present two different algorithms for converting such a solution to a solution with exactly k centers in polynomial time for fixed m. To speed up our algorithm, we propose using a combination of coresets and the k-means++ algorithm. We compare the performance of our algorithms with existing approximation algorithms on benchmark datasets, and find that our algorithms outperform existing methods in practice.

3 Optimizing Equitable Infrastructure Investment Decisions Under High Wildfire Risk Scenarios

Swati Gupta[1], Alyssa Kody[2], Daniel K. Molzahn[3], Ryan Piansky[3], Madeleine Pollack[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Argonne National Laboratory, Lemont, IL, [3]Georgia Institute of Technology, Atlanta, GA, Contact: pollack9@mit.edu

In this work, we model emergency power shutoffs to mitigate wildfire risk on a synthetic transmission network in Texas. To eliminate both wildfire risk and power loss, one can "underground" a transmission line at a high cost per mile. While considering multiple objectives, we explore how a fixed budget for line undergrounding is distributed across the network and which populations benefit most from the investment. Due to the intersection of network characteristics from the power grid, the spatiotemporal-varying distribution of wildfire risk, and demographic patterns; many vulnerable communities are more likely to experience power loss, according to our model. This necessitates the incorporation of "equity" objectives into the optimization model, and we study their impact on the structural properties of load shedding across the network.

4 Fairness and Memory in Online Learning

Jad Salem, U.S. Naval Academy, Annapolis, MD

In recent years, the design of online algorithms subject to fairness constraints has seen increased interest. For example, algorithms satisfying variants of individual fairness have been proposed for several online learning problems. When constraining online decisions, a key decision point is the memory of the constraint: how far back in time should one look when constraining the current decision? Should an offline fairness constraint be imposed across all time, or in a sliding window of length 50, or of length 100? In this talk, I explore the impact of the choice of memory on performance and fairness.

Causal Reinforcement Learning and Human In The Loop

Community Committee Choice Session

Session Chair: Gabriel Zayas-Caban, University of Wisconsin Madison, Madison, WI

Session Chair: Valerie Odeh-Couvertier, University of Wisconsin-Madison, Madison, WI

1 Quasi-Experimental Designs for Learning Health Systems

Valerie Odeh Couvertier, Gabriel Zayas-Caban, Brian Patterson, Amy Cochran, Kenneth Nieser, University of Wisconsin-Madison, Madison, WI, Contact: odehcouverti@wisc.edu

Learning systems use data to improve operations, with risk prediction algorithms playing a key role in deriving knowledge from data. While these algorithms identify individuals or processes that may benefit from interventions, measuring their impact remains a challenge. We develop a causal inference framework, with specific application to learning health systems, for estimating the average causal effect of intervening according to these continually assessed and updating risk prediction algorithms.

2 Can Humans be out of the Loop?

Junzhe Zhang, Columbia University, New York, NY, Contact: junzhez@cs.columbia.edu

Recent advances in Reinforcement Learning have allowed automated agents to achieve a high level of performance across a wide range of tasks, which, when supplemented with human feedback has led to faster and more robust decision-making. This paper studies an interactive reinforcement learning setting where the agent and the human have different sensory capabilities, disagreeing, therefore, on how they perceive the world (observed states) while sharing the same reward and transition functions. We show that agents are bound to learn sub-optimal policies if they do not take into account human advice, perhaps surprisingly, even when human's decisions are less accurate than their own. We propose the counterfactual agent who proactively considers the intended actions of the human operator, and proves that this strategy dominates standard approaches regarding performance.

3 Confounding-Robust Policy Improvement with Human-AI Teams

Ruijiang Gao[1], Mingzhang Yin[2], [1]University of Texas at Austin, Austin, TX, [2]University of Florida, Gainesville, FL, Contact: ruijiang@utexas.edu

Human-AI collaboration has the potential to transform various domains by leveraging the complementary strengths of human experts and Artificial Intelligence (AI) systems. However, unobserved confounding can undermine the effectiveness of this collaboration. In this paper, we propose a novel solution to address unobserved confounding in human-AI collaboration by employing the Marginal Sensitivity Model. We present a deferral collaboration framework for incorporating the marginal sensitivity model into policy learning from observational data, enabling the system to control for the influence of unobserved confounding factors. By adjusting for potential biases, our proposed solution enhances the robustness and reliability of collaborative outcomes.

4 A Reinforcement Learning Framework for Dynamic Mediation Analysis

Zhenke Wu, University of Michigan, Ann Arbor, MI, Contact: zhenkewu@umich.edu

Mediation analysis explores causal effects via mediator variables between treatments and outcomes, gaining attention in diverse scientific domains. Existing studies often focus on single-time-point-treatment scenarios. However, in applications like mobile health, sequential treatments and dynamic mediation effects are key. We propose a reinforcement learning (RL) framework to assess dynamic mediation effects in settings with infinite horizons. By decomposing the average treatment effect into immediate and delayed direct and mediation effects, we develop robust estimators to infer these causal effects. Extensive numerical studies, theoretical results, and mobile health dataset analysis demonstrate the superior performance of our method.

Capacity Management and Decision Making for Hospital Operations

Community Committee Choice Session

Session Chair: Hyojung Kang, University of Illinois at Urbana-Champaign, Champaign, IL

Session Chair: Gabriel Zayas-Caban, University of Wisconsin Madison, Madison, WI

1 Analyzing Temporal Visit Patterns of Frequent Emergency Department Users

Hyojung Kang[1], Lloyd Fernandes[2], [1]University of Illinois at Urbana-Champaign, Champaign, IL, [2]University of Illinois at Urbana-Champaign, CHAMPAIGN, IL, Contact: hyokang@illinois.edu

Frequent users of the emergency department (ED) contribute significantly to the overall number of ED visits. This study aims to analyze temporal visit patterns using similarity measures developed for semantic trees and identify clusters of frequent ED users. We will use electronic health records from multiple EDs that have different facility and patient characteristics to develop and validate the models.

2 Unveiling Bias in Sequential Decision Making: A Causal Inference Approach for Stochastic Service Systems

Juan David[1], Amy Cochran[2], Gabriel Zayas-Caban[3], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, [3]University of Wisconsin Madison, Madison, WI, Contact: davidgomez@wisc.edu

Decision-makers are often confronted with making a random number of decisions sequentially over time. How sequential decisions are made may depend on the decision-maker's perception of prior and analogous decisions and their outcomes. This phenomenon, known as sequential bias, violates a core assumption in causal inference that the decision for one person does not interfere with the potential outcomes of another. By connecting sequential bias in service systems to dynamic treatment regimes, and extending these latter settings to allow for a randomized number of decisions, we are to define and identify average causal effects for quantifying sequential bias. Subsequently, we propose estimators, and derive properties thereof. In a case study, we demonstrate that a provider's decision to route a patient in the Emergency Department impacts the care of future patients.

3 A Clinically Applicable Approach for Early Prediction of Septic Shock in ICU

Gyumin Kim[1], Juhyun Song[2], Hyo Kyung Lee[1], [1]Korea University, Seoul, Korea, Republic of; [2]Korea University Anam Hospital, Seoul, Korea, Republic of. Contact: jkp0123@korea.ac.kr

Numerous studies have presented early prediction systems for acute deterioration in ICUs, with a primary focus on achieving good predictive performance. Here, we propose a clinically applicable early prediction system and demonstrate its application for predicting septic shock in ICUs. The system is developed using the MIMIC-IV dataset and designed to be clinically applicable through the integration of three modules: prediction module generating timely adequate warnings, risk progression subtyping module, and risk subtype early detection module. Via our systematic approach, the system achieved considerable predictive performance for septic shock with clinical applicability, and enabled identifying risk progression subtypes that could potentially benefit from early detection.

Empirical Research in Marketplace Operations

Community Committee Choice Session

Session Chair: Rakesh Allu, Cornell University, Ithaca, NY

Session Chair: Vishal Gaur, Cornell University, Ithaca, NY

1 Understanding Matching Quality on Freelance Platforms Through Conversational Analytics

Jiannan Xu, Ashish Kabra, Kunpeng Zhang, University of Maryland, College Park, MD, Contact: jiannan@umd.edu

The past decade witnessed the rapid growth of online labor marketplaces. However, the key challenge for marketplace intermediaries remains to foster high-quality matches to ensure that outsourced tasks are completed successfully by freelancers. Understanding what leads to effective conversations can aid the design of better labor marketplaces. In this paper, we leverage machine learning techniques to explore the different linguistic aspects of conversational interactions in high-quality matches and low-quality matches. Specifically, we examine the temporal differences in sentiments expressed and topics discussed by recruiters and freelancers. Our results offer insights into the factors that influence successful matching and shed light on the underlying mechanisms of effective communication.

2 Signaling Competition in Two-Sided Markets

Fanyin Zheng[1], Omar Besbes[1], Yuri Fonseca[1], Ilan Lobel[2], [1]Columbia University, New York, NY, [2]New York University Stern, New York, NY

A central question for two-sided matching platforms is how to manage congestion and improve market outcomes. We study the impact of a detail-free lever: the disclosure of information to agents on current competition levels. Disclosing competition reduces the perceived value of popular units, but, at the same time, it can help agents on

the other side better elect across options. How large are such effects, and how do they affect overall market outcomes? We answer these questions empirically.

3 Service Indicators and Social Dynamics in Online Reviews Using Text

Anugna Reddy Gondi[1], Li Chen[2], Shawn Mankad[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, [3]North Carolina State University, Raleigh, NC, Contact: ag2446@cornell.edu

Existing research has shown that online customer reviews reflect not only customers' experience with the product/service but also the influence of other customers' ratings. In this work, we focus on service-oriented reviews (mainly restaurants) where operational factors such as wait time and service are frequently mentioned in the review content. We employ a word embedding approach to quantify such content and measure the impact of social dynamics in the reviews using both review ratings and textual content. By modeling the arrival of reviews via hazard processes with business-specific baseline rates, we separate the effects of social influence of past reviews from the underlying review behavior. Our results indicate that the influence of past review ratings and content on subsequent reviews is significant and can vary based on restaurant characteristics.

Customer Strategy and Learning in Queues

Community Committee Choice Session

Session Chair: Ran Snitkovsky, Tel Aviv University, Tel Aviv, Israel

1 Can Machines Solve General Queueing Problems

Opher Baron[1], Dmitry Krass[2], Arik Senderovich[1], Eliran sherzer[1], [1]University of Toronto, Toronto, ON, Canada; [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: opher.baron@rotman.utoronto.ca

We use a neural net to provide a fast and accurate predictor of the stationary system-length distribution of a GI/GI/1 queue - a fundamental queueing model with closed form solution.

We overcome three main challenges: (1) generating a library of training instances that covers a wide range of arbitrary inter-arrival and service time distributions, (2) labeling the training instances, and (3) providing continuous arrival and service distributions as inputs to the neural net. To overcome (1), we develop an algorithm to sample phase-type inter-arrival and service time distributions with complex transitions structure, (2) we use QBD to lable our training set, and (3) we find that using the first 5 moments of both distributions is sufficient. We show that our neural model is better than other methods in both accuracy and runtimes.

2 Naor's Unobservable Model with Partial Arrival Rate Information

John Hasenbein[1], Grani Adiwena Hanasusanto[2], Johan S. van Leeuwaarden[3], Wouter van Eekelen[3], [1]University of Texas-Austin, Austin, TX, [2]University of Illinois Urbana-Champaign, Urbana-Champaign, IL, [3]Tilburg University, Tilburg, Netherlands

We consider an M/M/s queueing model in which the arrival rate is a random variable whose distribution is an ambiguity set defined by its mean, variance, and support. We use results on distributionally robust optimization to study the decisions of a revenue maximizer, in the presence of strategic customers operating in the so-called unobservable framework.

3 Dynamic vs Static Pricing of Priority in a Queue with Uncertain Arrival Rate

Binyamin Oz, Gregory Skir, Elisheva Zur, Hebrew University of Jerusalem, Jerusalem, Israel. Contact: b.oz@huji.ac.il

We study an unobservable single-server queue with uncertain arrival rates, where customers arrive according to a Poisson process with a random arrival rate, and decide whether to pay for priority. We characterize the equilibrium customer behavior under different pricing and information-disclosure policies. The model is analyzed under two different assumptions regarding the customers' degree of rationality. The first assumes that customers are fully rational and take into account the fact that the ASTA (arrivals see time averages) property does not hold, and base their behavior on the RASTA (rate-biased ASTA) phenomenon. The second assumes that customers are naive and base their decision on the PASTA phenomenon, despite the non-Poisson arrival process.

4 Learning Algorithms for Service Systems with Strategic Customers

Ran Snitkovsky, Tel Aviv University, Tel Aviv, Israel

This talk will discusses a family of iterative algorithms for computing, or learning, Nash equilibria and optimal regulation in queueing games. Our purpose is to suggest robust, easy-to-implement stochastic approximation algorithms that learn customer equilibrium behavior and related quantities based on adaptive simulation of the underlying queueing game.

Stochastic Models in Healthcare

Community Committee Choice Session

Session Chair: Huiyin Ouyang, the University of Hong Kong, Hong Kong, Hong Kong

1 Resource Allocation in Urban Search and Rescue Operations During a Flooding Emergency

Huiyin Ouyang[1], Zheqi Zhang[2], Sukriye Nilay Nilay Argon[3], Serhan Ziya[3], [1]The University of Hong Kong, Hong Kong, Hong Kong; [2]Walmart global tech, Silicon Valley, CA, [3]University of North Carolina, Chapel Hill, NC, Contact: oyhy@hku.hk

This study aims to develop effective strategies for allocating limited resources to different areas during urban search and rescue operations in natural disasters. We model the resource allocation problem as a clearing system with limited rescue resources and formulate it as a Markov decision process. Our analysis reveals that the optimal policy for the stylized model has a threshold structure. We propose a dynamic heuristic policy for the multi-class resource allocation problem based on this structure, which performs close to optimal in numerical simulations. In a simulation study based on air-rescue operations during Hurricane Harvey, our policy outperforms other commonly applied scheduling policies. Our study provides valuable insights and practical solutions for improving the efficiency of urban search and rescue operations during natural disasters.

2 Rl or Url: Managing Outpatient (Tele)visits with Strategic Behavior

Nan Liu[1], Shan Wang[2], Noa Zychlinski[3], [1]Boston College, Chestnut Hill, MA, [2]Sun Yat-sen Univerisity, Guangzhou, China; [3]Technion - Israel Institute of Technology, Haifa, Israel. Contact: wangsh337@mail.sysu.edu.cn

Many outpatient care providers offer virtual service that patients can access via televisits. Televisits allow patients to wait to be seen in the location of their choice, protected from exposure to ill patients and without going through the trouble of physical travel. We develop a stylized queueing-game model, which incorporates patient strategic choice between virtual (or URL) and in-person (real-life, or RL) services, to study how best to manage a practice that simultaneously offers both. We find that the size of the system, measured by the total available service capacity relative to total patient demand, plays a determining role here. We also find that overall patient access to care may be hurt with the use of in-person incentives, unless the payment gap between the two channels is significantly large.

3 Emergency Department Modeling with Time-Varying Physician Productivity

Zhankun Sun[1], Huiyin Ouyang[2], [1]City University of Hong Kong, Kowloon, Hong Kong; [2]The University of Hong Kong, Hong Kong, China. Contact: zhanksun@cityu.edu.hk

Motivated by an intriguing observation on the time-varying physician productivity, we study a continuous-time optimal control problem to understand the transient behavior of individual physicians within their shifts in emergency departments (EDs). By applying Pontryagin's maximum principle, we characterize the optimal policy and provide insights into physician capacity, productivity, and throughput. We leverage the insights to model the complex ED system as a time-varying multi-server queue with shift-hour-dependent service rates. Validation using data from two Canadian EDs shows that our model can accurately capture the time-of-day-dependent patient waiting times.

Renewable Energy and Storage Investment

Community Committee Choice Session

Session Chair: Zuguang Gao, The University of Chicago, Chicago, IL

Session Chair: Nur Sunar, [1]</sup

1 Pay It Forward: On Renewable Energy Investments Under Fixed-Price and Fixed-Volume Forward Contracts

Alexandar Angelus[1], Alain Bensoussan[2], [1]Texas A&M University, College Station, TX, [2]University of Texas-Dallas, Richardson, TX, Contact: aangelus@mays.tamu.edu

We consider a firm's investment in renewable energy under correlated, stochastically evolving price and demand for renewable energy when the firm commits to a fixed-price or fixed-volume forward contract. Using infinite-horizon, continuous-time model, we establish both the threshold structure of the firm's optimal timing of the investment and its optimal capacity of investment. We derive explicit expressions for the optimal thresholds, capacity levels, and associated optimal profit functions. We explore the sensitivity of optimal decisions on the underlying model parameters and derive managerial insights.

2 Renewable, Flexible, and Storage Capacities: Friends or Foes?

Xiaoshan Peng[1], Owen Wu[1], Gil Souza[2], [1]Indiana University, Bloomington, IN, [2]University of Tennessee Knoxville, Knoxville, TN, Contact: xp1@iu.edu

In this paper, we optimize the joint operations of these three types of resources and identify the structure of the optimal operating policy--in particular, the optimal storage control policy. Furthermore, we optimize the investment mix of these resources and examine the investment relations among them (i.e., investment substitutes or complements). We explain the investment relations using the operational insights obtained from the storage control policy. We find that whether storage complements or substitutes other resources depends on how storage reduces operating cost and whether the potential cost reduction is constrained by charging or discharging. Through extensive numerical analysis using data from a Florida utility, government agencies, and industry reports, we demonstrate how storage operations drive the investment relations among these resources.

3 Design of Power Purchase Agreements with Renewable Energy Producers

Zuguang Gao[1], Nur Sunar[2], John R. Birge[3], [1]The University of Chicago, Chicago, IL, [2]UNC Kenan-Flagler Business School, Chapel Hill, NC, [3]University of Chicago, Chicago, IL

We study a firm that aims to sign a power purchase agreement (PPA) with a renewable energy producer. Using a stochastic control framework, we identify the optimal renewable PPA for the firm. Our analysis generates various valuable insights for both managers and policy makers.

Monday, October 16, 4:00 PM - 5:15 PM

Social Impact of Platforms

Community Committee Choice Session

Session Chair: Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA

Session Chair: Li Ding, 1</sup

1 The Impact of Social Nudges on User-Generated Content for Social Network Platforms

Zhiyu Zeng[1], Hengchen Dai[2], Dennis Zhang[3], Heng Zhang[4], Renyu Zhang[5], Zhiwei Xu[6], Zuo-Jun Max Shen[7], [1]Washington University in St. Louis, St. Louis, MO, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]Washington University in St Louis, ST LOUIS, MO, [4]Arizona State University, Phoenix, AZ, [5]The Chinese University of Hong Kong, Hong Kong, China; [6]Tsinghua University, Beijing, China; [7]University of California Berkeley, Berkeley, CA

To tackle the underprovision of user-generated content, we develop an intervention that leverages peer recognition. Via two field experiments (N=1,671,766) conducted on a video-sharing social network platform, we reveal that receiving peer recognition not only immediately boosts users' video production by 13.21% but also increases users' likelihood of giving recognition to others by 15.57%. Such effects last several days and are bigger when the recognition sender and recipients have a stronger tie. Our social network model, combined with the experimental data, shows that estimating and optimizing the overall impact of peer recognition on production over the entire platform requires accounting for its diffusion and over-time effects.

2 Reducing Traffic Incidents in Meal Delivery:Penalize the Platform or Its Independent Drivers?

Wenchang Zhang[1], Chris S. Tang[2], Liu Ming[3], Yue Cheng[4], [1]Indiana University, Bloomington, IN, [2]University of California-Los Angeles, Los Angeles, CA, [3]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [4]Peking University HSBC Business School, Shenzhen, China. Contact: mingliu@cuhk.edu.cn

As the on-demand meal delivery industry expands into a multi-trillion-dollar global market, traffic violations and accidents related to meal deliveries are surging at an alarming rate. By analyzing a three-stage Stackelberg game, we establish the following results. (1) Imposing higher penalties on meal delivery drivers for traffic incidents will have unintended consequences: It will prompt platforms to increase delivery payments, leading drivers to travel faster and ultimately causing more accidents and reduced profits for the platform. (2) Applying stricter penalties to the platform for traffic incidents will encourage it to lower delivery payments, which will, in turn, motivate drivers to travel at safer speeds. (3) The socially optimal policy penalizes only the platform for traffic violations and accidents, not the drivers.

3 From Red Tape to Regtech: How Do Online Platforms Facilitate International Trade?

Jingyuan Cui[1], Zhihan (Helen) Wang[2], Andrew Wu[2], [1]University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, MI

Although the impact of digital services on individual and micro entity decision-making has been well documented, empirical evidence on the effect of digital platforms on the macroeconomy is still rare. Leveraging shipment-level custom data from 2013 to 2017, we quantify the impact of a regulatory technology (RegTech) platform that facilitates value-added tax (VAT) rebates on regional exports in China. Our causal identification relies on the roll-out of the platform and a staggered treatment design. Our empirical results show that the availability of the RegTech platform directly increases regional aggregate export value, the number of shipments, as well as the value per shipment. Further, we utilize the variations in VAT rebate rates for different products to show that RegTech facilitates international trade by reducing the waiting time for VAT rebates.

4 Using Meta-Learning to Improve Military Aviator Performance

Xufei Liu, University of Pennsylvania, Philadelphia, PA, Contact: xufei@wharton.upenn.edu

For military aviators, functioning within a high-stress, no-fail work environment is a necessity. They have to make split-second decisions in the air, all while piloting 44,000 lbs of machinery and experiencing up to 9G's of acceleration. These unique circumstances increase an aviator's risk of hypoxia, and they must quickly learn how to manage their physiological reactions to these intense stressors. We train a CNN model on sensor data that records environmental and physiological factors of aviators-in-training, determining segments of their flight path where they are at risk or under-performing. Eventually, we will determine optimal moments during a flight for intervention to improve the aviator's learning curve and performance.

5 Breaking the Invisible Cage: Investigating the Gender Wage Gap in Gender-Blind Online Platforms

Li Ding, Basak Kalkanci, Georgia Institute of Technology, Atlanta, GA, Contact: basak.kalkanci@scheller.gatech.edu

We investigate differences in self-evaluation biases between genders as potential contributors to the gender wage gap in online platforms, and explore strategies to mitigate the gap. Leveraging a gender-blind online labor platform, we conduct a field experiment, wherein workers are presented with the opportunity to work on math grading tasks over two phases. We consider two interventions: (1) task recommendation, wherein workers are nudged to work on hard and high-paying (HH) tasks early on, and (2) giving workers performance feedback on the first task before they select the second task. We find that in the absence of a nudge, women are more likely to select easier and lower-paying tasks than men, and performance feedback alone reinforces this behavior. However, combining performance feedback with a nudge to take on HH tasks early on reduces the subsequent gender wage gap.

Strategic Collaboration and Coopetition in the Supply Chain

Community Committee Choice Session

Session Chair: Guangwen (Crystal) Kong, Temple University, Philadelphia, PA

Session Chair: Abhishek Roy, Temple University Fox School of Business, Philadelphia, PA

1 Resale-As-A-Service: The Impact of Second-Hand Platforms on Fashion Goods Retailer

Yuan Guo[1], Fernando Bernstein[2], Robert Swinney[2], [1]George Washington University, Washington, D.C., DC, [2]Duke University, Durham, NC, Contact: yuan.guo@gwu.edu

We examine how a retailer selling fashion apparel should account for a second-hand market amid changing fashion trends and diverging customer tastes. We propose a customer decision model that incorporates both customer purchase decisions (i.e., purchasing a new product, a used product, or no product) as well as their selling decisions (i.e., selling a used product) over time. Customers have heterogeneous tastes for product design and each product released by the retailer has random popularity in the market. We discuss how uncertainty in customer taste over time can affect the retailer's production decisions when the second-hand market is absent. Next, we explore how the presence of a second-hand platform affects the retailer's production decisions. Finally, we examine the potential benefit for the retailer from cooperating with a platform under Resale-as-a-Service.

2 The Role of Product Quality in Marketplaces

Leela Aarthy Nageswaran[1], Aditya Jain[2], Haresh B. Gurnani[3], [1]University of Washington, Seattle, WA, [2]Baruch

College, Zicklin School of Business, New York, NY, [3]Wake Forest University, Winston Salem, NC

Traditional retailers have started to offer marketplaces, wherein suppliers sell directly to customers. We study which mode of contracting -- marketplace, wholesale, or a hybrid -- will prevail when the supplier's product quality is uncertain. We show that the retailer may induce an equilibrium wherein a low-quality product is offered via marketplace and a high-quality product is offered via wholesale.

3 Collaborative New Product Development: Co-Creating with a Shared Supplier in the Presence of a Competitor

Abhishek Roy, Temple University Fox School of Business, Philadelphia, PA, Contact: abhishek.roy@temple.edu

Firms are increasingly involving their suppliers in co-creating new products and services through collaborative alliances. In many industries, such suppliers are shared by competing manufacturers, who may benefit from forming alliances and co-creating new products jointly with their shared suppliers. Using a game theoretic model, we analyze the strategic interactions in such a collaborative alliance and examine the strategic trade-offs that arise when competing buyers decide to co-create a common component with the supplier, instead of relying on the supplier to independently develop the component. We demonstrate that competing buyers may sometimes benefit from collaborating jointly with the shared supplier in co-creating common components, instead of shirking away from the collaboration or letting the supplier be the sole developer of the component.

Novel Business Models and Their Environmental and Social Footprint

Community Committee Choice Session

Session Chair: Philippe Blaettchen, Bayes Business School (formerly Cass), City, University of London, London, United Kingdom

1 Wastewater Recycling Capacity Investment in Urban Water Systems

Onur Boyabatli[1], Buket Avci[1], Qian Luo[2], [1]Singapore Management University, Singapore, Singapore; [2]Xi'an Jiaotong Liverpool University, Suzhou, China. Contact: oboyabatli@smu.edu.sg

Wastewater plays a pivotal role in water sustainability by closing the urban water cycle and serving as another water source. This paper investigates a wastewater recycling capacity optimization problem considering rainfall and recycling cost uncertainties in the integrated urban water management system. We formulate the water utility's decisions as a two-stage stochastic problem and characterize the optimal water allocation schemes and the optimal recycling capacity. We also conduct sensitivity analysis to investigate the impacts of rainfall and recycling cost variabilities on the optimal expected cost and recycling capacity. In this paper, we also conduct a case study using publicly available data to calibrate the model and conduct extensive numerical analysis to complement the analytical results.

2 Competitive Adoption of Mass Customization and Environmental Sustainability in Fashion

Aydin Alptekinoglu[1], Adem Orsdemir[2], [1]Pennsylvania State University, University Park, PA, [2]University of California Riverside, Riverside, CA, Contact: orsdemir@ucr.edu

We explore adoption of mass customization (MC) in a competitive environment as a solution to overproduction endemic in the fashion industry. Building on a demand model sensitive to product variety, price and a lead time for mass-customized products, we analyze a duopoly competition game that includes production technology selection between MP and MC. We uncover when MC adoption by one firm leads to higher profits for both firms and lower total environmental impact. We find low-to-medium marginal cost of production is more conducive for MC adoption to lead to greener outcomes. We ask two policy questions: (1) How does promoting MC in the sense of making the wait for mass-customized products more tolerable for consumers change the relationship between MC adoption and environmental impact? (2) What does charging a disposal fee for overproduction do for the same relationship?

3 The Impact of Variety on the Economic and Environmental Performance of a Fashion Rental Business Model

Vishal Agrawal[1], Ekaterina Astashkina[2], Anna Saez de Tejada Cuenca[3], [1]Georgetown University, Washington, [2]Ross School of Business, University of Michigan, Ann Arbor, MI, [3]IESE Business School, Barcelona, Spain. Contact: astash@umich.edu

Using the proprietary dataset from a US-based fashion rental company, we first analyze the impact of product variety on customer rental behavior and the company's operational performance. We find that higher variety leads to customers keeping their rented items for a shorter time, renting new items sooner, and overall renting more items. This, in turn, increases items' utilization: they get rented more times and spend less time idle. However, if variety is too high -- this relationship gets reversed. We then use these findings to illustrate how the tradeoffs related to company's economic and environmental performance metrics associated with increase in variety are resolved.

4 Business Model Choice for Heavy Equipment Manufacturers

Philippe Blaettchen[1], Niyazi Taneri[2], Sameer Hasija[3], [1]Bayes Business School (formerly Cass), London, United Kingdom; [2]Cambridge Judge Business School, Cambridge, United Kingdom; [3]Insead, Singapore, Singapore. Contact: philippe.blaettchen@city.ac.uk

Technological advances enable new business models for heavy equipment manufacturers allowing customers to access equipment without ownership. This study seeks to understand different emerging business models' profitability and environmental performance in light of salient economic and operational factors. We identify the optimal choice between a traditional ownership-based business model and access-based models using servicization or sharing. After-sales services, crucial for heavy equipment manufacturers, strongly affect this choice. We further provide a novel framework to analyze a business model's environmental impact and show that all models can create win-win situations for the manufacturer and the environment.

Operations and Technologies in E-commerce and Online Platforms

Community Committee Choice Session

Session Chair: Ruomeng Cui, Emory University, Decatur, GA

Session Chair: Wenchang Zhang, Indiana University, Bloomington, IN

1 The Economics of Digital Dark Patterns

Andrey Fradkin[1], Tesary Lin[1], Chiara Farronato[2], [1]Boston University, Cambridge, MA, [2]Harvard Business School, Brookline, MA, Contact: tesary@bu.edu

Companies often obfuscate cookie preference policies and consent forms in order to nudge users to share their data more than they would otherwise do. These practices, known as "dark patterns," are pervasive despite their effects being poorly understood. With the use of Webmunk, a browser extension developed for research studies of this type, we explore the effects of dark patterns on consumers' privacy choices and the effects that such choices have on the type and quantity of ads they receive. We are particularly interested in exploring how the effects of dark patterns differ across large and small companies, and the ensuing firms' competitive advantage in consumer data.

2 No Call, No Show: Impact of No Show and Its Remedies on Service Platforms

Nil Karacaoglu[1], Simin Li[2], Martin Lariviere[3], [1]The Ohio State University, Columbus, OH, [2]Tulane University, New Orleans, LA, [3]Northwestern University, Evanston, IL, Contact: simin.li@tulane.edu

Absenteeism can severely impact service platforms where each customer is assigned a designated service provider. With the rising popularity of service platforms, it is not uncommon for customers to bear the brunt of no-shows. In this study, we aim to empirically quantify the impact of no-shows on customer retention and lifetime value. We also investigate the effectiveness of two potential remedies platforms can offer to mitigate the adverse effects of no-shows. Finally, we construct and calibrate a model to determine the optimal no-show mitigation strategies for service platforms based on their specific characteristics. By doing so, we aim to provide service platforms with actionable insights that can help them reduce the impact of no-shows on customer retention.

3 A Moment for Reflection: De-biasing Server Evaluations

Hallie Cho, Vanderbilt University, Nashville, TN

Customers provide server feedback in an evaluation form where quantitative feedback is often solicited before qualitative feedback. Managers often use quantitative feedback as a standardized data source to judge the performance of servers, however research has shown that bias (e.g., demographic) exists in quantitative feedback. We examine the impact of changing the order of feedback (quantitative vs. qualitative) on bias.

Efficiency of Transportation and Transportation-Enabled Services

Community Committee Choice Session

Session Chair: Hai Wang, Singapore Management University, Singapore, Singapore

1 Temporal Equilibrium for Electrified Ride-Sourcing Markets Considering Charging Capacity and Driving Fatigue

Yuhao Liu[1], Zhibin Chen[1], Chi Xie[2], Kai Liu[3], [1]New York University Shanghai, Shanghai, China; [2]Tongji University, Shanghai, China; [3]Dalian University of Technology, Dalian, China. Contact: zc23@nyu.edu

Given their demand for charging, ride-sourcing electric vehicle (EV) drivers may have distinct work schedules from gasoline vehicle (GV) drivers, yielding significant impacts on the market supply when their penetration becomes high. We propose an equilibrium modeling framework based on a time-expanded network to describe the work schedules of EV and GV drivers with the consideration of their driving fatigue and EVs' charging opportunities subject to the limited charging infrastructure. To solve the equilibrium model, we develop a gap function-based method coupled with the column generation scheme in which a non-additive shortest path problem appears as a subroutine. Numerical examples reveal that the temporal equilibrium of the electrified ride-sourcing market is moderated by the charging capacity, EV penetration as well as the competition among drivers.

2 A Robust Data-driven Linear Programming Approach for Minimizing Energy Consumption in Railway Networks

Shuvomoy Das Gupta[1], J. Kevin Tobin[2], [1]MIT, Cambridge, MA, [2]Thales Canada, Toronto, ON, Canada. Contact: kevin.tobin@urbanandmainlines.com

We present a robust, data-driven linear programming model for minimizing total effective energy consumption in railway networks. In contrast with existing works that are either NP-hard or requires multi-stage optimization, our model involves a single linear programming problem. Our approach simultaneously minimizes total energy consumed by all the trains while maximizing the transfer of regenerative energy from braking trains to accelerating trains. The interplay between energy consumption and its reuse is modeled in an empirically validated data-driven manner. Furthermore, our model robustly safeguards against uncertainties that are inherent in railway networks. When applied to a real-world metro network, the timetables computed by our model outperformed existing timetables, achieving a significant reduction in effective energy consumption.

3 Learning in the Airspace for Combinatorial Network Routing

Xiyitao Zhu[1], Jing Gao[2], Lavanya Marla[3], Ankur Mani[4], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]university of minnesota, Sunnyvale, CA, [3]University of Illinois at Urbana-Champaign, Urbana, IL, [4]University of Minnesota - Twin Cities, Minneapolis, MN, Contact: xiyitao2@illinois.edu

In the US National Aviation System (NAS), aircraft rely on weather information for routing decisions. We propose that using en-route aircraft as sensors to collect updated weather information at the right place and right time maintains high-quality weather information that benefits the NAS. Motivated by the spatial and temporal correlations in weather, we propose a novel modeling framework for routing decisions on (airspace) networks with non-stationary Gaussian bandits, temporal information diffusion, and in particular, with combinatorial path structures. Our framework is also applicable to intra-city aircraft and unmanned aircraft such as UAVs and drones.

4 Assessing and Explaining the Efficiency of Urban Transportation Networks

Hao Hao[1], Hai Wang[2], Peter Zhang[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Singapore Management University, Singapore, Singapore

Urban transportation networks are critical systems for individual mobility and the economy. Traditional and emerging transportation-enabled services require assessing the routing efficiency in transportation networks for decision-making. This paper studies the efficiency of the fundamental class of routing problems - the efficiency of TSPs. Leveraging modern transportation data and the well-known BHH theorem, we propose a scalable method for assessing transportation networks' TSP efficiency under different demand distributions. We also implement interpretable models to find that the distribution of the network nodes, and the network topology are among the most significant features in explaining TSP efficiency. Finally, we conduct case studies on the TSP efficiency of urban service-level sub-networks, and the evolution of subway networks' TSP efficiency.

Game Theory and Discrete Optimization

Community Committee Choice Session

Session Chair: Gabriele Dragotto, Princeton University, Princeton, NJ

1 Capacity Planning in Stable Matching: An Application to School Choice

Federico Bobbio[1,2], Margarida Carvalho[3], Andrea Lodi[4], Ignacio Rios[5], Alfredo Torrico[6], [1]University of Montreal, Montreal, QC, Canada; [2]CIRRELT, Montreal, QC, Canada; [3]University of Montreal & CIRRELT, Montreal, QC, Canada; [4]Cornell Tech, New York, NY, [5]The University of Texas at Dallas, Richardson, TX, [6]Cornell University, Ithaca, NY, Contact: federico.bobbio@umontreal.ca

A successful application of Matching Theory is the admission of students to schools (SC). We introduce the problem of jointly allocating extra spots to schools and finding the best matching for the students. We analyze theoretically the problem, and we propose a novel MILP formulation. We show that its stability constraints can be separated in linear time, leading to an effective cutting-plane method. Our cutting-plane method outperforms MIP solving the generalizations of existing formulations. Moreover, we propose two heuristics that are effective for large instances. Finally, we use the Chilean SC data to demonstrate the impact of capacity planning. Our results show that our methodology can prioritize the assignment of previously unassigned students or improve those matched. These insights empower the decision-maker in tuning the matching to provide a fair solution.

2 Learning Rationality Parameters in Potential Games

Stefan Clarke, Princeton University, NJ

We propose a stochastic first-order algorithm to learn the rationality parameters of simultaneous and non-cooperative potential games, i.e., the parameters of the agents' optimization problems. Our technique combines an active-set step that enforces that the agents play at a Nash equilibrium, and an implicit-differentiation step to update the estimates of the rationality parameters. We detail the convergence properties of our algorithm and perform numerical experiments on Cournot and congestion games, showing that our algorithm effectively finds high-quality solutions (in terms of out-of-sample loss) and scales to large datasets.

3 A Geometric Algorithm for Stable Matching Problems

Chengyue He, Columbia Universiy, New York, NY, Contact: ch3480@columbia.edu

Gale-Shapley algorithm and its variants have been widely used to find stable matchings in many different settings. In this talk, we focus on a different, more general approach to find stable matchings due to Scarf. Scarf's algorithm is a pivoting procedure to find a special vertex---a dominating vertex---in matching polytopes, and such vertex can encode stable matchings. We studied the behavior of Scarf's algorithm when employed to find stable matchings on different classes of graphs/hypergraphs. While finding a dominating vertex is generally PPAD-hard, we prove that Scarf's algorithm runs in polynomial time on several classes of matching polytopes. Our results provide in particular a new polynomial time algorithm for stable matching problems. Meanwhile, we give evidence that some famous algorithms like Gale-Shapley are indeed implementations of Scarf's algorithm.

4 Information and Tractability in Many-To-Many Stable Matching

Aapeli Vuorinen, Columbia University, New York, NY

The stable marriage problem generalizes to instances where one or both sides can be matched to more than one partner, by replacing strict preference lists over candidates with choice functions over subsets of candidates. Such choice functions need only satisfy the conditions of substitutability and consistency for a stable match to exist and be found by Roth's generalization of the Deferred-Acceptance algorithm. However, the set of such choice functions is doubly exponential in size and the information required to describe them is too large, making them intractable for all but the smallest applications.
To overcome this computational roadblock, in this talk we present some results on a special class of choice functions, known as Kuhn choice functions. They are defined through the solution of a (classical) maximum weight matching problem in an auxiliary bipartite graph.

5 Who Plays First?

Gabriele Dragotto[1], Bartolomeo Stellato[2], [1]Princeton University, Princeton, NJ, [2]Princeton University, Princeton, NJ, Contact: gdragotto@princeton.edu

We consider the problem of determining which player should play first in a sequential game. In other words, given a series of selfish and interacting players, we are interested in determining the order of play that maximizes a function of the players' decisions. We formulate this problem as a mixed-integer optimization problem, and we propose an efficient algorithm to solve the problem by dynamically generating valid inequalities (i.e., cutting planes). We contextualize our framework in trajectory planning for autonomous vehicles and drones, portfolio optimization, and Cournot games.

Recent Advances in Optimization: Theory and Applications

Flash Session

Session Chair: Jeremy Curuksu, Amazon, New York, NY

1 Dynamics of Inverse Vertex Images in the Schwarz-Christoffel Integral: Kufarev's Differential Equations and Initial Conditions

Soninbayar Jambaa, National University of Mongolia, Ulaanbaatar, Mongolia. Contact: soninbayar@seas.num.edu.mn

The practical use of the well-known Schwarz-Christoffel integral formula is complicated by the determination of the inverse images of the vertices of a polygon that correspond to given side lengths. This work presents a method for determining these inverse images for rectilinear polygons, as well as a procedure for transforming the system of Kufarev ordinary differential equations that describe the movement of these inverse images into a form suitable for numerical analysis. The resulting dynamic system is then solved numerically, and the algorithm's effectiveness is demonstrated by its ability to preserve distances between the vertices during the cut. The article references the original method presented by Jambaa et al. in the Tomsk State University Journal of Mathematics and Mechanics, Vol. 5, No. 43 (2016).

2 What-If: A Method to Measure the Markov Property in Data Driven Reinforcement Learning

Jeremy Curuksu[1], Charles Prosper[2], [1]Amazon, New York, NY, [2]Amazon Web Services, Brisbane, Australia

Offline reinforcement learning can learn a policy from historical data collected from a Markov Decision Process. But when using historical data for offline learning, the reinforcement learning problem setup may not be Markov and the historical data may not have sufficient variability in states and actions to learn an optimal policy. We propose a method designed to determine if some available historical data was generated by a Markov Decision Process, and to measure the order of this Markov Decision Process. We use this method to show that learning from data simulated with a GPT model can improve the Markov property and overall quality of offline learning, with up to 25% increase in accumulated rewards in typical optimal control problems.

3 Discrepancy-based Distributional Robustness With Discrete Loss

Belleh Fontem, University of Massachusetts Lowell, Lowell, MA

The classical paradigm in distributionally robust decision-making presupposes connectedness of either the decision space, state space, or both. Driven by reliability considerations in supply chain planning, we use discrepancy-based ambiguity sets to explore distributionally robust models with piecewise affine, bounded discrete loss functions that are defined on decision, and state spaces which are discrete. For this class of problems, we propose an exact decomposition algorithm that in each iteration, solves a mixed integer linear program and a nonlinear convex program. We show that the algorithm's complexity scales linearly with the allowable maximum expected loss on account of all distributions in the ambiguity set. To demonstrate the algorithm's effectiveness, we run it on a large-scale unreliable sourcing problem with advance demand information.

4 A Study on the Gap-Time Relationship in Solving Scheduling Problem

Shaheen Pouya[1], Oguz Toragay[2], [1]Auburn University, Auburn, AL, [2]Lawrence Technological University, Southfield, MI, Contact: shaheen@auburn.edu

This article presents a study on the job shop problem, a combinatorial optimization problem that models scheduling and resource allocation in industrial settings. The article aims to investigate the relationship between the optimality gap and required computational resources, considering various optimality gap levels that are applicable in real-life situations. The study uses a Monte Carlo simulation to analyze the behavior of solvers in solving different sizes of random-generated scheduling problems. The findings of the study offer insights into the worthiness of reaching an optimal solution versus implementing a near-optimal solution and starting the work. The codes used in the study are accessible on the author's GitHub account.

5 Optimizing Bi-Objective Routing for Perishable Products with Customer Heterogeneity in Green Label Incentive on Time Slot Choice

Xinyue LIANG, Nengmin WANG, Xi'an Jiaotong University, Xi'an City, China. Contact: 95xinyue@gmail.com

The rapid growth of the perishable produce e-commerce market has led to a surge in their road freight. Prompt delivery is crucial for such products to minimize degradation over time and reduce missed deliveries. Therefore, offering customizable time slots might be necessary to ensure delivery efficiency. Growing customer awareness of sustainability sparked us to explore the use of green labels as an intrinsic motivator to steer customers to eco-friendly delivery options.

Accordingly, we develop a novel bi-objective VRP model with categorized-labeled time slots, aiming at optimizing both cost and customer satisfaction. Flexible vehicle departure times are allowed. Computational studies conducted by two meta-heuristics prove the efficiency of the solution methods. Finally, we draw managerial insights from the obtained Pareto frontier and sensitivity analysis.

6 Knowledge Graph Hashing Through Rotation

Yeshuai He[1], Jianqiang Cheng[2], Yong Ge[2], [1]University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ

Knowledge graph hashing is to infer binary vector representations of the graph. Compared with knowledge graph embedding that learns continuous vector representations, knowledge graph hashing could significantly reduce storage and computational time due to its binary nature. In this paper, we propose a novel discrete optimization framework for knowledge graph hashing. We treat the links between entities and relations in the graph as rotations to learn binary codes. An alternating optimization algorithm is then proposed to produce high-quality binary codes. Moreover, to control the margin hyperparameters in the Relu function, we use a dynamic range approach to adjust the tolerable margins in each iteration. Evaluation results demonstrate the superiority of the proposed algorithm against the direct binary representations of several state-of-the-art baselines.

Reinforcement Learning

Community Committee Choice Session

Session Chair: sajad Khodadadian, Georgia Institute of Technology, Atlanta, GA

1 Stochastic First-Order Policy Optimization for Robust Markov Decision Process

Yan Li[1], Guanghui Lan[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: yli939@gatech.edu

We consider the problem of solving robust Markov decision process (MDP), which involves a set of discounted, finite state, finite action space MDPs with uncertain transition kernels. The goal of planning is to find a robust policy that optimizes the worst-case values against the transition uncertainties, and thus encompasses the standard MDP planning as a special case. For (s,a)-rectangular uncertainty sets, we develop a policy-based first-order method, namely the robust policy mirror descent (RPMD), and establish linear convergence when the transition is known. We further develop a stochastic variant of the robust policy mirror descent method, named SRPMD, when the first-order information is only available through online interactions with the nominal environment, which attains an $O(1/\epsilon^2)$ sample complexity for finding an ϵ-optimal policy.

2 Revisiting the Linear-Programming Framework for Offline Reinforcement Learning with General Function Approximation

Asuman Ozdaglar[1], Sarath Pattathil[1], Jiawei Zhang[1], Kaiqing Zhang[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]University of Maryland, College Park, College Park, MD, Contact: jwzhang@mit.edu

Offline RL optimizes policies using a pre-existing dataset, without more environment interaction. Current research emphasizes sample-efficient offline RL algorithms to tackle large state-action spaces. The LP reformulation of Markov decision processes is significant, allowing sample-efficient offline RL with function approximation under partial data coverage and realizability assumptions. We reexamine this LP framework, offering a new version that enhances past results, softens assumptions, and reaches optimal statistical rates regarding sample size. This is attained by introducing suitable constraints and selecting function classes and initial state distributions. Our work may enhance the understanding of LP formulations and the associated primal-dual minimax optimization in offline RL.

3 Provably Efficient Model-Free Algorithms for Non-Stationary CMDPs

Honghao Wei[1], Arnob Ghosh[2], Ness Shroff[3], Lei Ying[4], Xingyu Zhou[5], [1]University of Michigan, Ann Arbor, MI, [2]Ohio State University, Columbus, OH, [3]The Ohio State University, Columbus, OH, [4]The University of Michigan, Ann Arbor, Ann Arbor, MI, [5]Wayne State University, Rochester Hills, MI, Contact: honghaow@umich.edu

We study model-free reinforcement learning (RL) algorithms in episodic non-stationary CMDPs, in which an agent aims to maximize the expected cumulative reward subject to a cumulative constraint on the expected utility (cost). In the non-stationary environment, reward, utility functions, and transition kernels can vary arbitrarily over time. We propose the first model-free, simulator-free RL algorithms with sublinear regret and zero constraint violation for non-stationary CMDPs in both tabular and linear function approximation settings with provable performance guarantees. Additionally, We present a general framework for addressing the well-known challenges associated with analyzing non-stationary CMDPs, without requiring prior knowledge of the variation budget.

4 Performance Bounds for Policy-Based Average Reward Reinforcement Learning Algorithms

Yashaswini Murthy[1], Mehrdad Moharrami[2], R. Srikant[1], [1]University of Illinois, Urbana, IL, [2]University of Iowa, Iowa City, IA, Contact: moharami@uiowa.edu

Many policy-based RL algorithms can be viewed as instances of approximate policy iteration (PI). In applications where average reward serves as the performance metric, discounted reward formulations with a high discount factor are commonly used. However, the corresponding theoretical performance bounds for the discounted reward scale with the square of the horizon. Consequently, the resulting performance bounds for average reward problems tend to go to infinity. Therefore, an open problem has been to obtain meaningful performance bounds for approximate PI and RL algorithms in the average-reward setting. In this paper, we address this open problem by deriving the first non-trivial finite-time error bounds for average-reward MDPs, which approach zero as the errors in policy evaluation and policy improvement tend to zero.

Recent Progress in Optimization Software IV

Community Committee Choice Session

Session Chair: Hans Mittelmann, Arizona State University, Tempe, AZ

1 Recent Developments of PDLP

Haihao Lu, University of Chicago, Chicago, IL

In this talk, we will talk about the recent computational and theoretical development of PDLP, a first-order method based LP solver.

2 Pushing the Limits of Computation: Solving Previously Unsolvable Instances

Yuji Shinano, Zuse Institute Berlin, Berlin, Germany

We have developed the Ubiquity Generator framework (UG), which is a software framework to parallelize state-of-the-art solvers on large-scale computing environments, for more than 10 years. The parallel solvers instantiated by the UG successfully solved more than 20 previously unsolved instances from MIPLIB(benchmark instances for Mixed Integer Programing), 5 instances from SteinLib (benchmark instances for Steiner Tree Problems), and 3 instances from QAPLIB (benchmark instances for Quadratic Assignment Problems).
In this talk, we present the latest status of UG and parallel solvers instantiated by the UG, including QUBO(Quadratic unconstrained binary optimization) solver QuBowl.

3 Mixed-Integer Presolve Progress in COPT

Nils-Christian Kempke, COPT GmbH, Berlin, Germany

Presolving is an essential component of modern MIP solvers. It cleans up the model, identifies structures in the problem, and tightens the formulation before the branch-and-cut search starts.
In this talk, we present new presolving techniques implemented in the Cardinal Optimizer (COPT). We discuss the underlying structures that are exploited and show how a careful mathematical analysis of those structures resulted in new presolving reductions. We also present computational experiments showing the impact of the new techniques.

Distributionally Robustness under Dynamic Environment

Community Committee Choice Session

Session Chair: Yifan Hu, 1</sup

1 The Curious Price of Distributional Robustness in Reinforcement Learning with a Generative Model

Laixi Shi[1], Gen Li[2], Yuting Wei[3], Yuxin Chen[3], Matthieu Geist[4], Yuejie Chi[5], [1]Carnegie Mellon University, Pittsburgh, PA, [2]The China University of Hong Kong, Hong Kong, China; [3]University of Pennsylvania, Philadelphia, PA, [4]Google Research, Brain Team, Paris, France; [5]Carnegie Mellon University, Pittsburgh, PA, Contact: laixishi@cmu.edu

This work investigates model robustness in reinforcement learning (RL) to address the ubiquitous sim-to-real gap in modern practice, by considering distributionally robust Markov decision processes (RMDPs). Despite recent efforts, the sample complexity of RMDPs is much less understood --- large gaps between existing upper and lower bounds, and it is unclear if distributional robustness bears any statistical consequences when benchmarked against standard RL.
We derive the sample complexity of RMDPs---using either

total variation or χ^2 divergence uncertainty set, and develop minimax lower bounds to benchmark its tightness. Our results deliver surprising messages that learning RMDPs is not necessarily easier or more difficult than standard MDPs --- depends heavily on the size and shape of the uncertainty set.

2 Distributionally Robust Policy Gradient for Offline Contextual Bandits

Anqi Liu, JHU, Baltimore, MD, Contact: aliu@cs.jhu.edu

Learning an optimal policy from offline data is notoriously challenging. We study the policy optimization problem in offline contextual bandits using policy gradient methods. We employ a distributionally robust policy gradient method, DROPO, to account for the distributional shift between the static logging policy and the learning policy in policy gradient. Our approach conservatively estimates the conditional reward distributional and updates the policy accordingly. We conduct experiments on real-world datasets under various scenarios of logging policies to compare our proposed algorithm with baseline methods in offline contextual bandits. We also propose a variant of our algorithm, DROPO-exp, to further improve the performance when a limited amount of online interaction is allowed.

3 Multistage Distributionally Robust Optimization Under Stochastic Disruptions

Haoxiang Yang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China

A stochastic disruption is a type of infrequent event in which the timing and the magnitude are random. We introduce the concept of stochastic disruptions, and a stochastic optimization framework is proposed for such problems. In this talk, we discuss two possibilities where we do not know the exact probabilistic distribution of the uncertainty under the stochastic disruption setting, one for the uncertainty magnitude and the other for the timing. We formulate a multi-stage distributionally robust optimization model while considering potential stochastic disruptions. To solve such complex models, we propose stochastic programming models for each case and solve them using cutting-plane methods. We present the computational results of our approach applied to an optimal power flow problem with N-1 contingencies.

1 Static and Dynamic Infrastructure System Monitoring Under Uncertain Time-Dependent Failures

Juan Estrada[1], Bo Zhou[1], Ruiwei Jiang[2], Siqian Shen[2], [1]University of Michigan at Ann Arbor, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: juanest@umich.edu

Modern society relies on infrastructure systems such as power grids, where aged components become unreliable, possibly triggering cascading failures, and thus should be monitored closely. We consider the problem of dispatching multiple maintenance fleets (e.g. drones) to examine different parts of a system, whose failures are probabilistic and depend on the fleet's arrival time. The goal is to balance the fleet's routing and operational cost with the uncertain cost of system failure and maintenance. We compare a static dispatch schedule by solving a stochastic integer nonlinear program and a dynamic dispatching policy based on updated failure probabilities. We demonstrate the numerical performance of the two approaches by testing the problem on IEEE 33-bus system.

2 Route Recommendation Optimization Under Unknown and Uncertain Travelers' Trust

Xinyu Fei[1], Bo Zhou[2], Ruiwei Jiang[1], Xi Jessie Yang[1], Siqian Shen[1], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan at Ann Arbor, Ann Arbor, MI, Contact: xinyuf@umich.edu

Route recommendation is a fundamental problem in transportation and arises in various applications, including autonomous navigation, shared mobility, and evacuation planning. Taking disaster response as an example, we consider evacuation route recommendation under ambiguous uncertain evacuees' trust, and the goal is to tradeoff between estimated travel time and crowdsourcing travel information gained from evacuees, to achieve better overall effectiveness of the recommended routes. We formulate a static stochastic mixed-integer program and a dynamic model with reinforcement learning, to update traffic, human trust, and route recommendations over time. We compare both models via numerical studies of diverse evacuation scenarios.

3 Trust-Aided Distributionally Robust Resource Allocation with Multi-Source Reference Information

Yanru Guo, Bo Zhou, Ruiwei Jiang, Xi Jessie Yang, Siqian Shen, University of Michigan, Ann Arbor, MI

Reference information plays an essential role in decision-making yet may vary across different information sources (e.g., mobile and fixed sensors in infrastructure systems). We consider resource allocation in stochastic dynamic systems, where we conduct multisource information fusion based on human trust, and design an ambiguity set of the probabilistic trust to attain robust solutions. We design a human-robot interaction process to simulate trust variation and adopt trial-and-error method to update trust. We demonstrate the performance of our approaches in applications of wildfire prevention and dynamic control.

4 Risk-Averse Reinforcement Learning for Real-Time Economic Dispatch

Bo Zhou[1], Ruiwei Jiang[2], Siqian Shen[2], Xian Yu[3], [1]University of Michigan at Ann Arbor, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]The Ohio State University, Columbus, OH, Contact: siqian@umich.edu

We study risk-averse reinforcement learning (RL) that controls dynamic risk of a sequence of rewards in infinite-horizon Markov Decision Processes (MDPs), where we adapt the Expected Conditional Risk Measures (ECRMs) and prove time consistency. Using a combination of expectation and conditional value-at-risk (CVaR), we reformulate the risk-averse MDP as a risk-neutral counterpart with augmented action space and manipulation on the immediate rewards. We further prove that the Bellman operator is a contraction mapping, which guarantees the convergence of any value-based RL algorithms. Accordingly, we develop a risk-averse deep Q-learning framework to reduce variance and enhance solution robustness, and demonstrate our methods for real-time economic dispatch on IEEE bus systems under uncertain power disruptions.

Challenges from Parking in Last-Mile Delivery

Community Committee Choice Session

Session Chair: Sara Reed, University of Kansas, Lawrence, KS

1 Delivery Drivers' Parking Preferences in Last Mile Urban Operations

Johanna Amaya[1], Trilce Encarnacion[2], Maira Delgado-Lindeman[3], [1]Pennsylvania State University, University Park, PA, [2]University of Missouri- St. Louis, Saint Louis, MO, [3]University of Cantabria, Santander, Spain. Contact: amayaj@psu.edu

In this paper, we examine drivers' perspectives regarding parking in urban areas in the northeastern United States. Stated preferences data were collected and analyzed using a mixed logit and a hybrid discrete choice models. The results show that searching time, walking time to the delivery destination, and cost of parking impact parking selection. Additionally, Safe Behavior, a moderating latent variable, influences parking choices and impacts drivers differently. We also observed that the first choice for drivers is to park in an available spot, followed by double parking. Even though drivers try to avoid parking in restricted areas, their first priority is making on time deliveries. The paper provides recommendations to policymakers and logistics service providers (carriers) to improve last-mile operations and reduce the cost of deliveries in urban areas.

2 On-Street Parking for Freight, Services, and E-Commerce Traffic in Us Cities

Diana Gineth Ramirez-Rios[1], Lokesh Kumar Kalahasthi[2], Jose Holguin-Veras[3], [1]University at Buffalo, Buffalo, NY, [2]Indian Institute of Technology Delhi, India, India; [3]Rensselaer Polytechnic Institute, Troy, NY, Contact: dgramire@buffalo.edu

We develop a simulation model incorporating freight and service vehicle demand estimates, probability distributions of parking durations, and industry sectors to estimate the on-street parking demand needs for urban commercial traffic in the US. Our paper shows results at the city block level and ZIP code level. We tested four demand management initiatives to reduce the peak-hour needs. The off-hours strategy, which indicates 30 % of freight pick-ups and deliveries and 51 % of service visits shifting to the off-hours, is the most effective one, with the potential to reduce daytime parking needs by 30 %. Results also show the need to dedicate curb space for FSA vehicle parking to satisfy time-of-day requirements.

3 Inclusive Curbside Parking Allocation for Cargo Bicycles

Rishi Verma, University of Washington, Seattle, WA

The use of cargo bicycles for last-mile delivery has been gaining traction in recent years due to their low environmental impact and impacts on traffic congestion compared to vehicles. However, using cargo bicycles for delivery means a different set of constraints and challenges than traditional vehicle delivery, for example, a different road network, parking availability, and delivery radius. In this study we will use a queueing model to analyze the curbside parking capacity of a street network for mixed fleet compositions of delivery vehicles and cargo bicycles. The same set of delivery requests may be undertaken by either cargo bicycle or delivery vehicle, thereby using different load sizes and speeds and affecting arrival rates for curbside parking spaces. The optimal parking allocation and curbside parking policy is determined.

4 Optimal Parking and Reservation Decisions for Last-Mile Delivery

Sara Reed[1], Ann Melissa Campbell[2], Barrett Thomas[2], [1]University of Kansas, Lawrence, KS, [2]University of Iowa, Iowa City, IA, Contact: sara.reed@ku.edu

Parking is a time-consuming component of last-mile delivery. We introduce the Stochastic Last-Mile Parking Problem (SLMPP) to model the search process for parking around a rectangular block that includes the customer location. When the driver finds an available parking spot, a solution to the SLMPP answers the question: should the driver park or drive on? We model the SLMPP as a Markov Decision Process and characterize the structure of the optimal policy. We then extend this model to the SLMPP with Reservations, where the driver decides whether to use a reservation spot outside the search block. Computational experiments identify an optimal fee threshold that the driver should be willing to pay for the reservation spot. We use these managerial insights to provide a trade-off analysis for urban planners' pricing reservation spots.

5 Steiner Traveling Salesman Problem with Online Parking Information: A Stochastic Shortest Path and Reinforcement Learning Framework

Venktesh Pandey[1], Tarun Rambha[2], [1]North Carolina Agricultural and Technical State University, Greensboro, NC, [2]Indian Institute of Science, Bangalore, India

The surge in multimodal curbside usage and e-commerce/food deliveries has led to limited availability of parking spaces, prompting the exploration of adaptive solutions to the delivery vehicle routing problem. In this study, we propose a novel approach that leverages historical and partially-observable real-time parking availability information to find the Hamiltonian tour minimizing the total expected cost. We compare two solution methods: an iterative stochastic shortest path (iSSP) and a scalable reinforcement learning (RL) method based on the underlying Steiner Traveling Salesman Problem. Additionally, accounting for municipality parking constraints and time windows, we quantify the productivity gains relative to traditional pre-trip tours and evaluate the tradeoffs between scalability and optimality of solutions from the iSSP and RL approaches.

Multi-objective Optimization and Applications

Contributed Session

Session Chair: Chelsea Greene, University of Washington, Bedford, NH

1 Optimization Model for Selecting Target Segment in Mass Marketing Campaigns

Cesar Salazar-Santander[1], Alejandro Francisco Mac Cawley[2], Carolina Martinez-Troncoso[1], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile; [2]Pontificia Universidad Catolica de Chile, Santiago, Chile. Contact: amac@uc.cl

Defining a target group for a mass marketing campaign is a non-trivial goal, which depends on the correct definition of the commercial stimuli and the selection of a customer target segment that will maximize the campaign's effectiveness. In this research, we propose a methodology based on a mixed multi-objective optimization formulation that allows determining a minimum continuous customer target segment for massive campaigns to maximize its effectiveness with a maximum budget constraint. The model multi-objective function maximizes the campaign's effectiveness while minimizing the "broadness" of the segments targeted, allowing the detection of the most effective and homogeneous target group possible. The methodology performance was benchmarked against traditional customer segmentation algorithms like K-Means and Greedy selection methodology.

2 Supplier Selection and Order Allocation Using a Multi-Objective Model, Integrated with Machine Learning Methods

Saman Hassanzadeh Amin, Toronto Metropolitan University, Toronto, ON, Canada. Contact: saman.amin@torontomu.ca

Supplier selection and order allocation is an important problem in purchasing and procurement. In this talk, a two-stage approach for supplier selection and order allocation planning is discussed. Stage 1 involves determining the values of the demands based on machine learning methods. In Stage 2, a new multi-objective model is introduced to select the best supplier(s) and to determine the order(s). The results show that the values of demands have effects on both the selected suppliers and the allocated orders to them.

3 A Data-Driven Algorithm to Rellocate Immigrants: A Challengue with Data Changes and Concept Drift

Daniel Romero Rodriguez[1], Gina Galindo[2], Santiago Buitrago[1], Alberto Brito[1], Leonardo Santiago[1], [1]Universidad del Norte, Barranquilla, Colombia; [2]Universidad del Norte, Puerto Colombia, Colombia. Contact: hromero@uninorte.edu.co

A data-driven approach is used to suggest locations for immigrants in a new country. We evaluate different alternatives to cope with data changes and model performance variations. The alternatives include data balancing, training models with the latest data, and mixed strategies. The algorithm and the strategies are evaluated on a testbed with information from Colombia and Venezuelan immigrants.

4 A Multiple Objective Optimization Problem to Allocate Budget for TB and HIV Care Delivery Programs in Diverse Regions

Chelsea Greene, Zelda B. Zabinsky, University of Washington, Seattle, WA, Contact: cgreene3@uw.edu

Tuberculosis (TB) is the leading cause of death among people living with HIV. As a result, administering integrated TB and HIV care in regions where the burden of TB and HIV co-infection is high effectively improves health outcomes. Community-based delivery programs, as opposed to facility-based care, have been shown to increase uptake but are more costly. We present a multiple objective optimization problem to determine the best combinations of delivery programs to administer TB and HIV care in a set of regions, given a budget constraint. We simulate TB and HIV disease progression with a dynamic transmission model to predict health outcomes given diverse regional parameters. We explore the set of Pareto optimal solutions for allocation of budget to delivery programs by region, considering noise in the objective functions inherent to infectious disease modeling.

Multi-modality in Air Transportation

Community Committee Choice Session

Session Chair: Ang Li, 1</sup

1 Airport Express Bus Dispatch Based On Airport Accessibility Maximization

Shriya Karam[1], Ang Li[2], Mark M. Hansen[3], [1]Massachusetts Institute of Technology, Boston, MA, [2]University of California-Berkeley, Emeryville, CA, [3]University of California-Berkeley, Berkeley, CA, Contact: shriyakaram@gmail.com

Through the 2021 $1.2 trillion Bipartisan Infrastructure Law, The U.S. Department of Transportation aims to create and sustain equitable and accessible intercity transportation systems. However, in accessing the intercity transportation system through airports, individuals' ability to travel to airports through a reliable ground transportation mode may inhibit their accessibility to intercity destinations. Using a cohort-based optimization approach, we determine the optimal allocation of a limited supply of express buses to serve an airport from a particular bus station by maximizing accessibility scores of census tracts to airports, accounting for the impact of census tracts' financial disadvantage. The approach and findings of the study provides a framework for examining the impact of ground access improvements based on accessibility as a planning metric.

2 Air Transport Demand in Europe and North-America: Estimation and Application in an Aviation Environmental Policy Game

Gianmarco Andreana[1], Gerben de Jong[2], Nicole Adler[3], [1]Hebrew University of Jerusalem, Jerusalem, Israel; [2]Seo Economics, Amsterdam, Netherlands; [3]Hebrew University, Jerusalem, Israel. Contact: gianmarco.andreana@mail.huji.ac.il

This paper estimates air transport demand for business and leisure segments in the European, North American, and transatlantic markets. Using a nested logit discrete choice model, we find significant differences in demand parameters across different segments and markets, with leisure travelers in North America being more price-sensitive than those in Europe. Additionally, non-price characteristics are valued higher by business passengers than leisure passengers in all markets. We apply our findings to an environmental game that demonstrates the impact of demand differences on the optimal level of environmental taxes in Europe and North America. This paper contributes to the literature on aviation demand, environmental policies for aviation, and game-theoretical approaches in aviation markets.

3 Multimodal UAV-Based Parcel Delivery for Congestion Mitigation

Ang Li, University of California-Berkeley, Emeryville, CA

Urban parcel delivery has emerged as a high growth market, and the resulting delivery traffic can pose great challenges in dense urban areas. There is growing interest in supplanting the conventional model of a dedicated delivery person operating a van to alternatives featuring new classes of vehicles such as drones, autonomous robots, and electric cargo bikes. This work proposes combined delivery strategies using trucks, cargo bikes and drones. We develop and compare multimodal delivery strategies with various mode combinations. Then, we evaluate the benefit of multi-modal delivery in both uncongested and congested transportation networks. Results show that multimodal delivery strategies outperform other strategies in congested situations. We suggest taking advantage of synergistic operation among emerging vehicle types for more efficient parcel delivery.

4 Skyport Location Problem for Urban Air Mobility System

Hyelim Shin[1], Taesik Lee[1], Hyun-Rok Lee[2], [1]KAIST, Daejeon, Korea, Republic of; [2]Inha University, Michuhol-gu, Korea, Republic of. Contact: hyelim.shin@kaist.ac.kr

Skyport, a designated area for take-off and landing of air taxis, is a basic element for an air taxi-based transportation service system. When planning a skyport network, it is important to consider midair congestion between air taxis, as it can increase the risk of collisions and operational complexity. This study proposes a novel hub location problem, which incorporates midair congestion caused by intersecting vehicles along hub-to-hub arcs. The problem is reformulated as a linear formulation by leveraging a property of the original problem, which involves nonconvex bilinear terms. Also, a heuristic algorithm is developed to handle large-scale problems. Analysis of the optimal skyport network designs under various environments shows that the viability of an air taxi service depends on several factors such as collision risk, system cost, and airspace design.

5 Design and Implementation of Urban Air Mobility (UAM) Corridor Systems: A Multi-Disciplinary Approach

XUAN Jiang[1], Hao Yang[2], Shangqing Cao[1], Junzhe Cao[3], Yuhan Tang[4], [1]UC Berkeley, Berkeley, CA, [2]Washinton University, Seattle, CA, [3]University of California, Berkeley, Berkeley, CA, [4]ucberkeley, berkeley, CA, Contact: j503440616@berkeley.edu

This paper presents a comprehensive and multi-disciplinary approach towards the design and implementation of such systems.We propose a novel framework integrating advanced computational models, regulatory considerations, and urban planning principles. The design process begins with the identification of potential aerial routes using Geographic

Information System (GIS) data. Next, we consider the socio-economic factors and local air traffic regulations to optimize these routes. The paper delves into the integration of vehicle-to-infrastructure (V2I) and vehicle-to-vehicle (V2V) communication systems to ensure the safe operation of aerial vehicles within these corridors. Our proposed framework incorporates the use of electric vertical take-off and landing (eVTOL) aircraft to mitigate these concerns.

AI and Transfer Learning in Economic Systems

Community Committee Choice Session

Session Chair: Yifan Yu, University of Washington, Seattle, WA

1 Correcting Differential Measurement Error on Outcome in Treatment Effect

Wendao Xue, University of Washington Seattle, Seattle, WA, Contact: wendaox@uw.edu

Measurement error is a ubiquitous element of the literature. There has been a considerable amount of research on correcting measurement errors in regression models, while little research has been conducted on potential outcome models for causal inference. I demonstrate in this paper that differential measurement error on the outcome variable could affect the treatment effect’s performance and reliability. Furthermore, I investigated the identification of the average treatment effect when there are differential measurement errors on outcome variables and proposed an estimator for the average treatment effect. I provide consistency and asymptotic normality results for the proposed estimator and apply them to survey data concerning crime behavior studies.

2 Asymmetric Shapley Value for Augmented Data Valuation

Xi Zheng[1], Xiangyu Chang[2], Ruoxi Jia[3], Yong Tan[1], [1]University of Washington, Seattle, WA, [2]Xi’an Jiaotong University, Xi’an, China; [3]Virginia Polytechnic Institute and State University, Blacksburg, VA, Contact: xzheng01@uw.edu

As data becomes the fuel for technological and economic growth, a fundamental challenge is to quantify the value of data in algorithmic decision-making. Shapley Value, a classic notion from cooperative game theory, has been applied to measure the value of data points in supervised machine learning. Data augmentation techniques are widely used in machine learning tasks to reduce overfitting and boost performance. However, the Shapley Value has some key limitations when valuing augmented datasets; for example, the values ignore causal structure in the data. We propose a novel framework that utilizes Asymmetric Shapley Value for better valuation of augmented datasets and an efficient algorithm based on the K-nearest neighbors (KNN) model family. We demonstrate the utility of our framework in diverse data market settings.

3 Correcting Machine Learning Generated Variable Bias in Regression Models

Jingwen Zhang, wendao xue, Yifan Yu, Yong Tan, University of Washington, Seattle, WA, Contact: jingwenz@uw.edu

In recent times, machine learning generated features are increasingly being used as independent variables in empirical research. However, machine learning algorithms can have measurement errors. Directly plugging such features in the final model may result in biased estimation and hence inaccurate conclusions. In light of this, we examine the problem of correcting bias arising from machine learning algorithms in both linear and partial linear regression models. We propose multiple estimators that utilize two-stage least square method and generalized method of moments to correct such bias. We demonstrate the asymptotic consistency and normality of our estimators. We conduct extensive Monte Carlo simulations and also use Amazon review data to compare the performance of our estimators with other existing methods.

4 Exploring Strategic Behavior with Different Identity of Chatbot: Emotion Expression and Manipulation

Yu Kan, University of Washington, Lynnwood, WA

As organizations increasingly turn to Artificial Intelligence (AI) for addressing customer complaints, understanding the dynamics of user interactions with AI and human agents becomes imperative. In this study, we investigate customers’ strategic behavior when interacting with different agent types. We employ a two-round lab experiment, where participants are randomly assigned to an AI-based agent, a ChatGPT-based agent, a human agent, or an undisclosed identity group. Participants express their level of feeling and decide on the acceptance of proposed solutions by the assigned agent. We observed participants in undisclosed identity group felt less negative but paradoxically expressed more negativity. Our findings contribute to the growing body of research on AI-user interactions, suggesting intriguing dynamics of agent’s identities.

5 Digital Sculptors: Utilizing Generative AI to Boost Online Review Helpfulness

Xingchen Xu[1], Wendao Xue[1], Yifan Yu[1], Lin Jia[2], Yong Tan[1], [1]University of Washington, Seattle, WA, [2]Beijing Institution of Technology, Beijing, China. Contact: yifanyu@uw.edu

This work explores the effectiveness of using generative AI (ChatGPT) to boost online review helpfulness. Providing helpful reviews is the fundamental economic value of online review platforms. Generative AI technologies, such as ChatGPT, may potentially be used by the platforms to rewrite online reviews and boost the perceived helpfulness of existing reviews. Therefore, ChatGPT may be used to monetize existing digital assets of online review platforms.

Deep Learning Applications in OM

Community Committee Choice Session

Session Chair: Antoine Desir, INSEAD, 263 Avenue Daumesnil, France

1 A Practical End-to-End Learning for Inventory Management in E-Commerce

Meng Qi[1], Yuanyuan Shi[2], Yongzhi Qi[3], Chenxin Ma[4], Rong Yuan[4], Di Wu[5], Zuo-Jun Max Shen[6], [1]Cornell University, Ithaca, NY, [2]University of California San Diego, La Jolla, CA, [3]JD.com, Beijing, China; [4]JD.com, Santa Clara, CA, [5]JD.com, Mountain View, CA, [6]University of California Berkeley, Berkeley, CA

We consider a multi-period inventory management problem faced by E-commerce companies. We propose a one-step end-to-end (E2E) framework that uses deep learning models to output the suggested replenishment amount directly from input features without any intermediate step. The E2E model is trained to capture the behavior of the optimal dynamic programming solution under historical observations without any prior assumptions on the distributions of the demand and the VLT. By conducting a series of thorough numerical experiments using real data from one of the leading e-commerce companies, we demonstrate the advantages of the proposed E2E model over conventional PTO frameworks.

2 Deep Learning for Choice Modeling

Xiaocheng Li[1], Kalyan Talluri[2], Hanzhao Wang[1], [1]Imperial College Business School, London, United Kingdom; [2]Imperial College Business School, London, VT, United Kingdom

Choice modeling has been a central topic in the study of individual preference or utility across many fields including economics, marketing, and operations research. While the vast majority of the literature on choice models has been devoted to the analytical properties that lead to managerial and policy-making insights, the existing methods to learn a choice model from empirical data are often either computationally intractable or sample inefficient. In this paper, we develop deep learning-based choice models under two settings of choice modeling: (i) feature-free and (ii) feature-based. Our model captures both the intrinsic utility for each candidate choice and the effect that the assortment has on the choice probability. Synthetic and real data experiments demonstrate different aspects of the proposed models' performances.

3 Using Neural Networks to Guide Data-Driven Operational Decisions

Ningyuan Chen[1], Saman Lagzi[2], Joseph Milner[1], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto Rotman School of Management, Toronto, ON, Canada. Contact: ningyuan.chen@utoronto.ca

We propose to use Deep Neural Networks to solve data-driven stochastic optimization problems. Given the historical data of the observed covariate, taken decision, and the realized cost in past periods, we train a neural network to predict the objective value as a function of the decision and the covariate. Once trained, for a given covariate, we optimize the neural network over the decision variable using gradient-based methods because the gradient and the Hessian matrix can be analytically computed. We characterize the performance of our methodology based on the generalization bound of the neural network. We show strong performance on two signature problems in operations management, the newsvendor problem and the assortment pricing problem.

4 Improving Greedy Algorithms for Assortment Optimization Problems with Machine Learning

Antoine Desir[1], Axel Parmentier[2], [1]INSEAD, 263 Avenue Daumesnil, France; [2]Ecole Nationale des Ponts et Chaussées, Champs sur Marne, France. Contact: antoine.desir@insead.edu

Assortment optimization is an important problem that arises in many practical applications such as retailing and online advertising. In this paper, we propose a new data-driven approach to assortment optimization that leverages recent advances in learning machine learning pipelines with combinatorial optimization layers. Under the MNL model, the optimal assortment is revenue ordered. Instead, our approach can be interpreted as a smart greedy algorithm that returns a score ordered assortment, where the scores are learned from data. Since the scores are learned offline, our approach is as fast as a greedy algorithm. Moreover, we conduct extensive numerics and show that it returns near optimal solutions for a variety of choice models and constrained settings.

1 Hydrogen in Texas: Fueling a Local, Equitable Energy Transition

Jerry Potts, Sergio Castellanos, University of Texas at Austin, Austin, TX, Contact: jerry.potts@utexas.edu

Hydrogen has emerged as an alternative fuel source to decarbonize hard-to-electrify sectors. As demand increases, the development of the hydrogen supply chain is likely to have substantial impacts on long-term grid planning decisions. In this work, we develop an open-source capacity expansion model to co-optimize the hydrogen supply chain along with the electricity sector in Texas. We identify necessary expansions to hydrogen production, transport, and storage to meet projected hydrogen demand and the expected impact on long-term grid planning across a breadth of economic and policy scenarios. The results of this model are then evaluated based on their environmental and economic impacts to quantify inequitable impacts across communities.

2 Designing Retirement Strategies for Coal-Fired Power Plants to Mitigate Air Pollution and Health Impacts

Wei Peng, Carla Campos, Penn State, University Park, PA

By considering six coal plant retirement strategies for Pennsylvania that vary by targets and priorities, we find the spatial distribution of the air quality impacts depends on which units are shut down and where. In addition, Pennsylvania's coal retirement decisions also influence the power generation and associated air quality impacts in the rest of the PJM region.

3 Assessing the Tradeoff of Efficiency for Autonomy in Powering African Microbusiness Operations

Ogechi V. Nwadiaru[1], Erin Baker[2], [1]University of Massachusetts, Amherst, MA, [2]University of Massachusetts, Amherst, MA, Contact: onwadiaru@umass.edu

In this work we explore, energy insecurity in urban poor productive use settings and attempt to establish an economic case for energy storage as a replacement for existing backup alternatives.

4 Historical Inequities in the Location and Deployment of Energy Infrastructure in the United States

Erin Mayfield, Dartmouth College, Hanover, NH

This presentation evaluates historic inequities in the location and deployment of energy infrastructure using regression and machine-learning based methods. We focus on three case studies the provide differential insights. First, we evaluate systemic inequities on the basis of income, race, and education of greenhouse gas-producing power plants and industrial infrastructure locations. Next, we evaluate monetary and non-monetary drivers of utility-scale solar and wind deployment. Finally, we investigate the socioeconomic, demographic, and political drivers of residential technology adoption (e.g., electric vehicles, distributed solar, heat pumps) in rural areas.

Computational Methods for Uncertainty Quantification II/II

Community Committee Choice Session

Session Chair: Moses Chan, Northwestern University, Evanston, IL

1 Active Learning of a Recursive Non-additive Emulator for Multi-fidelity Computer Experiments

Junoh Heo, Chih-Li Sung, Michigan State University, East Lansing, MI, Contact: heojunoh@msu.edu

In this talk, we introduce the Recursive Non-Additive (RNA) emulator, a flexible model for integrating multi-fidelity computer experiments. Unlike conventional methods, RNA avoids the additive assumption and captures complex relationships using Gaussian process modeling. It efficiently computes the posterior predictive mean and variance in a closed form, enhancing computational efficiency. Furthermore, we introduce an active learning strategy to optimize accuracy while managing computational costs and selecting fidelity levels and input locations. The RNA emulator shows promising potential for enhancing the analysis of complex systems with varying fidelity data.

2 Discovering Active and Co-Active Subspaces for High Dimensional Computer Models

Kellin Rumsey, Los Alamos National Laboratory, NM

Active Subspaces are becoming an increasingly important technique for dimension reduction. Recent research has demonstrated that active subspace calculations can be obtained in closed form, conditional on a Gaussian process surrogate. We produce the relevant calculations for a more general case which can be applied to the GP, recovering previous results as a special case, or applied to the models constructed by other regression techniques including multivariate adaptive regression splines. Using a MARS surrogate has many advantages including improved scaling, better estimation of active subspaces in high dimensions and the ability to handle a large number of prior distributions in closed form. In one real-world example, we obtain the active subspace of a radiation-transport code with 240 inputs and 9,372 model runs in under half an hour.

3 Performance Analysis of Sequential Experimental Design for Calibration of Simulation Models

Ozge Surer[1], Stefan Wild[2], [1]Miami University, Oxford, OH, [2]Berkeley Lab, Berkeley, CA, Contact: surero@miamioh.edu

Simulation models often have parameters that need to be calibrated using observed data. For expensive simulation models, calibration is typically done using an emulator of the simulation model. Using a sequential selection of parameters to build the emulator can drastically improve the efficiency of the calibration process. The rate of the speed up in a sequential design is further affected by other factors such as the run time of a simulation model and the time to select parameters. This work provides a performance analysis study on the difference between sequential and batch-sequential synchronous and asynchronous procedures in experimental design with different acquisition functions.

4 Maximum One-Factor-at-a-Time Designs for Screening in Computer Experiments

Qian Xiao[1], Roshan V. Joseph[2], Douglas M. Ray[3], [1]University of Georgia, Athens, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]US Army DEVCOM Armaments Center, Picatinny Arsenal, NJ, Contact: roshan@isye.gatech.edu

Identifying important factors from a large number of potentially important factors of a highly nonlinear and computationally expensive black box model is a difficult problem. Morris screening and Sobol' design are two commonly used model-free methods for doing this. In this work, we establish a connection between these two seemingly different methods in terms of their underlying experimental design structure and further exploit this connection to develop an improved design for screening called Maximum One-Factor-At-A-Time (MOFAT) design. We also develop efficient methods for constructing MOFAT designs with a large number of factors. Several examples are presented to demonstrate the advantages of MOFAT designs compared to Morris screening and Sobol' design methods.

Spatiotemporal Decision Intelligence

Community Committee Choice Session

Session Chair: Ziyue Li, University of Cologne, Kowloon, Hong Kong

Session Chair: Fugee Tsung, HKUST(GZ), Kowloon, Hong Kong

1 Spatial Temporal Data Inference via Self-Supervised Inductive Tensor Decomposition

Man Li[1], Fugee Tsung[2], [1]HKUST, Hong Kong, Hong Kong; [2]HKUST(GZ), Kowloon, Hong Kong. Contact: mlicn@connect.ust.hk

Spatiotemporal data inference is an important task in many domains. Most research on spatiotemporal data analysis has focused on random missing data imputation, while paid little attention to blockout missing and segment missing - recovering signals from unseen sensors and continuous-time missing, and most matrix/tensor completion methods are not inductive. Therefore, we propose a self-supervised probabilistic tensor decomposition model to recover all-type missing signals for spatial temporal data. Random sub-tensors are generated based on the topology structure as training samples and by maximizing the log-likelihood of all reconstructed sub-tensors, unifying basis are extracted which can be transferred to the same type of inference task. Empirical results on real-world spatiotemporal datasets demonstrate the effectiveness of out model.

2 Deep Insights into Noisy Pseudo Labeling on Graph Data

Botao Wang[1], Fugee Tsung[2], [1]Hong Kong University of Science and Technology, Hong Kong SAR, China; [2]HKUST(GZ), Kowloon, Hong Kong

Pseudo labeling is a wide-applied strategy to enlarge the labeled dataset by self-annotating the potential samples during training. However, the incorrect label can be fatal to the spatiotemporal data. The inappropriate pseudo labeling may result in the performance degrading of the base model, especially on graph data where the noise can propagate. Thus, we present the pseudo labeling error analysis that the error is bounded by the confidence threshold and consistency of prediction. Accordingly, we propose a cautious pseudo labeling methodology in which we pseudo label samples with high confidence. The improvement on convergence property of the proposed algorithm is theoretically illustrated. The proposed algorithm consistently improves the base models and outperforms other pseudo labeling algorithms in link prediction and node classification tasks.

3 Spatial-Temporal Anomaly Detection from the Perspective of Graph Relational Learning

Weiqi Zhang, Hong Kong University of Science and Technology, Kowloon, Hong Kong, China

System monitoring and anomaly detection is a crucial task in daily operation. With the rapid development of industrial systems, multiple sensors get involved to represent the system state from different perspectives, which inspires us to detect anomalies considering feature dependence relationship. Thus, we propose a novel Graph Relational Learning Network to detect anomalies from the perspective of between-sensor dependence relationship learning. Variational AutoEncoder serves as the overall framework. Graph Neural Network and stochastic graph relational learning strategy are also imposed to capture the between-sensor dependence. A composite anomaly metric is established with the learned dependence structure explicitly. The experiments on four real-world datasets show superiority in detection accuracy, anomaly diagnosis, and model interpretation.

Multimodal Data Analysis for Interconnected and Distributed Systems

Community Committee Choice Session

Session Chair: Mostafa Reisi, University of Florida, Gainesville, FL

Session Chair: Elif Konyar, University of Florida, Gainesville, FL

1 Multimodal Cooperative Federated Data Fusion

Mohammad Amini, University of Florida, Gainesville, FL

Multimodal data fusion is a technique that combines data from multiple sources to gain a comprehensive understanding of complex systems. However, multi-modal data is often decentralized, and sharing sensitive data can compromise individual privacy. To address this issue, we propose a cooperative federated multimodal data fusion approach that preserves the privacy of data sources. With a federated approach, computations are performed locally on each dataset without requiring direct access to data. The approach has potential applications in healthcare, finance, and transportation, where sensitive data is involved, to enable more effective and secure collaboration among organizations.

2 Online Monitoring and Identifying Correlated Patterns Between Data Streams

Xinmiao Luan, Arizona State University, Tempe, AZ

The development of the manufacturing systems has made it increasingly necessary to monitor the data generated by multiple interconnected subsystems with rapid incoming of samples. Based on online learning techniques, we develop a general online monitoring approach for interconnected system, focusing on a basic scenario on monitoring of two connected subsystems, where each subsystem produces big data streams with several variation patterns in normal working conditions in this work. When special situation happens and new associations occur, a very small amount of computation is sufficient to update the system status and compute the control statistics by using this approach.

3 A Hybrid Prognostic Method for Rotating Machinery by Fusing Direct and Indirect Degradation Characteristics

Haitao Liao, University of Arkansas, Fayetteville, AR

It is often difficult to obtain direct degradation characteristics (DCs), which directly reflect the health of a machine, in real-time. Instead, indirect DCs are easy to collect. Traditional machine learning and model-based prognostic methods may not be precise when handling such data. This work presents a Direct-Indirect DCs Fusion method that combines direct and indirect DCs to predict the remaining useful life of the machine under time-varying conditions. The method accounts for time-varying covariates, converts indirect DCs to direct DCs under moderate sample sizes with a loop-Generative Adversarial Network (GAN), and describes the gradual degradation and sudden shocks in direct DCs. The method outperforms several benchmarks in RUL prediction as demonstrated in an industrial application.

4 Causal Graph Discovery from Self and Mutually Exciting Time Series

Song Wei[1], Yao Xie[1], Christopher Josef[2], Rishikesan Kamaleswaran[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]Department of Surgery, Emory University School of Medicine, Atlanta, GA, [3]Department of Biomedical Informatics, Emory University School of Medicine, Atlanta, GA, Contact: swei70@gatech.edu

We present a generalized linear structural causal model, coupled with a novel data-adaptive linear regularization, to recover causal directed acyclic graphs (DAGs) from time series. By leveraging a recently developed Variational Inequality (VI) formulation, we cast the causal discovery problem as a general convex optimization. Furthermore, we develop a non-asymptotic recovery guarantee and quantifiable uncertainty by solving a linear program to establish confidence intervals. We validate our theoretical results and show the competitive performance of our method via extensive numerical experiments. We show the effectiveness of our approach in recovering highly interpretable causal DAGs over Sepsis Associated Derangements (SADs) while achieving comparable prediction accuracy to powerful ``black-box'' models such as XGBoost.

Energy Systems Integration

Community Committee Choice Session

Session Chair: Dharik Sanchan Mallapragada, MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA

1 The Tradeoffs Between Land-Use Constraints, and Indirect Carbon Emissions with the Development of Hydrogen Infrastructure in the Western Interconnection

Grant T. Aguinaldo, Neha Patankar, Binghamton University, Binghamton, NY, Contact: grant.aguinaldo@gmail.com

With the rising interest in using hydrogen to decarbonize the hard-to-electrify portions of the energy sector comes the need for the infrastructure to produce and transport hydrogen at scale. While past work has shown that solar hydrogen can be continuously produced at an industrial scale, care must be exercised not to ignore the spatial constraints in the indirect carbon emissions when connecting these plants to the grid and the potential for land-use conflicts. Since spatial considerations are necessary when siting a renewable hydrogen plant, a better understanding of the tradeoffs between possible land-use constraints and the embodied emissions from the produced hydrogen is needed. This presentation will highlight ongoing efforts to understand these tradeoffs when developing hydrogen infrastructure in the Western Interconnection.

2 Interactions Between Hybrid Power Plant Development and Local Transmission in Congested Regions

Julie Mulvaney Kemp, Lawrence Berkeley National Laboratory, Berkeley, CA, Contact: jmulvaneykemp@lbl.gov

This presentation will investigate plant-grid dynamics in highly congested regions - which offer insight into future grid conditions - to determine whether variable renewable energy generators, energy storage, and hybrid plants reduce or increase the need for nearby transmission. Whether or not a hybrid plant increases or decreases local transmission value depends on the plant's technological specifications (e.g., degradation costs) and regulatory environment (e.g., restrictions on grid charging). Therefore, advances in storage tech and policy decisions will influence which results will be realized. The financial implications of transmission expansion on hybrid and stand-alone plants will also be addressed. Results are based on real-time nodal price data and location-specific solar and wind profiles for 2018-2021 at 23 wind and solar plant locations in the U.S.

3 Optimizing India's Net-Zero Power System Planning Through Repurposing Coal Power Plants

Yifu Ding[1], Dharik Sanchan Mallapragada[2], [1]MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, [2]MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, Contact: yifuding@mit.edu

India's energy demand is projected to increase by 50% by 2040 due to rapid electrification, most through the adoption of air conditioners in the building sector. However, its current power system depends heavily on coal power plants. These plants predominantly rely on low-quality coal, producing significant carbon emissions and air pollution. Despite setting a target of adding 500 GW of renewable energy by 2030, India has yet to propose a phase-out plan for its coal plants. Routine power system planning only focuses on renewable investments and will likely fall into carbon lock-in because of a lack of system flexibility. This talk will present power system planning strategies through repurposing coal power plants, aiming to cancel the coal lock-in effect and achieve the least-cost net-zero system.

4 No Grid is a (Voluntary) Island, Connecting Texas to the Western Grid

Drew Kassel, Joshua Rhodes, Michael Webber, The University of Texas at Austin, Austin, TX, Contact: drew.kassel@utexas.edu

Maintaining grid reliability in Texas is of increasing concern due to the recent failure of the ERCOT grid. Subsequent tight grid conditions have further eroded confidence. Most of the suggested solutions focus on simply building more power plant capacity. This study explores the option of building meaningful amounts of transmission capacity between ERCOT and its western neighbor WECC. For this analysis, we use the open-source capacity expansion model, GenX, to simulate different developmental pathways of ERCOT and WECC, with and without the ability to connect the regions, while simultaneously optimizing cost and avoiding outage events by planning for winter storms. We find that the model shows a strong preference for building a multi thousand-megawatt connection between ERCOT and WECC, resulting in a cheaper and cleaner pathway to maintaining reliability.

5 Reliability Assessment of Power Grid Operations Considering Correlated Dependency from Gas Pipeline Delivery

Zhi Zhou[1], Neal Mann[1], David Sehloff[1], Eric Tatara[2], Sinem Perk[1], Mitchell Krock[1], Akintomide Akinsanola[1], [1]Argonne National Laboratory, Lemont, IL, [2]Argonne National Laboratory, ARGONNE, IL, Contact: zzhou@anl.gov

Decarbonizing the electric grid intensifies the interaction between the grid and natural gas pipelines, both of which and their interplay are vulnerable to extreme weather. This research develops a modeling workflow to assess the joint risks of extreme weather on electricity and gas pipeline systems. The approach considers climate change scenarios, using a probabilistic model to characterize uncertainty of future extreme weather events using output from climate models. Additionally, an extended power grid operational model is utilized to accurately represent weather-affected grid inputs. With this model, the study evaluates grid reliability in terms of resource outage probability and, ultimately, load curtailment probability and expectation. A case study illustrates the methodology using a synthetic grid and pipeline system resembling ISO New England system.

CC-North 229B

Oil, Gas, and the Future of Energy

Community Committee Choice Session

Session Chair: Benjamin D. Leibowicz, The University of Texas at Austin, Austin, TX

1 Optimal Investment Planning for Oil and Gas Production Networks with Fixed Production Profiles

Donghao Liu[1], Benjamin D. Leibowicz[2], Jonathan F. Bard[3], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]University of Texas, Austin, TX, Contact: q33311131@gmail.com

This talk will be given to solve a newly devised model for oilfield planning problem. The model introduces a fixed production profile for all the wells and an overall investment budget. This model poses a higher demand for algorithm design. A heuristic based decomposition method will be introduced to solve the model efficiently.

2 Coordination Problems and Incentive Pass-Through in Carbon Capture, Utilization, and Storage Development

Abdullah Albeladi[1], Benjamin D. Leibowicz[2], [1]The University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, Contact: albeladi@utexas.edu

The deployment of carbon capture, utilization, and storage (CCUS) technologies is crucial for achieving climate change mitigation goals. However, despite the 45Q tax credit incentives, progress has been slow. Our research examines whether coordination problems, where multiple agents must contribute to the development of CCUS infrastructure, could explain the limited deployment. To this end, we construct an equilibrium model of the CCUS market formulated as a mixed complementarity problem, which represents CO_2 capturers, pipeline operators, traders, utilizers, and storers as strategic players. Additionally, we investigate incentive pass-through and assess how 45Q revenues are apportioned to different players in the CCUS market.

3 The Effects of Policy Uncertainty and Risk Aversion on Carbon Capture, Utilization, and Storage Investments

Connor Colombe[1], Benjamin D. Leibowicz[2], Benjamin Mendoza[3], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]The University of Texas at Austin, Austin, TX

Carbon capture, utilization, and storage (CCUS) systems capture CO2 and either put it to productive use (utilization) or safely sequester it underground (storage). While model-based analyses suggest an important role for CCUS in climate change mitigation pathways, CCUS infrastructure investment has been slow to materialize. We hypothesize that the slow pace of CCUS deployment is driven in large part by policy uncertainty regarding government incentives for CCUS and investors' risk aversion. We test this hypothesis by developing a CCUS infrastructure network optimization model formulated as a two-stage stochastic program. Future incentive levels are uncertain and risk aversion is incorporated through an objective function with conditional value at risk. As a case study, we apply our model to the TX and LA Gulf Coast under the 45Q federal tax incentives for CCUS in the US.

4 Integrated Energy System Modeling for Decarbonizing Pjm: Identifying Optimal Strategies for Net-Zero Emissions

Shantanu Tarun Chakraborty[1], Nicole Xiaoyang Shi[1], Dharik Sanchan Mallapragada[1], John E. Parsons[2], Pablo Duenas Martinez[1], [1]MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: shan2312@mit.edu

This study models a comprehensive energy system for decarbonizing the PJM region. At present, heavy industries in the region are reliant on coal and gas with limited renewables. The integrated model incorporates hydrogen, CCS, and renewables to achieve a low-carbon future. Optimization and capacity expansion models identify optimal strategies for transitioning PJM to net-zero emissions. The study emphasizes the impact of network constraints and spatial distribution of resources. Scenario analysis reveals trade-offs and synergies between technologies. The importance of hydrogen as an energy vector, and CCS's potential to offset emissions and renewable power generation are underscored. This research contributes to understanding investment requirements for a low-carbon PJM system in terms of generation, transmission, and storage resources.

5 Equitable Low-Carbon Transition Pathways for California's Oil Extraction

Ranjit Deshmukh[1], Paige Weber[2], Olivier Deschenes[3], Danae Hernandez-Cortes[4], Tia Kordell[5], Ruiwen Lee[5], Christopher Malloy[3], Tracey Mangin[5], Measrainsey Meng[6], Sandy Sum[5], Vincent Thivierge[5], Anagha Uppal[7], David W. Lea[8], Kyle Meng[9], [1]University of California Santa Barbara, Santa Barbara, CA, [2]University of North Carolina, Chapel Hill, NC, [3]University of California Santa Barbara, Santa Barbara, CA, [4]Arizona State University, Tempe, AZ, [5]University of California Santa Barbara, Santa Barbara, CA, [6]University of California Santa Barbara, Santa Barbara, CA, [7]University of California Santa Barbara, Santa Barbara, CA, [8]University of California Santa Barbara, Santa Barbara, CA, [9]University of California Santa Barbara, Santa Barbara, CA, Contact: rdeshmukh@ucsb.edu

Oil supply-side policies---setbacks, excise tax, and carbon tax---are increasingly considered for decarbonizing the transportation sector. To examine health, labor, and equity impacts of policy-driven decarbonization pathways, we combine an empirical field-level oil production model, an air pollution model, and an employment model to characterize spatially-explicit 2020--2045 decarbonization scenarios from various policies applied to California, a major oil-producer with ambitious decarbonization goals. We find setbacks generate the largest avoided mortality benefits from reduced air pollution and the largest lost worker compensation, followed by excise and carbon taxes. Setbacks also yield the highest share of health benefits and the lowest share of lost worker compensation borne by disadvantaged communities.

New Developments in Energy Markets

Community Committee Choice Session

Session Chair: Daniel Bienstock, Columbia University, New York, NY

1 Comparing Profit-Maximizing Offer Behavior of Generators in Centrally Versus Self-Committed Wholesale Electricity Markets

Yuzhou Jiang[1], Ramteen Sioshansi[2], [1]The Ohio State

University, Columbus, OH, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: rsioshan@andrew.cmu.edu

We study the incentive properties of the two primary approaches to incorporating unit-commitment decisions in wholesale electricity markets. One approach is centralized unit commitment, wherein generating firms provide complex multi-part offers that specify their non-convex fixed and variable operating costs. The second approach is self-commitment, whereby firms determine unit-commitment decisions for their generating units individually and submit simple offers for the provision of energy. We find that the profit of the profit-maximizing firm does not differ significantly between the two market designs but that system costs can be higher under a self-committed design.

2 Data-Driven Inverse Optimization for Marginal Offer Price Recovery in Electricity Markets

Zhirui Liang, Johns Hopkins University

This talk presents a data-driven inverse optimization (IO) approach to recover the marginal offer prices of generators in a wholesale energy market. By leveraging underlying market-clearing processes, we establish a closed-form relationship between the unknown parameters and the publicly available market-clearing results. Based on this relationship, we formulate the data-driven IO problem as a computationally feasible single-level optimization problem. The solution of the data-driven model is based on the gradient descent method, which provides an error bound on the optimal solution and a sub-linear convergence rate. The effectiveness of the proposed method is demonstrated in a realistic NYISO 1814-bus system.

3 An Incentive Compatible Mechanism for Alignment of Day-Ahead and Real-Time Markets

Agostino Capponi, Bo Yang, Columbia University, New York, NY

We study whether virtual bidding can achieve its intended purpose of reducing the premium between the day ahead and real-time markets and prevent the underbidding behavior of power generators and load-serving entities. Using a game theoretical model, we show that virtual bidding aligns day ahead and real-time market prices, if there are sufficiently many virtual trades. If virtual bidding is absent, the load-serving entity exerts its market power and underbids in the day ahead market if the extra savings from such an action outweigh the potential losses from a small capacity realization. In contrast, if the prices are aligned, the load-serving entity increases its demand bid in the day ahead market to balance the risks from capacity and demand realizations, and incentivize renewable power suppliers to increase their offers.

4 Assessing Price Distributions in Future Electricity Grid Markets with a Stochastic Production Cost Model

Kaleb Smith, Jacob Mays, Cornell University, Ithaca, NY, Contact: ks885@cornell.edu

This talk considers the evolution of spot price distributions arising in power markets as systems transition to high levels of wind, solar, and storage. In systems dominated by thermal resources with minimal storage, marginal costs and therefore clearing prices are driven by fuel costs, enabling modelers to rely on simplified deterministic formulations to approximate price behavior. Future price formation may instead be increasingly driven by opportunity costs, necessitating a more sophisticated representation of uncertainty and intertemporal constraints. We describe the mechanics of price formation with storage, employ a stochastic production cost model to simulate prices in a modeled future system, and highlight the differences between the simulated prices and those that would arise in a deterministic analysis.

5 Opportunities for Heavy Industry to Exploit Market Structure

Alexandra M. Newman[1], Andrea Brickey[2], Daniel Bienstock[3], [1]Colorado School of Mines, Golden, CO, [2]South Dakota School of Mines and Technology, Rapid City, SD, [3]Columbia University, New York, NY, Contact: anewman@mines.edu

Heavy industry is associated with some of the most energy-intensive operations. Opportunities exist to capitalize on storage technologies and market pricing structures to lower energy costs by shifting certain operations to lower-priced time periods. We demonstrate, via several case studies, how optimizing production schedules can realize these gains.

CC-North 231A

Learning, Optimization, and Control for Carbon-neutral Electric Grids

Community Committee Choice Session

Session Chair: Sivaranjani Seetharaman, Purdue University, West Lafayette, IN

1 Plug-and-play Control For Resilient Renewable-rich Microgrids

Sivaranjani Seetharaman, Purdue University, West

Lafayette, IN
The large-scale integration of renewable distributed energy resources (DERs) such as rooftop solar panels and wind turbines, has led to architectures where several DERs, storage units, and loads are aggregated into clusters known as microgrids. Such low-cost microgrids can also improve clean energy access to remote and underserved communities. However, microgrids are vulnerable to stability issues due to DERs that can connect or disconnect from the network in an ad-hoc manner. In this context, we will present a new distributed control framework for resilient plug-and-play operation of renewable-rich microgrids. We will utilize the notion of dissipativity to design local controllers such that global network stability and robustness is maintained under arbitrary plug-and-play operations, without requiring any redesign of existing controllers in the network.

2 A Consensus-Based Multi-Agent Reinforcement Learning Framework for Voltage Control with Peer-to-Peer Energy Trading

Andrew Liu[1], Chen Feng[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: andrewliu@purdue.edu

Distributed renewable energy and storage resources via peer-to-peer (P2P) trading can stimulate their adoption and bring lower-cost energy to consumers. While decentralized multi-agent reinforcement learning (MARL) frameworks exist to automate prosumers' bidding strategies in a P2P market, such approaches lack theoretical backing; nor can they account for network constraints. To address these, we propose a consensus-update MARL that enables prosumers to communicate with each other while collectively learning to maintain voltage constraints. Conditions for convergence are established and simulations show the consensus-based MARL can lead to higher profits from P2P trading than a decentralized MARL without communication.

3 Microgrid OS: A Platform for Workplace Decarbonization

Lucien D. Werner, Yiheng Xie, Thuy-Linh Le, Steven H. Low, California Institute of Technology, Pasadena, CA, Contact: lwerner@caltech.edu

Microgrid Operating System (OS) is a software platform that enables energy applications such as demand response, carbon reduction, and peak shaving to operate on top of any microgrid hardware (e.g., batteries, PV, EV charging, flexible load). In this talk we first present its three-layer architecture, consisting of data, modeling, and optimization. We then discuss our deployments of the data and modeling layers in a large-scale testbed on the Caltech campus, addressing the common painpoints of obtaining high-quality timeseries data and network models. Through case studies of resiliency planning and carbon footprint reduction, we demonstrate the necessity of these data and modeling efforts in supporting a range of energy and carbon optimization applications.

On-Demand Transportation Services

Community Committee Choice Session

Session Chair: Philipp Afeche, University of Toronto, Rotman School of Management, Toronto, ON, Canada

1 Autonomous Vehicles in Ride-Hailing and the Threat of Spatial Inequalities

Francisco Castro[1], Jian Gao[1], Sebastien Martin[2], [1]University of California, Los Angeles, Los Angeles, CA, [2]Northwestern University, Evanston, IL, Contact: jian.gao.phd@anderson.ucla.edu

This paper studies how the potential introduction of autonomous vehicles (AVs) in a fleet of human drivers (HVs) may impact the quality of service and the equality of access to transportation on ride-hailing platforms. We formulate a game-theoretical queueing model in which a platform aims to maximize its profit while HVs make strategic joining decisions. Our results demonstrate that the introduction of AVs may deteriorate the service level. We then reveal that the reduction of service level is not homogeneous across areas in a city: while the more profitable high-demand areas, such as downtown areas, may see a high concentration of vehicles and reasonable service levels, remote locations may suffer from a drop in service level. Then, using New York City data, we build a simulation that more closely resembles the operations of a ride-hailing platform.

2 Price-Waiting Trade-Offs in Ride-Hailing Platforms

Katerina Giannoutsou, Andrew Daw, University of Southern California, Marshall School of Business, Los Angeles, CA

We present a model for studying a ride-hailing platform that is faced with price and delay-sensitive riders and drivers, and is considering offering two different service classes which are differentiated in prices and delays. We explore the "price of two sides", show that the preferences of drivers impact the delays the riders experience and demonstrate that achieving the "full optimum" of price differentiation may not be feasible or optimal for a platform under all market conditions.

3 Role Of Mobility-on-Demand In Hybrid Transportation: A Dual Sourcing Approach

Sunil Chopra[1], Sebastien Martin[2], Partha Mishra[2], Karen Smilowitz[1], [1]Northwestern University, Evanston, IL, [2]Kellogg School of Management, Northwestern University, Evanston, IL, Contact: partha.mishra@kellogg.northwestern.edu

Motivated by new hybrid operations in transportation, we study a novel dual-sourcing problem with a trade-off between cost and responsiveness. In our setting, the slower source offers batched service at a fixed rate (e.g., shuttles), while the faster source has unit capacity and operates on demand (e.g., Uber). We assume the fast server's cost-per-capacity is more than that of the slow server. A central planner must control the slow server's service rate and choose when to use the fast server to minimize the cumulative expected waiting and service provision cost. Our key finding reveals that the optimal policy limits total demand to a finite threshold at any time. Beyond this, new demand is instantly directed to the fast source. An interesting implication of this result is that Ubers should only be used to cap the waiting passenger queue in an optimal hybrid operation.

4 Effectiveness Of Supply-Side Financial Incentives In Ride-hailing Networks With Spatial Demand Imbalance And Strategic Drivers

Uta Mohring[1], Philipp Afèche[2], Andre Augusto Cire[3], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Rotman School of Management, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada. Contact: uta.mohring@rotman.utoronto.ca

When matching riders with self-interested drivers in a spatial network, ride-hailing platforms face two challenges: (i) there are spatial demand imbalances that require some repositioning of drivers to serve the total rider demand, and (ii) the self-interested drivers strategically decide whether to join the network and if so, whether to wait for the next rider or reposition when not serving riders. We study the effects of supply-side financial incentives on drivers' decentralized repositioning decisions and the resulting repositioning equilibrium and evaluate their effectiveness in achieving the equilibrium under centralized repositioning.

CC-North 232A

Hybrid Quantum-Classical Methods for Optimization

Community Committee Choice Session

Session Chair: David Bernal Neira, NASA Ames Research Center, Palo Alto, CA

1 Using Quantum and Physics-Inspired Methods for Constrained Optimization: Reformulations, Decomposition Algorithms, Software and Benchmarking

David Bernal Neira, Purdue University, West Lafayette, IN

Optimization problems arise in different areas and solving these problems efficiently is essential for various applications. Quantum computers have the potential to efficiently solve nonlinear and combinatorial problems. However, current quantum computers cannot efficiently address practical problems; they are limited to small sizes and do not handle constraints well. We present different approaches to formulating and solving Quadratic Unconstrained Binary Optimization (QUBO) problems through unconventional computation methods, including but not limited to quantum algorithms, via open-source toolkit in Julia QUBO.jl. Finally, we show a hybrid classical-quantum algorithm to solve mixed-binary quadratically constrained programs via decomposition strategies leading to QUBO subproblems that can be solved by novel hardware (see arXiv:2207.13630)

2 Accelerating Coherent Continuous Variable Machines Using Momentum

Robin Brown[1,2], David Bernal Neira[3,2], Davide Venturelli[2],

Marco Pavone[1], [1]Stanford University, Stanford, CA, [2]Universities Space Research Association, Mountain View, CA, [3]NASA Ames Research Center, Palo Alto, CA, Contact: rabrown1@stanford.edu

Recently, Khosravi et al (2022) proposed a coherent continuous variable machine (CCVM) that encodes continuous variables using the quadrature operators of quantum optical modes, demonstrating improvements over SoTA classical heuristics. The dynamics of the CCVM encourage optimization via optical pulses corresponding to the negative gradient of the objective, however standard gradient descent is known to be trapped by local minima and hampered by poor problem conditioning. In this work, we propose to modify the CCVM dynamics using more sophisticated pulse injections based on techniques such as momentum and ADAM. We show that by using momentum updates rather than gradients for the pulse injections, we improve performance over both the original CCVM variants by increasing the probability of success and reducing the number of simulation timesteps.

3 Specialized Gaussian Process Modifications for Shot-Efficient Quantum-Classical Optimization

Farshud Sorourifar[1], Diana Chamaki[2,3], Norm M. Tubman[2], Joel A. Paulson[4], David E. Bernal Neira[2,3], [1]Ohio State University, [2]NASA Ames Research Center, Moffett Field, CA, [3]USRA Research Institute for Advanced Computer Science, Mountain View, CA, [4]Ohio State University, Columbus, OH

Quantum computing (QC) has been gaining traction due to its potential to address computationally challenging problems. Currently, QC success currently depends on hybrid quantum-classical optimization to build a circuit to represent the problem. however, such problems are difficult to solve; the observations from the circuit are noisy, and QC time is expensive.This work leverages the differences in quantum optimization algorithms to provide a more shot-efficient Bayesian optimization strategy. Specifically, we provide a means to exploit the 2riodicities of the rotation angles and use low-shot circuit observations to warm start the Bayesian optimization. We demonstrate the effectiveness of our proposed approach through an ablation study and show that using both proposed features statistically outperforms the other approaches with high confidence.

4 Iterative Quantum Optimization

Stuart Hadfield[1,2], [12]NASA Ames, Moffett Field, CA

Achieving real-world quantum advantage for hard combinatorial optimization problems remains an elusive goal. A recent paradigm seeks to utilize quantum devices in a novel way, as part of a hybrid quantum-classical loop that iteratively reduces a sequence of smaller problems. Here we describe recent progress on Iterative Quantum Optimization (IQO), providing a unifying framework for several quantum and classical algorithms. We generalize IQO to a much wider class of problems including those with hard constraints, and show how IQO is easily extended to a tree-search variant that incorporates backtracking and branch-and-bound, to enable further effective searching when additional computational resources are available. Finally, we show experimental and numerical evidence that IQO can lead to significantly improved performance on existing noisy quantum hardware.

5 Parameter Setting for Quantum Approximate Optimization of Weighted Problems

Dylan Herman[1], Shree Hari Sureshbabu[1], Ruslan Shaydulin[1], Joao Basso[2], Shouvanik Chakrabarti[1], Yue Sun[1], Marco Pistoia[1], [1]JPMorgan Chase, New York, NY, [2]Department of Mathematics, University of California, Berkeley, Berkeley, CA, Contact: dylan.a.herman@jpmorgan.com

We develop parameter setting heuristics for QAOA applied to weighted problems. First, we derive optimal parameters for QAOA with depth p=1 applied to the weighted MaxCut problem under different assumptions on the weights. Second, for p>1 we prove that the QAOA energy landscape for weighted MaxCut approaches that for the unweighted case under a simple rescaling of parameters. Also, we prove that for p=1 the QAOA objective sharply concentrates around its expectation, which means that our parameter setting rules will hold with high probability for a random weighted instance. We numerically validate this approach on a dataset of 34,701 weighted graphs with up to 20 nodes. Third, we propose a general heuristic rescaling scheme inspired by the analytical results for weighted MaxCut and demonstrate its effectiveness on the portfolio optimization problem as an example.

Quantum Linear Algebra and Optimization

Community Committee Choice Session

Session Chair: Mohammadhossein Mohammadisiahroudi, Lehigh University, Bethlehem, PA

Session Chair: Zeguan Wu, 1</sup

1 Hybrid HHL with Dynamic Quantum Circuits on Real Hardware

Romina Yalovetzky, Pierre Minssen, Dylan Herman, Marco Pistoia, JPMorgan Chase, Manhattan, NY, Contact: romina.yalovetzky@jpmorgan.com

This work advances a hybrid variant of the Harrow-Hassidim-Lloyd (HHL) algorithm that is suitable for noisy intermediate-scale quantum devices. First, we reduce the circuit complexity of the eigenvalue estimation component by leveraging newly available quantum-hardware features for implementing dynamic quantum circuits, such as mid-circuit measurements, qubit reset and reuse, and quantum conditional logic. Second, we introduce a novel method for scaling the linear-system matrix such that the eigenvalue estimation is more accurate. We empirically demonstrate the effectiveness of these Hybrid HHL enhancements by applying this algorithm to small portfolio optimization problems, executed end-to-end on the Quantinuum System Model H1-2 trapped-ion quantum computer.

2 An Inexact Feasible Quantum Interior Point Method for Linear and Quadratic Optimization

Zeguan Wu, Mohammadhossein Mohammadisiahroudi, Brandon Augustino, Xiu Yang, Tamas Terlaky, Lehigh University, Bethlehem, PA, Contact: zew220@lehigh.edu

Quantum linear system algorithms (QLSAs) have the potential to speed up algorithms that rely on solving linear systems. Interior Point Methods (IPMs) yield a fundamental family of algorithms for solving optimization problems. IPMs require the solution of a Newton linear system at each iteration, thus QLSAs can potentially speed up IPMs. Such quantum-assisted IPM (QIPM) provides inexact solution for the Newton linear system due to the noise in contemporary quantum computers. Typically, an inexact search direction leads to an infeasible iterate. In our work, we propose an inexact feasible QIPM (IF-QIPM) and show its advantage in solving linear optimization and linearly constrained convex quadratic optimization problems.

3 Quantum Relaxation for Quadratic Programs over Orthogonal Matrices

Andrew Zhao[1], Nicholas C. Rubin[2], [1]University of New Mexico, Albuquerque, NM, [2]Google, San Francisco, CA, Contact: azhao@unm.edu

Quadratic programming over the (special) orthogonal group encompasses a broad class of optimization problems such as group synchronization, point-set registration, and simultaneous localization and mapping. Such problems are instances of noncommutative quadratic optimization over orthogonal matrices. In this work, we establish an embedding of this class of problems onto a quantum Hamiltonian. Determining extremal states of this Hamiltonian provides an outer approximation, analogous to classical approaches such as semidefinite relaxations. In this talk, I will describe how this relaxation of a classical problem into a quantum one arises naturally, its connections with well-studied problems in quantum physics, and potential avenues for quantum advantage, in particular when tackling problems over the special orthogonal group (i.e., rotation matrices).

4 Quantum Algorithms for Hedging and the Learning of Ising Models

Patrick Rebentrost[1], Yassine Hamoudi[2], Maharshi Ray[3], Xin Wang[4], Siyi Yang[5], Miklos Santha[6], [1]Centre for Quantum Technologies, National University of Singapore, singapore, Singapore; [2]Université de Paris, IRIF, CNRS, Paris, France; [3]Mie University, Tsu city, Japan; [4]Institute for Quantum Computing, Baidu Research, Beijing, China; [5]Centre for Quantum Technologies, National University of Singapore, Singapore, Singapore; [6]Université de Paris, IRIF, CNRS, Centre for Quantum Technologies and MajuLab UMI 3654, National University of Singapore, Singapore, Singapore. Contact: maharshi91@gmail.com

In the Hedge algorithm by Freund and Schapire, an allocation into different strategies is chosen for multiple rounds and each round incurs corresponding losses for each strategy. The algorithm obtains a favorable guarantee for the total losses even in an adversarial situation. This work presents quantum algorithms for such learning tasks. For T time steps and N strategies, we exhibit run times of about $O(\mathrm{poly}(T)\sqrt{N})$ for estimating the losses and for betting on individual strategies by sampling. In addition, we discuss a quantum analog of the Sparsitron, a machine learning algorithm based on the Hedge algorithm. The quantum algorithm inherits the provable learning guarantees from the classical algorithm and exhibits polynomial speedups. The speedups may find relevance in finance and machine learning, for example, for learning generalized linear models or Ising models.

Graph Optimization for Computer Vision

Community Committee Choice Session

Session Chair: Bo Jones, Rice University, Houston, TX

1 Graph-Theoretical Approach to Robust 3D Normal Extraction of LiDAR Data

Wenbo Sun, Arpan Kusari, University of Michigan Transportation Research Institute, Ann Arbor, MI

A major challenge in LiDAR data analysis arises from the irregular nature of LiDAR data that forces practitioners to either regularize the data using some form of gridding or utilize a triangular mesh such as triangulated irregular network (TIN). While there have been a handful applications using LiDAR data as a connected graph, a principled treatment of utilizing graph-theoretical approach for LiDAR data modelling is still lacking. In this presentation, we formulate the normal estimation problem in an optimization framework, where we find the corresponding normal vector for each LiDAR point by utilizing its nearest neighbors and simultaneously enforcing a graph smoothness assumption based on point samples. We provide a simulation study on repeated randomly generated datasets and a case study on a large scale synthetic plane extraction dataset.

2 Uncertainty-Aware Efficient Subgraph Isomorphism Using Graph Topology

Arpan Kusari[1], Wenbo Sun[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Transportation Research Institute, Ann Arbor, MI, Contact: kusari@umich.edu

Subgraph isomorphism or subgraph matching is a NP-complete problem with edge weights taking real values and being subject to measurement noise and possible anomalies. In the absence of node labels, these subgraph matching methods do not work. We propose a method for identifying the node correspondence between a subgraph and a full graph in the inexact case without node labels in two steps - (a) extract the minimal unique topology preserving subset from the subgraph and find its feasible matching in the full graph, and (b) implement a consensus-based algorithm to expand the matched node set by pairing unique paths based on boundary commutativity. To demonstrate the effectiveness of the proposed method, a simulation and a case study is performed on the Erdos-Renyi random graphs and the image-based affine covariant features dataset respectively.

3 Clique Relaxations for Outlier Rejection in Point Cloud Registration

Bo Jones[1], Illya V. Hicks[2], [1]Rice University, Houston, TX, [2]Rice University, Houston, TX, Contact: bo.jones@rice.edu

For registering two point clouds, past work has demonstrated improvements in registration accuracy when employing an initial preprocessing step in which a consistent set of initial correspondences is selected. This is accomplished by finding a cohesive subgroup in the consistency graph having vertices potential correspondences. Others have used the maximum clique, maximum density subgraph and maximum k-core to determine cohesive subgroups. We investigate the effectiveness of using maximum edge weight clique and other clique relaxations, including k-plex, for this purpose.

4 Robin: A Graph-Theoretic Approach to Reject Outliers in Robust Estimation Using Invariants

Jingnan Shi[1], Heng Yang[2], Luca Carlone[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Harvard University, Cambridge, MA, Contact: jnshi@mit.edu

Many estimation problems in robotics and computer vision require estimating unknown quantities in the face of outliers. Outliers are typically the result of incorrect data association or feature matching, and they adversely affect the quality of solutions. This work develops an approach, named ROBIN, to prune outliers. First, we use the theory of invariance to quickly check if a subset of measurements are mutually compatible without explicitly solving the corresponding estimation problem. Second, we develop compatibility hypergraphs, where measurements are modeled as vertices and mutual compatibility as edges. We generalize existing results showing that the inliers form a clique in a compatibility hypergraph and typically belong to the maximum clique. We demonstrate the effectiveness of ROBIN on several geometric perception problems.

Models of Disease Transmission and Prevention in Service Systems

Community Committee Choice Session

Session Chair: Mohammad Delasay, Stony Brook University, Stony Brook, NY

Session Chair: Sherwin Doroudi, University of Minnesota, Minneapolis, MN

1 Stochastic Analysis of Disease Transmission via Infectious Aerosols in the M/G/Infinity Queue

Sherwin Doroudi, Alexander Wickeham, University of Minnesota, Minneapolis, MN, Contact: sdoroudi@umn.edu

We present a stochastic model of disease transmission via infectious aerosols. Our model considers individuals (some infectious and others susceptible) that arrive to and depart from an M/G/infinity queuing system. Infectious individuals release infectious aerosols that decay over time during their sojourn in the system, with these particles possibly persisting in the system even after the individual emitting them departs. Meanwhile, a susceptible customer becomes infected if the concentration-time product of its exposure to infectious aerosols exceeds an exponentially distributed threshold. Using a variety of queueing-theoretic techniques we derive expressions (in terms of integrals and special functions) for the probability that a susceptible customer entering the system becomes infected.

2 A Study on Queueing Topology for Reducing Customer Overlaps in Service Systems

Jin Xu[1], Young Myoung Ko[2], Min Kong[3], Jamol Pender[4], [1]Huazhong University of Science and Technology, Wuhan, China; [2]Pohang University of Science and Technology, Pohang, Korea, Republic of; [3]Anhui Normal University, Wuhu, China; [4]Cornell University, Ithaca, NY, Contact: youngko@postech.ac.kr

During pandemics, effective queue management reduces infection risk. This paper explores queueing topologies and flow control policies, introducing average overlapping time and number of overlapped customers as infection risk metrics. We examine serial and parallel topologies, designing practical flow control schemes for serial systems. The grocery store model reveals a risk-efficiency tradeoff and bounded waiting time. Parallel topology with even splitting results in fewer overlaps but not shorter overlapping time. Join-the-shortest-queue achieves smaller overlapping time and number with slight efficiency loss. We discuss risk preferences, mixed topologies, and service distributions.

3 The System-Specific Basic Reproduction Rate in Queueing Networks

Kang Kang[1], Sherwin Doroudi[2], Mohammad Delasay[3], [1]Evidera, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, [3]Stony Brook University, Stony Brook, NY

The system-specific basic reproduction rate is a recently introduced queueing-theoretic metric that measures the risk of disease transmission in small-scale service facilities that can be modeled as queueing systems. The specific computation of this metric is based on capturing the stochasticity in each customer pair's sojourn time overlap. This work considers the derivation of this metric in queueing networks with adequate service capacity. We present a high-level overview of the dynamics of queueing network models and describe our transmission model, which governs disease transmission between customers within these queueing networks. We provide illustrative examples and analytical details.

OR Applications in Elections

Community Committee Choice Session

Session Chair: Charles Thraves, University of Chile, Santiago, Chile

1 On the Detection of Outlier Ballot Boxes Using Ecological Inference

Charles Thraves, University of Chile, Santiago, Chile

We present a novel technique to estimate an RxC Ecological Inference model. The model is used to detect outlier ballot boxes in an election where we know the votes obtained by candidates and aggregate demographic information of voters. The Ecological Inference model is used to estimate the voting probabilities, and then these are used to compute the p-values of each ballot box.

2 Measurement of Constituency Size Based on Minimum Campaign Distance and Application to Evaluate the Merger of Electoral Districts

Yuichiro Miyamoto[1], Toshio Nemoto[2], [1]Sophia University, Tokyo, Japan; [2]Bunkyo University, Chigasaki, Kanagawa, Japan

The area and population of an electoral district are main indicators of its constituency size. They are not, however, indicators that can be used to limit the merger of electoral districts for Japan's upper house of councilors. This study proposes the minimum campaign distance (MCD) that is calculated via the Prize collecting Traveling Salesman Problem (PCTSP) as a new indicator for measuring constituency size and examines relevant issues based on actual measurements, with the aim of using this indicator to evaluate such mergers. With characteristics different from those of area and population, the MCD is an indicator that can be used to limit such mergers. We also present the result of the computational experiments. Test instances are generated from the Japanese national census.

3 The Polls and the Presidential Election in 2020 ...And 2024

Arnold I. Barnett, Massachusetts Institute of Technology, Cambridge, MA, Contact: abarnett@mit.edu

In 2020 as in 2016, polls about the presidential election are believed to have performed miserably. But sophisticated aggregators like FiveThirtyEight use the polls as raw materials, making adjustments for their biases and offering probabilistic forecasts. We assess how well FiveThirtyEight fared in 2020. Spoiler alert: the results are surprising.

4 Assessing and Mitigating Security Risks Associated with Voting by Mail

Carmen Haseltine, Laura Albert, University of Wisconsin-Madison, Madison, WI, Contact: haseltine@wisc.edu

In recent years there has been additional scrutiny on the security and reliability risks associated with election processes, particularly absentee voting. However, no analytical tools presently exist to help election officials assess and mitigate risks while balancing key performance metrics. To address this knowledge gap, we develop a discrete time Markov chain model of the vote-by-mail (VBM) process capturing VBM performance, threats, and mitigations. The modeling approach leverages attack graphs that characterize malicious and non-malicious threats. Additionally, the model links attack graphs to security mitigations and impact to VBM processes. The model is constructed using a real-world case study data from Wisconsin.

1 Too Many Meetings? Scheduling Rules for Team Coordination

Guillaume Roels[1], Charles J. Corbett[2], [1]INSEAD, Fontainebleau, France; [2]University of California-Los Angeles, Los Angeles, CA

Workers in knowledge-intensive industries often complain of having too many meetings, but organizations still give little thought to deciding when or how often to meet. Using a stylized game-theoretic model, we investigate the efficiency and robustness of various coordination scheduling rules.

We show that small teams allow a more fluid, i.e., worker-driven, approach to scheduling coordination, while larger teams benefit from the addition of time-based controls to reserve some minimal amount of productive time or to enforce coordination after some point. Also, a fixed-interval meeting schedule works well for very large teams. Our research helps formalize the tension between meeting (coordinating) and producing, and indicates how to adapt team coordination scheduling rules to the degree of worker heterogeneity and team size.

User-generated Content and Online Review

Community Committee Choice Session

Session Chair: Keumseok Kang, KAIST, Miami, FL

Session Chair: JaeHong Park, Kyunghee University, Seoul, Korea, Republic of

1 Does Rich Information Matter in Online Review Videos?

Bongjin Sohn[1], Heejin Joo[2], Gunwoong Lee[1], [1]Korea University, Seoul, Korea, Republic of; [2]Georgia State University, Atlanta, GA, Contact: bjsohn@korea.ac.kr

This study investigates the reasons behind online users' inclination towards simpler information when assessing complex products through online review videos. By incorporating concepts from information overload and media richness theory, we suggest that users encounter information overload due to the complexity in both the review video and the product itself, which consequently drives them to favor less informative content. From the analysis of 2,050 YouTube review videos focusing on wrist-watch products, the study finds that increased level of information in the review videos has a negative effect on user evaluation, particularly when it comes to technically complex products. These findings offer valuable insights for video creators and platform providers in effectively managing review videos.

2 Examining the Dynamic Growth Pattern of Self-Help Apps: Empirical Study with Dynamic Factor Models

Haeyoon Shin[1], Ho Jung Yoon[2], JaeHong Park[1], [1]Kyung Hee University, Seoul, Korea, Republic of; [2]Sejong University, Seoul, Korea, Republic of. Contact: hy32604@khu.ac.kr

The number of self-help apps has sharply increased in mobile markets. Despite the increasing popularity of self-help apps, previous studies overlooked identifying the factors behind the growth. Especially the growth of mobile apps is a dynamic and multifaceted process, with multiple factors interacting with each other. For example, the number of users, active users, user-generated content, and profits are mutually dependent on each other's growth. So, we aim to unveil the dynamic growth pattern of self-help apps. We empirically predict the profit of the self-help app with Dynamic Factor Models. We use deep learning methods to compare the performance. Our study is the first to explore and predict the growth of self-help apps with various factors' interdependence. This study will help to understand self-help apps' growth, enabling them to make more effective decisions.

3 The Heterogeneous Effect of Media User Generated Contents in the Business Models of Mobile Games: Evidence from Youtube

Seungwook Jin, Keumseok Kang, KAIST College of Business, Seoul, Korea, Republic of. Contact: tdns03@kaist.ac.kr

This research examines the impact of user-generated content (UGC) sentiments on the sales of mobile games, using comments on YouTube as a measure. The study finds that positive UGC sentiments about paid-to-play (P2P) mobile games have a promotional effect on revenue, while UGC sentiments related to free-to-play (F2P) games decrease revenue. Positive UGC sentiments affect downloads and short-term retention, while negative sentiments affect playing time and long-term retention of F2P games.

Federated Data Analytics Beyond Deep Networks: Showcasing the Power of Collaboration

Community Committee Choice Session

Session Chair: Raed Al Kontar, University of Michigan, Ann Arbor, MI

1 Heterogeneous Matrix Factorization

Naichen Shi, Raed Al Kontar, Salar Fattahi, University of Michigan, Ann Arbor, MI

In myriad statistical applications, data are collected from related but heterogeneous sources. These sources share some commonalities while containing idiosyncratic characteristics. More specifically, consider the setting where observation matrices from N sources are generated from a few common and source-specific factors. We show that under appropriate conditions on the alignment of source-specific factors, the problem is well-defined and both shared and source-specific factors are identifiable. To solve this problem, we propose a new class of matrix factorization algorithms, called Heterogeneous Matrix Factorization. HMF is easy to implement, and is intrinsically distributed. Through a variety of empirical studies, we showcase the advantageous properties of HMF and its potential application in feature extraction and change detection.

2 Collaborative Sequential Design via Consensus: Showcasing the Power of Collaboration for Optimal Design

Xubo Yue[1], Raed Al Kontar[2], Albert Solomon Berahas[2], [1]University of Michigan, Ann Arbor, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: maxyxb@umich.edu

Optimal design is a challenging task within many engineering applications. This challenge arises from the need for extensive trial and error efforts, often done through simulations or running field experiments. This paper proposes a new collaborative sequential design framework built upon the consensus mechanism. Clients collaboratively determine their next experimental points through a consensus optimization framework. In the early stages, clients rely more on each other to borrow strength and information to maneuver through the stages with scant data. In the late stages, each client will focus more on individual optimization problems to find a desirable solution. Experiments show that our proposed collaborative framework can accelerate the sequential design process efficiently and effectively.

3 Collaborative Bayesian Optimization via Leader-Conditioned Surrogates

Qiyuan Chen[1], Raed Al Kontar[2], Liangkui Jiang[3], Hantang Qin[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]University of Wisconsin-Madison, Madison, WI

The increased computational power of edge devices has opened a new paradigm of collaborative analytics. This work focuses on collaborative Bayesian optimization (BO) where agents collaborate to efficiently optimize black-box functions without necessitating sensitive data exchange. We introduced a class of leader-conditioned surrogates where agents harness Bayesian optimal designs from strongly performing collaborators to improve and fast-track their optimization process. Our approach presents the first general-purpose collaborative BO framework compatible with any Gaussian process kernel and the most known acquisition functions. Despite our approach's simplicity, we show that it enjoys elegant theoretical guarantees and significantly outperforms state-of-the-art methods, especially when agents feature heterogeneity in their black-box functions.

4 Adversarial Client Detection in Internet of Federated Things with Non-Parametric Subspace Monitoring

Xianjian Xie, Arizona State University, Tempe, AZ, Contact: xxie43@asu.edu

The Internet of Federated Things (IoFT) represents a network of interconnected systems with federated learning as the backbone, facilitating collaborative knowledge acquisition while ensuring data privacy for individual systems. The wide adoption of IoFT, however, is hindered by security concerns, particularly the susceptibility of federated learning networks to adversarial attacks. In this paper, we propose an effective non-parametric approach FedRR, which leverages the low-rank features of the gradient space generated by federated learning to address the adversarial attack problem. Besides, our proposed method is capable of accurately detecting adversarial clients with precise average run length under no attack scenarios.

1 Navigating Responsible University Expansion: The Art of Data-Driven Course Scheduling

Özge Aygül[1], **Shima Azizi[2], Andrew C. Trapp[1], [1]Worcester Polytechnic Institute, Worcester, MA, [2]St. John's University, Queens, NY**

Our study focuses on the multi-objective timetabling problem faced by universities in assigning courses to locations and meeting patterns while planning for long-term resource allocation. We aim to answer the question of how to efficiently use teaching space under yearly enrollment fluctuations due to expansion and contraction. The presence of overlapping instructor preferences and need to maintain responsible classroom densities leads to conflicts that we refer to as *overflow sections*. We propose to dynamically address overflow sections by relaxing capacity and splitting larger sections. To address, we introduce a hierarchical mixed-integer nonlinear program and simulate a variety of scenarios while considering faculty preference and utilization of locations. Our findings can assist universities make informed decisions for responsible long term planning.

2 D-optimal Data Fusion: Exact And Approximation Algorithms

Yongchun Li, Weijun Xie, Georgia Institute of Technology, Atlanta, GA

We study the D-optimal Data Fusion (DDF) problem that aims to select a small number of new data points in the presence of heterogeneous data, to maximize the overall information collected. We show that the DDF problem is NP-hard and has no constant-factor polynomial time approximation algorithm. Therefore, to solve the DDF problem effectively, we design an exact algorithm, aimed at solving the DDF problem to optimality. We further derive a family of submodular valid inequalities and optimality cuts, which can significantly enhance the algorithm performance. We also develop scalable randomized-sampling and local-search algorithms with provable performance guarantees. Finally, we test our algorithms using real-world data on the new phasor-measurement-units placement problem for modern power grids, considering the existing conventional sensors.

3 Improving Clinical Trial Efficiency with a Probabilistic Enrollment Estimation Model"

Dongjin Lee, Rebecca Vislay-Wade, Moderna, Cambridge, MA, Contact: dooungjin@gmail.com

Enrollment estimation is vital for successful clinical trials, as inaccurate estimates can cause delays, insufficient supplies, and resource misallocation. Moderna has developed a state-of-the-art probabilistic model based on the Poisson-gamma model to address these issues. This model accounts for critical variables, providing precise enrollment estimates while considering patient recruitment uncertainty. The approach enables efficient planning and decision-making, with the model updating estimates using Bayesian techniques as new data becomes available. The model's output can be applied to various activities, such as clinical supplies, finance, and manufacturing, optimizing production and reducing waste.

4 Predicting Municipal Solid Waste on the City Scale

Joshua Grassel, Kazi Wahadul Hassan, Adolfo Raphael Escobedo, Arizona State University, Tempe, AZ, Contact: jgrassel@asu.edu

Interest in studying how human systems interact with the environment is growing rapidly. We seek to understand these interactions with the intention of adjusting these systems to decrease our negative impact on both the natural environment and social well being. One such system is solid waste management. This research focuses on municipal solid waste (MSW), and how to predict waste quantity and material characterization in the US. There is still little public visibility on quantities and material breakdown. Existing studies are often either very narrow in scope, e.g. pertaining to a single city for a single year, or summarized so broadly that the data is impracticable. In this research, we gathered data and developed a predictive model to predict MSW quantity by material type down to the city scale.

5 Multi-commodity Hub Location-allocation Model With Synchronous And Asynchronous Flows

Kazi Wahadul Hasan[1], Adolfo Raphael Escobedo[2], Pitu Mirchandani[1], [1]Arizona State University, Tempe, AZ, [2]North Carolina State University, Raleigh, NC

In this research, two separate mixed integer programming (MIP) models have been proposed for multi-commodity network flow problem while incorporating the decision of hubs locations with finite capacity. The application of this model includes the flow of recyclable materials from the garbage bins to the end markets. The first formulation deals with asynchronous flow which means that materials are transported from multiple sources to the hubs following different schedules. This situation is explained by asynchronous waste streams. The second model accounts for the simultaneous material flow to the hub following synchronized schedules. This scenario is illustrated with separation of waste streams at the sources. The models are tested with small- and large-scale dataset and the computational performance of the MIP solvers are recorded.

Statistical Learning Methods for Causal Inference and Data-Driven Decision Making

Community Committee Choice Session

Transferred Q-Learning

Elynn Chen, New York University, New York, NY

We consider both batch and online Q-learning with knowledge transfer, using samples from a target reinforcement learning (RL) task as well as source samples from different but related RL tasks. The proposed transferred Q-learning algorithm contains a novel re-targeting step that enables vertical information-cascading along multiple steps in an RL task, besides the usual horizontal information-gathering as transfer learning (TL) for supervised learning. We establish the first theoretical justifications of TL in RL tasks by showing a faster rate of convergence of the Q-function estimation in the offline RL transfer, and a lower regret bound in the offline-to-online RL transfer under certain similarity assumptions. Empirical evidences from both synthetic and real datasets are presented to backup the proposed algorithm and our theoretical results.

On Heterogeneous Treatment Effects in Heterogeneous Causal Graphs

Hengrui Cai, Department of Statistics, University of California Irvine, Irvine, CA

Heterogeneity andcomorbidity are two interwoven challenges associated with various healthcareproblems that greatly hampered research on developing effective treatment andunderstanding of the underlying neurobiological mechanism. Very few studieshave been conducted to investigate heterogeneous causal effects (HCEs) ingraphical contexts due to the lack of statistical methods. To characterize thisheterogeneity, we first conceptualize heterogeneous causal graphs (HCGs) bygeneralizing the causal graphical model with confounder-based interactions andmultiple mediators. Such confounders with an interaction with the treatment areknown as moderators. This allows us to flexibly produce HCGs given differentmoderators and explicitly characterize HCEs from the treatment or potentialmediators on the outcome. We establish the theoretical forms of HCEs and derivetheir properties at the individual level in both linear and nonlinear models.An interactive structural learning is developed to estimate the complex HCGsand HCEs with confidence intervals provided. Our method is empiricallyjustified by extensive simulations and its practical usefulness is illustratedby exploring causality among psychiatric disorders for trauma survivors.

1 Efficient Speed-Oriented Sparse PCA for Dimension Reduction

Yifan Xie[1], Tianhui Wang[1], Junyoung Kim[2], Kyungsik Lee[2], Myong Kee Jeong[1], [1]Rutgers University, Piscataway, NJ, [2]Seoul National University, Seoul, Korea, Republic of. Contact: yifan.xie@rutgers.edu

Sparse Principal Component Analysis (SPCA) is an interpretable alternative to ordinary PCA for high-dimensional data. It enhances sparsity in components, boosting interpretability while reducing susceptibility to noise. Conventional SPCA solves a non-convex optimization problem to identify sparse components, but it can be computationally challenging, especially for high-dimensional data. This paper proposes a speed-oriented SPCA method that sequentially identifies sparse components with minimal angles to ordinary PCA counterparts. The proposed method reduces computational complexity and increases efficiency, particularly for large-scale datasets, while retaining core SPCA attributes. Computational tests demonstrate its viability as an efficient alternative for analyzing data and coping with computational difficulties in conventional SPCA.

2 Multi-Source Cross-Weight Ensemble Method for Virtual Metrology in Semiconductor Manufacturing

Tianhui Wang[1], Jaeseung Baek[2], Yifan Xie[1], Myong Kee Jeong[1], [1]Rutgers University, Piscataway, NJ, [2]Northern Michigan University, Marquette, MI, Contact: tw507@ rutgers.edu

In Industry 4.0, sensors used in monitoring production processes generate massive data for machine learning to enhance efficiency and quality. In semiconductor manufacturing, multi-source data poses challenges for building virtual metrology (VM) models due to varying attributes. Creating separate prediction models for each source leads to a loss of redundancy and reduced tolerance for data uncertainty. We propose a novel boosting method for the prediction of critical dimensions in VM. It integrates data fusion, adapts to multi-source data, and considers the impact of multi-source data during sampling distribution updates. Numerical results demonstrate its superiority over benchmarks, with lower mean squared error and robust performance despite the noise in real-life semiconductor VM data.

3 Data-Driven Newsvendor Literature Review: A Topic Modeling Approach

Adeela Gulzari, University of North Texas, Denton, TX

Retailers who sell perishable items face a challenge in deciding how much to order to balance holding and penalty costs. The classical newsvendor model addresses this issue by assuming that the demand distribution is known. However, data-driven newsvendor methods do not require knowledge of the demand distribution and instead use datasets to find solutions. While extensive research has been conducted on the classical newsvendor model, studies on data-driven newsvendor models are limited. In this review paper, we apply text mining techniques to analyze 185 articles published between 1958 and 2023. The analysis includes summarizing the articles, identifying key topics and terms in the field, and tracking changes in research areas over time.

4 From Local to Global Learning for Data-driven Dynamic Inventory Control: A Practical Application of Prescriptive Analytics

Felix G. Schmidt, University of Würzburg, Würzburg, Germany. Contact: felix.schmidt@uni-wuerzburg.de

Building on weighted sample average approximation, we develop a practical prescriptive analytics approach for the real-world dynamic inventory control problem of a large network of pharmacies with many heterogeneous products. Using contextual feature information, we propose a "global learning" model that is trained simultaneously across all products to specify conditional sample weights. The results of our numerical experiments suggest a significant improvement over models that are trained separately for each product.

1 Organization of Platform Markets: Coordination, Decision Rights and Information

Nabita Sree Penmetsa, Krishnan S. Anand, University of Utah, Salt Lake City, UT, Contact: nabita@ business.utah.edu

Should decision making in a platform market be centralized or decentralized, i.e., controlled by the platform or by agents? To study this question, we define the coordination structure (CS) of the platform market as the combination of two elements: its decision rights structure ('who decides what') and information endowment ('who knows what'). We model a platform providing services through independent, competing agents, and parameterize the degree of competition among agents. Demand uncertainty can be partly alleviated through information. We model different facets of information endowment, including local and aggregate intelligence, the ability to acquire and share intelligence, and non-transferable specific knowledge of both the platform and agents.

2 Sharing Versus Rental of 'Need-To-Use' Goods

Stefan Napirata[1], Alexander Kupfer[2], Steffen Zimmermann[1], Barrie R. Nault[3], [1]Ulm University, Ulm, Germany; [2]University of Innsbruck, Innsbruck, Austria; [3]University of Calgary, Calgary, AB, Canada. Contact: stefan.napirata@uni-ulm.de

Many firms need specific goods to fulfill their projects. Besides selling such`need-to-use' goods -- those with inelastic demand, some producers also offer a rental option to business customers. Alternatively, customers can borrow these goods via emerging B2B sharing platforms from peer-to-peer lenders that have purchased the good. This leads to producer-platform competition in providing temporary access to `need-to-use' goods. Analyzing producer and platform pricing as well as customers' decisions, we find that only a two-part tariff allows the platform to coexist with the producer. Customers with high need to use purchase and lend, with medium need to use borrow via the platform, and with low need to use rent from the producer. Counterintuitively, we further find that producer-platform competition leads to lower welfare compared to a B2B sharing platform alone.

3 Price Generative AI or Keep It Free

Di Yuan[1], Manmohan Aseri[2], Vibhanshu Abhishek[3], [1]Gies College of Business UIUC, Champaign, IL, [2]Katz Graduate School of Business at University of Pittsburgh, Pittsburgh, PA, [3]UCI Paul Merage School of Business, Irvine, CA, Contact: di.yuan@pitt.edu

The remarkable advancements in generative AI have raised questions about the implications of such technology. As the name suggests, generative AI (GenAI) generates content. Therefore, an important question is how it will affect user-generated content (UGC) platforms. A UGC platform can adopt GenAI to help its content creators, e.g., by providing a ChatGPT plug-in. While GenAI is expected to improve content creation productivity, it could impact content creators differently. We use a game-theoretic model to analyze strategic interactions between content creators. We show that providing GenAI may lead to an exodus of high-quality content creators and a lower profit for the platform. In addition, we find that charging a price for using GenAI not only leads to an additional source of revenue for the platform but also prevents the exodus of high-quality content creators.

4 Information Technology and Accruals

Rahat Jafri, Vaarun Vijairaghavan, University of Calgary, Calgary, AB, Canada. Contact: rahat.jafri@ucalgary.ca

This study investigates the impact of IT on accruals. Accounting earnings are essential for forecasting future cash flows, but accruals can impede the accuracy of such predictions. Accruals are subjective and influenced by accountants' judgment, which the availability and processing of information can shape. We hypothesize that IT can reduce accrual size by improving operational efficiency and increase accrual accuracy by producing more precise accounting estimates. Our preliminary findings support this hypothesis, revealing a negative impact of IT investment on accrual size. Overall, our study provides valuable insights into the potential of IT to improve accounting information for investment decisions.

5 Capacity Planning for Services: The Role of Customer Mental Accounts

Rajiv Mukherjee[1], Sreekumar R. Bhaskaran[2], Sanjiv Erat[3], [1]Texas A&M University, College Station, TX, [2]Southern Methodist University, Dallas, TX, [3]University of California-San Diego, La Jolla, CA

In many industries, consumers who purchase services pay a fixed upfrontfee for access, and then consume the service over a period of time. In this article, we examine the implications of such temporal separation of purchase and consumption on a user's consumption choices, and on the firm's optimal strategy.

Applications of Data Analytics in Emerging IS Issues

Community Committee Choice Session

Session Chair: Jin Sik Kim, The University of Tennessee at Chattanooga, Chattanooga, TN

1 Telehealth and the Management of Chronic Health Conditions in Vulnerable Populations: A Study of Latino Patients with Diabetes in Southern California

Cristina M. De Haro[1], John Billimek[2], Vijay C. Gurbaxani[3], [1]University of California - Irvine, Irvine, CA, [2]University of California - Irvine, Irvine, CA, [3]University of California-Irvine, Irvine, CA, Contact: cdeharoa@uci.edu

We present a retrospective cohort study of patient engagement in telehealth in a large, integrated health system in Southern California. We look at provider visits - before and during COVID-19 -to understand if transitioning to telehealth removes barriers to access to healthcare.

We also evaluate the effect of telehealth on the management of chronic health conditions, such as diabetes, among vulnerable populations, especially Latino patients.

2 Effect of Rival's Status and Performance Signals on User Engagement: Randomized Field Experiment in Mobile Gaming

Tandon Ayushi[1], Swanand Deodhar[2], Abhas Tandon[3], Abhinav Tripathi[3], [1]Mahindra University, Hyderabad, India; [2]Indian Institute of Management, Ahmedabad, India; [3]Word Fighter-2, Bangalore, India. Contact: swanandd@imma.ac.in

There is an ambiguity surrounding status and performance effects on online engagement. Status maybe rooted in past performance, making them interchangeable proxies of latent expertise. In contrast, the status may be decoupled from performance wherein the former drives behavioral outcomes independently. Thus, behavioral effects of status and performance signals remain unclear. We address these questions using a randomized field experiment on a two-player multi-round mobile game. We expose players randomly to rival's status and performance signals and measure the player's engagement. We find that the focal player is more likely to quit the game if the rival exhibits higher in-game performance. However, this effect is contingent on the rival's status and past performance. Further, we find these contingent effects to be predicated on the player's motivation.

3 Overcoming the Novelty Discount: The Roles of Open-Source Development in the Initial Coin Offerings (Icos)

Ziyi Xiong[1], Rong Liu[2], Yan Chen[3], Chihoon Lee[2], [1]The University of Tennessee at Chattanooga, Chattanooga, TN, [2]Stevens Institute of Technology, Hoboken, NJ, [3]University of Missouri-Kansas City, Kansas City, MO

Extensive literature has indicated that investors are biased against novelty in the evaluations of new ventures. However, few studies have focused on identifying avenues to help entrepreneurs and innovators overcome this bias. In addition to confirming the existence of a bias against novelty in initial coin offerings, our research draws on signaling theory to suggest such bias can be mitigated by reducing the technological uncertainty. From an analysis of 1845 new ventures raising funds through initial coin offerings, we find that publishing open-source codes—and especially signaling the activeness, richness and popularity of the development process through the open-source repositories—can alleviate information asymmetry and technical uncertainty, helping dissolve or even reverse the bias against novelty.

4 Exploring the Future of Telemedicine Incorporated with the Generative Artificial Intelligence

Soo Il Shin[1], J.B. (Joo Baek) Kim[2], Olu Mbanugo[1], [1]Kennesaw State University, Kennesaw, GA, [2]University of Tampa, Tampa, FL, Contact: sshin12@kennesaw.edu

Telemedicine (a.k.a. telehealth, e-health, etc.) refers to using telecommunication technologies to provide medical information and services. With the emergence of generative artificial intelligence (AI) and the application of large language models (LLM), telehealth services greet a new era and change its paradigm. Our goal is to 1) explore how people make sense of telemedicine service in applying the generative AI features which possibly replace certain healthcare provider roles and 2) delve into the functionalities of the generative AI impacting the better quality of the telemedicine service. Our research employs one of the well-known generative AI applications (e.g., ChatGPT) to answer research questions. Discussions will follow.

Community Committee Choice Session

Session Chair: Lianlian Jiang, TX

1 Can Social Connectedness Inhibit Online Trade? the Effects of Digital Distance on Peer-To-Peer Lending

Amin Sabzehzar[1], Yingxin Zhou[2], Jingbo Hou[3], [1]Tulane University, New Orleans, LA, [2]Georgia State University, Atlanta, GA, [3]Arizona State University, Tempe, AZ

The extant literature has shown offline preferences manifest in online peer-to-peer lending platforms, inhibiting online transactions in those markets. The findings of this research suggest that digital distance, as measured by the rate of Facebook friendship between two countries, can also influence lending actions in bi-country lending. Building on a dataset from Kiva.org, we show that digital distance significantly and negatively affects bi-country lending actions, on top of other distance-related barriers discussed in the literature. The results also shed light on the role of government policy regarding local IT accessibility, showing that the greater level of IT infrastructure, adoption, and freedom on the web can, to an extent, compensate for the negative effect of digital distance on prosocial lending.

2 Stay Reticent or Loquacious? How to Manage Updates in Medical Crowdfunding Campaigns

Chenzhang Bao[1], Wen Zhang[2], Min Kyung Lee[3], [1]Oklahoma State University, Tulsa, OK, [2]Baylor University, Waco, [3]Baylor University, Waco, TX, Contact: chbao@okstate.edu

Medical crowdfunding has become a popular option to raise medical funds. We draw on the two-factor theory to examine the critical role of fundraisers disclosing campaign details and status via updates in driving fundraising. We collect a unique dataset that captures granular details about the fundraising process and implement a combination of econometric and machine learning approaches to test our hypotheses. We observe that initial exposure to updates can greatly reduce uncertainty and foster trust, which impacts habituation and contributes to positive responses from donors. However, excessive updates may become tedious and also spur concerns and doubts, leading to negative impressions. Our study enhances the theorization of information disclosure in the crowdfunding literature and offers implications to solve the aggravated medical expenses crisis.

3 What Doesn't Kill You Makes You Stronger? Evidence from Vampire Attack on Decentralized Exchange

Xiang(Shawn) Wan[1], Xi Zhao[2], Jian Li[2], Xinyu Zang[3], Hsing K. Cheng[3], [1]Santa Clara University, Santa Clara, CA, [2]Xi'an Jiaotong University, Xi'an, China; [3]University of Florida, Gainesville, FL, Contact: xwan@scu.edu

We implement a quasi-experimental design to examine the impact of the vampire attack on the decentralized exchange (DEX) platform by leveraging the vampire attack launched by Sushiswap (the attacker) against Uniswap (the incumbent DEX). We examine both the deposit-side and exchange-side impact of the vampire attack on the operational performance of the liquidity pools on Uniswap. Surprisingly, we find no significant effect of the vampire attack on the liquidity on the deposit side. Moreover, the vampire attack significantly increases the incumbent's trading volume on the exchange side. We further find that cloning the incumbent platform alone will not effectively hurt the incumbent until combined with the tokenized rewards. We provide an in-depth analysis of the underlying reasons for these intriguing results.

4 How Do Human Investors Collaborate with AI Investment Tools in Financial Investments? Evidence from Microlending

Lianlian (Dorothy) Jiang[1], Cathy (Liu) Yang[2], Xitong Li[2], [1]University of Houston, Houston, TX, [2]HEC Paris, Jouy-en-Josas, France. Contact: ljiang@bauer.uh.edu

Using a differences-in-differences design, this paper explores how human investors collaborate with AI investment tools in financial investments after AI investment tools have been adopted by investors. We explore this using detailed data from a leading peer-to-peer microlending platform. We find that individual investors after AI investment tools have been adopted, designate the AI tools to invest in financial investments with lower risk compared to the investments made by investors themselves. We propose a mechanism for this empirical observation-more time and processing capacity freed by AI tools. We argue that investors save more time and processing capacity since some work has been delegated to AI tools. Thus, investors can allocate more time to more challenging investments with higher risk levels.

Funding, Investments, and Supply Chains

Community Committee Choice Session

Session Chair: Jussi Keppo, National University of Singapore, Singapore

Session Chair: Ruiting Zuo, National University of Ssingapore, Singapore, Singapore

1 The Wisdom of Strategically Diverse Crowds

Yanwei Jia[1,2], Jussi Keppo[3], Ville Satopaa[4], [1]Columbia University, New York, NY, [2]Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]National University of Singapore, Singapore, Singapore; [4]INSEAD, Paris, France

We investigate the impact of strategic diversity on predictions made by a group of interacting agents. We define strategic diversity as the heterogeneity of agents' strategic tendencies, such as conformity and contrarianism. We find that strategic diversity can have a negative impact on crowd predictions, as agents' strategic tendencies become more pronounced as the overall level of conformity in the crowd increases. However, we also find that a mild contrarian crowd can induce the best performance for both the typical individual and the group consensus prediction. We propose a new aggregation scheme that assigns greater weight to contrarian viewpoints that contain more independent private information. We show that this aggregator can improve the accuracy of crowd predictions under mild conditions and with a large crowd.

2 Equal Employment Opportunity in Supply Chains

Jing Wu, Chinese University of Hong Kong, Hong Kong, Hong Kong

This paper examines whether principal customer firms infuse EEO policy in their dependent suppliers using a novel workplace EEO measure based on the textual analysis of online job postings. We demonstrate that the suppliers adjust workplace EEO practices to cater to their principal customers. Furthermore, the supplier's adverse workplace EEO incidents will increase the likelihood of supply chain relationship termination, especially when the customer's workplace EEO level is high. At last, we find that higher customer workplace EEO levels boost suppliers' innovation performance, measured by patent quantity and quality, suggesting economic benefits associated with the diffusion of workplace EEO practices along supply chains.

3 A Continuous Time Framework for Sequential Goal Based Investing

Agostino Capponi[1], Yuchong Zhang[2], [1]Columbia University, New York, NY, [2]University of Toronto, Toronto, NY, Canada. Contact: ac3827@columbia.edu

We develop a continuous time framework for sequential goals-based investing, where the objective is to maximize expected weighted utility from goal fundedness. We show that the complexity of the procedure to recover the optimal control can be significantly reduced by rewriting the HJB equation in terms of standard deviation and mean of minimum-variance portfolio returns. We find that it is optimal to fund an expiring goal up to the level where the marginal benefit of additional fundedness is exceeded by the marginal opportunity cost of subtracting wealth from future goals. An investor with all-or-nothing utility is more risk averse towards an approaching goal if she is well funded, but also takes excessive risk if she is not on track with upcoming goals, compared to an investor with flexible goals.

4 Economics of Multi-Tier Supply Chain Financing: Operational Flexibility

Volodymyr O. Babich, Georgetown University, Washington, DC

We compare immediate- and remote-tier supply chain financing by solving for equilibrium among multiple firms and investors, in the model with endogenous credit risk. Interestingly, remote-tier financing is often an inferior choice even if the supply chain firms that provide financing are identical in all financial characteristics. Thus, understanding the supply chain position of firms is essential. We identify several economic forces that affect the decision to use multi-tier financing: credit risk spillover, accumulation of forecast noise, and loss of operational flexibility. We provide conditions for remote-tier financing to be preferred and compare the preferences of individual firms and the supply chain. New technologies, like Blockchain, have removed some of the barriers to multi-tier financing adoption. We show that several crucial barriers remain.

5 Dynamic Pricing for Equity Crowdfunding

Bretislav Hajek[1], Jussi Keppo[2], Steven Kou[3], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]Boston University, Boston, MA, Contact: bretislav.h@u.nus.edu

Crowdfunding is often used to test demand and raise initial project funds. Equity crowdfunding (i.e., selling company shares) can be facilitated using blockchain and smart contracts. These approaches allow entrepreneurs to optimize a price and a marketing effort in real-time based on incoming demand. Furthermore, the crowdfunding platform charges fees for equity issuances, which creates a principal-agent problem between the entrepreneurs and the platform. We analyze the optimal dynamic strategies of the participants, showing that dynamic equity pricing improves the crowdfunding campaign results relative to the corresponding static pricing.

Applications in Market Design II

Community Committee Choice Session

Session Chair: Yan Chen, Duke University, Durham, NC

1 Prize or Price: A Mechanism for Encouraging Innovation

David Ridley[1], Sandro Brusco[2], Giuseppe Lopomo[3], [1]Duke University, Durham, NC, [2]Stony Brook University, Stony Brook, NY, [3]Duke University, Durham, NC

Under the priority review voucher program, the US Food and Drug Administration (FDA) rewards good deeds with speed for a different drug. Upon FDA approval of a new drug for a neglected disease like Ebola, the developer receives a voucher it can use to speed a drug for a commercial disease like diabetes. Companies have sold vouchers for more than $300 million each, but prices have fallen to $100 million due to increased voucher supply. There are at least two problems with the voucher program: fallen prices for vouchers and high prices for neglected-disease drugs. To increase voucher prices and reduce drug prices, we propose a mechanism in which the FDA only grants vouchers to drugs with high quantities sold. More broadly, we show how to include regulatory speed in mechanism design.

2 Stability, Fairness and the Pursuit of Happiness in Recommender Systems

Gerdus Benade, Nachiketa Sahoo, Boston University, Boston, MA

Top-k personalized recommendations are ubiquitous, but are they stable? Given complete information, do buyers and sellers prefer to participate in matches formed by top-k recommendations rather than pursuing offline matches? When exposures are unconstrained, top-k recommendations are stable. When exposures are constrained e.g., due to limited inventory, stable recommendations need not exist. Maximizing buyer welfare under unit exposure constraints is stable, PO and swap-envy free for orthogonal buyers, identical buyers, and buyers with dichotomous values. Most of these properties are retained for arbitrary exposure constraints. Variants of common recommendation strategies lead to substantial instability and envy in three real-world datasets. Among them, maximizing buyer welfare yields the most stable outcomes and near-zero swap-envy.

3 Income Pools for Superstar Markets

Timothy Chan, Ningyuan Chen, Craig Fernandes, University of Toronto, Toronto, ON, Canada. Contact: craig.fernandes@mail.utoronto.ca

"Superstar" markets have been identified in industries like entrepreneurship, sports, music, and entertainment, where a small group of individuals earn significantly more than their peers. In response, we propose an income pool where individuals agree to share a portion of their future earnings if any one of them reaches a specific salary milestone. We are the first to develop a mathematical model to analyze income pools, focusing on stability. Our model shows that risk-averse agents prefer to join income pools, but no finite-sized stable pool exists. However, given an upper bound on pool size, we can find stable pools, including a single Pareto optimal pool. We also derive a sufficient condition for the stability of epsilon-stable pools. We include a case study of real professional baseball player data that demonstrates a 30% increase in social welfare due to pooling.

4 Market Design for Influencer Advertising Platform

Yan Chen, Duke University, Durham, NC, Contact: yan.chen@duke.edu

We model an advertising platform in which advertisers contract with an intermediary (influencer) to reach targeted users. We analyze the performance of a market in which platform leverages information about the underlying influencer-follower network (i.e., each influencer's reach), under optimal and simple-to-implement pricing strategies. We also compare payoffs of market participants to payoffs in decentralized schemes in which advertisers and influencers engage directly, without full information about the underlying network.

Network Design Under Varied Settings

Contributed Session

1 The Service Network Design Problem Under Uncertain Order Arrival and Demand Using a Rolling Time Horizon

Ryan Tramp[1], Nickolas K. Freeman[2], [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, Contact: rjtramp@crimson.ua.edu

Logistic firms handle thousands of individually packaged orders of many different products daily that must be delivered promptly to customers. This issue creates a problem for logistic firms on how best to fulfill orders in a cost-efficient manner while maintaining high levels of customer satisfaction. Stochastic service network design problems (SSNDP) are one set of problems that tackle this tradeoff, with the literature focusing on uncertain demand. While this modeling approach works in most cases, it falters when the firm does not know the amount of each product ordered as well as when the customer will place the order. This research provides an alternate formulation of the SSNDP that considers uncertainty in the amount ordered and the arrival of orders using a rolling time horizon scheme and solving using associated heuristics.

Session Chair: Roger Chen, University of Hawaii at Manoa, Honolulu, HI

2 Long-Term Capacity and Topology Planning for a Large Delivery Network

Cansu Agrali[1], Onur Can Saka[1], Faheem Zafari[1], Daniel Guimarans[1], George Iosifidis[2], Amit Kumar[1], [1]Amazon, Luxembourg City, Luxembourg; [2]TU Delft, Delft, Netherlands

Amazon's delivery network consists of fulfillment centers, delivery stations, and sort centers that act as hubs where volume is sorted and consolidated. In this work, we extend the Hub Location Problem to multiple years to account for opening/closing costs and network flow stability.

The problem is formulated as a Mixed Integer Linear Programming (MILP) model. We apply a set of techniques to reduce complexity and scale up to continent-size network requirements: a) reducing the candidate hub set through clustering, b) reducing the number of decision variables by a set of feasible path constraints, and c) applying an incremental approach to solve the MILP model. Our results prove the scalability of our method based on network size and the length of the time period. We also conduct a sensitivity analysis that highlights the influence of the number of candidate hub locations.

3 Resource Planning in Logistics Parks

Pascal Wolff, Ningbo China Institute for Supply Chain Innovation, MIT Global SCALE Network, Ningbo, China

The importance of logistics parks has grown significantly in recent years as critical nodes in supply chain networks. This research paper focuses on resource planning in logistics parks, using a case study of a logistics park in Southern China. It introduces novel optimization models to efficiently plan resources, particularly workforce, and evaluate resource-sharing potentials among facilities. The paper also identifies future research directions in this domain.

4 Pedestrian Route Choice: Recursive Modeling Approaches

Xiazhi Zhang, Roger Chen, Poya Harirchi, University of Hawaii at Manoa, Honolulu, HI, Contact: rbchen@hawaii.edu

Active travel modes, such as walking, play a central role in transportation planning and analysis. Unlike vehicles, pedestrian travel does not necessarily follow defined fixed roadways and segments. Using a discrete network (even a dense one) to approximate pedestrian movement and congestion may be unsatisfactory. *This paper considers recursive route choice models and the advantages for non-motorized contexts where the underlying network is complex and dense due to a wider range of movement across infrastructures, such as open plazas.* GPS data were collected from a group of volunteers from the University of Hawaii at Manoa yielding about 500 pedestrian trip segments that supports estimating a recursive logit model of route choice.

Sustainable Cities and Urban Transportation

Contributed Session

Session Chair: Zhufeng Fan, Carnegie Mellon University, Pittsburgh, PA

1 A Continuous Approximation Approach for Charging and Rebalancing Micromobility Deviceswith Battery Constraints

Demetra Protogyrou[1], Leila Hajibabai[2], [1]North Carolina State University, Raleigh, NC, [2]North Carolina State University, Raleigh, NC

Shared micromobility devices can be found all over major cities as personal transportation means for residents and tourists. Charging and balancing these devices incur significant costs to stakeholders as devices must either be picked up by the company or must be picked and dropped off at established stations. This study formulates a model that presents the utilization of electric micromobility systems and repositioning them either to another ride or to a charging station. The battery limits are also modeled as capacity constraints. A continuous approximation technique is developed to solve the problem with low computational burden. The numerical experiments are designed to evaluate the solution quality and performance with respect to a benchmark.

2 A Multi-Phase Approach for Solving Dial-A-Ride Problems

YU-SHUAN CHEN, YU-TING HUNG, SHENG-I CHEN, NATIONAL YANG MING CHIAO TUNG UNIVERSITY, HSINCHU, Taiwan. Contact: eva101888.mg11@nycu.edu.tw

The Dial-a-Ride Problem is to determine a minimum-cost vehicle route to satisfy demand and other restrictions. To solve the problem, we propose a multi-phase approach, where the first phase develops heuristics to partition the vertices into clusters based on distances and time window constraints, while the second phase determines the optimal tour to traverse clusters using the mixed integer problem. The last phase finds the shortest path of vertices in each cluster. We use public problem instances to evaluate the performance of the proposed method. The results show that our method can obtain high-quality solutions within a short timeframe.

3 Sustainable Public Bike-Sharing System in Network Redesign

Cheng-Feng Wu[1], David M. Chiang[2], Guan-Tyng Wu[1], MENG-CHEN LIN[3], [1]National Taipei University, Taipei, Taiwan; [2]National Taiwan University, Taipei, Taiwan; [3]Hubei University of Economics, Wuhan, China. Contact: d99741006@ntu.edu.tw

Facility delocation is important for transportation and social sustainability after the bike-sharing system is implemented since the execution should be examined to support the strategy in the network. The delocation in network design is to enhance value creation in a network by reorganising facility locations for efficient allocation of resources. This study presents an optimisation model designed to determine the delocation of bike stations for the redesign of a public bike-sharing system under the evaluation of data in the real world. The results of illustrative examples in this study indicate that the efficiency of operating a public bike-sharing system is enhanced as delocation is involved in the network redesign, thereby increasing the benefits for the user, public and private sector interests, and the sustainability of the public bike-sharing system.

4 A Static Bike Repositioning Problem with Trailers

Pin Yin Chiang, Chin Sum Shui, En Chi Hsu, Yueh Ting Chen, National Yang Ming Chiao Tung University, Hsinchu City, Taiwan. Contact: jpy0813208.c@nycu.edu.tw

Bike-sharing system (BSS) has become a vital part of urban transportation that bike repositioning is necessary to maintain serviceability. When BSS expands, a higher bike station density will locate stations at locations where vehicles can hardly access. So, other modes of repositioning must be adopted. This paper proposes a two-echelon repositioning problem with trucks and man-powered bike trailers to relocate bikes among hardly accessed and normal stations. A mixed integer linear programming model is formulated to minimize total operating cost as the sum of CO_2 emission cost and travel cost. Using an illustrative example from Taiwan, the results show that (1) integrating two vehicle types for relocation can achieve minimum cost; (2) very high CO_2 emission cost can alter the routes; and (3) the total cost decreases when the vehicle capacities increase.

5 Taking a Multimodal Optimization Approach to Equitable Bike Share Station Siting

Zhufeng Fan, Carnegie Mellon University, Pittsburgh, PA

Despite recent popularity, bike share systems face challenges with sparse and inequitable service distribution, particularly in low-income areas. This study presents a method for estimating transit service supply incorporating micromobility, using bus schedules and bike station location data. A bi-objective optimization model, which balances equity and potential bike share demand, is developed to examine how stakeholder equity preferences shape bike share system design. The results reveal bike share systems can markedly enhance public transit supply, especially in areas with bike stations. A high emphasis on equity improves transit access for disadvantaged communities, while a balanced equity preference lessens transit disparities among various disadvantage levels. Numerous stations are needed for effective population coverage.

Advances in Reinforcement Learning

Contributed Session

Session Chair: Saunak Kumar Panda, University of Houston, Houston, TX

1 Safe Rl Prompting for Llms for Solving Data Management Challenges

Alexander Zadorojniy, IBM Research, Haifa, Israel. Contact: zalex@il.ibm.com

We consider the problem of usage of Large Language Models (LLMs) for data management tasks such as imputation and error detection. As task complexity increases as well as the need for accurate responses, so does the need for well-crafted prompts, which allow LLMs to learn in context. We propose to formulate the problem of prompt tuning as an RL problem. Moreover, we intend to craft prompting in a safe way avoiding dangerous decisions and finally getting Safe RL prompting for LLMs to tackle data management task challenges.

2 Efficient Reinforcement Learning in Unknown Continuous Environments

Mohamad Kazem Shirani Faradonbeh, University, Dallas, TX

One of the most popular dynamical models for continuous environments are linear time-invariant systems that evolve according to stochastic differential equations. A ubiquitous problem in these systems is learning to take actions to minimize a quadratic cost function when the dynamics matrices are unknown. We discuss novel and fast reinforcement learning policies that learn the optimal actions fast. In fact, the proposed policy efficiently balances exploration versus exploitation by carefully randomizing the parameter estimates such that the regret grows as the square-root of time and the number of parameters. Theoretical performance analysis as well as flight-control simulations will be presented to illustrate efficiency.

3 Reinforcement Learning with Non-Contrastive Learning to Enhance Sample Efficiency in Atari

Jaehoon Kim[1], Young Jae Lee[1], Mingu Kwak[2], Youngjoon Park[3], Seoung Bum Bum Kim[1], [1]Korea University, Seoul, Korea, Republic of; [2]Georgia Institute of Technology, Atlanta, GA, [3]LG AI Research, Seoul, Korea, Republic of. Contact: jhoon0418@korea.ac.kr

Deep reinforcement learning has shown impressive performance in solving sequential decision-making problems. However, it requires extensive interactions with image-based environments. To address this challenge, improving sample efficiency has become a promising solution. We propose an approach that combines reinforcement learning with non-contrastive learning, and incorporates environmental dynamics to enhance sample efficiency. Our method also provides an effective learning strategy for state representation, leveraging gated recurrent units to capture temporal information. We demonsrate the effectiveness of the proposed method through experiments on the Atari game benchmark, limiting the environment interactions to 100k steps.

4 Reinforcement Learning for Image Classification

Byeongeun Ko, Seoung Bum Kim, Korea University, Seoul, Korea, Republic of. Contact: byeongeun_ko@korea.ac.kr

We present a reinforcement learning-based approach that leverages data augmentation techniques to improve the accuracy of image classification tasks. We define the essential components of reinforcement learning and create a simulator that enables the model to learn more autonomously when additional learning is required. Our experiments with various benchmark datasets demonstrate that the reinforcement learning-based approach outperforms the conventional convolutional neural networks in terms of classification accuracy, highlighting its potential to effectively address classification problems using reinforcement learning.

5 A Statistical Online Inference Method for Regularized Q-Learning Algorithm

Saunak Kumar Panda[1], Yisha Xiang[1], Ruiqi Liu[2], [1]University of Houston, Houston, TX, [2]Texas Tech University, Lubbock, TX, Contact: spanda@uh.edu

Reinforcement learning algorithms are widely used for decision-making tasks in various domains. However, the performance of these algorithms can be impacted by high variance and instability, particularly in environments with noise or sparse rewards. In this paper we propose a framework to perform statistical online inference for a regularized Q-learning approach called G-learning. We adapt the functional central limit theorem (FCLT) for G-learning under weaker conditions, and then construct confidence intervals for parameters via random scaling. We conduct experiments to perform inference on both G-learning and its traditional counterpart Q-learning using random scaling and other benchmark methods and report their coverage rates on a grid world problem for comparison.

1 Big Data in Esports. an Introduction to Melee and Project Slippi

Matthew Martell, University of Washington

In the last 10 years, data analytics has become a key part of the Esports industry. Even casual fans of many games utilize data to improve their play. One rich and largely untapped Esports data source is project Slippi for Super Smash Brothers Melee. Every game played on the platform is recorded, with frame-by-frame data collected including game state and button presses. We develop a pipeline for analyzing large data sets of this type, such as what would be collected after a large tournament. As a proof of concept, we provide an exploratory data analysis on the effects of proposed anti-stalling rules for major tournaments, with a focus on one of the game's most contentious players, Juan Debiedma, aka Hungrybox.

2 NFL Draft Pick Drivers: How Much Do Team Needs Influence Draft Day Decisions?

Gerardo Gonzalez[1], Jesse Pietz[2], Joe Wilck[3], [1]USAF Academy, USAF Academy, CO, [2]US Air Force (Ret), Colorado Springs, CO, [3]Bucknell University, Lewisburg, PA

National Football League (NFL) teams place tremendous importance in preparing for the league's amateur draft each spring. The teams must decide their draft strategy, evaluate their current roster, and evaluate prospective players as they prepare for this multi-day event every spring. Our talk begins with a multifactor analysis for NFL draft pick evaluation. We then use our analysis to assess the marginal value of a drafted player by position and pick. We conclude by comparing our analysis with observed draft picks to understand the motivation behind draft day decisions in the NFL.

3 Employing Machine Learning and Data Science to Compare Women's and Men's Soccer Competitions

Mohammad Abdullah, John McCarty, Maha Yazbeck, Ramero Rodriguez Buno, Abedallah Al Kader, Sura Alhanouti, Amirreza Talebi, The Ohio State University, Columbus, OH

Machine learning approaches were utilized to characterize some of the optimal strategies in soccer domain to improve the performance of players and coaches decision-making. Features contributing to the success of a shot are investigated. Furthermore, statistical competitions were conducted between male and female players with 14 variables considered. Clustering algorithm was also applied to analyze shot locations and goal-scoring probabilities.

4 Medical Locations and Staffing for a Mass Endurance Event

Abigail J. Crocker, Donghao Liu, Katrina F. Maynor, University of Texas at Austin, Austin, TX, Contact: ajcrocker14@utexas.edu

Mass endurance events pose an inherent risk of injury to their participants and medical team response times directly impact participant outcomes. Therefore, locations of medical stations and space-time distribution of medical personnel require critical consideration. We employ a mixed integer linear program to a half marathon case study, extending the capacitated facility location problem to additionally incorporate movement of medics between fixed medical locations. In an application area dominated by various general guidelines and historical observations for particular race courses, we take an optimization approach which can be applied to various topologies and even new races which lack the benefits of institutional knowledge.

Advances in Optimization

Contributed Session

Session Chair: Alexander Shkolnik, University of California, Santa Barbara, Santa Barbara, CA

1 Buying from a Competitor: A Model of Knowledge Sharing and Innovation

Dominique Lauga[1], Matthew Selove[2], Mohammad Zia[2], [1]University of Cambridge, Cambridge, United Kingdom; [2]Chapman University, Orange, CA

Many firms buy a production input from a competitor. We develop a game theory model in which a firm can buy an input from a competitor or a third party in each period, and in order to innovate, the firm must invest in improving the input and must share the resulting knowledge with its chosen supplier. We find that buying from the competitor: (1) mitigates price competition in the consumer market, and (2) puts the competitor in a stronger negotiating position in the second period if the focal firm invests in innovation. In equilibrium, if the value of the innovation is sufficiently low or sufficiently high, the firm buys from its competitor. However, if the value of innovation lies in an intermediate range, and there is sufficient horizontal product differentiation, then the firm buys from the third party to ensure innovation occurs.

2 The Value of Information and Stochastic Programming: Extensions to Partial and Imperfect Information

Tomasz Slusarczyk, Austin Saragih, Massachusetts Institute of Technology, Cambridge, MA, Contact: tomaszsl@mit.edu

More than fifty years after the seminal paper of Avriel and Williams (1970) on the value of information and stochastic programming, there has been minimal development towards imperfect and partial information. In this paper, we extend this methodology to quantify the value, cost, and benefit of partial and imperfect information gathering in stochastic programming and develop a tradeoff between acquiring many moderately accurate information or few very accurate information and provide an optimal approximation algorithm to solve it. New mathematical and computation results are presented. We also implement the methodology to a capacity planning case study.

3 A Dantzig-Wolfe Decomposition Approach to Solve an Integrated Project and Personnel Scheduling Problem

Brede Sørøy, Anders Nordby Gullhav, Norwegian University of Science and Technology, Trondheim, Norway. Contact: brede.soroy@ntnu.no

We consider an integrated project and personnel scheduling problem with preemption and resource transportation with applications in the construction industry. This is a hard problem, and it takes a long time to solve it to optimality, especially when there are many projects to schedule. In many cases, the direct mixed-integer programming formulation gives a weak dual bound in the branch-and-bound search. Therefore, we propose a Dantzig-Wolfe reformulation of the

problem that includes columns of feasible project schedules. Using this approach yields a tighter formulation, and the optimality gaps are improved.

4 The Contingencies of Knowledge Complexity During the Search Process for Future Innovation

Tara Li, Drexel University, philadelphia, PA, Contact: fl343@drexel.edu

5 Large Deviations of Affine Processes

Alexander Shkolnik, University of California, Santa Barbara, Santa Barbara, CA, Contact: shkolnik@ucsb.edu

We develop an large deviations principle for the general class of affine processes that includes as special cases all Lévy processes, continuous-time branching and Hawke's processes, the Ornstein-Uhlenbeck and Bessel diffusions, Cox-Ingersol-Ross processes and their many generalizations. Our large deviation asymptotics are of the Friedlin-Wentzell type and thus contribute to the study of dynamical systems subject to random perturbations. These perturbation are driven by small-noise diffusions as well by jump noise with paths of (in)finite variations and/or (in)finite jump activity. We establish our results using the Dawson-Gartner projective limits approach as well as the method of exponential martingales. We provide an explicit representation of the large deviations rate function for the case of finite jump activity.

Robust, Bilevel, and Network Optimization

Community Committee Choice Session

Session Chair: Luca Wrabetz, University of Pittsburgh, Pittsburgh, PA

1 Adaptive Shortest-Path Interdiction of Multiple Followers

Luca Wrabetz, University of Pittsburgh, Pittsburgh, PA

We describe a variant of the shortest-path interdiction problem, where a finite number of followers (or more generally, scenarios) exist for the leader to interdict. In other words, there are a finite number of different arc-cost vectors in the network. With this discrete uncertainty set in mind, we pose a robust version of the shortest-path interdiction problem, where the leader can compute multiple interdiction policies to interdict the followers. We reformulate the resulting max-min-max-min problem as an MIP, and extend a Bender's Decomposition approach from the shortest-path interdiction literature to solve our problem. Additionally, we use an exact enumeration algorithm to optimally partition the followers, and compute an optimal policy for each resulting cluster. Finally, we develop a greedy approximation algorithm for our interdiction problem.

2 Network Enhancement via Robust Interdiction Methods

Thanakrit Piyachayawat[1], Ningji Wei[2], [1]Texas Tech University, Lubbock, TX, [2]Texas Tech University, Lubbock, TX

In the classic network interdiction games, the leader (the first decision-maker) has been traditionally introduced as an attacker, aiming to disrupt their opponent's solutions, such as paths, connected components, or spanning trees. In this work, we propose a novel reinterpretation of the leader's role as a network user, focusing on enhancing their network structures while mitigating uncertainties originating from multiple sources. To address this class of problems, we have developed new reformulation methods. We demonstrate that, under both the optimistic and pessimistic perspectives, the optimal robust solutions can be obtained using single-level mixed linear programming formulations. These findings open up avenues for studying and addressing problems with more complex conditions.

3 Designing Optimal Location-Based Discount Policies for Online Retail Distribution with Customer Preferences Uncertainty

Svetlana Riabova, Jose L. Walteros, University at Buffalo, Buffalo, NY, Contact: sriabova@buffalo.edu

As online retail continues to grow, so too will the need for efficient last-mile delivery solutions. Our approach is centred on providing customers with pick-up locations as alternatives for home delivery and offering them discounts to make that choice more attractive. We argue that distributing incentives in a clever way to consolidate deliveries could yield a significant reduction in the retailer's operational costs while still prioritizing customer satisfaction. We consider a bilevel optimization problem that captures the decision-making process of both the retailer and its customers, designed to identify an optimal discount policy. The uncertainty arises from the leader's lack of knowledge of the followers' preferences. We develop a solution framework based on robust optimization that progressively refines the uncertainty sets, as new purchases are observed.

4 Network Design for Supply Resiliency via Connected Dominating Sets

Foad Mahdavi Pajouh[1], Oleg Prokopyev[2], Somayeh Moazeni[3], [1]Stevens Institute of Technology, Hoboken, NJ, [2]University of Pittsburgh, Pittsburgh, PA, [3]Stevens Institute of Technology, Hoboken, NJ

Resilient network system design, aimed at preserving operability in the presence of component failures, is prevalent in practice. Given an undirected graph with weighted vertices, the connected-dominating-set Interdiction problem aims to find a minimum cost subset of edges to be blocked such that the weight of every connected dominating set in the blocked subgraph remains above a threshold level. This paper studies the problem of finding the least cost of constructing additional edges to increase the blocker's minimum-cost to a given value. We discuss the problem's computational complexity and establish conditions to characterize its feasible solutions and to express an IP formulation. We propose several branch-and-bound algorithms for the problem. These algorithms are assessed on randomly generated networks and a network of distribution centers.

Information, Learning and Incentive Management

Contributed Session

Session Chair: Shijth Kumar Payyadakkath Meethale, Solbridge International School of Business, Daejeon, Korea, Republic of

1 The Impact of Gamified Competitive Structures on User Engagement in the Educational Online Platforms

Agnieszka Kloc[1], Rodrigo Belo[2], Ting Li[1], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Nova SBE, Carcavelos, Portugal

We study the impact of leaderboard competition intensity on user engagement in an online learning platform context. Our randomized field experiment with students preparing for the final school exams reveals that students engage more when competition is less intense. Specifically, they are more engaged when competing against groups with more spread-out scores and when they are farther away from both their upward and downward competitors. Moreover, low-confidence students become more active when their upward competitor is farther away, while competitive students decrease activity under the same conditions. Our findings suggest that implementing a competitive feature demands attention to the created competitive conditions and the type of user participating in the competitive environment. A one-size-fits-all approach is not effective in promoting user engagement.

2 Connectedness for On-Demand Learning: A Field Experiment on Social Presence Cues

Azel Shokparova[1], Zagira Asrymbetova[1], Seung Hyun Kim[2], Yeolib Kim[1], [1]Ulsan National Institute of Science and Technology, Ulsan, Korea, Republic of; [2]Yonsei University, Seoul, Korea, Republic of. Contact: azel.shokparova@unist.ac.kr

On-demand learning platforms face a fundamental challenge of enhancing users' learning outcomes and retaining them by constantly motivating them to make progress and complete courses. To address this challenge, we propose a novel approach based on social presence theory that enhances the learner's connectedness to the instructor and platform, leading to increased engagement and progress. Specifically, we examine the efficacy of push notifications with social presence cues related to instructor and humor based on internet memes, by conducting a randomized field experiment. The results indicate that both treatments increase clickthrough and progress rates, but only instructor-initiated interventions retain a positive effect over time. This study provides valuable insights into the effective use of social presence and meme marketing in on-demand learning.

3 Adoption of Ideas from Innovation Contests - Evidence from a Korean Bank

Shijith Kumar Payyadakkath Meethale[1], InHyouk Koo[2], [1]Solbridge International School of Business, Daejeon, Korea, Republic of; [2]Woosong University, Daejeon, Korea, Republic of

Open innovation contests have democratized the innovation process in a firm. Extant research on innovation contests has analyzed characteristics of the contest participants and the design elements of a contest to understand its relationship with contest outcomes. While most of these studies have focused on the idea generation phase of the contest, we focus on the idea selection and adoption phase. This study aims to develop a theoretical framework by using data from an innovation contest at a large banking firm to gain a comprehensive understanding of the adoption process when ideas are sourced from multiple contributors. We draw from innovation diffusion theory to understand the process of idea adoption by a focal firm engaged in open innovation by relying on the evaluation parameters from the real decision process in the organization.

Machine Learning Methods in Healthcare

Contributed Session

Session Chair: Mary Ogidigben, Pennsylvania State University, State College, PA

1 Tracking Early Heart Disease Using Deep Learning for Small and Imbalanced Datasets

Elham Nasarian[1], Danial Sharifrazi[2], Sakshi Pranay Taori[1], Vivek Joshi[3], Kwokleung Tsui[1], Roohallah AlizadehSani[4], Creed Jones[3], [1]Virginia Tech, Blacksburg, VA, [2]Islamic Azad University, Shiraz, Iran, Islamic Republic of; [3]Virginia Tech, Blacksburg, VA, [4]Deakin University, Geelong, Australia. Contact: elhamn20@vt.edu

Heart Disease is a leading cause of mortality in the US, with coronary artery disease (CAD) being the most common form. In this research, we proposed a methodology that uses machine learning and deep learning methods to track stenosis in each coronary artery. Our framework applied autoencoder (AE), SMOTE, and conventional neural networks (CNN) to balance and generate data for more accurate detection in early stages. Our results demonstrated that the accuracy of this proposed method for CAD diagnosis in early stages was 95.36 and was higher than random forest (RF), decision tree (DT), support vector machine (SVM), logistic regression (LR), XGBOOST, and artificial neural networks (ANN). This methodology could be developed in variety healthcare and medicine applications to handle imbalanced and small datasets.

2 Prediction of Cardiovascular Mortality in Nash Liver Transplant Recipients Using Machine Learning

Yasin Fatemi[1], Mohsen Nikfar[1], Amir Oladazimi[1], Haley Hoy[2], Haneen Ali[1], [1]Auburn University, Auburn, AL, [2]University of Alabama Huntsville, Huntsville, AL, Contact: yzf0024@auburn.edu

Cardiovascular disease (CVD) is the leading cause of mortality among non-alcoholic steatohepatitis (NASH) patients who underwent liver transplants. Therefore, early identification of CVD patients is crucial for timely intervention and prevention of adverse outcomes. In this study, a Machine Learning (ML) model was developed to predict the risk of cardiovascular death among 10,872 NASH patients between 1987 and 2022. Logistic Regression (LR), Random Forest (RF), Decision Tree (DT), and XGboost (XGB) as estimators for RFE and SFM were all applied in the study. Additionally, prediction models were developed using Support Vector Machine (SVM), RF, and XGB. Results showed that the best prediction model was XGB with applying SFM-DT features.

3 A Study of Bias in Machine Learning Techniques in Predicting Non-Alcoholic Fatty Liver Disease (NAFLD)

Mary Ogidigben, Soundar Kumara, Pennsylvania State University, University Park, PA, Contact: meo5362@psu.edu

Non-alcoholic fatty liver disease (NAFLD), which affects 25% to 30% of the world's population, is an umbrella term that refers to a range of conditions caused by excess fat in the liver of a person who drinks little to no alcohol. In NAFLD review papers, race and ethnicity have been found to be two of the significant factors contributing to the development of NAFLD. However, in many prediction studies utilizing machine learning techniques, race and ethnicity are not included as significant factors. Therefore, we use machine learning techniques to study whether race and ethnicity are statistically significant to the predicted outcome of a patient having NAFLD.

Operations Management Applications

Contributed Session

Session Chair: Amirhossein Jafarzadeh Ghazi, Ontario Tech University, Toronto, ON, Canada

1 Managing Perishable Inventory when Strategic Customers Form a Reference on Product Availability

Hasan Arslan, Seokjin Kim, Suffolk University, Boston, MA

Consider a retailer selling a perishable product in the presence of strategic customers who use their reference on product availability to time their purchases. Each short period, the retailer determines a stocking quantity before random demand is realized and strategic customers learn from the retailer's stocking quantity to update their reference. We characterize the structural properties of single-period, two-period, and infinite-horizon problems, and conduct numerical studies on an infinite horizon to compare an optimal dynamic policy and the corresponding optimal static

policy which sets a fixed stocking quantity over time. A near-optimal performance of optimal static policy with an average profit gap of less than 1% is remarkable and contrasts with that in the two-period model which may be far worse.

2 A Research Outlook on Supply Chain Sustainability and Product Returns

M. Ali Ulku[1], Ulku Gurler[2], Eyup Emre Berk[2], [1]Dalhousie University, Halifax, NS, Canada; [2]Bilkent University, Ankara, Turkey. Contact: ulku@dal.ca

Consumers may return products for various reasons: The product received may be the wrong color or size, function poorly, damaged during shipment, or purchased impulsively and regretted. Product returns and, thereby, product return policies may profoundly impact sustainable supply chain logistics, adding extra strain on the already challenging reverse logistics operations and eating up resources from forward logistics of supply chains. Moreover, the enormous growth in omnichannel shopping makes studying product returns from consumer behavior and sustainable supply chain perspectives critical. In this short talk, we will draw on some relevant theories and optimality results, discuss practical implications, and point to future research venues for mitigating the impact of product returns on supply chain sustainability through the quadruple bottom line approach.

3 Order Acceptance and Detailed Scheduling in a Job Shop with Discrete and Batch Processing Machines

Dheeban Kumar Srinivasan Sampathi, Purushothaman Damodaran, Northern Illinois University, DeKalb, IL, Contact: dheebankumar141@gmail.com

Customization of products to increase customer satisfaction has resulted in a high mix low volume production. Many manufacturers adopt a Make-To-Order approach to minimize costs and meet customer deadlines. This study deals with processing customer orders with a set of operations on resources in a job shop environment, with linear precedence constraints, deterministic processing times, due dates, job size, and selling price. Jobs may also recirculate. The objective is to maximize profit and ensure that all accepted orders are completed on time. The job shop includes discrete processing machines and a batch processing machine that can process multiple jobs if its capacity is not exceeded. The Mixed Integer Linear Program helps to identify which orders to accept and a detailed schedule for all the accepted orders.

4 Cost Sharing and Revenue Sharing Contracts for Collaborative Quality Improvement in a Supply Chain with Product Recall

Amirhossein Jafarzadeh Ghazi, Nader Azad, Salma Karray, Ontario Tech University, Oshawa, ON, Canada

Quality-related product recalls can be arduous incidents for the entire supply chain. Considering the rising cost of quality, a manufacturer and a retailer may adopt collaborative quality improvement strategies to enhance the performance of a supply chain with a risk of a product recall. We develop a manufacturer Stackelberg game model and investigate whether cost- or revenue-sharing contracts can benefit the supply chain with recall. We also examine the impact of bargaining on designing a collaborative agreement. We find that revenue- and cost-sharing contracts can improve product quality, recall probability, and the manufacturer's and retailer's profits compared to a non-collaborative contract. Furthermore, a revenue-sharing through bargaining contract is best-off in terms of improving quality, recall probability, and the manufacturer's profit.

1 Remanufacturing Facility Installation Decisions Under Uncertain New Product Purchasing Cost and Return Products Remanufacturing Cost

Mohammad Ahnaf Sadat, K Jo Min, Iowa State University, Ames, IA, Contact: sadat@iastate.edu

In this paper, we consider a company that currently relies on external purchases to meet customer demand and has the flexibility to install a remanufacturing facility. With the key assumption that the remanufactured products can fully substitute new products' demand, we determine the value of such flexibility and identify the optimal size and timing for installing the remanufacturing facility under the uncertain external purchasing prices and return products' remanufacturing costs. To address this problem, we adopt a profit maximization criterion and employ the real options theory as our modeling framework. Specifically, we utilize a Least-Square Monte Carlo simulation approach to obtain a solution. The study aims to provide valuable insights into the strategic considerations and potential economic benefits of installing a remanufacturing facility.

2 Managing Inventories and Suppliers in Assembly Systems with Random Demand and Supply Capacity

Ramesh Bollapragada[1], Uday Rao[2], Jun Zhang[3], [1]San Francisco State University, San Francisco, CA, [2]University of Cincinnati, Cincinnati, OH, [3]Amazon, Dallas, TX, Contact: rameshb@sfsu.edu

We consider stock positioning in a pure assembly system controlled using installation base-stock policies. When component suppliers have random capacity and end-product demand is uncertain, we characterize the system's inventory dynamics. We show that components and the end product play convex complementary roles in providing customer service. We propose a decomposition approach that uses an internal service level to independently determine near-optimal stock levels for each component. Compared with the optimal, the average error of the decomposition approach is 0.66% across the tested instances. Compared with current practice, this approach has the potential to reduce the safety-stock cost by 30%. Finally, we analytically show how a multi-echelon pure assembly system may be converted into an equivalent two-echelon assembly system to which all our results apply.

3 Energy-Efficient Wheelset Maintenance Scheduling Under Uncertainty: An Approximate Dynamic Programming Approach

Zheng Tian, Tsinghua University, Beijing, China. Contact: tianz19@mails.tsinghua.edu.cn

This research originates from a real-world wheelset maintenance scheduling problem, where two types of uncertainties exist: the arrival time of the wheelset and the needed maintenance time in some operations. In the real world, the maintenance time may last for hours and the electricity consumption is relatively high. Therefore, our objective is to minimize a combination of the total tardiness and the total electricity cost under time-of-use electricity prices. We proposed an approximate dynamic programming approach for this problem, and the performance of our algorithm is validated using the maintenance data from a railway bureau in China. The results show that the proposed algorithm significantly outperforms the method currently used in practice.

4 Distributed Feedback Control Algorithm Combined With Deep Q Learning For Energy-aware Last-mile Delivery

Seokgi Lee, Youngstown State University, Youngstown, OH, Contact: slee10@ysu.edu

As large-scale online markets have exploded in recent years, they have a high split rate of orders as a result of this shift in shopping patterns. Accordingly, consolidating and delivering split orders from the same customer has been addressed as a major problem in leveraging green logistics in online retailing. In this study, the last-mile logistics situations are analyzed to address two interrelated questions: (i) what would be the optimal order and shipment consolidation policy in last-mile delivery, and (ii) what would be the resulting vehicle routing plan that improves operational and service performance. We present an integrated decision-making framework that simultaneously determines vehicle routing plans and consolidation policies. In particular, dynamic control combined with Deep Q learning is introduced and its technical benefits are presented.

Network Flows and Minimum Cuts in Ranking, Clustering, Machine Learning, Imaging and Diversity Problems

Keynote Session

1 Network Flows and Minimum Cuts in Ranking, Clustering, Machine Learning, Imaging and Diversity Problems

Dorit Simona Hochbaum, University of California-Berkeley, Berkeley, CA

A significant category of integer programming problems, called "monotone" (IPM, Integer Programming Monotone), finds its solution by employing a minimum cut algorithm

on an associated graph. Within this category, numerous well-known clustering problems fall under the umbrella of ratio IPM problems. Remarkably, it has been demonstrated that these and the respective ratio problems can all be resolved using a parametric cut procedure, which exhibits the same computational complexity as a single minimum cut procedure. Other applications of IPM include drug ranking, the identification of active neurons in calcium imaging movies, and a wide array of machine learning and classification tasks.

For several problems classified as NP-hard, the incorporation of modeling flexibility transforms them into efficiently solvable IPM problems. This modeling flexibility is exemplified in scenarios such as the threat detection problem, co-segmentation problem, and text summarization problem. In the context of text summarization, for instance, this flexibility is manifested by replacing the concept of minimum similarity with maximum dissimilarity.

A specialized subset within the realm of NP-hard problems is the "budgeted" IPM problems, which incorporate an additional budget constraint. In the case of budgeted IPM problems, it is established that the entire efficient frontier can be generated through the parametric cut procedure. Furthermore, the breakpoints within the efficient frontier are optimal and facilitate the derivation of high-quality solutions for the respective problem. These problems find applications in diverse fields, including facility dispersion, quadratic knapsack, maximum diversity, and text summarization.

The Markov Random Field (MRF) problem originally emerged in the context of machine vision. For convex deviation functions and bilinear separation, the MRF can be efficiently solved through a parametric cut algorithm with a "best possible" runtime. MRF with general convex functions is equivalent to the convex dual of the minimum cost network flow problem, which is also solved efficiently. Applications of the MRF model span various domains, encompassing image segmentation, customer segmentation, credit risk assessment for countries, student paper competitions, semiconductor yield prediction, isotonic regression, general ranking, and recently, the aggregation of voter preference rankings.

Capturing Emerging Targets and Performing Reconnaissance Over Uncertain Terrain

Tutorial Session

Session Chair: Hari Balasubramanian, University of Massachusetts, Amherst, Amherst, MA

1 Search and Rescue over Uncertain Terrain in Humanitarian and Military Contexts: Capturing Emerging Targets and Performing Reconnaissance

Rajan Batta, John Becker, Esther Jose, Nastaran Oladzad-Abbasabady, University at Buffalo, Buffalo, NY

This tutorial introduces and discusses two topics that are related to the application of search and rescue operations over uncertain terrains, which are common in both humanitarian and military situations. The first topic is focused on search path optimization for recording emerging targets (search victims). After this, the case of camouflaging targets and multiple vehicles is considered, with a focus on how these features complicate the problem and change routing strategies. The second topic is search and exploration problems on transportation networks with unknown characteristics. Prize collection problems on such networks are detailed for the single vehicle case. Examples and computational results are presented. The tutorial ends by presenting emerging topics related to emergency response and reconnaissance applications over uncertain terrains.

New Developments in Dynamic Pricing: Optimization and Learning

Community Committee Choice Session

Session Chair: Arash Asadpour, Zicklin School of Business, New York, NY

1 Adaptive Learning for Joint Pricing and Inventory Control

Sharon Wang[1], Yining Wang[2], Boxiao Chen[1], Zhengyuan Zhou[3], [1]University of Illinois Chicago, Chicago, IL, [2]University of Texas at Dallas, Richardson, TX, [3]Stern School of Business, New York University, New York, NY, Contact: bbchen@uic.edu

We consider the joint pricing and inventory control problem for multiple products over a planning horizon of T periods. Demand distribution for one product depends on the prices of all the other products. We consider the situation where neither the demand-price relationship nor the distribution of demand noise is known and develop online learning algorithms that converge at the optimal rate.

2 Extreme Value Theory and the Single Item Dynamic Pricing Problem

Josh Reed, New York University, New York, NY

We consider the single item dynamic pricing problem in an asymptotic regime where the selling horizon tends to infinity. In this regime, the firm is under less pressure to immediately sell its remaining inventory and instead may shift the focus of its pricing strategy to customers whose item valuations lie in the right tail of the item valuation distribution. The statistical theory of extreme values plays a central role in this setting and so we refer to this regime as the extreme value regime. Our main results provide the asymptotics of the optimal expected revenue, selling price and purchasing probability in the extreme value regime. We also compare the performance of the optimal pricing policy against an upper bound derived by the deterministic version of the problem and we provide easy to implement pricing policies that are shown to be asymptotically optimal.

3 Optimization of Booking Limits for Hotel Room Categories

Andrew Vakhutinsky[1], Zijie Zhou[2], [1]Oracle Labs, Burlington, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: andrew.vakhutinsky@oracle.com

We consider a problem of simultaneously optimizing booking limits for multiple hotel room categories. The problem is formulated to explore a tradeoff between generating revenue by overbooking certain categories and minimizing penalties for exceeding the hotel capacity. Although the problem is similar to the well-known airline revenue management with multiple fair classes, it has several distinctions such as various lengths of stay, which makes the problem significantly more difficult to solve. In order to account for the inaccuracies in the estimation of the reservation cancellation probabilities that used as an input to the problem, it is solved using robust optimization approach. The empirical application of this optimization model is demonstrated by computing recommendations for booking limits based on the real-life reservation data from a middle-size hotel.

4 Dynamic Pricing for Multi-Product Consumer Electronics Trade-In Program

Zhuoluo Zhang[1], Murray Lei[2], Sean Zhou[3], [1]CUHK Business

School, Hong Kong, Hong Kong; [2]Queen's University, Kingston, ON, Canada; [3]Chinese University of Hong Kong, New Territories, China. Contact: yl64@queensu.ca

We study a dynamic pricing problem where a firm sells both new and used products. The firm acquires used products through trade-in programs, where customers sell their used products either for cash or for upgrade credits. The firm further refurbishes the used products and then sells them to consumers. In view of the challenge of solving the optimal pricing policy, we develop two simple and provably effective heuristic policies based on the solution to a deterministic relaxation. In particular, one policy set prices statically before the selling horizon, whereas the second policy dynamically adjusts prices. We give performance bounds for both policies, and show that the dynamic policy significantly improves the static policy. We further generalize our findings to various settings motivated by real-world applications.

1 Selling and Renting Mechatronics (Digitally Controlled Physical Goods)

Xianfeng Meng, Guang Li, Anton Ovchinnikov, Smith School of Business, Queen's University, Kingston, ON, Canada. Contact: 16xm4@queensu.ca

Firms that sell digital goods routinely utilize free-premium-upgrade business models for product differentiation. When downloading an app, one can try a free version first, then pay to unlock permanent premium functionality or rent additional temporary functionality. Recent technological advances allow physical goods firms to do the same: they can create products with identical hardware that are digitally controlled to allow for similar differentiation. This paper presents a stylized model to explore when physical goods firms should adopt such digitally-enabled product differentiation instead of the traditional product line design with high- and low-end products.

2 Pricing and Assortment Optimization Under a Model with Bulk Returns

Jacob Feldman[1], Sahika Sahan Konur[2], [1]Olin Business School, Saint Louis, MO, [2]Texas State University, San Marcos, TX, Contact: sahika.sahankonur@txstate.edu

We develop a model for bulk product returns and study its corresponding assortment and pricing problems.

3 Assortment Optimization Under Multiple-Discrete Customer Choices

Heng Zhang[1], Hossein Piri[2], Tim Huh[3], Hongmin Li[4], [1]Arizona State University, Tempe, AZ, [2]Haskayen School of Business-University of Calgary, Calgary, AB, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]Arizona State University, Tempe, AZ, Contact: hzhan388@asu.edu

We discuss an assortment optimization problem where customers can buy multiple products and multiple units of each product. We adopt the multiple-discrete-choice (MDC) model to model consumer choice, characterize the performance of revenue-ordered assortments, and show that assortment optimization is NP-hard in general. We present an algorithmic framework that delivers near-optimal algorithms for different variations of the problem and can be extended to the mixture of MDC models. We propose approaches to fit data and incorporate uncertainty into the model for assortment purposes. The study provides theoretical foundation and practical guidance for businesses to make realistic decisions about product assortment.

4 Revenue Management with Joint Assortment and Price Optimization Under the Markov Chain Choice Model

Anton J. Kleywegt[1], Hongzhang Shao[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: steveshao@gatech.edu

We consider a seller who jointly determines the product assortment and the product prices while managing a network of resources with limited capacity. Existing approaches for joint assortment and price optimization cannot incorporate resource constraints. We show that under the Markov chain choice model (including the multinomial logit model), the joint optimization problem can be reformulated as a tractable convex conic optimization problem. We also give sufficient conditions for existence of an optimal solution with constant prices even with constrained resources, and for existence of an optimal solution with both constant assortment and constant prices.

Emerging Topics in Revenue Management

Community Committee Choice Session

Session Chair: Deniz Akturk, University of Chicago Booth School of Business, Chicago, IL

Session Chair: Süleyman Kerimov, Rice University, Houston, TX

1 Platform Competition in Two-Sided Networks

John R. Birge, Emin Ozyoruk, University of Chicago, Chicago, IL, Contact: emin.ozyoruk@chicagobooth.edu

We study the impact of competition on ride-hailing platforms. The riders are sensitive to price and delay, and the drivers value high wages and utilization. The efficiency of the platforms improves with the density, and the drivers are randomly located in relation to the riders. The platforms simultaneously choose prices, service standards, and wages. The game admits a tractable form where each platform chooses a full price, enabling us to characterize the equilibrium and establish its existence and uniqueness. The results suggest that the ride-hailing industry benefits from economies of scale -- The unit cost of attracting drivers is decreasing in demand. Multiple platforms can enter and co-exist due to the multihoming drivers and variability in the system. However, a limited number of platforms can achieve economies of density and be profitable.

2 A New Class of Revenue Management Problems with Overbooking and No-Shows: Shoring up Trust Between Shippers and Carriers in Container Shipping

Jacob Feldman[1], Panos Kouvelis[2], [1]Olin Business School, Saint Louis, MO, [2]Washington University in St. Louis, Saint Louis, MO, Contact: jbfeldman@wustl.edu

In the container shipping industry, the story of overbooking is filled with tales of chronic mistrust between shippers and carriers. Specifically, loose and unenforceable contracting practices have led to a failed market where shippers constantly renege on their agreement to produce containers as promised, and as a result, carriers overbook too frequently in an effort to hedge against this no-show behavior. In this paper, we propose and study a deposit-based booking system that draws inspiration from current practices, and we study the carrier’s sequential online booking problem.

3 The Cost of Impatience in Dynamic Matching: Scaling Laws and Operating Regimes

Angela Kohlenberg[1], Itai Gurvich[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: angela.kohlenberg@kellogg.northwestern.edu

We study matching queues with abandonment. We identify non-asymptotic and universal scaling laws for the matching loss due to abandonment - the “cost-of-impatience” - of a two-sided queue with impatient customers and servers. We identify four operating regimes that characterize all sets of model parameters; these subsume asymptotic (heavy-traffic) regimes. The scaling laws for each regime reveal the fundamental structure of the cost-of-impatience and show that its order-of-magnitude is fully determined by (i) a “winner take all” competition between two single-sided queues representing extreme combinations of impatience and utilization, and (ii) the ability to “build” inventory on the server side. Practically important is that when servers are impatient, the cost-of-impatience is given by an insightful expression where only the minimum patience rate appears.

4 Approximations for Serving Impatient Users with Stochastic Service Times

Sebastian Perez Salazar, Rice University, Houston, TX

Motivated by serving users in call centers and ride-sharing applications, we consider the discrete-time sequential problem of serving impatient users with stochastic service times by a single server. There are n users, and each user leaves the system with a known probability. At each time step, we serve a user who spends a stochastic amount of time being served. Each user has a known valuation, and the goal is to find a policy that maximizes the expected value collected from the served users. For general stochastic service times, this problem is NP-hard to solve. In this work, we present efficiently computable approximations via linear programming and greedy schemes.

Pricing and Selling Strategies

Contributed Session

Session Chair: Kangning Wang, Stanford University, Palo Alto, CA

1 Price Signal in Conspicuous Consumption

Mengqi Zhang, University of Colorado Boulder, Boulder, CO, Contact: mengqi.zhang@colorado.edu

In conspicuous consumption, if consumers lack information on actual demand distribution, they are uncertain about the level of exclusivity for which they are willing to pay a premium. We show that the price set by a monopolistic seller who has full knowledge of demand distribution can serve as a signal for consumers to estimate the level of exclusivity. Conspicuous consumption based on the price signal mechanism exhibits a conventional pattern of selling to fewer consumers at a higher markup. However, the nature of this mechanism tends to cause consumers to underestimate the conspicuous value, resulting in a loss for the seller or even the elimination of conspicuous consumption. Our findings are robust in both contexts where consumer types are subject to binary and continuous distribution.

2 Implications of iBuyer Intermediation on Price Discrimination in the Housing Market

Yuan Cheng, Chris Forman, Peng Liu, Cornell University, Ithaca, NY

We study whether iBuying, a technology-driven business model, attenuate or exacerbate the existing price discrimination in the housing market. Using housing transaction and mortgage data of top iBuying markets, we quantify the impact of iBuyer activities on the price discrimination using a repeat sales framework. We document that Black and Hispanic buyers pay price premia compared to their white counterparts for comparable housing in the studied metro areas. Further we examine iBuyer's role in attenuating the price discrimination in the housing market and investigate the corresponding mechanism.

3 Benefit of Opaque Selling for Inventory Management

Mingyang Fu, Xiaobo Li, National University of Singapore, Singapore, Singapore. Contact: fumingyang@u.nus.edu

In this study, we explore the concept of opaque selling—wherein specific product details are withheld until after purchase—and its benefit on inventory management. We find that the advantages of opaque selling extend beyond merely allocation flexibility. Even in scenarios with minimal or no allocation flexibility, sellers can still derive benefits from opaque selling. We further establish that, in larger markets, a mixed opaque selling strategy effectively balances inventory costs and revenue, thereby improving the profit. Moreover, we show that even in the asymmetric market, slight flexibility introduced through opaque selling can lead to almost constant relative inventory savings as the market size increases.

4 Fair Price Discrimination

Siddhartha Banerjee[1], Kamesh Munagala[2], Yiheng Shen[2], Kangning Wang[3], [1]Cornell University, Ithaca, NY, [2]Duke University, Durham, NC, [3]Stanford University, Stanford, CA

A seller is pricing identical copies of a good to a stream of unit-demand buyers. Each buyer has a value on the good as his private information. The seller only knows the empirical value distribution of the buyer population and chooses the revenue-optimal price. We consider a widely studied third-degree price discrimination model where an information intermediary with perfect knowledge of the arriving buyer's value sends a signal to the seller, hence changing the seller's posterior and inducing the seller to set a personalized posted price. We aim to find signaling schemes that is fair to the buyers, and we show the surprising existence of a novel signaling scheme that simultaneously 8-approximates all welfare functions that are non-negative, monotonically increasing, symmetric, and concave (e.g. the utilitarian social welfare, the Nash welfare, and the max-min welfare).

New Directions in Pricing and Revenue Management

Community Committee Choice Session

Session Chair: Kostas Bimpikis, Stanford University, Stanford, CA

Session Chair: Daniela Saban, Stanford University, Palo Alto, CA

1 Blockchain Mediated Persuasion

Kimon Drakopoulos[1], Irene Yuan Lo[2], Justin Mulvany[3], [1]University of Southern California, Data Sciences and Operations, Los Angeles, CA, [2]Stanford University, Stanford, CA, [3]University of Southern California, Los Angeles, CA, Contact: justin.mulvany@marshall.usc.edu

An ex-post informed Sender wishes to persuade a rational Bayesian Receiver to take a desired action, as in the classic Bayesian Persuasion model studied by Kamenica and Gentzkow (2011). However, we consider settings in which Sender cannot reliably commit to a signal mechanism. An alternative approach is to consider a trustworthy mediator that receives a reported state of the world from Sender and then, based on this report, generates a signal realization for Receiver. Such mediation can be implemented via costly blockchain technology. Surprisingly, we show that this cost differentiated mediation succeeds where free mediation fails. By requiring Sender to pay the mediator for different signal realization, we can effectively incentivize them to truthfully report, which in turn allows for beneficial persuasion to take place.

2 Market Fragmentation and Inefficiencies in Maritime Shipping

Kostas Bimpikis, Giacomo Mantegazza, Stanford University, Stanford, CA

Maritime shipping dominates current supply chains, transporting both raw materials and finished goods. However, about 47% of oil tanker and dry-bulk ships sail empty (ballast) at any point in time due to many factors, e.g., that trade flows are imbalanced and the market for transportation is fragmented. We exploit data provided by a maritime analytics firm and establish that consolidating the market for oil tankers can decrease ballasting by as much as 30% through better load-vessel matching. To address practicality and market-power concerns, we also show that organizing vessels into shipping pools of 10-20 units each (2-3% of the total fleet) can cut ballasting by over 25%. This provides another rationale for the growing trend of shipping pools and shows the scope of sustainability gains available solely by optimizing resource allocation in today's supply chains.

3 Designing a Loyalty Program in a Multi-Channel Context

Antoine Feylessoufi[1], Ersin Korpeoglu[1], Mika Sumida[2], [1]University College London, London, United Kingdom; [2]Marshall School of Business, University of Southern California, Los Angeles, CA, Contact: a.feylessoufi@ucl.ac.uk

With the advent of platforms in the hospitality industry, consumers can now often choose between booking a room directly through hotel channels or indirectly through a platform. Platforms may help hotels reach a larger customer base but it comes at the expense of the profit margin. Loyalty programs are a key tool for hotels to mitigate this loss. We investigate the optimal loyalty design program when managing this multi-channel problem using a novel dataset from a hotel chain spanning over 4 years.

4 Algorithmic Pricing, Transparency, and Discrimination in the Gig Economy

Daniel Chen, Gad Allon, Kenneth Moon, University of Pennsylvania, Philadelphia, PA

Algorithms control pricing and match customers and workers in the gig economy. Despite their prevalence, algorithms face several critiques: they lack transparency, can be biased, and can be inefficient. We empirically analyze these issues and show that algorithms lose efficiency from two sources: competition between platforms and misaligned worker incentives. We model workers' strategic responses to variation in pricing and estimate counterfactuals on the effects of minimum wage and transparent pricing policies.

Decisions Under Not-So-Perfect Data

Community Committee Choice Session

Session Chair: Sarah Cen, Massachusetts Institute of Technology, Cambridge, MA
Session Chair: Devavrat Shah, Massachusetts Institute of Technology, Cambridge, MA

1 Machine Learning Who to Nudge: Combining Predictive Modeling and Causal Targeting

Susan Athey[1], Niall Keleher[2], Jann Spiess[3], [1]Stanford University, Stanford, CA, [2]Textio, Seattle, WA, [3]Stanford Graduate School of Business, Stanford, CA, Contact: jspiess@stanford.edu

We estimate the value of targeting in a large-scale field experiment with over 53,000 college students, where the goal was to use "nudges" to encourage students to renew their financial-aid applications. Our preferred approach combines a simple causal model of student decisions with a non-parametric machine-learning model that predicts baseline response rates. We compare this hybrid approach to two benchmarks. First, we target based on a causal forest that estimate heterogeneous treatment effects directly. This approach yields sizable benefits over sending nudges to a randomly selected group, but the estimation of treatment effects is so noisy that the return to targeting is 20-50% lower. Second, a purely predictive policy that targets those students with a low predicted probability of renewing financial aid does significantly worse than assigning nudges randomly.

2 No Star is Good News: Rerandomization Based on P-Values (ReP) from Covariate Balance Tests

Anqi Zhao[1], Peng Ding[2], [1]Duke University, Durham, NC, [2]University of California, Berkeley, Berkeley, CA, Contact: az171@duke.edu

Scientific publications often report covariate balance tables with not only covariate means by treatment arm but also the associated p-values from statistical tests of their differences. The practical need to avoid small p-values as indicators of poor balance motivates balance check and rerandomization based on these p-values (ReP) as an attractive tool for improving covariate balance in randomized experiments. Despite the possibly already widespread use of ReP in practice, the literature lacks results about its implications on subsequent inference, subjecting many effectively rerandomized experiments to inefficient analyses. To fill this gap, we examine a range of possibly useful schemes for ReP and recommend the combination of ReP with fully interacted regression to ensure both covariate balance and convenient and efficient inference.

3 Adaptive Estimation of Intersection Bounds
Vira Semenova, University of California, Berkeley, Berkeley, CA, Contact: semenovavira@gmail.com
This paper studies averages of intersection bounds -- the bounds defined by the infimum of a collection of regression functions -- and other similar functionals of these bounds, such as averages of saddle values. Examples of such parameters are Frechet-Hoeffding bounds, Makarov (1981) bounds on distributional effects. The proposed estimator classifies covariate values into the regions corresponding to the identity of the binding regression function and takes the sample average. The paper shows that the proposed moment function is insensitive to first-order classification mistakes, enabling various nonparametric and regularized/machine learning classifiers in the first (classification) step. The result is generalized to cover bounds on the values of linear programming problems and best linear predictor of intersection bounds.

1 Constant Approximation for Network Revenue Management with Markovian Correlated Customer Arrivals
Jiashuo Jiang, the Hong Kong University of Science and Technology, Hong Kong, China. Contact: jsjiang@ust.hk
The NRM problem allocates fixed resources to serve customers over a finite horizon stochastically. This paper proposes a more general scenario where customer arrivals over different periods can be correlated by using a system state that evolves over time according to a time-inhomogeneous Markov chain. An LP approximation is derived for the NRM problem under this correlated model, which provides a tighter upper bound on the total reward collected by the optimal policy. A bid price policy is developed using this LP, which guarantees to collect at least 1/(1+L) fraction of the total reward collected by the optimal policy, where L is the maximum number of resources required by a customer. Overall, this work presents a new model, an LP approximation, and a bid price policy for solving the NRM problem with correlated customer arrivals, with a theoretical guarantee on its performance.

2 Entropic Regularization for Adversarial Robust Learning
Jie Wang, Yao Xie, Georgia Institute of Technology, Atlanta, GA, Contact: jwang3163@gatech.edu
This study investigates the problem of adversarial robust learning by applying entropic regularization. Our approach involves reformulating the classical adversarial risk minimization problem as a distributionally robust optimization problem, utilizing the infinite-type Wasserstein distance, and adding entropic regularization to the objective function. Our proposed model offers better tractability results compared to the original formulation. Additionally, we provide statistical guarantees, including the regularization effect and uncertainty quantification of the proposed model. Our numerical experiments demonstrate that our approach outperforms heuristic methodology.

3 Foresee the Next Line: On Customer Behavior and Information Disclosure in Tandem Queues
Jingwei Ji, University of Southern California
Many services consist of multiple stages, where each stage requires some waiting before completion. Although customers may observe the queue in front of them, they usually have no information about the waiting situation in the next queue. Our paper aims to examine the behavior of customers when such information is either provided or not, and to study the value of queue-length information in such systems. We assume a two-stage tandem queueing system, with an admission queue followed by a treatment queue. Customers observe the queue length at arrival to each queue and may join or balk. We first study the fully observable model, in which queue-length information of both queues is available to customers at the time they arrive to the system. We calculate the equilibrium strategy and show that it is not necessarily a function of the total number of customers in the system. Next, we study the partially observable model, in which customers observe each queue length only at arrival

to it, i.e., they do not observe the second queue length when they arrive to the system. We prove the existence of an equilibrium strategy in this model and derive a condition under which the equilibrium is a threshold strategy. For both models, we show that customers who join the system never renege.

4 Residual-Based Distributionally Robust Optimization Under Decision-Dependent Uncertainty

Zoey Zhu, Guzin Bayraksan, Xian Yu, The Ohio State University, Columbus, OH, Contact: zhu.2166@buckeyemail.osu.edu

In this paper, we study a data-driven distributionally robust optimization (DRO) model under decision-dependent uncertainty. We adopt regression models to learn the latent decision dependency and then construct ambiguity sets around the learned model using empirical residuals. Specifically, we build sample-based ambiguity sets, where both the sample values and the distribution probabilities are within a bounded distance of the estimated ones. We investigate the asymptotic optimality and rate of convergence of solutions obtained using this type of ambiguity sets. Through numerical experiments, we validate our theoretical results in the limited data regime.

Reinforcement Learning: Statistical Complexity and Applications on Operations

Community Committee Choice Session

Session Chair: Nian Si, Stanford University, Stanford, CA

1 Dyadic Reinforcement Learning

Shuangning Li, Harvard University, Cambridge, MA

Mobile health aims to enhance health outcomes by delivering interventions to individuals. The involvement of care partners often proves crucial in helping individuals managing medical conditions. This presents opportunities to design interventions that target the dyadic relationship--the relationship between a target person and their care partner--with the aim of enhancing social support. In this paper, we develop dyadic RL, an online reinforcement learning algorithm designed to personalize intervention delivery. Here, multiple sets of interventions impact the dyad across multiple time intervals. The developed dyadic RL is Bayesian and hierarchical. We establish a regret bound for dyadic RL and demonstrate dyadic RL's empirical performance through simulation studies on both toy scenarios and on a realistic test bed constructed from prior data.

2 Optimal Sample Complexity Of Reinforcement Learning For Mixing Markov Decision Processes

Shengbo Wang, Jose Blanchet, Peter W. Glynn, Stanford University, Stanford, CA, Contact: shengbo.wang@stanford.edu

We consider the optimal sample complexity theory of tabular RL for controlling the infinite horizon discounted reward in a MDP. Optimal min-max complexity results have been developed for tabular RL in this setting, leading to a sample complexity dependence on □ and □ of the form \tilde □((1-□)^{-3}□^{-2}), where γ is the discount factor and □ is the tolerance solution error. However, in many applications of interest, the optimal policy (or all policies) will induce mixing. We show that in these settings the optimal min-max complexity is \tilde □(t_{mix}(1-□)^{-2}□^{-2})$, where t_{mix} is the total variation mixing time. We further apply our analysis to the average reward setting. Our analysis is based on regeneration-type ideas, that, we believe are of independent interest since they can be used to study related problems for general state space MDPs.

3 Policy Evaluation with General Function Approximation: Efficient Algorithms and Instance-Dependent Guarantees

Wenlong Mou, UC Berkeley, Berkeley, CA

A long-standing puzzle in reinforcement learning (RL) literature is whether RL is harder than statistical learning. The answer is yes-and-no: while regression methods can be applied to RL with function approximation, the geometry of Bellman equation needs to be taken into account. In this talk, I present recent advances in RL that provide non-asymptotic and instance-optimal guarantees. Focusing on function approximation methods for policy evaluation. I establish a novel class of optimal and instance-dependent oracle inequalities for projected Bellman equations, as well as efficient computational algorithms achieving them. The results reveal the additional price of RL compared to regression. Among other results, I will highlight how our novel algorithm tackle existing instability issue known as ``the deadly triad''.

4 Avoiding Model Estimation in Robust Markov Decision Processes

Wenhao Yang, Peking University, Beijing, China

Robust Markov Decision Processes (MDPs) are getting more attention for learning a robust policy which is less sensitive to environment changes. There are an increasing number of works analyzing sample-efficiency of robust MDPs. However, most works study robust MDPs in a model-based regime. In this work, we first transform the original robust MDPs into an alternative form, as the alternative form allows us to use a model-free method to solve the robust MDPs. Meanwhile, we prove the alternative form still preserves the role of robustness. With this new formulation, we devise a sample-efficient algorithm to solve the robust MDPs, including a generative model mechanism and markovian data mechanism, from which we benefit lower memory space $O(|S||A|)$.

Advancements in Simulation

Community Committee Choice Session

Session Chair: Xueping Li, University of Tennessee, Knoxville, Knoxville, TN

1 Simulation-Based Evaluation of Dispatching Policies in a Multiple Flow Service System

Yang Sun[1], Yang Li[2], Yuan Ye[2], [1]California Northstate University, Elk Grove, CA, [2]California State University, Sacramento, Sacramento, CA, Contact: yang.sun@cnsu.edu

Many service systems today encounter multiple customer flows. For instance, due to the COVID-19 pandemic, most restaurants now deal with online orders and dine-in customers at the same time. Consequently, service stations within a restaurant, such as the front desk and the kitchen, confront additional complexities when allocating resources and scheduling customer orders. In this research, we use discrete event simulation models and conduct simulation experiments to assess dispatching policies in a service system facing multiple customer flows. Through comparative analysis, the service system can determine the best set of staffing and dispatching decisions that ensure service efficiency and effectiveness under various conditions.

2 Simulation as an Environment (SaaE) - Unleash the Power of Simulation for Machine Learning

Xueping Li, University of Tennessee, Knoxville, Knoxville, TN

In this research, we develop a general framework of using simulation as an environment (SaaE) for machine learning model training. Specifically, we present how to build a connection between a simulation model and a deep reinforcement learning algorithm. Due to the versatility of simulation, this SaaE framework thus allows one to optimize nearly any simulation model, thus combining the power of both simulation and machine learning. A suite of use cases demonstrates the flexibility and effectiveness of this framework.

3 Spatial Digital Twins for Urban Resilience and Emergency Management

Olufemi A. Omitaomu, Oak Ridge National Laboratory, Oak Ridge, TN

The recent advances in digital transformation are enabling the creation of fit-for-purpose digital representations of industrial operations and processes using collected data and information. This presentation describes a vision for prototyping a "Smart Metaverse City" to combine the unique advantage of the Metaverse technology with the two-way connectivity of a digital twin city application. This synergy aims to create a virtual environment for immersive geovisualization to help researchers and the public understand the complex urban system through science-based and data-driven approaches. We demonstrate our vision and discuss its application opportunities through a real-world example, a digital twin city developed at the Oak Ridge National Laboratory, to facilitate participatory, smart, and sustainable urban area management.

4 Gas Stations Outage Simulator for Integrated Oil and Natural Gas Situational Awareness

Brandon Miller, Olufemi A. Omitaomu, Nagendra Singh, Taylor Hauser, Bennett Morris, Oak Ridge National Laboratory, Oak Ridge, TN, Contact: millerba@ornl.gov

Gas stations are vulnerable to extreme weather events and cyber events, which impact their operations and pose risks to their infrastructure, data, and customers. A gas station outage refers to any gas stations experiencing a disruption in or lack of fuel supply. During an outage, stations are unable to provide fuel to customers due to a fuel shortage. Outages occur due to natural disasters, cyber-attacks, pipeline disruptions, etc., and can last for days or weeks. These outages delay first responders and search and rescue, and hinder evacuations during crises. Despite this, there is no singular source of real-time fuel availability data. The tracking tools that do exist rely on crowdsourcing, which is inaccurate at best. To this end, the Stations Outage Simulator (SOS) is a data-driven queueing model that simulates fuel availability during extreme events in near-real-time.

Advances in Decision Analysis
Community Committee Choice Session
Session Chair: Canan Ulu, Georgetown University, Washington

1 A Walk Down Memory Lane: How Personal Memories Influence Stock Investment and Information Processing
Alessandra Cillo[1], Giovanni Burro[2], alessandro castagnetti[1], Giovanni Paolo Crespi[3], [1]LIUC University, Castellanza (Va), Italy; [2]Bocconi University, Milan, Italy; [3]Università Cattaneo LIUC, Castellanza, Italy. Contact: acillo@liuc.it
Investing in the stock market is a pivotal decision in household finance. Stock investment is substantially more profitable than investment in other asset classes. We experimentally test stock market participation and how financial memories influence stock investment. After eliciting memories and before the investment task we provide, to some participants, positive and truthful financial information about the stock they are about to invest in. We rationalize our findings in light of a memory-based model that builds upon two main elements of memory recall: similarity and interference.

2 The Discount Rate for Investment Analysis Applying Expected Utility
Manel Baucells[1], Sam Bodily[2], [1]Darden School of Business, Playa Vista, CA, [2]Darden School of Business, Charlottesville, VA, Contact: baucellsm@darden.virginia.edu
In decision analysis, expected utility of discounted cash flows is the traditional approach to incorporate risk aversion into the evaluation of a project. The choice of discount rate, as well as the convergence with the CAPM approach from finance, have always been in question. To address this gap, we adopt a standard setup having both treasuries and the stock market as alternatives to the project. We find a unique rate to discount all final capital---from the project and the market---that allows setting the horizon at the termination of the project. For practitioners who discount only the project's cash flows, while ignoring the market, we propose an adjusted discount rate which, under certain assumptions, correctly compensates for the omission. Under these same assumptions, we verify that the approach agrees with Smith and Nau's integrated roll-back procedure.

3 The Impact of Choice on the Utilization of Ai in Decision-Making
Matthew R. Leitao[1], Jennifer Logg[2], Canan Ulu[3], [1]Georgetown University, Washington, DC, [2]Georgetown University, Washington, DC, [3]Georgetown University, Washington, Contact: mrl118@georgetown.edu
Decision-making plays a pivotal role in shaping the outcomes and success of organizations. With the use of Artificial Intelligence (AI) as decision-makers, organizations can improve the accuracy and efficiency of their decisions enabling businesses to save valuable time, resources, and capital. Our studies explore the relationship between the availability of AI models and decision-makers adoption of AI. By providing decision-makers with diverse sets AI models, we expect to increase their inclination to incorporate AI in decision-making. This research contributes to understanding the importance of AI adoption and its impact on decision quality, operational efficiency, and competitive advantage.

4 Appreciation of Advice from Algorithms and Human-In-The-Loop Systems
Canan Ulu[1], Alessandra Cillo[2], Emanuele Borgonovo[3], Alessandro Ortis[4], Sebastiano Battiato[4], [1]Georgetown University, Washington, DC, [2]LIUC University, Castellanza (Va), Italy; [3]Bocconi University, Milano, Italy; [4]University of Catania, Catania, Italy
We investigate how individuals react to advice coming from a human-in-the-loop system where advisors who give the advice have access to algorithms in comparison to direct algorithmic advice and advice from human advisors who do not have access to algorithms. Our results suggest that people appreciate direct algorithmic advice as much as (sometimes more than) advice from a human-in-the-loop system in forecasting tasks. Both the advice from an algorithm and the advice from a human-in-the-loop system are appreciated more than the advice from other human advisors. The appreciation of direct algorithmic advice is more pronounced when the algorithm produces confident forecasts and wanes when experts are part of the human-in-the-loop system.

5 Biseparable Representations of the Certainty Equivalents
Michal Lewandowski[1], Jacek Chudziak[2], [1]Warsaw School of Economics, Warsaw, Poland; [2]University of Rzeszow, Rzeszow, Poland. Contact: michal.lewandowski@sgh.waw.pl

We consider the following biseparable representation of the certainty equivalent of a binary monetary gamble: $F(x,y;p)=u^{-1}(u(y)+w(p)[u(x)-u(y)])$, where u is the utility function and w is the probability weighting function. We provide a simple set of axioms characterizing this form and a few special cases. In particular, we discuss the rank-dependent case with general w, the rank-independent case with self-conjugate w, and the case of expected utility where w is an identity function. For all these cases, we analyze both the model for all binary lotteries and the case of a limited domain of so-called simple prospects $(x,y_0;p)$ where payoff y_0 is fixed.

Socially Responsible and Sustainable Operations

Community Committee Choice Session

Session Chair: Luyi Yang, University of California, Berkeley, Berkeley, CA

1 Seeing Beauty in Ugly Produce: A Food Waste Perspective

Zheng Han[1], Bin Hu[2], Milind Dawande[3], [1]DePaul University, Chicago, IL, [2]University of Texas at Dallas, Richardson, TX, [3]The University of Texas at Dallas, Richardson, TX

The concept of ugly produce involves selling cosmetically unconventional but perfectly edible produce to reduce food waste. While advocates argue that selling ugly produce in retail reduces food waste, skeptics contend that alternative buyers such as restaurants could consume these products. We present a model of a farm selling produce to a retailer and an alternative buyer, which shows that retailing ugly produce can reduce food waste but may also decrease retailer profit, resulting in grocery chains' reluctance to carry these products. However, the study suggests that a dedicated retailer selling ugly produce, competing with a conventional retailer, can achieve the same reduction in food waste. We also highlight the effectiveness of implementing a food landfill tax in reducing food waste.

2 Collective Renewable Power Purchase Agreement (PPA) - Negotiation and Risk Sharing Mechanism

Xiaoxuan Hou, Shi Chen, University of Washington, Foster School of Business, Seattle, WA, Contact: xxhou@uw.edu

Background: Lately, corporate power purchase agreement (PPA) gained popularity among buyers like Google and Amazon as the main vehicle to achieve their renewable goals. Yet signing a PPA remains difficult for small-to-medium-sized corporate buyers, to which collective PPAs emerged as a potential solution. Method: We build Nash bargaining-based economic models to compare the performance of four negotiation mechanisms for these small-to-medium buyers : separate negotiation, agent-based negotiation (different price), agent-based negotiation (same price), and joint negotiation. Results: Agent-based (same price) negotiation results in the largest equilibrium renewable project size. Buyers prefer collaboration over negotiating separately, yet it may be difficult for them to reach an agreement on the exact collaboration mechanism.

3 Labor, Skills, and Product Recovery

Cerag Pince[1], Atalay Atasu[2], [1]Quinlan School of Business, Loyola University Chicago, Chicago, IL, [2]INSEAD, Fontainebleau, France

Motivated by a third-party remanufacturer (3PR) of consumer products, we study the workforce capacity investment problem in product recovery operations. We analyze how a remanufacturing firm should determine its workforce's quantity and type when the number and complexity of units to be processed are random. We characterize the optimal solutions for different workforce strategies and identify the conditions when one strategy dominates the other.

4 Privacy-Preserving Data-Driven Inventory Management

Lorraine Yuan[1], Elena Belavina[2], Karan Girotra[3], [1]Cornell Tech/Cornell University, New York, NY, [2]Cornell University, New York, NY, [3]Cornell Tech/Johnson Cornell University, New York, NY, Contact: hy557@cornell.edu

The use of customer data (demographics, past purchases, etc.) for inventory management can improve firm profits and customer service levels. Yet, large-scale use of such data increases the risks of breaching customers' privacy. This paper develops differential-privacy based privacy-preserving adaptations for three data-driven newsvendor pipelines: the usual two-step predict-then-optimize method, and two newer joint predict-and-optimize methods. We characterize the tradeoff among privacy loss, profits and consumer surplus for the privacy preserving versions of these three approaches. We show that both joint approaches outperform the two-step approach to preserve privacy: Obfuscating customer data can be done with less profit loss by considering downstream optimization problems, we can privatize outputs with less noise and more targeted noise injection.

Managing and Modeling Human Capital

Community Committee Choice Session

Session Chair: Mary Davis, 1</sup

Session Chair: Nicholas Pollack, 1</sup

1 Informing United States Air Force Manpower Decisions with Realistic Constraints Using Reinforcement Learning

Garth Terlizzi, Air Force Manpower Analysis Agency, San Antonio, TX, Contact: garth.terlizzi.2@us.af.mil

The United States Air Force (USAF) human capital ecosystem is a closed, complex system that manages over 300,000 active-duty personnel. Historical management practices allowed senior leaders to make decisions about changing future programs without assessing whether personnel could be developed quickly enough to meet these rapidly changing future targets. In this system, data-driven, effective accession planning is crucial to maintaining a healthy balance of skillsets. We demonstrate a reinforcement learning approach to develop high-quality accession plans to adapt to these targets, as well as a structured approach to inform senior leaders about consequences of programmatic decisions to AF personnel management.

2 Resolving Air Force Wide Data Disconnects: Constructing Robust Human-Capital Models Under Improved Data Integration

Nicholas Pollack, San Antonio, TX

The United States Air Force (USAF) operates a largely closed human capital ecosystem, training junior personnel to grow into senior personnel. Thus, managing scarce experience via assignments and promotions is a vital policy topic. Historically, the USAF approach was constrained by heavily siloed data and processes, as well as limited storage and computation. We demonstrate revisions to two sets of policies made possible by recent increases in data efficacy. First, we show work on models to examine the effects of promotions and grade structure on Airman compensation, experience, retention, and career stability. Second, we show approaches to develop sustainable grade structures in response to fluctuating mission requirements.

3 A New Approach to Career Field Matching For Commissioning Air Force Cadets

Daniel Laird, US Air Force Personnel Center, Universal City, TX

Every year, the Air Force Personnel Center (AFPC) assigns graduating cadets from the United States Air Force Academy (USAFA) and various Reserve Officer Training Corps (ROTC) detachments to their career fields, denoted by Air Force Specialty Codes (AFSCs). Due to the innovations made recently to combine both sources of commissioning (USAFA and ROTC) and all three line-officer "accessions groups" (USAF Rated, USSF, and USAF Non-Rated) into one optimization model, AFPC can improve the DAF line-officer accessions process by adjusting the production guidance letter (PGL), which outlines how many new lieutenants AFPC must match to each AFSC per year. This new classification model is equipped to directly incorporate the output of an improved sustainment model chartered by the Air Force Manpower Analysis Agency (AFMAA) that quantifies the tradeoffs of assigning more or fewer new lieutenants into each specific AFSC. By incorporating more information on the manpower needs of each career field, the Air Force officer accessions matching model can make more informed and data-driven decisions on the most efficient allocation of its human capital.

Response and Recovery to Disasters and Disruptions

Contributed Session

Session Chair: Harsh Anand, University of Virginia, Charlottesville, VA

1 Utilizing Multimedia Big Data Analytics to Evaluate Transportation Disruptions in near Real Time Following Hurricane Events

Adetola Odebode[1], Ashlea Bennett Milburn[1], Jose Azucena[1], Haitao Liao[1], Serhan Dagtas[2], Xiao Huang[1], Sharafat Hossain[2], [1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas, Little Rock, AR, Contact: aoodebod@uark.edu

Emergency responders are driven by logistical issues like what resources are needed, when and where, and how those resources should be delivered during disaster events. For a disaster response to be successful and effective, situational awareness of the state of the transportation infrastructure along which key movements, such as supply distribution and search and rescue missions must occur, is crucial. To do this, we develop a framework that uses cutting-edge data analytics tools and techniques to route important resources while taking advantage of social media and other data sources for essential and timely information. We present the work in progress toward implementing this framework using Hurricane Harvey as a testbed.

2 A Scenario-Based Optimization Model for Designing Reverse Logistics Network of End-Of-Life Building as Disaster Preparedness

Moddassir Khan Nayeem[1], Omar Abbaas[1], Shahriar Tanvir Alam[2], [1]University of Texas at San Antonio, San Antonio, TX, [2]University of Southern California, Los Angeles, CA, Contact: moddassirkhan.nayeem@my.utsa.edu

The primary goal of the preparedness stage of disaster management is to increase the likelihood of survival for victims. Reconstructing outdated structures is a crucial part of earthquake preparedness. Therefore, the goal of this study is to lessen the impact of earthquakes through the reconstruction of obsolete structures and develop a mixed-integer linear programming (MILP) model for designing a reverse logistics network. This optimization model seeks to maximize expected profit while minimizing landfilling activities by recycling construction materials. The quantity of waste generated at demolition sites is considered uncertain and to hedge against the uncertainty stochastic programming approach is applied.

3 Evaluating the Effectiveness of Hurricane Evacuation Orders by Leveraging Large-Scale Human Mobility Patterns

Harsh Anand, Majid Shafiee-Jood, Negin Alemazkoor, University of Virginia, Charlottesville, VA, Contact: yyf8rj@virginia.edu

Evacuation orders are vital for emergency preparedness, yet their effectiveness in increasing evacuation rates remains uncertain. This study examines the causal effect of evacuation orders using passively collected high-fidelity mobility data. By employing causal inference methods, we estimate the effectiveness of mandatory evacuation orders during Hurricane Dorian across 2,617 census block groups in Florida. We further investigated "shadow evacuation" patterns to understand evacuation order responses in areas without evacuation zones and areas with evacuation zones but no orders. The findings shed light on the efficacy of evacuation orders and their broader implications for community responses.

Behavioral Queueing Science

Community Committee Choice Session

Session Chair: Kenneth Schultz, Unaffiliated, Englewood, OH

Session Chair: Armann Ingolfsson, University of Alberta, Edmonton, AB, Canada

1 A Critical Assessment of the Interpretation of Wait Abandonment as a Manifestation of Customer Impatience and Service Failure

Agust Thorbjornsson, Reykjavik University, Reykjavik, Iceland. Contact: agust@framsaekni.is

Based on customer surveys and data from a bank and a utility call center, we investigated whether call abandonments are a manifestation of customer impatience and service failure. We found that 32% of bank and 51% of utility customers abandoned without experiencing impatience, and that customers may have been impatient long before abandoning. This contradicts the assumption made by the "patience" distribution, that customers are initially patient but become impatient and abandon if they wait long enough. Abandonments without impatience seem to largely explain the hazard rate peak, which typically occurs early in the waiting process. Thus, the terms patience distribution and average patience time are misleading. Abandonments seem to have a similar impact on the overall customer experience as the far more likely event of experiencing impatience before receiving service.

2 Calculating Service Rates from Empirically Obtained State-Dependent Mean Service Times

Likang Ding[1], Bora Kolfal[2], Armann Ingolfsson[2], [1]University of Alberta, Edmonton, AB, Canada; [2]University of Alberta, Edmonton, AB, Canada. Contact: likang@ualberta.ca

Queueing models are typically formulated in terms of service rates but recent empirical queueing research focuses on expected service times. We analyze service times in Markovian queueing models with state-dependent service rates. Our primary research question is to analyze the relationship between service rates and expected service times. We provide closed-form solutions to convert service rates into expected service times and vice versa. Contrary to what is sometimes assumed, in general, expected service times are not the inverse of service rates, and service times in state-dependent Markovian systems are not exponentially

distributed. We find conditions under which monotonicity in service rates implies monotonicity in expected service times. Furthermore, we compare the results of our model with state-dependent non-Markovian models in the literature.

3 Model Development and Validation for the Call Center of a Non-Profit Organization

Arash Asgari, Armann Ingolfsson, Saied Samiedaluie, University of Alberta, Edmonton, AB, Canada. Contact: aasgari@ualberta.ca

We develop a novel model to replicate the observed average wait times and abandonment proportions in the call centre of a non-profit organization, in which the agents might become unavailable because of after-call work, meetings, or breaks. Initially, we explored the Erlang-S model, which allows for variability in agents' availability by expanding the parameter set of the commonly used Erlang-A model. Although the Erlang-S model yields improved outputs compared to the Erlang-A model, we achieve more valid results by extending the Erlang-S model to incorporate a two-phase unavailability period for agents. This two-phase approach involves a short period, such as call wrap-up time, followed by a longer period, such as going on a break.

4 The Sooner, the Better? - Behavioral Pitfalls with Pre-Ordering Newsvendors

Anne Dohmen[1], Michael Becker-Peth[2], Stephanie N. Eckerd[1], Lance Saunders[1], [1]University of Tennessee, Knoxville, TN, [2]Erasmus University Rotterdam, Rotterdam, Netherlands. Contact: m.beckerpeth@rsm.nl

Firms launching new product lines need to ensure they have enough product to meet initial orders, but not too much as to have large amounts of excess. Firms will often order "pre-order" raw materials based on long term forecasts to ensure availability of the needed components at product launch. Closer to time of the launch, updated demand parameters may prove that initial orders were inaccurate. Companies can have the opportunity to change their orders after the information is updated to reflect the more accurate forecast. Any changes to initial orders often comes with a 'change fee' to compensate for the effort required by the planner and/or supplier. We investigate how and when decision makers adjust their orders in these circumstances in a laboratory newsvendor experiment.

Fairness and Equity in Operations

Community Committee Choice Session

Session Chair: Phebe Vayanos, University of Southern California, Los Angeles, CA

Session Chair: Bill Tang, University of Southern California, Los Angeles, CA

1 Algorithm-assisted Decision Making and Racial Disparities in Housing: A Study of the Allegheny Homelessness Assessment Tool

Lingwei Cheng, Carnegie Mellon University, Pittsburgh, PA

Homelessness is a long-standing challenge in the US, with Black Americans experiencing over three times the lifetime rates of homelessness compared to non-Hispanic whites. Long-term public housing is effective in reducing homelessness, but bias in resource allocation can perpetuate disparities. This study explores the impact of the Allegheny Homelessness Assessment Tool (AHA), an algorithm-based assessment, on racial disparities in housing. AHA predicts adverse outcomes and standardizes assessments using administrative data. Analyzing pre and post-AHA housing data, we find caseworkers align more with risk scores after deployment. Disparities in Permanent Supportive Housing enrollment are reduced post-AHA, with higher rates of service for Black clients in some cases. The influence of caseworkers' overrides of the tool on racial disparities is also examined.

2 Community/Committee'S Choice Submission

Osonde Osoba, 1</sup

3 Learning Optimal Policies for Allocation of Scarce Resources

Bill Tang[1], Cagil Kocyigit[2], Phebe Vayanos[1], [1]University of Southern California, Los Angeles, CA, [2]University of Luxembourg, Luxembourg, Luxembourg. Contact: yongpeng@usc.edu

We study the problem of allocating scarce societal resources of different types to heterogeneous individuals based on their observed covariates. We leverage administrative data collected in deployment to design a policy that maximizes expected outcomes while satisfying budget and fairness constraints. Our proposed policy waitlists each individual for the resource maximizing the difference between their estimated mean treatment outcome and the estimated resource dual-price or, roughly, the opportunity cost of using the resource. Resources are then allocated as they arrive, in a first-come first-serve fashion. We demonstrate that our data-driven policy converges to the optimal out-of-sample policy under technical assumptions. We evaluate the performance of our approach on the problem of designing policies for allocating scarce housing resources in Los Angeles.

4 Fairness in Contextual Resource Allocation Systems: Metrics and Incompatibility Results

Nathanael Jo[1], Bill Tang[1], Kathryn Dullerud[2], sina Aghaei[2], Eric Rice[1], Phebe Vayanos[1], [1]University of Southern California, Los Angeles, CA, [2]USC, Los Angeles, CA, Contact: phebe.vayanos@usc.edu

We study critical systems that allocate scarce resources to satisfy basic needs. These systems often support communities disproportionately affected by systemic racial, gender, or other injustices, so it is crucial to design these systems with fairness considerations in mind. We propose a framework for evaluating fairness in contextual resource allocation systems that can be applied to evaluate the fairness properties of a historical policy, as well as to impose constraints in the design of new (counterfactual) allocation policies. Our work culminates with a set of incompatibility results that investigate the interplay between the different fairness metrics we propose. Our framework can help guide the discussion among stakeholders in deciding which fairness metrics to impose when allocating scarce resources.

Analytics for Healthcare Operations

Community Committee Choice Session

Session Chair: Nan Liu, Boston College, Chestnut Hill, MA
Session Chair: Miao Bai, University of Connecticut, Storrs, CT

1 Does Physician’s Choice of when to Perform EHR Tasks Influence Total EHR Workload?

Umit Celik[1], Sandeep Rath[2], Saravanan Kesavan[3], Bradley R. Staats[4], [1]UNC Kenan-Flagler Business School, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, [3]University of North Carolina-Chapel Hill, Chapel Hill, NC, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: umit_celik@kenan-flagler.unc.edu

Physicians spend over 5 hours daily on Electronic Health Record (EHR) systems, with additional after-hours work, leading to burnout and appointment delays. This study explores how physicians’ decisions regarding the timing of EHR tasks impact total EHR time and after-work hours. Analyzing data from 150,000 appointments and 74 physicians, the research finds that pre-appointment EHR work reduces overall EHR workload and after-work hours, while post-appointment EHR work decreases after-work hours but increases total EHR time. Increasing idle time between appointments encourages both pre- and post-appointment EHR work. These findings have managerial implications, helping healthcare administrators optimize EHR workflows and appointment schedules to alleviate physician burnout caused by excessive EHR use.

2 Optimizing Bed Assignments in Real-Time for a Hospital Command Center

Arlen Dean[1], Mohammad Zhalechian[2], Mark P. Van Oyen[3], [1]University of Michigan, Ann Arbor, MI, [2]Indiana University, Bloomington, IN, [3]Industrial & Operations Engr., Ann Arbor, MI, Contact: arlend@umich.edu

We report on our research with a large, highly utilized hospital to coordinate bed assignments. These decisions are complicated by patients’ varying care needs and rooms/beds’ distinct features. To overcome these challenges, we develop and implement an optimization model that leverages operational practices with real-time patient and system information.

3 Helping the Captive Audience: Advance Notice of Diagnostic Service for Hospital Inpatients

Miao Bai[1], Nan Liu[2], Zheng Zhang[3], [1]University of Connecticut, Storrs, CT, [2]Boston College, Chestnut Hill, MA, [3]Zhejiang University, Hangzhou, China. Contact: zhengzhang@zju.edu.cn

Inpatients are often treated as on-demand for hospital diagnostic service, and they are notified only when service capacity is available. This arrangement causes significant chaos and inefficiencies in hospital operations. We propose an innovative scheduling approach called ``advance notice’’ to manage hospital diagnostic practice. Patients are placed in a common queue waiting to be called for service, and they will be provided both a fixed preparation time and a guaranteed service time window in advance. It calls for two decisions: who to serve now and who to send advance notices to. We formulate a Markov Decision Process model to optimize these decisions dynamically. Via a novel variable transformation, we reveal the hidden antimultimodular structure of the problem and show how optimal decisions should be adjusted in response to changes in system load.

4 Early Reservation for Follow-Up Appointments when Continuity of Care Matters

Yichuan Ding[1], Diwakar Gupta[2], Shenghai Zhou[3], [1]McGill

University, Montreal, QC, Canada; [2]University of Texas, Austin, TX, [3]Central South University, Changsha, China

Our emperical study shows that high prioritized follow-up (PFU) appointments leads to high level of Continuity of Care (COC). To maintain a certain level of COC, we develop a principal-agent model to inspire doctors do consequently book an appropriate number of PFU appointments. We show that the portion of PFU based contract is the best one among several contracts.

Tuesday, October 17, 8:00 AM - 9:15 AM

OR Applications for Medical Decision-making

Community Committee Choice Session

Session Chair: Daniel Felipe Otero-Leon, University of Michigan, Ann Arbor, MI

1 Optimizing Vaccine Site Selection Considering Queuing Costs: A Game-Theoretical Approach

Peng Dai, Industrial and System Engineering University of Southern California, Los Angeles, CA

Vaccines are crucial for pandemic management, and in the COVID-19 pandemic, drive-through vaccinations were widely used. Vaccination sites should be optimized for residents' convenience, considering both travel and queuing times. We formulate this as an extension of the p-median problem, using Hirotaka's approximation to estimate queue times and formulate a mixed-integer convex optimization problem. We also construct a game-theoretic model to estimate the "price of anarchy," which provides the cost associated when residents can freely choose which vaccination site to attend. Our approach offers new insights into the potential inefficiencies of a decentralized decision-making process in a medical resource allocation network.

2 Finding the Optimal Time for Message-Based Intervention to Medical Students

Zequn Chen, Wesley Javier Marrero, Thomas Thesen, Dartmouth College, Hanover, NH, Contact: zequn.chen.th@dartmouth.edu

Medical students tend to suffer from heavy workload and long study periods, which leads to tremendously mental health issues. We develop an automated mental health intervention system for medical students. Our medical student data contains indexes such as age, sex, race, as well as the corresponding anxiety scores. We leverage student digital data to build predictive model and make the anxiety prediction. Secondly, we define the states and transition probability based on the predictive outcomes. Then we take advantage of the Markov Decision Process to model students' mental state transition process. Finally, we construct the optimal stopping time model to obtain the optimal initial intervention time.

3 Linkage of a Microsimulation to a Location-Optimization Model to Maximize the Clinical and Economic Value of Point-Of-Care Devices in Zimbabwe

Carolina Vivas-Valencia[1], Alyssa Amick[2], Clare Flanagan[2], Karen Webb[3], Andrea Ciaranello[2], Mohammad Jalali[2], [1]The University of Texas at San Antonio, San Antonio, TX, [2]Harvard Medical School, Boston, MA, [3]Organization for Public Health Interventions and Development, Harare, Zimbabwe. Contact: carolina.vivasvalencia@utsa.edu

In this study, we linked microsimulation and allocation models to inform the placement of point-of-care (POC) devices. First, using a model of pediatric HIV (CEPAC), we projected clinical and cost outcomes for different HIV-exposed infants. Second, we integrated the CEPAC model to an expanded location optimization model to examine the placement of POC devices that maximize clinical and economic outcomes.

4 Quantifying The Impact Of Interventions On Covid-19 Transmission: An Open-source Agent-based Modeling Approach

Sebastian A. Rodriguez-Cartes[1], Maria Esther Mayorga[1], Julie L. Swann[1], Julie Simmons Ivy[2], [1]North Carolina State University, Raleigh, NC, [2]University of Michigan, Ann Arbor, MI, Contact: sarodri4@ncsu.edu

When studying the spread of infectious diseases, individuals' actions are essential in preventing contagion across populations. In this study, we aimed to analyze the impact of interventions on COVID-19 transmission when accounting for individual decision-making. We implemented behavioral models to recreate agents' decision to wear a mask and get vaccinated, accounting for critical factors such as personal beliefs, the agent's context, and the system's state regarding infections. We used an open-source agent-based framework for infectious diseases to incorporate these models and analyze different health outcomes. Our results can be used to provide insights about population level outcomes derived from individual conduct. Moreover, we promote open access to the model as it is a flexible tool for studying the transmission dynamics of different infectious diseases.

5 Who Goes Next? Optimizing the Allocation of Adherence-Improving Interventions

Daniel Felipe Otero Leon[1], Mariel Sofia Lavieri[1], Brian T. Denton[2], [1]University of Michigan, Ann Arbor, MI, [2]Industrial and Operations Engineering, University of Michigan, Ann Arbor, MI, Contact: dotero-leon@mgh.harvard.edu

Long-term adherence to medication is a critical factor in preventing cardiovascular disease (CVD). Physicians may recommend adherence improving interventions; however, these are costly and limited in their availability. We developed a binary integer program (BIP) model to select patients for intervention under budget constraints. We further studied a long-term adherence prediction model using dynamic logistic regression (DLR) model to predict the risk of future non-adherence. We trained and tested our model to longitudinal data for CVD in a large cohort of patients seen in the VA health system. We proposed an algorithm that combines the DLR and BIP models to decrease the number of CVD events.

Healthcare Analytics and Sequential Decision Making

Community Committee Choice Session

Session Chair: Yonatan Mintz, University of Wisconsin Madison, Madison, WI

Session Chair: Katherine Adams, University of Wisconsin-Madison, Monona, WI

1 Designing Interpretable and Personalized Treatment Assignment for Substance use Among Adolescents and Young Adults

Han Kyul Kim, Phebe Vayanos, University of Southern California, Los Angeles, CA, Contact: hankyulk@usc.edu

Substance abuse among adolescents and young adults is a critical social issue in the United States. Yet, current treatment assignments in most facilities rely on treatment availability rather than data-driven approaches. In this work, we investigate the impact of data-driven treatment assignment using the GAIN dataset, a comprehensive longitudinal dataset capturing real treatment outcomes. By employing causal inference and prescriptive trees, we develop a personalized and interpretable treatment assignment policy. Moreover, we explore a method to ensure fairness in the price of interpretability in the treatment assignment process. This research aims to empower clinicians and social workers by integrating data-driven decision making into treatment allocation, thereby enhancing their capacity to assist adolescents and young adults effectively.

2 Personalized Health Recommendations for Kidney Disease Patients: A Method Integrating Simulation and Markov Decision Processes

Yiwen Cao, Sze-chuan Suen, University of Southern California, Los Angeles, CA, Contact: ycao0253@usc.edu

Personalized screening and disease management plans may improve outcomes for kidney disease patients, as one-size-fits-all policies are still widely adopted in current practice. In this work, we integrate a microsimulation model with a Markov Decision Process (MDP) to maximize lifetime net monetary benefits (which considers both health outcomes and financial costs). This allowed us to capture the performance of treatment plans and expected health outcomes with respect to patient characteristics including gender, health status[S1] , and age. We performed scenario analyses to provide cohort-specific recommendations for treatment plans.

3 Stopping the Revolving Door: MDP-Based Decision Support for Community Corrections Placement

Xiaoquan Gao, Pengyi Shi, Nan Kong, Purdue University, West Lafayette, IN, Contact: gao568@purdue.edu

We study the incarceration-diversion decision problem to reduce jail overcrowding and recidivism rates by leveraging community corrections. We build a large-scale Markov decision process (MDP) model to balance the tradeoffs among congestion, recidivism, and violation. The salient features of the criminal justice setting, including deterministic service times and occupancy-dependent costs, present significant theoretical and algorithmic challenges. We propose a unified approach with system coupling and policy deviation bounding to compare value functions. We establish the convexity of the value function, which provides a theoretical basis for developing an efficient algorithm based on a separation of time scales. We showcase the effectiveness of our algorithm in solving real-world problems through a case study using data from our community partner.

4 Model Based Reinforcement Learning for Personalized Heparin Dosing

Qinyang He, UW-Madison, MADISON, WI

One of the key challenges in sequential decision making is optimizing systems safely in the case of partial information especially when both states and system dynamics are unknown. For instance, the setting of computing heparin doses for patients fits this paradigm since the concentration of heparin in the patient cannot be measured directly and the rates at which patients metabolize it vary greatly between individuals. To address above challenges in heparin dosing we build a predictive model based on pharmacokinetics parameterized individually by patient. Using this personalized model, we can accurately infer patients' states and predict future therapeutic effects. With this learned information, we propose dosing algorithms that robustly keep patients safe in face of observational errors.

Drug Shortage Modeling and Analytics

Community Committee Choice Session

Session Chair: Noah Chicoine, Northeastern University, Boston, MA

Session Chair: Zohreh Raziei, Northeastern University, Boston, MA

1 A Deep Reinforcement Learning Aided Inventory Control Approach for Managing Drug Shortages: Impact of Information Sharing

Zohreh Raziei, Ozlem Ergun, Northeastern University, Boston, MA, Contact: raziei.z@northeastern.edu

The COVID-19 pandemic has brought to light the inadequate resilience of pharmaceutical supply chains, resulting in drug shortages and inefficient inventory management. To address this issue, our study proposes a novel approach that employs a multi-agent deep reinforcement learning (DRL) decision support system. This system models agents' behaviors and examines the impact of information-sharing during disruptions in the supply chain. Our proposed framework is applicable to both cooperative and competitive scenarios, allowing for a detailed exploration of the level of granularity required for effective information-sharing. Consequently, our approach highlights the significant role played by unknown order lead times and demand, which are crucial elements of the supply chain during periods of drug shortages.

2 Modeling Optimal Sourcing Policies With Estimated Release Date Information In Hospital Settings

Noah Chicoine, Jacqueline Griffin, Northeastern University, Boston, MA, Contact: chicoine.n@northeastern.edu

During drug shortages, pharmaceutical manufacturers provide health centers with estimated release dates (ERDs), point estimates of when the next product release will be and when the health center should expect to receive inventory replenishment. Previous studies have shown how inaccurate ERD information can affect people's decisions to seek alternative sources for critical medications. To help health care professionals make critical and costly sourcing decisions, we utilize a POMDP learning model and showcase its ability to mitigate costs in real ERD contexts when compared to standard inventory management policies.

3 Reimbursement Policy and Drug Shortages

Xuejun Zhao[1], Justin Jia[2], Hui Zhao[3], [1]Purdue University, West Lafayette, IN, [2]University of Tennessee, Knoxville, TN, [3]The Pennsylvania State University, University Park, PA, Contact: justinjia@utk.edu

In 2005, Medicare changed its drug reimbursement policy from an Average Wholesale Price (AWP) regime to an Average Sales Price (ASP) regime. The years following the change witnessed severe drug shortages. We develop a drug supply chain model and conduct analysis to address the continued debate on the impact of the reimbursement policy on drug shortages. We find that the ASP policy actually possesses resilience to drug shortages due to the policy's unique structure.

4 When Should the FDA Inspect Pharmaceutical Manufacturing Facilities to Better Mitigate Drug Shortages?

Daniel Kosmas, Ozlem Ergun, Northeastern University, Boston, MA, Contact: d.kosmas@northeastern.edu

Deciding when to inspect pharmaceutical manufacturing facilities is a complex problem for the FDA; strict regulation enforcement can force low-profit facilities to close due to excessive maintenance costs, while lax enforcement allows for regulation violations to persist, both of which can cause drug shortages. We propose a finite-horizon POMDP model to assist in determining when to inspect these facilities. We theoretically show that this problem can be reduced to only needing to consider whether or not to inspect immediately. Our numerical results highlight the importance of allocating more resources to high-risk facilities that produce drugs that highly impact public health. We additionally find that optimal inspection time is more sensitive to changes in the penalty from an unexpected disruptive event occurring the longer it has been since the last inspection.

5 Mitigating Drug Shortages in Global Pharmaceutical Supply Chains Under Multiple Types of Strain

Martha L. Sabogal De La Pava[1], Emily L. Tucker[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: msaboga@clemson.edu
Pharmaceutical supply chains are affected by decisions made by companies, governments, and society at large. Failures in supply chain operations may lead to drug shortages, which endanger patients' health and affect the costs of healthcare systems. Such failures may reflect fragile supply chains that are designed and managed with mis-specified estimates of uncertain events. We introduce a global supply chain design model that integrates multiple types of strains and study policies to mitigate their effects on a company's economic performance and drug shortages. We study the impact on strategic facility-location decisions and on drug shortages globally and by country income level classification.

Location Analysis of Alternative Fuel Vehicles

Community Committee Choice Session

Session Chair: Ibrahim Capar, Bowling Green State University, Bowling Green, OH

1 Electric Vehicle Charging Network Design with Capacity and Service Considerations

Ibrahim Capar[1], Ozgur M. Araz[2], Ismail Capar[3], [1]Bowling Green State University, Bowling Green, OH, [2]University of Nebraska–Lincoln, Lincoln, NE, [3]Texas A&M University, College Station, TX, Contact: icapar@bgsu.edu
Recently, improving the infrastructure for Electric vehicles (EVs) has been a major focus of organizations around the world. In this paper, we present a service network design framework to improve the infrastructure for EVs with quality of service constraints taken into consideration. We present a novel charging station location model with capacity allocation. The model maximizes the EV traffic flow captured and minimizes the average service time for drivers. Our results highlight how charging times at stations affect the quality of service in the whole service system by quantifying the improvements on flow coverage while reducing waiting times. The value of faster chargers in increasing the coverage and reducing the average waiting times is also highlighted in relation to a service provider's budget constraints.

2 Electric Vehicle Fleet Charging Policies: An Optimal Stopping Approach

Ehsan Mahyari[1], Nickolas K. Freeman[2], [1]The University of Alabama, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, Contact: emahyari@crimson.ua.edu
We propose a model for deciding when to recall electric vehicles (EVs) for charging. Our model, based on the optimal stopping problem, identifies near-optimal policies, i.e., charge thresholds, to optimize charging decisions. We envision the proposed method being driven by the state of charge information for EVs composing the fleet, which would be actively monitored by Electric Vehicle Charging Management Systems (EVCMS). Embedding such an optimization model in the EVCMS will allow its control unit to make recommendations regarding whether to charge individual EVs or not. Our model minimizes costs and maximizes reliability, enhancing overall efficiency of EV fleet charging. Leveraging real-time charge data and our optimization approach, the EVCMS dynamically adapts and improves decision-making, achieving informed and optimal charging strategies for EV fleets.

Applications of Stochastic Models in Service Operations

Community Committee Choice Session

Session Chair: Xiaoshan Peng, Indiana University, Bloomington, IN

1 Dynamic Scheduling with Bayesian Updating of Customer Characteristics

Buyun Li[1], Xiaoshan Peng[2], Owen Wu[3], [1]Kelley School of Business; Indiana University, Bloomington, IN, [2]Indiana University, Bloomington, IN, [3]Indiana University, Bloomington, IN, Contact: libu@iu.edu
We study the dynamic scheduling problem in a multi-class queueing process, where the system manager updates their belief about the service rewards and waiting costs of each class using Bayesian method. We propose a state-dependent index, characterized by the busy period of the queue, that can be used as a basis for an optimal index policy when only one class of customer rewards and waiting costs is unknown. Although the index policy is not optimal for more general systems, we numerically test the performance of the policy. To evaluate the performance of our proposed

policy, we design computational tests using various scenarios and compare it with existing policies in terms of key performance metrics.

2 Asymptotically Optimal Appointment Scheduling in the Presence of Patient Unpunctuality

Nikolai Lipscomb, The Institute for Defense Analyses, Alexandria, VA

We propose a method for scheduling a large patient system by examining the fluid limit of a queue-based appointment system that maximizes the expected net revenue. The fluid limit leads to an optimal control problem that, due to the unpunctuality, is difficult to solve analytically. We propose a time-discretized numerical scheme for approximately solving the problem in the form of a quadratic program with a linear number of constraints in the discretization. Using this method, we are able to derive asymptotically optimal appointment schedules under patient unpunctuality. We examine the behavior of these schedules under different unpunctuality assumptions and test the performance of the schedules on real data in a simulation study. Surprisingly, the optimal schedules can involve block booking of patients, even if the unpunctuality distributions are continuous.

3 Operating Three-Sided Marketplaces: Pricing and Spatial Staffing in Food Delivery Systems

Zhe Liu[1], Yiwen Shen[2], Yanwei Sun[1], [1]Imperial College Business School, London, United Kingdom; [2]HKUST, Hong Kong, China. Contact: zhe.liu@imperial.ac.uk

We study a food delivery platform's joint pricing and staffing problem under endogenous participation of three sides: restaurants, customers and deliverers. Using a state-dependent queueing model where service rates depend on the imbalance of all three sides due to spatial frictions, we study the system's equilibrium behavior in heavy traffic and show through asymptotic analysis how platform controls balance capacity utilization and service quality. We characterize the platform's impact on all three sides and show that the platform's value lies in (i) *increased market output* as the platform boosts demand for restaurants and offers faster delivery for customers, and (ii) *delivery resource pooling* that saves the restaurants' logistic costs and increases deliverer utilization.

4 A Stochastic Optimization Model for Service Configuration in Serial Systems with Nonhomogeneous Arrivals

Randy M. Grivel[1], Jorge A. Sefair[2], Ronald G. Askin[3], [1]Arizona State University, Tempe, AZ, [2]University of Florida, Gainesville, FL, [3]Arizona State University, Tempe, AZ, Contact: rgrivel@asu.edu

Many service systems are tasked with scheduling service channels to accommodate random, nonhomogeneous arrivals. We present a stochastic optimization model for the case of a two stage serial system with finite buffer. The model selects schedules for a fixed set of human servers and schedules their break times to minimize customer wait times. A case study of scheduling screening lanes for an airport is presented.

Empirical Evaluation of the Effects of Technology and Policy Changes on Healthcare Delivery

Community Committee Choice Session

Session Chair: Jing Dong, Columbia University, New York, NY

Session Chair: Maria R. Ibanez, Kellogg School of Management at Northwestern University, Evanston, IL

1 How Recreational Cannabis Legalization Affects Hospital Operations: Workload Ramifications and Speeding up Care for Other Patients

Max Yakovlev[1], Maria R. Ibanez[2], [1]Kellogg School of Management at Northwestern University, Evanston, IL, [2]Kellogg School of Management at Northwestern University, Evanston, IL, Contact: maksim.yakovlev@kellogg.northwestern.edu

Many US states have legalized recreational cannabis in the last decade. Using a difference-in-differences approach, we study the effect of recreational cannabis legalization (RCL) on hospital operations. We find that RCL alters the workload of hospital staff by changing the patient mix: While there is a null effect on total inpatient admissions, more cannabis-related patients are admitted, increasing workload complexity. More strikingly, hospitals speed up care for non-cannabis patients, with RCL lowering lengths of stay by 2.6%. We attribute this phenomenon to cannabis generating workload for hospital staff that reduces the resources available to other patients. We further find adverse effects on experiential quality of care and medical professionals' compliance. These findings inform hospital managers about the impact of legalization on hospitals.

2 What Can Personal Statements Tell Us? Insights About Physicians' Personality Traits and Clinical Performance

Susan F. Lu[1], Jianing Ding[1], Karthik Kannan[2], [1]Purdue University, West Lafayette, IN, [2]University of Arizona, Tucson, AZ

In this study, we investigate the impact of physicians' personality traits on their clinical performance, and we find that leveraging personality traits offers a promising pathway toward understanding physician behavior and their clinical performance. Specifically, we use physicians' personal statements posted on an online physician review platform and extract 2,073 physicians' personality traits from the unstructured physician personal statement following the Big Five model of personality. To address non-random matching between patients and physicians, we adopt a quasi-random setting to study patients with accidental injuries who arrived at emergency departments (EDs) in Florida.

3 The Interplay Between Hospital Reputation and Experiential Quality Rating

Ankita Shirahatti[1], Anita L. Tucker[2], [1]Questrom School of Business, Boston, MA, [2]Boston University, Boston, MA, Contact: ashiraha@bu.edu

Patients have more information about hospitals and potential care that ever before. Two major sources such information include government-published ratings of hospital quality (e.g. CMS stars and HCAHPS ratings) alongside reviews from community members published on online platforms (e.g. ZocDoc, Google, and Facebook). Using datasets of scraped online reviews of hospitals and admissions to hospitals in MA, we extract prevalent features of patient experience and sentiment towards those features to better understand the effects of online reviews on hospital demand. We further use this information compare safety-net hospitals to non-safety-net hospitals and better understand the link between reputation and utilization patterns for hospitals with varying patient-payer-mixes.

4 The Effects of Senior Living Communities on Healthcare Utilization and Outcomes

Carri Chan[1], Ann Bartel[1], Minje Park[1], Fanyin Zheng[2], [1]Columbia Business School, New York, NY, [2]Columbia University, New York, NY, Contact: cwchan@gsb.columbia.edu

This research investigates the impact of senior living communities, specialized housing arrangements for the elderly, on healthcare utilization and outcomes of Medicare enrollees. With the growing aging population, the number of senior living communities is rapidly increasing in the United States. The study findings provide insights into the effect of senior living facilities on healthcare costs and patient outcomes. We also discuss policy implications that suggest the potential benefits of senior living communities in reducing Medicare expenditures.

Risk Management in Reinforcement Learning

Community Committee Choice Session

Session Chair: Parshan Pakiman, University of Illinois-Chicago, Chicago, IL

Session Chair: Selvaprabu Nadarajah, University of Illinois at Chicago, Chicago, IL

1 Operational Risk Management: Optimal Inspection Policy

Youngsoo Kim[1], Yuqian Xu[2], [1]University of Alabama, Tuscaloosa, AL, [2]UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, Contact: ykim106@ua.edu

In light of the importance of operational risk and its current regulation in the financial services industry, we study how a financial firm should design inspection policies to manage operational risk losses based on a continuous-time principal-agent model framework. We first consider two commonly used inspection policies, namely, random and periodic policies. We find that random policy is not always optimal, and it is dominated by periodic policy if the inspection cost is low. Also, we construct a hybrid policy that strictly dominates random policy and weakly dominates periodic policy, which suggests that a proper reduction of the random element in the inspection policy, in the manner of our proposed hybrid policy, can always improve its performance.

2 Self-Adapting Risk Management in Demand Learning

Parshan Pakiman[1], Boxiao Chen[1], Selvaprabu Nadarajah[1], Stefanus Jasin[2], [1]University of Illinois Chicago, Chicago, IL, [2]University of Michigan, Ann Arbor, MI

We study the dynamic pricing of a product over a finite horizon in the presence of demand-model ambiguity. A retailer sets prices at pre-specified times (e.g., weekly) such that each price level can apply to many customers. Therefore, the retailer faces a significant risk of loss in total revenue if many arrivals observe a suboptimal price based on an incorrect demand model. We develop a pricing policy that learns the true demand model based on the online arrival of demand data and trades off between minimizing risk and maximizing expected revenue. We develop regret bounds for our policy and show that it outperforms benchmarks prioritizing either risk minimization or revenue maximization.

3 Assignment-Delay Mechanisms for UAV Airspace Assignment

Paul Friedrich[1], Ludwig Dierks[2], Sven Seuken[1], [1]University Zurich, Zurich, Switzerland; [2]Kyushu University, Nishi-ku, Japan. Contact: dierks@ifi.uzh.ch

The number of unmanned aerial vehicles (UAV) flights is forecast to grow rapidly. However, it is not yet well understood how to best assign airspace to UAV's. Most jurisdictions currently assign flights on a First-Come-First-Serve (FCFS) basis, however we find that such assignments risk market failure once airspace becomes congested. In this paper, we formalize the airspace assignment problem as a Markov-Decision-Process and demonstrate how finding optimal policies is infeasible. We restrict our attention to the class of incentive-compatible assignment-delay mechanisms that assign UAV operators their most preferred available flight path but can delay assignment. We demonstrate how already single parameter mechanisms from this class improve outcomes over FCFS and demonstrate how better policies can be learned from past data or during market operation.

Empirical Retail Operations

Community Committee Choice Session

Session Chair: Stanley Lim, Michigan State University, East Lansing, MI

Session Chair: Chloe Kim Glaeser, University of North Carolina at Chapel Hill Kenan-Flagler Business School

1 Design of Curated Subscription Services in Retailing: Role of Transparency and Selection Process

Yuanyuan Ding, Karen L. Donohue, Necati Ertekin, University of Minnesota, Minneapolis, MN

Curated subscription services, where customers periodically receive a customized set of products, are gaining traction as a new retail business model. Industry reports reveal that customers subscribe to such services for a variety of reasons, ranging from the convenience of outsourcing shopping tasks to a desire for a fun surprise. While the design of these services is evolving, two important pre-delivery features are often considered: whether to provide transparency into the product collection and, if so, what level of consumer involvement to build into the selection process. We will conduct a lab experiment to provide insight into which set of features are most appropriate for different customer segments.

2 Reducing Food Waste in U.S. Food Banks: The Role of Distribution Strategies

Fan Zou[1], Pelin Pekgun[2], Luv Sharma[2], Sanjay L. Ahire[2], [1]Florida State University, Tallahassee, FL, [2]University of South Carolina, Columbia, SC

Food banks serve an important role in addressing food insecurity by matching the supply of excess food with the demand of the food-insecure population. We provide the impact of a direct distribution strategy, an increased trucking capacity or an increased pantry size on the level of food waste in the distribution process, which can help food banks make more informed decisions on where to invest their limited resources to reduce food waste.

3 Enhancing the Competitiveness of the Nanostore Channel: Manufacturer-Enabled Provision of Value-Added Digital Services

Rafael Escamilla[1,2], Jan C. Fransoo[1], Robert Rooderkerk[3], [1]Tilburg University, Tilburg, Netherlands; [2]Kuehne Logistics University, Hamburg, Germany; [3]Erasmus University-Rotterdam School of Management, Rotterdam, NY, Netherlands. Contact: r.escamilla@tilburguniversity.edu

The core, strategic channel for consumer-packaged goods manufacturers in emerging markets has been slow to digitize. Yet, digitization promises important operational benefits for manufacturers and nanostores alike. In this project, we investigate how the provision of manufacturer-enabled value-added digital services by nanostore shopkeepers influences shopkeepers' transactional behavior. For this, we partnered with a large, multinational manufacturer leading a strategic an initiative allowing nanostores to offer value-added digital services. Leveraging detailed transactional sell in data, we investigate the overall benefits to the manufacturer, by examining its sell in to both adopting nanostores as well as neighboring stores located in close proximity.

4 Image-Based Similarity for Demand Forecasting

Junyi Sha[1], David Simchi-Levi[2], Michelle Wu[3], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]MIT Institute for Data, Systems, and Society, Cambridge, MA, Contact: jsha@mit.edu

We present our research in collaboration with a large European fashion retail where we focused on demand forecasts at the style level. We show how we combined text data, structured data, and product images in generating our forecast. In this process, we introduce a new concept of similar products to improve forecast accuracy.

Data and Operations

Community Committee Choice Session

Session Chair: Karan Girotra, Cornell Tech/Johnson Cornell University, New York, NY

Session Chair: Xiaoyue Yan, Cornell University, Ithaca, NY

1 Data-driven Decisions In Supply Chains: Contracts, Algorithms And Efficiency

Xiaoyue Yan[1], Elena Belavina[2], Karan Girotra[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, New York, NY, [3]Cornell Tech/Johnson Cornell University, New York, NY, Contact: xy393@cornell.edu

We study the performance of revenue sharing and wholesale price contracts in supply chains where firms make data-driven inventory/pricing decisions. In these supply chains, each tier uses historical and contemporaneous data on demand and demand-relevant covariates to directly arrive at their optimal decisions, as opposed to the traditional paradigm where demand estimates are first exogenously specified, followed by a separate optimization stage. We find that when there is a lot of historical data, or there are several covariates that tend to have positive skew and high variance, wholesale-price contracts tend to unexpectedly yield higher supply chain profits than revenue-sharing contracts—a stark contrast with well-known findings in the supply chain literature.

2 Planning Bike Lanes with Data: Ridership, Congestion, and Path Selection

Sheng Liu[1], Auyon Siddiq[2], Jingwei Zhang[3], [1]University of Toronto, Toronto, ON, Canada; [2]University of California-Los Angrles, Los Angeles, CA, [3]UCLA, Los Angeles, CA, Contact: jingwei.zhang.phd@anderson.ucla.edu

We study the bike lane planning problem considering its conflicting effects in reducing and increasing traffic congestion. In an extensive case study in Chicago, we estimate adding 25 miles of prescribed bike lanes can lift cycling mode share from 3.6% to 6.1%, with at most an 9.4% increase in driving times.

3 Attribute-Based Pricing: A Novel Formulation and Convergent Algorithms

Mengzhenyu Zhang[1], Chris Ryan[2], Wei Sun[3], Shivaram Subramanian[4], Markus Ettl[5], [1]UCL, London, United Kingdom; [2]UBC, Vancouver, BC, Canada; [3]IBM T. J. Watson Research Center, Yorktown Heights, NY, [4]IBM, Frisco, TX, [5]IBM Research, Yorktown Heights, NY, Contact: zhenyu.zhangmeng@ucl.ac.uk

Attribute-based pricing---giving a price to potential product attributes individually and allowing customers to choose the attributes that form the final product---has been shown to improve customer satisfaction in the hospitality industry. In this paper, we consider the problem of finding optimal attribute prices to maximize the expected revenue from selling to a customer who chooses one product from a set of products that differ by only a few attributes. Because of complicated substitution effects among the final products that share common attributes, expected revenue is not concave in attribute prices. Nonetheless, we provide an algorithm to solve the attribute pricing problem and show that it converges to a stationary point that provides a high-quality solution to the problem.

4 Reinforcement Learning For Pricing And Inventory Control Under Censored Demand

Korel Gundem[1], Gah-Yi Ban[2], Zhengling Qi[3], [1]George Washignton University, Washington, DC, [2]Imperial College Business School, London, United Kingdom; [3]The George Washington University, D.C., Contact: korelgundem@gwu.edu

Learning optimal inventory and pricing strategies from the censored batch data posits a unique challenge in practice. In this paper, we adopt the framework of offline reinforcement learning (RL), adapting the idea of a pessimistic Fitted Q-Iteration (FQI) algorithm to learn the optimal inventory control and pricing policy in the censored demand scenario. Specifically, we propose to learn two different optimal Q-functions, which address the violation of Markovian assumption due to the censored demand. We then show that our algorithm can find the optimal optimal with a finite sample regret guarantee under some mild conditions. Lastly, we conduct a simulation study to showcase the effective performance of our method. Overall, our work offers a new solution and insight for the inventory-pricing territory.

5 Data-Driven Clustering and Feature-Based Retail Electricity Pricing with Smart Meters

N. Bora Keskin[1], Yuexing Li[2], Nur Sunar[3], [1]Duke University, Durham, NC, [2]Johns Hopkins Carey Business School, Baltimore, MD, [3]UNC Kenan-Flagler Business School, Chapel Hill, NC, Contact: bora.keskin@duke.edu

We consider an electric utility company that serves N customers over T periods. In each period, the company observes the customers' consumption and high-dimensional features on customer characteristics and exogenous factors. The space of features is partitioned into clusters based on similarity, and in each cluster, there is a distinct relationship between consumption and features. The company knows neither the underlying cluster structure nor the corresponding consumption models. We design a data-driven clustering-and-pricing policy to learn these elements on the fly and prove that our policy achieves near-optimal profit performance in terms of N and T. We also conduct a case study on a real-life data set from a utility company in the U.S., and we show that our policy significantly outperforms the historical decisions of the utility company.

Socially Responsible and Sustainable Operations

Community Committee Choice Session

Session Chair: Can Zhang, Duke University, Durham, NC

1 When Should the Off-Grid Sun Shine at Night? Optimum Renewable Generation and Energy Storage Investments

Christian Kaps, Simone Marinesi, Serguei Netessine, The Wharton School, Philadelphia, PA, Contact: marinesi@wharton.upenn.edu

We develop a model of strategic capacity investment in both renewable generation and storage to match demand with supply in off-grid use-cases, while relying on fossil fuel as backup. Since the model is intractable, we derive two tractable approximations that provide bounds on the optimal solutions. Utilizing real-life data from three geographically-diverse islands, we find that one of our simplified models yields investment capacities remarkably close to the optimal decisions. We then leverage properties of the model to identify the strategic relation between the two investment decisions, as well as derive a simple yet effective heuristic to determine which storage technology, within a given portfolio, can turn a profit in the broadest set of market conditions, and thus is likely to be adopted first.

2 Institutional Voids and Electric Vehicles: Exploring the Contingent Role of Supply Chain Capabilities and Organizational Intention

Fatima Gillani[1], Muhammad Shakeel Sadiq Jajja[2], [1]Nottingham Trent University, Nottingham, United Kingdom; [2]Lahore University of Management Sciences, Lahore, Pakistan. Contact: ssj@lums.edu.pk

The purpose of this study is to explore the impact of institutional voids that exist in supply chains of developing economies and how they impact the initiatives of firms related to the adoption of Electric Vehicles (EVs). The study also unearths the role of supply chain capability as a contingent factor that enables sense making and management of uncertainties thus minimizing or combating the impact of institutional voids. This results in positive change in intention and initiatives related to EVs provision in the market and adoption respectively. The supply chain capabilities and organizational intention to enter EVs market further impact the firm's EVs initiatives. We empirically examine these relationships using data from incumbent firms in the Pakistani automotive value chain. The data is analyzed using structural equation modeling.

3 Contracting for Sustainability Practices in Smallholder Supply Chains

Yuan Shi[1], Joann de Zegher[2], Yanchong (Karen) Zheng[3], [1]MIT, Cambridge, MA, [2]MIT Sloan, Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: yuansh@mit.edu

We study contract design for sustainable practices by farmers in an environment with uncertain agricultural product price and limited resources. We utilize a novel principal-agent model where the principal aims to implement a sustainable practice while farmers allocate their limited resources between sustainability and agricultural production. Our results identify a simple and nearly optimal cost-based premium contract that is cost-efficient and robust to price fluctuations. Using data from Indonesia's palm fruit market, we estimate that the proposed contract could lead to a cost reduction of over 20% compared to common yield-independent contracts. Our findings emphasize the importance of incorporating sustainability incentives directly into agricultural markets, rather than implementing them alongside agricultural production as separate initiatives.

4 Rent-To-Own Contracts in Developing Economies

Jose A. Guajardo[1], Elaheh Rashidinejad[2], Gonzalo Romero[3], [1]University of California-Berkeley, Berkeley, CA, [2]Rotman School of Management, Toronto, ON, Canada; [3]Rotman, University of Toronto, Toronto, ON, Canada.

Contact: jguajardo@berkeley.edu
We study consumer's payment behaviour under Rent-to-Own business models in developing economies where income uncertainty and hassle costs exists. We use a dynamic programming model to examine different contract designs that firms selling off-grid energy products offer to their customers to minimize expected time to ownership and improve social welfare.

Renewable Energy and Climate Change

Community Committee Choice Session

Session Chair: Karthik Murali, Oregon State University, Corvallis, OR

1 Additionality of Carbon Offsets: Project-Specific vs. Standardized Baselines

Safak Yucel[1], Vishal Agrawal[2], Soudipta Chakraborty[3], [1]Georgetown University, Washington, DC, [2]Georgetown University, Washington, [3]University of Kansas, Lawrence, Contact: safak.yucel@georgetown.edu

Despite their popularity in combating climate change, the fundamental concern for carbon offsets is additionality: whether or not the emissions reduction represented by an offset would have occurred without the revenue from its sale. That is, an offset is additional if it is due to actual reduction in emissions. To assess additionality, a registry calculates emissions reduction, i.e., the difference between business-as-usual emissions and the emissions upon project completion. Given that business-as-usual emissions is unobservable for the registry, it assigns a baseline to a developer through two methods: Under the project-specific method, the developer self-reports its business-as-usual emissions; under the standardized method, the registry assigns a common baseline to all developers. We compare economic and environmental implications of these two methods.

2 An Effective Stationary Policy for Managing Residential Energy Storage

Na Rea Cho[1], Youngsoo Kim[1], Karthik Murali[2], Mesut Yavuz[1], [1]University of Alabama, Tuscaloosa, AL, [2]Oregon State University, Corvallis, OR

We formulate the homeowner's cost-minimization problem as a stochastic program in the presence of time-of-use tariffs and sellback credits. We show that an effective stationary policy consists of a fill-up-to threshold invoking strategic purchasing in the off-peak period and a sell-down-to threshold requiring strategic selling in the peak period. We develop an efficient heuristic to determine these thresholds. The proposed policy achieves 94% of the cost reductions attainable with perfect information. Through case studies, we show strategically managing home energy storage using a simple stationary policy makes this technology significantly more attractive even in communities where it would add no value if managed passively. We demonstrate how this policy can be adjusted to and perform well under seasonally-varying demands and time-of-use pricing over the year.

3 Subsidizing Circularity Under Costly Recycling and Material Scarcity

Nilsu Uzunlar[1], Alan Scheller Wolf[1], Siddharth Singh[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University College London, London, United Kingdom. Contact: nuzunlar@andrew.cmu.edu

Considering technological enhancements, policy incentives, and the reduction in costs, it is estimated that clean energy adoption will increase rapidly in the near future. Unfortunately, this increased adoption faces two significant hurdles. First, existing installations are projected to be retired earlier than their estimated usable lifetime, creating a significant waste problem considering the economically unviable green disposition options. Second, producers are already having a difficult time acquiring crucial raw materials for product manufacturing. We explore how policy initiatives and investments may be able to ameliorate both of these problems.

A Panel Discussion on Successfully Entering the Data Profession

Panel Session

Session Chair: Zohar Maia-Aliya Strinka, Analytics Strategies, Thornton, CO

1 Successfully Transitioning into the Data Profession

Zohar Maia-Aliya Strinka, Analytics Strategies, Thornton, CO, Contact: zstrinka@gmail.com

Many aspects of the data field have existed for decades including Operations Research. However, there is a large breadth of skills needed to succeed in the data profession and most formal training programs only cover a limited subset such as operations research, data science, statistics, or computer science. In order to successfully transition into the data field, would be data professionals need to bridge the gap from their educational background to the full set of skills needed. In this discussion, we will cover some of this gap and what future data practitioners can do to bridge it.

Large Scale Network Design at Amazon

Community Committee Choice Session

Session Chair: Cristiana L. Lara, Amazon, Bellevue, WA
Session Chair: Xiaoyan Si, Amazon, Seattle, WA

1 Re-Engineering Amazon’s Logistics Network to Optimize for Speed, Cost, and Selection

Shahbaaz Mubeen Mamadapur, Amazon, Bellevue, WA

During the pandemic, Amazon’s network grew rapidly as we added more warehouses, trucks, and labor to keep pace with the demand surge. Prior to 2023, Amazon operated a national shipping model which was not scalable. In 2023, Amazon regionalized its domestic US network wherein the US is divided into 8 regions. Each region is designed to be highly self-sufficient and covers its own demand as much as possible. In this talk, we discuss the challenges faced when operating a national network model and our approach to transition it into a regional model.

2 Regionalized Fulfillment - Region Sizing and Resource Allocation

Yuan Li, Amazon, Bellevue, WA

Due to Amazon’s rapid growth, the complexity of its US fulfillment network has surged. The national fulfillment strategy we once relied on is no longer feasible for scalability. To address this, we propose breaking the network into smaller, self-sufficient regions. Each region would handle the majority of its demands locally from facilities within the region, leading to faster deliveries. This presentation offers an overview of how we define these regions and allocate resources such as fulfillment centers, ship and storage capacities, to meet region demands effectively.

3 Structure of Fulfillment Networks: Distributed to Hierarchical Structure with Hub-And Spoke Behavior

Kaushik Sinha, 1</sup

Evolution of distributed fulfillment networks (aka national fulfillment models) to hierarchical, hub and spoke structure (aka regional fulfillment model) shows interesting network signatures that guide network performance. This can be leveraged for intentional network design and alter its behavior to align with intended strategic outcomes. In this talk, we demonstrate the distinctive network signatures, their impact on network flow dynamics and how individual regional flow dynamics can be viewed through the lens of almost equitable partitions and associated graph-theoretic measures.

4 Inventory-Aware E-Commerce Network Design

Semih Atakan, Amazon.com, Seattle, WA, Contact: atakans@amazon.com

Over the years, Amazon’s fulfillment operations have experienced significant growth, leading to several structural changes in its fulfillment network. In the initial part of the presentation, we delve into this journey and highlight the transition of the fulfillment network from a point-to-point structure to a hub-and-spoke model, ultimately arriving at its current “post-regionalization” state. In the subsequent portion of the talk, we discuss the significance of inventory and its role in designing an efficient e-commerce fulfillment network. Lastly, we outline the family of optimization models that can be employed to capture the inventory state and produce a desirable network structure.

5 Velocity-aware Inventory Placement

Cristiana L. Lara[1], David Mildebrath[2], [1]Amazon, Bellevue, WA, [2]Amazon, Seattle, WA, Contact: larcrist@amazon.com

Amazon offers millions of unique items for sale on its website. The popularity of these items is not evenly distributed, and the mean weekly demand for different products on Amazon spans multiple orders of magnitude. Because of this enormous scale and selection, deciding how to optimally place inventory throughout our fulfillment network is very challenging. Directly modeling all products is intractable, and down-sampling products does not adequately capture the behavior of the long tail. We propose a scalable method for modeling both head and tail demand, and placing the inventory to best utilize our network assets. Our model matches the ship and storage capacity of nodes in our network with the velocity profile of demand in order to minimize fulfillment cost. We use this framework to derive insights on the relationship between placement strategy and customer experience.

Recent Advances in Mixed-Integer Nonlinear Programming

Community Committee Choice Session

Session Chair: Rui Chen, [1]</sup

1 Branch-and-bound for D-optimality with Fast Local Search and Variable-bound Tightening

Gabriel Ponte[1], Marcia Fampa[2], Jon Lee[1], [1]University of Michigan, Ann Arbor, MI, [2]Universidade Federal-Rio de Janeiro, Rio de Janeiro, Brazil

We develop a branch-and-bound algorithm for the D-optimality problem, a central problem in statistical design theory, based on two convex relaxations, employing variable-bound tightening and fast local-search procedures, testing our ideas on randomly-generated test problems.

2 Integer Programming Games For Invasive Species Prevention

Hyunwoo Lee, Robert Hildebrand, Esra Toy, Virginia Tech, Blacksburg, VA, Contact: hyunwoolee@vt.edu

We study the prevention of aquatic invasive species (AIS) in approximately 12,000 Minnesota through joint resource allocation of counties and approach the problem via integer programming games and bi-level optimization. We employ the Budgeted Maximum Coverage Problem (BMCP) to optimize the allocation of AIS inspection centers, delving into distinct strategies between state and county levels. State-level decision-maker pursues maximal inspections at the state via pooled budget, while county-level counterparts prioritize inspections at the counties using their designated budgets. By considering each county's self-interest, we formulate the N-player game for BMCP, particularly exploring edge-weighted BMCP within directed and undirected graphs. Notably, within undirected bipartite graphs, the N-player game has a Pure Nash Equilibrium (PNE).

3 Regularized MIP Model for Optimal Power Flow with Battery

Dahye Han, Georgia Tech

Battery operation is modelled with binary variables due to its complementary nature of charging and discharging. Such MILP formulation are relaxed to an LP formulation for simplicity when applying the battery in the context of power system problems. Concerns have been raised that such LP relaxation results in impractical solutions. In the study, we propose a new MILP model called Regularized MIP for battery operation in the optimal power flow problem. We prove that the model has zero-integrality gap under mild assumptions. Furthermore, the optimal solution from this model is always feasible to the original problem and close to the optimal solution of the original problem. These nice properties allow application of the model in much complex settings. We present results on two-stage stochastic programming and trilevel min-max-min problem with binary variables in all levels.

4 The Mixed-Integer Nonlinear Decomposition Toolbox in Pyomo

Zedong Peng[1], David Bernal Neira[2], Ignacio E. Grossmann[3], [1]Purdue University, West Lafayette, IN, [2]NASA Ames Research Center, Palo Alto, CA, [3]Carnegie Mellon University, Pittsburgh, PA, Contact: peng_zedong@126.com

This work presents the Mixed-Integer Nonlinear Decomposition Toolbox in Pyomo (MindtPy), which supports different decomposition algorithms to solve both convex and nonconvex Mixed-Integer Nonlinear Programs(MINLP). For convex MINLP problems, MindtPy provides the Extended Cutting Plane method, Outer-Approximation method, a novel Regularized Outer-Approximation method and the Feasibility Pump method. For nonconvex MINLPs, MindtPy provides both a local and a global Outer-Approximation method. Besides iteratively solving the MIP problem and the fixed NLP problem, MindtPy also supports the so-called single-tree implementation of decompositions algorithms. More importantly, MindtPy also integrates the above algorithms with advanced techniques such as solution pool, tabu-list, and Auto-Persistent Pyomo Solver Interfaces to perform better.

Session Chair: Dimitri Papadimitriou, 1</sup

1 Queueing-Based Mixed-Integer Nonlinear Optimization Models for Network Design: Models, Reformulations, and Algorithms

Miguel Lejeune, George Washington University, Arlington, VA

We present several queueing-based optimization models to design networks in which the objective is to minimize the response time. The networks are modelled as collections of interdependent M/G/1 or M/G/K queueing systems. The optimization models take the form of nonconvex MINLP problems with fractional and bilinear terms. We derive a reformulation approach and propose new optimality-based bound tightening (OBBT) techniques. In particular, we propose new MILP and feasibility OBBT models that can derive multiple variable bounds at once. The proposed approach is applied to the drone-based delivery of external defibrillators to out-of-hospital cardiac arrests and naloxone to overdoses. Computational experiments based on real-life ascertain the computational efficiency of the approach and its impact on the probability of survival of patients.

2 On Proximal Method For Problems With Inexact Stochastic Oracles

Yin Liu[1], Sam Davanloo[2], [1]The Ohio State University, Columbus, OH, [2]The Ohio State University, Columbus, OH, Contact: liu.6630@osu.edu

Many recent machine learning applications require solving optimization problems in the absence of exact stochastic oracles. For instance, in many such applications, having access to an unbiased oracle is impossible or requires significant computation.This talk focuses on composite optimization problems with objective functions in the form of the sum of a smooth and non-smooth function where the smooth function can only be evaluated through an inexact stochastic oracle.We propose Bregman-type stochastic optimization algorithms and establish theoretical guarantees on their computational complexities. We also provide numerical studies validating our findings.

3 On the Importance of On-Manifold Optimization Techniques for Rigid Body Pose

Brennan S. McCann, Morad Nazari, Embry-Riddle Aeronautical University, Daytona Beach, FL, Contact: mccannb4@my.erau.edu

Simultaneous analysis of rotational and translational motion of the rigid body presents challenges for optimal control and path planning. Two common pose representations are the special Euclidean group SE(3) and dual quaternions. The attitude representation on SE(3) is a rotation matrix on the special orthogonal group SO(3), whereas the attitude representation in dual quaternions is a quaternion. Generally, both pose representations above are Lie groups and Riemannian manifolds. Therefore, on-manifold techniques are employed here for pose optimization problems to avoid unnecessary constraints intended to preserve properties inherent to the pose representation.

4 Global Optimization of Nonsmooth Weakly Convex Functions via Simulated Annealing

Tim Tsz-Kit Lau[1], Han Liu[2], Jean-Christophe Pesquet[3], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, [3]CentraleSupélec, Université Paris-Saclay, Gif sur Yvette, France. Contact: timlautk@gmail.com

We study the problem of finding global minima of a nonsmooth and weakly convex function via simulated annealing. More specifically, we study a discretization of the continuous-time simulated annealing process. While almost all existing works assume Lipschitz smoothness of the function so that its gradient exists and is continuous, we relax this stringent assumption and allow it to be nonsmooth. We instead find the global minimizers of its Moreau envelope since it is more well-behaved. We hence propose a preconditioned version of the discrete simulated annealing algorithm based on the Moreau envelope and establish its global convergence guarantee. Numerically, we illustrate the efficacy of the proposed algorithm with simple low-dimensional examples and large-scale applications to statistics and machine learning.

ONR Program Review: Nonlinear Optimization

Community Committee Choice Session

Session Chair: David Phillips, Office of Naval Research, University of New Mexico, Catonsville, MD

1 On First-Order Primal-Dual Algorithms for Minimax Problems

N. Serhat Aybat, Penn State University, University Park, PA, Contact: nsa10@psu.edu

We overview our recent research results on the stochastic accelerated primal-dual (SAPD) method for solving convex-concave minimax problems using a stochastic first-order oracle. We characterize the bias-variance trade-off for SAPD and provide tight bounds for the expected distance and gap metrics leading to (near) optimal rate results; we also give high-probability bounds for SAPD to describe/control the tail event behavior of the iterate sequence. Furthermore, we discuss how SAPD can be embedded in an inexact proximal point method to solve weakly convex-(strongly) concave minimax problems achieving the best known complexity bounds for this class. Finally, we discuss how to incorporate a backtracking scheme to compute a stationary point for the stochastic nonconvex minimax problems without requiring to know Lipschitz constants of the coupling function.

2 Lower Complexity Bound of First-Order Methods for Affinely Constrained Nonconvex Nonsmooth Problems

Yangyang Xu, Rensselaer Polytechnic Institute, Troy, NY

For affinely constrained nonconvex nonsmooth problems, the upper-bound complexity results of first-order methods have been established. A lower bound result is still lacking though there is for smooth problems. In this talk, I will present one lower bound result of first-order methods for a special class of affinely constrained nonconvex nonsmooth problems. Our results show that the nonsmooth term makes the problems significantly harder than smooth counterparts. Additionally, I will present a new inexact proximal gradient algorithm and show that it is worst-case optimal within the considered function class. Hence, our lower bound is tight to a class of affinely constrained nonconvex nonsmooth problems.

3 Policy Gradient: Estimation, Convergence and Beyond Cumulative Rewards

Mengdi Wang, Princeton University, Princeton, NJ

In offline RL, estimating the value or gradient of a policy often suffers from distribution shift. We will review the statistical theory of off-policy policy evaluation and consider the problem off-policy policy gradient estimation. We present a Policy Gradient Bellman Equation and shows how to leverage Q function approximator for policy gradient estimation via a double fitted iteration. We show that the double fitted iteration is equivalent to a model-based plug-in estimator. Further, the PG estimation error bound is determined by a restricted chi-square divergence that quantifies the interplay between distribution shift and function approximation. Next, we show how to extend policy gradient method and its convergence analysis to RL beyond cumulative rewards.

4 Random Methods for Large-Scale Optimization

Angelia Nedich, ASU, Tempe, AZ

A new class of methods is considered for problems with a large number of constraints such as those arising in estimation and classification, reinforcement learning, and artificial intelligence. We consider a class of algorithms that use randomization to cope with the large number of constraints. We present our recent results for a problem with many linear constraints, which is treated by a penalty method using one-sided Huber-loss function. We study the infeasibility properties of the solutions to the penalized problems, propose a random incremental penalty method, and investigate its convergence properties. In particular, we show that the iterates converge to a solution of the original problem almost surely and in expectation, and establish convergence rate of the method in terms of the expected function values.

Differentiable Programming with Applications in Power and Energy Systems

Community Committee Choice Session

Session Chair: Robert Mieth, NJ

Session Chair: Jan Drgona, [1</sup]

1 Grid-Siphyr: An End-To-End Physics-Informed Framework for Integer Optimization in Power Systems

Rabab Haider[1], Anuradha Annaswamy[2], [1]MIT, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: rhaider@mit.edu

Classical approaches for integer optimization remain prohibitively slow for dynamic applications where fast and frequent decision making is required. Data driven methods offer speed, but out-of-the-box implementations typically cannot enforce hard constraints or address mixed integer variables. To close this gap, we propose SiPhyR, a physics-informed end-to-end learning to optimize framework that integrates system constraints, operating principles, and an integer rounding function into a differentiable learning framework. We deploy SiPhyR for grid reconfiguration, an emerging paradigm where the grid topology and distributed solar dispatch are optimized for system efficiency. Results show Grid-SiPhyR can learn to optimize while preserving feasibility and enjoying scalability. Further, it supports grid efficiency, operability, and clean energy goals.

2 Folded Optimization for End-To-End Model-Based Learning

Ferdinando Fioretto, James Kotary, Syracuse University, Syracuse, NY, Contact: nandofioretto@googlemail.com

Integrating constrained optimization models in deep networks has advanced both fields, but backpropagation through optimization mapping poses challenges due to the lack of a closed form. Unrolling, a common approach, uses automatic differentiation through an iterative solver but can face accuracy and efficiency issues. Analytical differentiation avoids these problems but has rigid requirements. This talk offers insights into backpropagation of unrolled optimizers, leading to a system for generating equivalent and efficiently solvable analytical models. It also presents a unified view of unrolling and analytical differentiation in constrained optimization mappings. Experiments show the approach's potential in computation and expressiveness across structured prediction and decision-focused learning tasks.

3 Solving Hard Power Grid Problems Using End-To-End Learning: A Case Study for Wildfire Risk Mitigation

Deepjyoti Deka, Los Alamos National Laboratory, Los Alamos, NM

Resilient power grid operation has become crucial in the face of worsening events like flood, hurricanes and forest fires. In addition to physical constraints, resilient grid optimization considers multiple operational uncertainties (renewable generation, grid damage) and control variables (topology switching, on/off of emergency generators) that complicate the model. This talk describes the benefits of using Machine learning (ML), particularly end-to end learning for computationally efficient solution to grid resiliency. We will discuss two use-cases for end to end learning. The first will pertain to selection of finite wildfire scenarios to solve wildfire risk-aware grid optimization using ML. The second use case will use end-to-end learning to speed-up global optimization in power grids with discrete control variables.

Decision Rules for Dynamic Decision Making

Community Committee Choice Session

Session Chair: Eojin Han, Southern Methodist University, Dallas, TX

1 Nonlinear Decision Rules Made Scalable by Nonparametric Liftings

Eojin Han[1], Omid Nohadani[2], [1]Southern Methodist University, Dallas, TX, [2]Benefits Science Technology, Arlington, MA, Contact: eojinh@smu.edu

Decision rules provide approximate solutions by restricting decisions to simple functions of uncertainties in dynamic robust optimization. In this paper, we consider a nonparametric lifting framework where the uncertainty space is lifted to higher dimensions to obtain nonlinear decision rules. We propose two nonparametric liftings, which derive the nonlinear functions by leveraging the uncertainty set structure and problem coefficients. Both methods integrate the benefits from lifting and nonparametric approaches, and hence, provide scalable decision rules with performance bounds. Numerical comparisons with competing methods demonstrate superior computational scalability. These observations are magnified in multistage problems, suggesting practical applicability of the proposed nonparametric liftings in large-scale dynamic robust optimization.

2 Two-Stage Decision Rules for Multistage Adaptive Robust Optimization

Maryam Daryalal[1], Ayse Nur Arslan[2], Merve Bodur[3], [1]HEC Montreal, Montreal, QC, Canada; [2]Institut de Mathematiques de Bordeaux, Talence, France; [3]University of Toronto, Toronto, ON, Canada. Contact: maryam.daryalal@hec.ca

In this talk, for a broad class of multistage adaptive robust optimization problems, we present the class of two-stage decision rules that impose a predefined structure on a subset of the decision variables in future stages, with the goal of building an approximate model that returns feasible first-stage solutions. The result is a two-stage robust optimization (2ARO) approximation of the original multistage problem, leading to novel techniques that reveal new theoretical and practical avenues. We show that in some special cases, constraint-and-column generation algorithm converges (finitely/asymptotically) to the exact solution of the 2ARO problem, otherwise the K-adaptability approach is applicable. We demonstrate the performance of our solution framework over multistage versions of newsvendor, location-transportation, and capital budgeting problems.

3 Optimize-via-predict: Conditions for Out-of-sample Optimality in Data-driven Optimization

Gar Goei Loke[1], Taozeng Zhu[2], Ruiting Zuo[3], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Dongbei University of Finance and Economics, Dalian, China; [3]The Hong Kong University of Science and Technology, Guangzhou, China. Contact: loke@rsm.nl

Under the context of data-driven optimization, we consider out-of-sample optimality over the sampling distribution, and propose prescriptive solutions as a decision rules mapping data sets to decisions. We prove sufficient conditions for out-of-sample optimality and present an optimization problem that solves for such a candidate solution, which can be computed efficiently. Finally, we illustrate our model on the newsvendor model, and find strong performance when compared against alternatives in the literature

4 Integrating EV Fleet Flexibility into Robust Optimal Planning of Local Power Grids

Linda Punt, Gar Goei Loke, Yashar Ghiassi, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands. Contact: punt@rsm.nl

The unpredictable and flexible nature of electric vehicle (EV) demand poses both a challenge and an opportunity to distributed power networks. Accounting for this flexibility during the planning phase is critical to prevent overprovisioning. This requires supply-demand matching at all nodes and at all times, where decisions are the link capacities and per-node storage capacity. However, the stochastic nature of EV demand in time, space, and quantity complicates this task. We address this problem by modeling the aggregate of EVs and presenting a two-stage multi-period moments uncertainty robust optimization model. Using real data from a local grid, we demonstrate that our model can reduce grid investment costs by taking advantage of EV fleet flexibility.

Non-Smooth and Bilevel Convex Optimization

Community Committee Choice Session

Session Chair: Nam Ho-Nguyen, The University of Sydney, The University of Sydney, Australia

Session Chair: Dabeen Lee, Institute for Basic Science (IBS), Pittsburgh, PA

1 First-Order Methods for Bi-Level Optimization

Shimrit Shtern, Lior Doron, Technion - Israel Institute of Technology, HAIFA, Israel. Contact: shimrits@technion.ac.il

Simple bilevel problems are optimization problems in which we want to find an optimal solution to an inner function that minimizes an outer objective function. Such problems appear in many machine learning and signal processing applications. We present the ITerative Approximation and Level-set EXpansion (ITALEX) approach that is designed for bilevel problems with norm-like outer functions, which are not required to be either smooth or strongly convex. ITALEX alternates between expanding the level-set of the outer function and approximately optimizing the inner problem over this level-set. Using first-order methods such as proximal gradient and generalized conditional gradient to optimize the inner function, we prove that ITALEX has a feasibility convergence rate of O(1/k) and an optimality convergence of O(1/√k), which are the best known rates for this setting.

2 Projection-Free Non-Smooth Convex Programming

Kamiar Asgari[1], Michael Neely[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA 9008, CA, Contact: kamiaras@usc.edu

This paper presents a sub-gradient based algorithm to solve constrained non-smooth convex optimization without taking projections onto the feasible set. The well studied conditional gradient methods (also known as Frank-Wolfe type algorithms) also avoid projections. However, they are only designed to handle smooth objective functions. The proposed algorithm treats non-smooth problems and achieves an □-suboptimal feasible solutions after O(□^-2) iterations (which matches existing lower bounds). The algorithm yields similar performance in expectation when the deterministic sub-gradients are replaced by stochastic sub-gradients.

Other proposed projection-free algorithms for non-smooth problems are based on conditional gradient methods. Our new algorithm is however derived from the (stochastic) projected sub-gradient descent method.

3 Non-Smooth, Holder-Smooth, and Robust Submodular Maximization

Dabeen Lee, KAIST, Daejeon, Korea, Republic of. Contact: dabeenl@kaist.ac.kr

We study the problem of maximizing a continuous DR-submodular function that is not necessarily smooth. We prove that the continuous greedy algorithm achieves an [(1-1/e) OPT-epsilon] guarantee when the function is monotone and Holder-smooth, meaning that it admits a Holder-continuous gradient. For functions that are non-differentiable or non-smooth, we propose a variant of the mirror-prox algorithm that attains an [(1/2)OPT-epsilon] guarantee. We apply our algorithmic frameworks to robust submodular maximization and distrbutionally robust submodular maximization under Wasserstein ambiguity. In particular, the mirror-prox method applies to robust maximization to obtain a single feasible solution, and for distributionally robust maximization, we deduce and work over a reformulation whose objective function is Holder-smooth.

4 Projection-Free Convex Bilevel Optimization

Khanh-Hung Giang-Tran[1], Nam Ho-Nguyen[1], Dabeen Lee[2], [1]The University of Sydney, Sydney, Australia; [2]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of. Contact: nam.ho-nguyen@sydney.edu.au

We study convex bilevel optimization, where an upper-level convex function is minimized over the set of minimizers of another lower-level convex function. While various first-order algorithms exist for solving this problem, they rely on projection-type operations. In this work, we propose algorithms which instead employ linear optimization oracles, which can be advantageous in various settings. We draw on connections between bilevel optimization and exact regularization, primal-dual methods and online convex optimization to derive convergence guarantees of our methods.

Innovative Material Handling Systems

Community Committee Choice Session

Session Chair: Jennifer A. Pazour, Rensselaer Polytechnic Institute, Troy, NY

1 Drone-Assisted Material Handling for Smarter Manufacturing

Julio Jiménez-Sarda[1], Daniel F. Silva[2], Alice E. Smith[3], [1]Auburn University, Auburn, AL, [2]Auburn University, Auburn, AL, [3]Auburn University, Birmingham, AL

Amidst labor shortages, increasing land prices, and other aspects of the post-pandemic world, our logistics chain must take the next technological leap. Automated material handling equipment often requires valuable floor space and specialized layouts. Uncrewed aerial vehicles (UAVs) present a flexible and potentially cost-effective alternative. To explore the potential benefits and challenges of such systems, we used a version of the CVRP to model a realistic manufacturing environment. As a proof-of-concept, we outfitted a commercially available drone with pickup-and-carry capabilities. We found that, even with limited carrying capacity, there are potential benefits compared to ground-based material handling systems. Additionally, we identified potential challenges and safety considerations when developing our pickup and carrying mechanisms.

2 Deploying Robotic Resources in Redesigned Retail Stores Supporting Omnichannel Services

Joyjit Bhowmick[1], Sebastian Köhler[2], Georg Fischer[2], Kai Furmans[3], Jennifer A. Pazour[1], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Karlsruhe Institute of Technology, Karlsruhe, Germany; [3]KIT, Karlsruhe, Germany. Contact: joyjittspl@gmail.com

The proliferation of e-commerce services shifts the in-store logistics once done by shoppers to retailers. And how best to support both online and in-store customer channels efficiently and seamlessly is a current challenge for retailers. We develop an agent-based simulation framework to evaluate redesigned retail store layouts supporting both customer types and which integrate data collected from lab experiments deploying a newly designed modular robotic platform to assist with the logistical tasks. This framework is used to identify the feasible range of attributes of the robotic platform as well as the decision trade-offs in terms of customer satisfaction and store performance.

3 Inventory and Order Fulfillment Policies for Ship-From-Store Omnichannel Strategy

Vishal Bansal[1], Arnab Bisi[2], Debjit Roy[3], Prahalad Venkateshan[4], [1]Indian Institute of Management Calcutta, Kolkata, India; [2]Johns Hopkins University, Baltimore, MD, [3]Indian Institute of Management Ahmedabad, Ahmedabad, India; [4]Indian Institute of Management Ahmedabad, Vastrapur, Ahmedabad, India

An omnichannel retailer with a distribution center and a retail store has to make important, interlinked decisions - (1) how much inventory to keep at the retail store, and (2) where to fulfill the online demand from and how much. In this work, we model the integrated inventory replenishment and online demand allocation decisions for an omnichannel retailer employing the ship-from-store strategy. We analyze this problem for both single-period and multi-period settings. We extend the analytical framework of the single-period problem by providing a finite-horizon MDP formulation for the multi-period problem. Our findings suggest that for a single-period setting, decentralized inventory replenishment and demand allocation system maximizes the profit of the omnichannel retailer for low values of the incentive.

4 Retail on Autonomous Wheels: A Time-Sensitive Traveling Salesman Problem

Zhuolun Dong[1], Junyu Cao[2], Wei Qi[3], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]Tsinghua University, Beijing, China. Contact: dongzhuolun@utexas.edu

Driven by the potential of wheeled retail stores, we present a model, theory, and insights into their operations. We consider a new business model where a wheeled mobile retail store transverses across the service region, seeks suitable locations to perch at, and fulfills local demand. We propose and analyze a model that incorporates the time-sensitive factors (local demand and freshness) into the TSP, which we call the "time-sensitive TSP". The model focuses on the strategy of the mobile store to maximize the total reward. We derive the upper and lower bounds of the optimal reward in the asymptotic regime using the continuous approximation approach. Numerical studies are conducted to demonstrate the performance of the model framework. Our findings suggest that mobile retail has the potential to be more profitable compared to stationary retail.

Logistics of Supply Chain Disruptions

Community Committee Choice Session

Session Chair: Bahar Cavdar, Texas A&M University, College Station, TX

1 Restoration of Infrastructure Networks Under Incomplete Information

Subhojit Biswas, Bahar Cavdar, Joseph Geunes, Texas A&M University, College Station, TX, Contact: subhojit.biswas@tamu.edu

Restoring power to a disrupted distribution network requires dispatching crews to affected areas in an effort to diagnose and repair all faults in the power network, with a goal of minimizing population-weighted disruption time. The resulting disruption time depends on crew routing decisions on the corresponding transportation network, as well as on the fault locations and distribution network structure. A lack of information on the nature and locations of power network faults compounds the difficulty of solving this already complex combinatorial problem. Given a set of nodes without power, as well as a probability that each node is faulty, we seek a node visit sequence that minimizes weighted service disruption time. We model this problem as an MDP and propose an approximate dynamic programming solution approach that employs state-space-reduction techniques.

2 Harnessing Prognostics and Health Management for Multi-Vehicle Routing and Maintenance

Iman Kazemian[1], Murat Yildirim[2], [1]Wayne state university, Detroit, MI, [2]Wayne State University, Detroit, MI, Contact: hj5980@wayne.edu

Vehicle prognostics and health management is a central problem in fleet management that focuses on harnessing sensor data for predicting vehicle-specific failure risks. Effectively harnessing these predictions within a fleet management problem requires optimal integration of these vehicle-specific failure risks within fleet-level routing and maintenance by considering a multitude of complex operational interactions. In this talk, we propose a unified framework that integrates sensor-driven vehicle prognostics into a joint multi-vehicle routing and maintenance optimization model. Our framework leverages real-time sensor-drive failure predictions to enable informed decisions about maintenance and routing. The proposed model outperforms conventional maintenance models by reducing costs, improving productivity, and minimizing downtime.

3 A Model for Fortifying Distribution Network Nodes Subject to Disruptions

Pelin Kesrit, Bahar Cavdar, Joseph Geunes, Texas A&M University, College Station, TX, Contact: pelkechrid@gmail.com

We consider a distribution network for delivering a natural resource or physical good to a set of nodes, each of which serves a set of customers, in which flow disruptions may occur. Each node receives flow through a path from one or more source nodes so that a node experiences a disruption if it occurs at any node on that path. All nodes are subject to a future disturbance of an uncertain degree of severity, for which we determine a fortification level that enables the node to withstand. We maximize the expected number of customers who do not experience a disruption, given a limited fortification budget. We formulate the problem as a mathematical program, characterize the properties of optimal solutions, and provide methods for determining optimal fortification levels under various assumptions on the probability distribution of the disturbance severity and the network structure.

4 Repair Crew Routing for Infrastructure Network Restoration

Bahar Cavdar[1,2], Qie He[3], Feng Qiu[4], [1]Texas A&M University, College Station, TX, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]Amazon, Santa Clara, CA, [4]Argonne National Laboratory, Lemont, IL, Contact: bcavdar@tamu.edu

Abstract:
We study a repair crew routing problem to restore a disrupted power network where technical crew travels to a number of sites to repair damaged equipment with minimum total service disruption time. We call this problem the Power Restoration Traveling Repairman Problem. The main challenge in this problem is that the service disruption time in a location depends on the interaction of the routing sequence with both networks, i.e., the road network and the power grid. To solve the problem, we develop an exact method based on bi-directional dynamic programming. We then improve the method by reducing the search space with solution upper and lower bounds, and threshold rules derived from the precedence relations in the power network. We also propose efficient heuristic variants of the method. We present computational results to compare our method with benchmark heuristics.

Co-Design and Coordination of Mobility Systems

Community Committee Choice Session

Session Chair: Zardini Gioele, ETH Zurich

1 Integrating Load Bundling and Pricing for Decarbonizing Freight Operations

Maxime Bouscary[1], Aron Brenner[1], Alexandra Li[1], Mazen Danaf[1], Saurabh Amin[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: mbscry@mit.edu

A major challenge in decarbonizing the trucking industry is to reduce deadhead (empty miles) under tight reliability constraints. Here we propose to leverage today's digital brokerage platforms that facilitate matching between shippers and carriers to jointly design load bundles and pricing strategies to tradeoff between expected reduction in empty miles and total served load. Crucially, we account for the strategic behavior of carriers in terms of their accept/reject decisions and spatial positioning to be matched with desirable loads. We also account for reliability preferences of shippers (e.g., tight versus flexible appointment windows). Our results demonstrate that jointly recommending and pricing load bundles can maximally reduce expected empty miles while limiting the probability of unserved load to a small value.

2 Joint Design of Transportation Systems and User Schedules

Matt Tsao, Lyft, CA

We propose a community detection approach for schedule staggering to reduce congestion in transportation systems. Transportation systems experience congestion in large part due to positive correlation in user demand. If people need to be at work by 9:00am, there will be high demand and congestion in the network around this time. Schedule staggering aims to reduce congestion by perturbing user schedules (e.g., change work hours to 10am-6pm for some fraction of the population), thereby decorrelating them. However, the perturbations must be done in a way that does not disrupt the couplings between users' schedules. We use community detection to determine how to stagger user schedules while preserving the dependencies between schedules.

3 Transit Line Planning and Optimization in Multimodal Transportation Networks

Duan Ning, Cornell University, NY

As mobility-on-demand services revolutionize urban transportation by providing convenient transportation choices to the general population, they also motivate the re-design of traditional transit service to better integrate with a multi-modal environment. Recent attempts include using heuristics or data-driven approaches to handle the problem. However, there has been limited work on general optimization frameworks for the planning multimodal transportation system in a systematic and tractable manner. We study the problem of designing efficient transit line routes and frequencies to serve demand given the availability of complementary first- and last-mile on-demand services in the network. Using integer programming and column generation, we demonstrate the usefulness of our approach on a case study with real data from New York City.

Railway Train platoons: Control and Optimization

Community Committee Choice Session

Session Chair: Fan Pu, Texas A&M

Session Chair: Zhikai Wang, 1</sup

1 Passenger-Oriented Metro Train Scheduling with the Virtual Coupling Technology

Zhikai Wang, 1</sup

The imbalanced distribution of passenger demand in temporal and spatial dimensions brings great challenges to the train scheduling problem. To address the above problem, this paper proposes an integrated optimization model to solve the train scheduling problem considering the virtual coupling technology. The objective of this model is to balance the offered capacity and passenger demand. Moreover, some non-linear constraints are introduced to formulate the un/couple process of trains. Then, this model is transformed into an integer programming (IP) model which can be solved by the CPLEX optimizer. Finally, a case study is developed to verify the effectiveness of the train scheduling model. The computational results show that the balance between passenger demand and offered capacity is improved after applying the virtual coupling technology.

2 Adaptive Fault-Tolerant Fixed-Time Cruise Control for Virtually Coupled Train Set

Di Wang, Beijing, China

This paper studies the problem of fixed-time cruise control for VCTS. Firstly, by analyzing the dynamic evolution of the VCTS in an actual environment, a second-order VCTS train-following dynamic model is formulated with considering actuator faults, uncertain resistance, unknown disturbances, and control input saturation. Then, a novel barrier functions-based fixed-time sliding model control method is proposed to deal with the state constraints. To deal with parametric uncertainty, adaptive fault-tolerant control and core function technologies are integrated into the same framework. Furthermore, by using a function approximation method to handle the control input saturation, an adaptive fault-tolerant fixed-time cruise controller is designed. Finally, the effectiveness of the proposed method is validated in simulation analysis.

3 A Branch-And-Cut Approach for the Scheduling of Train Platoons in Urban Rail Networks

Simin Chai, Beijing Jiaotong University, Beijing, China. Contact: smchai@bjtu.edu.cn

In this study, we investigate the scheduling of train platoons for urban rail networks with time-dependent demand to mitigate passenger inconvenience. We propose a mixed-integer linear programming (MILP) model that simultaneously optimizes the train-platoon (de)coupling strategies, arrival/departure times at each station, and the running orders of trains, while considering limited rolling stock resources at the depots and the safety of trains at cross-line zones. To tackle computational challenges in real-world instances, we develop a customized branch-and-cut solution algorithm, based on the analysis of mathematical properties of our MILP model, to generate (near-)optimal solutions more efficiently. Real-world case studies based on the operational data of Beijing metro network are conducted to verify the effectiveness of our approach.

4 A Technical Demonstration of Virtual Coupling in Metros

Xiaolin Luo, Beijing Jiaotong University, Beijing, China. Contact: luo_xiaolin713@163.com

The development of a technical demonstration project of virtual coupling in China will be presented. First, the aims of this demonstration will be discussed. Then, the protection and cooperative train control methods, as two key technologies for virtual coupling, will be presented. Finally, field-test results will be provided to show the performance of virtual coupling.

1 Airline Flight Network Expansion with Strategic Aircraft Leasing Decisions

M. Selim Akturk[1], Alper Atamturk[2], Ozge Safak[3], [1]Bilkent University, Ankara, Turkey; [2]Berkeley Analytics, Berkeley, CA, [3]University of Bath, Bath, United Kingdom. Contact: akturk@bilkent.edu.tr

The ability to match fleet capacity to increasing passenger demand is a crucial factor affecting the airlines' profit. This work develops a mathematical model for the airlines to determine the optimal number of leased aircraft while simultaneously generating a schedule with new market routes to make a reliable estimate on the operational costs and revenue. Since the fuel and carbon emission costs are the most significant components of operational costs, this work links the strategic aircraft leasing decisions to the operational aircraft assignment decisions. Consequently, we consider not only the seat capacity of the aircraft alternatives in response to new demand but also the fuel efficiency of the aircraft along with the uncertainty due to airport congestion as a function of airlines' decisions on flight departure times.

2 Capacity Finder: Strategic Departure Reroute Recommendations for Sustainable Aviation

Aditya Saraf, Ryan Laroza, ATAC, Santa Clara, CA

When inclement weather closes down departure routes/ fixes in multi-airport, metroplex environments, it results in large taxi out delays with flights waiting in long departure queues on airport surfaces with engines on. This creates unnecessary fuel-burn and emissions. ATAC, in collaboration with NASA's ATD-2 and Digital Information Platform (DIP) projects, has developed a capability called the NAS Capacity Finder Service (NCFS) that innovatively integrates real-time data processing, machine learning, and multi-objective optimization capabilities to solve this complex problem. NCFS provides guidance on delay, fuel, and emissions-saving departure reroutes in upcoming departure banks to airline and FAA stakeholders.

3 Simulating Evtol Energy Consumption and Operation

Eric S. Miller, National Renewable Energy Lab, Golden, CO, Contact: Eric.Miller@nrel.gov

Electric Vertical Takeoff and Landing Aircraft (eVTOL) are an emerging technology advancing rapidly, and likely to be commercially available in the next five years. eVTOLs are not expected to replace an existing mode of transportation, rather, they are expected to provide a new service called urban air mobility (UAM). To gain some insight into the positive and negative impacts of UAM, NREL created the Future Aerospace Vehicle Energy Simulation (FAVESim) tool, which uses a physics-based model to estimate energy consumed by eVTOLs flying fixed routes, and an agent-based model to simulate the interaction of eVTOLs with vertiports, passengers, and electric grid infrastructure. The tool is used to estimate how many passengers can be served in a day, how long they have to wait for flights, and how much power and energy will be required to charge the eVTOL aircraft.

4 Airline Network Planning Considering Climate Impact: Assessing New Operational Improvements

Mahdi Noorafza[1], Bruno Santos[1], Zarah Zengerling[2], Sharpanskykh Alexei[1], [1]TU Delft, Delft, Netherlands; [2]Deutsches Zentrum für Luft- und Raumfahrt (DLR), Hamburg, Germany. Contact: b.f.santos@tudelft.nl

We developed a multi-objective airline network and schedule design framework to facilitate the modeling of climate-aware airline operational improvements. While considering financial and climate response objectives, we modeled intermediate stop-overs and lower flight altitudes as operational improvements. We analyzed the impact of considering climate impact in the planning of operations of three different airline types: one main-hub-and-spoke (KLM), one smaller multi-hub airline (TAP), and one low-cost carrier (easyJet). Results show that airlines could lower environmental impact by 10-36% when considering climate response objectives.

Generative AI for Business Analytics: New Paradigm, New Challenges

Community Committee Choice Session

Session Chair: Denghui Zhang, Stevens Institute of Technology, Hoboken, NJ

1 Learning to Generate with Small Data

Hua Wei, Arizona State University, AZ

This talk explores the strategies of data generation under the real-world setting of small data, i.e., the real-world data could be sparse and hard to obtain. The objective is to improve the accuracy and efficiency of data generation by training machine learning models to learn from real-world data. Specifically, this talk will introduce some of our latest work on traffic data, and the follow-up generative model and control model facing the small data.

2 Will ChatGPT Encourage Plagiarism and IP Infringement?

Denghui Zhang, Stevens Institute of Technology, NJ

This topic explores whether ChatGPT, a powerful language model, encourages plagiarism and IP infringement. It discusses the risks associated with relying solely on ChatGPT for content creation, highlighting how easy text generation may tempt users to plagiarize or infringe copyrighted material. Addressing this issue requires understanding responsible AI usage and adhering to ethical guidelines. By examining the implications of ChatGPT on plagiarism and IP infringement, this topic aims to foster a discussion on balancing AI capabilities and maintaining content integrity and legality.

3 Making Sense of Bot Moderation in Online Communities with Large Language Models

Zihan Chen, Lei Zheng, Feng Mai, Stevens Institute of Technology, Hoboken, NJ

Online communities employ diverse bots to moderate user activities, from identifying aberrant behaviors to fostering creativity. Although these bots provide automation, optimize workflows, and boost productivity, they also induce disruptions and unintended consequences detrimental to community survival. In this study, we harness Large Language Models to examine community perceptions, interpretations, and use of bots for various moderation tasks within online communities. By identifying key factors that influence decisions around bot adoption, we deliver novel insights into AI's role and effective bot governance in decentralized online communities. This research enriches the understanding of AI's societal impacts and aids in crafting efficient, accountable AI-based moderation tools for future use.

Learning Algorithm in Managing Service Systems

Community Committee Choice Session

Session Chair: Pengyi Shi, Purdue University, West Lafayette, IN

1 Branch-And-Price for Prescriptive Contagion Analytics

Michael Lingzhi Li, Harvard Business School, Boston, MA

Predictive contagion models are ubiquitous in epidemiology, social sciences, engineering, and management. This paper formulates a prescriptive contagion analytics model where a decision-maker allocates shared resources across multiple population segments, each governed by continuous-time dynamics. These problems feature a large-scale mixed-integer non-convex optimization structure with ordinary differential equations as constraints. We develop a branch-and-price methodology based on: (i) a set partitioning and column generation decomposition; (ii) a state-clustering algorithm for the pricing problem; and (iii) a tri-partite branching scheme to circumvent non-linearities. Extensive experiments demonstrate algorithm scalability, and it can save up to 12,000 extra saved lives over a three-month horizon in a COVID-19 vaccination campaign.

2 An Operational Perspective to Online Content Moderation

Tingrui Shi[1], Amir Anastasios Alwan[2], Rene A. Caldentey[3], Amy R. Ward[4], [1]The University of Chicago, Chciago, IL, [2]University of Chicago Booth School of Business, Pewaukee, WI, [3]The University of Chicago, Chicago, IL, [4]The University of Chicago Booth School of Business, Chicago, IL, Contact: tshi1@chicagobooth.edu

The rapid growth of social media users in recent years has led to an increase in the prevalence of harmful content on social media platforms, making online content moderation more important than ever. Content moderation systems nowadays highly rely on artificial intelligence (AI) due to the unprecedented scale of such systems. However, human reviewers are still essential for moderating ambiguous content and providing labels for the training of AI models. We use a Bayesian learning framework to model the AI's classification accuracy as a function of the labeling activities conducted by human reviewers. We derive a fluid approximation for our model and investigate the operational problem of optimally allocating the capacity of the human reviewers in order to minimize long-term misclassification and holding costs.

3 Approximate Dynamic Programming for Multiclass Scheduling Under Slowdown

Jing Dong[1], Berk Gorgulu[2], Vahid Sarhangian[3], [1]Columbia University, New York, NY, [2]University of Toronto, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada. Contact: bgorgulu@mie.utoronto.ca

In many service systems, service times of customers can be correlated with waiting times. Scheduling under such dependency is challenging as a Markovian state description requires keeping track of all customers' waiting history. We propose an approximate dynamic programming algorithm for multi-class scheduling with wait-dependent service times. Our algorithm can generate policies with simple structures and achieve strong performance which we illustrate in a healthcare setting using real data.

4 Inpatient Overflow Management with Proximal Policy Optimization

Jim Dai[1], Pengyi Shi[2], Jingjing Sun[3], [1]Cornell University & CUHK-Shenzhen, Ithaca, NY, [2]Purdue University, West Lafayette, IN, [3]Chinese University of Hong Kong, Shenzhen, Shenzhen, Guangdong Province, China

Overflow patients to non-primary wards can effectively alleviate congestion in hospitals, while undesired overflow also leads to issues like mismatched service quality. Therefore, we need to trade-off between congestion and undesired overflow. This overflow management problem is modeled as a discrete-time Markov Decision Process with large state and action space. To overcome the curse-of-dimensionality, we decompose the action at each time into a sequence of atomic actions and use an actor-critic algorithm, Proximal Policy Optimization, to update policy. Moreover, we tailor the design of neural network which represents policy to account for the daily periodic pattern of the system flows. Under hospital settings of different scales, the PPO policies consistently outperform some commonly used state-of-art policies significantly.

Sensor-Driven Forecasting, Operations and Maintenance in Energy Systems

Community Committee Choice Session

Session Chair: Murat Yildirim, Wayne State University, Detroit, MI

1 A Sensor-Driven Operations and Maintenance Planning Approach for Grid-Tied PV Solar Plants

Sakir Karakaya[1], Murat Yildirim[2], [1]Ministry of Science, Industry and Technology, Ankara, Turkey; [2]Wayne State University, Detroit, MI, Contact: sakir.karakaya@sanayi.gov.tr

This study proposes an integrated operations and maintenance planning model for PV solar plants, which are geographically distributed in different locations, to maximize total profit by minimizing total maintenance costs. The model harnesses sensor-driven data reflecting the degradation occurred in the performance of each unit including PV arrays, inverters, and transformers. It is characterized as a two-stage stochastic program in which demand and unit degradation are handled as uncertain; and optimal maintenance crew routing, preventive and corrective maintenance, and power generation decisions are made simultaneously. The experimental results show that the proposed model outperforms periodic and reliability-based maintenance policies in terms of optimum solution values obtained.

2 A Degradation Embedded Stochastic Optimization Framework For Maintenance And Inspection In Energy Systems

Muhammet Ceyhan Sahin[1], Deniz Altinpulluk[2], Murat Yildirim[1], Shijia Zhao[3], Feng Qiu[4], [1]Wayne State University, Detroit, MI, [2]Wayne State University, Clinton Township, MI, [3]ANL, Westmont, IL, [4]Argonne National Laboratory, Lemont, IL

This paper introduces a holistic framework for enhancing maintenance and inspection scheduling of marine energy systems. By integrating real-time sensor data, predictive analytics, and an innovative optimization model, the framework minimizes costs, extends asset lifespan, and boosts availability. It effectively handles degradation uncertainties through optimized maintenance, crew routing, and inspection. Experimental results on a 20-asset marine energy system validate its superiority over traditional methods.

3 A Physics-Guided Machine Learning Model for Wind Energy Forecasting and Its Value to Offshore Wind Operations

Feng Ye[1], Joseph Brodie[2], Travis Miles[3], Ahmed Aziz Ezzat[4], [1]Rutgers University, Piscataway, NJ, [2]AKRF Inc., New York, NY, [3]Rutgers University, Piscataway, NJ, [4]Rutgers University, Piscataway, NJ, Contact: fy97@soe.rutgers.edu

This presentation will consist of two parts: First, we present a physics-guided machine learning model for offshore wind energy forecasting, called AIRU-WRF. Second, we demonstrate how AIRU-WRF can be used as input to optimal short-term operations and maintenance decisions in offshore wind farms. Our experiments have been extensively tested using real-world data from the offshore wind energy areas in the NY/NJ Bight where several GW-scale offshore wind projects are soon to be operational.

4 A Robust Optimization Framework for Condition-Based Operations and Maintenance

Murat Yildirim[1], Deniz Altinpulluk[1], Farnaz Fallahi[1], Mohammad Javad Feizollahi[2], [1]Wayne State University, Detroit, MI, [2]Georgia State University, Atlanta, GA

We formulate a novel robust optimization model to manage operations, maintenance and degradation in multi-component systems. Our approach embeds degradation models within a robust optimization formulation to explicitly capture complex degradation uncertainties due to component-to-component interactions and operational loading. Comprehensive case studies demonstrate that the proposed approach offers significant improvements in reliability and cost.

Engineering-Informed Machine Learning for Additive Manufacturing

Community Committee Choice Session

Session Chair: Weizhi Lin, University of Southern California, Los Angeles, CA

Session Chair: Qiang Huang, University of Southern California, Los Angeles, CA

1 Process-Informed Small-Sample Learning of 2D Freeform Shapes in Additive Manufacturing Using Printing Primitives

Weizhi Lin[1], Yuanxiang Wang[2], Qiang Huang[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: weizhili@usc.edu

Additive manufacturing (AM) poses challenges for accuracy control due to complex geometries and limited training samples. This study proposes a small-sample learning approach for 2D freeform shapes through a process-informed dimension reduction strategy. The infinite-dimensional product space is transformed into a finite-dimensional printing primitive space via design segmentation. These primitives, comprising of smooth curve segments and non-smooth corners, effectively capture smooth deviation patterns and sharp transitions in shape profiles. Rather than analyzing the entire shape deviation, the model focuses on modeling printing primitive deviations, considering process-informed covariates including curvature, size, and location effects. The 2D shape deviation profile is then reconstructed by connecting predicted primitive deviations.

2 Physics-Informed Data-Driven Modeling for Generalizable Geometric Error Prediction and Compensation in Two-Photon Lithography

Sixian Jia[1], Jieliyue Sun[2], Andrew Howes[2], Michelle Dawson[2], Kimani C. Toussaint[2], Chenhui Shao[1], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Brown University, Providence, RI, Contact: sixianj2@illinois.edu

Two-photon lithography (TPL) is an additive manufacturing technique for creating micro-and nano-scale three-dimensional (3D) structures. Geometric compliance is crucial for ensuring the quality and functionality of TPL-produced 3D structures. This talk will present a novel, generalizable data-driven modeling framework based on physical principles to predict and compensate for geometric errors across structure designs and process parameters. The modeling framework decomposes geometric features into a global trend determined by process parameters and a local variation term representing small-scale spatial effects. Experimental results obtained from a large-scale experimental design will be presented to demonstrate the effectiveness of the proposed framework in terms of modeling accuracy, generalizability, and geometric compliance improvement.

3 Explainable AI for Layer-Wise Emission Prediction in Selecting Laser Melting

Vidita Gawade[1], Yuebin Guo[2], Weihong (Grace) Guo[1], [1]Rutgers, The State University of New Jersey, Piscataway, NJ, [2]Rutgers University-New Brunswick, Piscataway, NJ

The dynamic behavior of melt pools in select laser melting is very challenging to model using physics-based and conventional black-box data-driven models. Explainable Artificial Intelligence is developed in this work to advance the understanding of convoluted links of non-sequential process physics, online time series sensing data, and process anomaly (e.g., overheating in the melt pool). A Deep Neural Network-Long Short-Term Memory (DNN-LSTM) model integrates the process parameter knowledge with process history information through online sensing data. Three methodologies, namely, Shapley Additive Explanations (SHAP), Integrated Gradients (IG), and Local Interpretable Model-Agnostic Explanations (LIME) are implemented and compared to enable local and global model interpretation, transparency, and generalizability of the DNN-LSTM model.

4 Enhancing Data Privacy for Metal-Based Additive Manufacturing via Generative Diffusion Modeling

Durant Fullington, Starkville, MS

The objective of this research is to develop a de-identification mechanism for metal-based additive manufacturing (AM) process data, utilizing a generative diffusion modeling framework. The need for AM process data privacy stems from the growth of collaborative data sharing framework, used to develop robust *in-situ* anomaly detection models. However, data sharing frameworks can compromise the confidential design information within the AM process data. The proposed diffusion modeling approach provides a novel methodology by infusing print path de-identification measures into the image augmentation, resulting in a surrogate image with design information masked. This allows for more precise data de-identification and the ability to maintain data usability for anomaly detection, as the reconstructed images maintain similarity with the prior data distribution.

Collective Intelligence and Ambiguity Models

Contributed Session

Session Chair: Tri-Dung Nguyen, University of Kent, Canterbury, United Kingdom

1 Harnessing Collective Intelligence Under a Lack of Cultural Consensus

Necdet Gurkan[1], Jordan Suchow[2], [1]Stevens Institute of Technolgy, Hoboken, NJ, [2]Stevens Institute of Technology, Hoboken, NJ, Contact: ngurkan@stevens.edu

We present a nonparametric Bayesian model that extends Cultural Consensus Theory, a mathematical framework for inferring group consensus, by introducing a latent construct that maps between pre-trained deep neural network embeddings of an entity and the consensus belief amongst one or more subsets of respondents regarding those entities. We applied our extended CCT to various domains, including risk perceptions of technologies, leadership perception, first impressions of faces, and humor perception Compared to existing methods, our approach better leverages the underlying structure and interconnectedness of beliefs, contributing to a more comprehensive understanding of collective intelligence and serving as a potential foundation for consensus-aware information technologies.

2 Metawisdom of the Crowd: How Choice Within Aided Decision Making Can Make Crowd Wisdom Robust

Jon Atwell[1], Marlon Twyman[2], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA

Decision support systems present individuals with decision aids--discrete presentations of relevant information, frames, or heuristics--to enhance the quality and speed of decision making, but have the potential to bias group judgments by limiting predictive diversity. We redescribe the wisdom of the crowd as often starting with the choice of decision aids and define “metawisdom of the crowd” as when collective choice of aids leads to higher crowd accuracy than randomized assignment to the same aids, a comparison that accounts for the information content of the aids. In two experiments we find strong evidence of metawisdom. It comes about through diverse errors arising through the use of diverse aids, not through widespread use of the aids that induce the most accurate estimates; the microfoundations of crowd wisdom appear in the first choice.

3 Multidisciplinary Learning Through Collective Performance Favors Decentralization

John Meluso, Laurent Hébert-Dufresne, University of Vermont, Burlington, VT, Contact: john.meluso@uvm.edu

Members of multidisciplinary teams often complete distinct, interrelated pieces of larger tasks. This makes it difficult for individuals to separate the performance effects of their own actions from the actions of interacting neighbors. In this work, we show that individuals can also learn from network neighbors through artifacts (like performance metrics). When individuals innovate (“exploring” searches), dense networks hurt performance by increasing uncertainty. In contrast, dense networks help performance when individuals refine work (“exploiting” searches) by efficiently finding optima. We find that decentralization improves multidisciplinary team performance across a battery of 34 tasks, suggesting new design principles for multidisciplinary teams.

4 An Application of Smooth Ambiguity Model to Determine Value of Data

Saurabh Bansal[1], Ying He[2], [1]Penn State University, University Park, PA, [2]University of Southern Denmark, Odense, Denmark. Contact: yinghe@sam.sdu.dk

The performance of data-driven optimization and classification protocols typically depends on the quantity of data available. We use the Smooth Ambiguity Model to provide a new quantification of this performance. This quantification can help managers determine how much data to collect. We illustrate the application of this development in an industry setting.

5 Operations Research Games Under Uncertainty and Distributional Ambiguity

Tri-Dung Nguyen[1], Xuan Vinh Doan[2], [1]University of Kent, Canterbury, United Kingdom; [2]University of Warwick, Coventry, United Kingdom. Contact: tn264@kent.ac.uk

The aim of this paper is to address a fundamental challenge of incorporating uncertainty into cooperative games, particularly operations research games. We introduce a new solution concept of (robust) least chance decisions for cooperative games under uncertainty and distributional ambiguity, which is motivated by the concept of least core solutions for deterministic cooperative games. We develop a framework to find those decisions and compute their (robust) least chance dissatisfaction for cooperative games under normally distributed uncertainty and moment-based distributional ambiguity. We demonstrate how the framework can be applied to several operations research games including resource-sharing games, project selection games, and general linear production games with detailed analytical results.

CC-North 229A

Ensuring an Equitable Energy Transition

Community Committee Choice Session

Session Chair: Parth Vaishnav, University of Michigan, Ann Arbor, MI

1 Quantifying Confidence in Electricity Rate Plan Recommendations for Low-to-Moderate Income Homes in Detroit

Xavier Farrell, Johanna L. Mathieu, University of Michigan, Ann Arbor, MI

Electricity Rate Plan Recommender Systems (EPRS) are a class of tools developed to help electrical utility customers find rate plans that could save them money on their utilities. ERPS generate recommendations using past home energy usage data or other home specific features such as appliance ownership and occupancy. However, the homeowner's future electricity usage characteristics cannot be precisely predicted, and therefore, the same must be said about their future savings (or losses) obtained by adopting an EPRS recommendation. Thus, the homeowner must ask, how confident can they be that the recommended rate plan will incur the least cost relative to the alternatives. To answer this question, this work applies least-squares temperature dependent load modelling techniques and statistical bootstrapping methods to estimate confidence intervals for the next year's expected savings for each recommendation. The method is then applied to one year of hourly smart meter data for 800+ households in Detroit, MI. The confidence interval for the expected savings of each household is then validated against the each household's true savings in the following year as computed from the following year's energy usage data.

2 Introducing Environmental Justice Considerations into Grid Planning Models via Air Pollution Modeling to Develop Equitable Decarbonization Pathways

Jordan French, Sergio Castellanos, University of Texas at Austin, Austin, TX, Contact: jordanfrench@utmail.utexas.edu

Capacity expansion models have proven valuable for developing cost-optimized decarbonization portfolios for grid systems; however, air pollution and environmental justice impacts are often neglected or oversimplified. This work attempts to address this gap in the literature by pairing an open-source capacity expansion model with a pollutant dispersion model, to develop decarbonization pathways for California and Texas grids and model proposed natural gas plants' NOx emissions. The plants with the greatest environmental justice impacts are then restricted in another iteration of capacity expansion modeling, demonstrating the use of environmental justice constraints in the development of equitable grid decarbonization pathways.

3 Equity Benefits of Strategic Home Electrification

Kevin Kircher, Purdue University, West Lafayette, IN, Contact: kircher@purdue.edu

Replacing natural gas appliances by efficient electric alternatives can reduce greenhouse gas emissions and air pollution from residential buildings. A home that fully electrifies can also disconnect from the gas pipeline network, saving hundreds of dollars per year in connection fees. However, a gas utility's operating and maintenance (O&M) costs do not, in general, decrease as electrified homes disconnect gas service. Uncoordinated electrification can lead gas utilities to spread the same O&M costs over fewer homes, increasing connection fees for the homes that remain. This is an equity problem, as earlier adopters of modern electric appliances tend to be wealthier and whiter. This talk will illustrate how strategically electrifying at the neighborhood level can improve equity outcomes by enabling staged shut-down of pipeline sections.

4 Identifying Equitable Pathways to Heating Electrification in Rural, Northern Communities

Ana Dyreson[1], Chelsea Schelly[2], Dave Bohac[3], Roman Sidortsov[2], Adnan Hilal[1], Lester Shen[3], Josh Quinnell[3], [1]Michigan Technological University, Houghton, MI, [2]Michigan Technological University, Houghton, MI, [3]Minnesota Center for Energy and Environment, Minneapolis, MN, Contact: adyreson@mtu.edu

Beneficial electrification is considered imperative for widespread decarbonization of the economy, and planning this transition must consider the distribution of impacts across society. We focus on the impacts of electrification in rural, northern, communities, specifically to address the reliable and equitable transition of space heating to electricity and the use of rural land for wind, solar, and storage development. To assess the impacts on real communities, we work with three clusters of counties, one each in northern Minnesota, Wisconsin, and Michigan, with an emphasis on including the voices of Indigenous and post-industrial communities. This presentation describes the project's community engagement approach and the initial findings around perceptions and preferences around electric heat pumps and readiness of single-family homes for electrification.

5 Distributional Pricing and Impacts of Retail Electric Deregulation

Noah Dormady, The Ohio State University, Columbus, OH, Contact: dormady.1@osu.edu

Considerable research time and attention has been given to optimizing wholesale electricity markets and bulk power systems. However, very little attention is paid to consumer impacts for end users in retail energy markets. Retail electric deregulation, or 'retail choice' is considered a market-based policy that enables competition in retail markets. This paper evaluates the efficiency and distributional results from retail choice markets in a large retail deregulated state. It reports on database development consisting of every daily retail choice offer by every marketer in every investor-owned utility territory in Ohio for nearly ten years. It compares procurement auction-based pricing with the retail choice construct. A comparative distributional analysis is performed.

Policy-Enabling Models in the Power Sector

Community Committee Choice Session

Session Chair: Afzal Siddiqui, Stockholm University, Kista, Sweden

1 Dynamic Incentives for Flexible Electric Vehicle Charging

Nicolò Daina, Columbia University, New York City, NY, Contact: nd2741@columbia.edu

In the transition to full-electric road transportation, utilities, distribution system operators and policy makers need to ensure full coordination with the power grid. This requires flexibility in electric vehicles (EV) charging. Recent surveys of current UK and US EV drivers, highlighted that there is a general interest in smart charging programs, but there are concerns about partially losing control of the charging operation and that financial incentives are key. These attitudes are likely to be stronger amongst the general drivers' population, who is about to switch to electric cars. We present here a choice-based dynamic pricing/incentive approach to promote flexibility in EV charging choices, fully integrated with EV charging scheduling. Unlike typical choice-based demand management, our approach operates with real-time requests without pre-booking.

2 Equilibrium Uniqueness in a Wholesale Electricity Market with Renewable Generation and Demand Uncertainty

Ben Chaiken[1], Joseph Edward Duggan[2], [1]Parametric Portfolio Associates, Seattle, WA, [2]University of Dayton, Dayton, OH, Contact: bfchaiken@gmail.com

This work explores the uniqueness of Nash-Cournot equilibria in wholesale electricity markets with both thermal and renewable generation in the presence of demand uncertainty. We derive criteria guaranteeing a unique equilibrium for an energy market where each firm owns a share of renewable generation and analyze the effects of increasing renewable generation on the multiplicity of equilibria. This extends the

uniqueness results proven by Lagerlöf (2006) to a market model that incorporates renewable generation in the manner of Acemoglu et al. (2017).

3 An Analysis of Mitigating Measures for Inc-Dec Gaming in Market-Based Redispatch

Felipe VdS Araujo, Audun Midttun Systad, Jens Løken Eilertsen, Ruud Egging, NTNU, Trondheim, Norway. Contact: felipe.van.de.s.araujo@ntnu.no

Market-based redispatch enables the participation of more providers of flexibility in electricity markets. However, this design may allow for strategic behaviour by market participants. One strategy, inc-dec gaming, has been shown to aggravate electricity transmission congestions and reduce overall social welfare. We investigate mitigating actions against strategic behaviour in market-based redispatch. To test the impact of those actions, we developed a bi-level two-stage stochastic framework to represent day-ahead and balancing electricity markets. The agents' behaviour is modelled as an equilibrium problem with equilibrium constraints and solved through diagonalisation. The adverse effects on social welfare are in part reversed by the mitigating measures while at the same time introducing a trade-off between the welfare of the participants.

4 Build Back Better? Transmission Planning in an Imperfectly Competitive Power Sector with Environmental Externalities

Farzad Hassanzadeh Moghimi[1], Trine K. Boomsma[2], Afzal Siddiqui[1], [1]Stockholm University, Kista, Sweden; [2]University of Copenhagen, Copenhagen, Denmark. Contact: farzad@dsv.su.se

The power sector's decarbonisation requires an increase in variable renewable energy (VRE) capacity, which introduces production intermittency. The Nordic countries possess flexible capacities, but their incentives may not align with society's interests in a deregulated industry. To address this, we use a bi-level optimisation framework for transmission planning in a VRE-dominated power system. Our research aims to mitigate market imperfections and develop welfare-enhancing policy insights by answering two questions: (1) How should transmission planning be adapted to reduce the impact of market power in a 2030 decarbonisation scenario? (2) How are transmission capacities, generation adoption, and CO2 emissions affected if the damage cost from CO2 emissions is not fully reflected in the CO2 price?

Optimization and Machine Learning in Power Systems

Community Committee Choice Session

Session Chair: Minseok Ryu, Argonne National Lab

1 Differentially Private Algorithms for Synthetic Power System Datasets

Vladimir Dvorkin, Audun Botterud, Massachusetts Institute of Technology, Cambridge, MA

While power systems research relies on the availability of real-world network datasets, data owners (e.g., system operators) are hesitant to share data due to security and privacy risks. To control these risks, we develop privacy-preserving algorithms for the synthetic generation of optimization and machine learning datasets. Taking a real-world dataset as input, the algorithms output its noisy, synthetic version, which preserves the accuracy of the real data on a specific downstream model or even a large population of those. We control the privacy loss using Laplace and Exponential mechanisms of differential privacy and preserve data accuracy using a post-processing convex optimization. We apply the algorithms to generate synthetic network parameters and wind power data.

2 Employing Optimization Tools Developed by the Machine Learning Community to Solve Large Scale Power Flow Optimization Problems

Samuel Chevalier, Belgium

A number of highly successful optimization algorithms designed for training neural networks have emerged from the Machine Learning (ML) community in recent years. Such algorithms, however, are seldom used for solving the constrained optimization problems which are ubiquitous in power systems. In this talk, we report on the successes and challenges associated with solving large scale security constrained power flow optimization problems using two popular ML optimizers: Adam and L-BFGS. These tools are used in conjunction with a variety of penalization, projection, and clipping routines in order to find feasible, high-quality solutions to highly complex power system optimization problems.

3 Data-Driven Linearization for Optimal Power Flow

Terrence W K Mak, Monash University, Melbourne, Australia. Contact: Terrence.Mak@monash.edu

With increasing penetration of renewable and continuous development of smart grids, faster control and optimization techniques are needed. Recently, machine learning has been widely studied to speed up the computation of optimization tasks. Even though deep learning techniques can be extremely accurate, designing/tuning deep learning architectures for the whole problem is nontrivial and retraining these architectures to cope with changing operational/engineering decisions may not be feasible on the field. Instead of learning the whole problem, the work investigates on extracting and learning a ***common subproblem - the nonlinear power flow.*** Data augmentation and learning frameworks will be presented, and linear approximation for the original problem will be discussed. Preliminary results on AC optimal power flow and load restoration problems will be shown.

4 Forecasting and Asset Bundling for Renewable Energy

Hanyu Zhang[1], Mathieu Tanneau[2], Pascal Van Hentenryck[1], [1]ISyE Georgia Tech, Atlanta, GA, [2]Georgia Tech, Atlanta, GA

Renewable energy raises new challenges in forecasting and market-clearing operations for power systems. Their volatility and the sheer number of distributed renewable assets create significant challenges that have not been encountered before. This presentation reviews recent progress in forecasting wind and solar energy sources and in preparing these forecasts for use in stochastic optimization. In particular, the presentation reviews the use of transformer architectures for forecasting large-scale time series arising in renewable energy, as well as novel optimization algorithms for bundling time series.

New Modeling Perspectives for Low Carbon Power Systems

Community Committee Choice Session

Session Chair: Olivier Massol, IFP School, Rueil-Malmaison, France

Session Chair: Tim Schittekatte, MIT, Cambridge, MA

1 Exploring the Mechanics of Hybrid Markets for Electricity

Alexis Lebeau[1], Olivier Massol[2], [1]CentraleSupélec & EDF, Palaiseau, France; [2]IFP School, Rueil-Malmaison, France. Contact: alexis.lebeau@edf.fr

The idea that electricity market design models should evolve in the context of the energy transition is gaining momentum. In particular, it is argued that the traditional Energy-Only Market model needs to be complemented with a long-term framework for investments and retirements. The process of defining how this long-term framework should be implemented is only being initiated, however, and market designers have many dimensions and possible options to explore. As a contribution to this endeavor, this paper analyzes one possible hybrid design option relying on long-term contracts and phase-out compensations through a quantitative exercise based on optimization and dynamic simulations.

2 SDDP Models of Demand Response : A Promising Framework and Applications to Europeans Case Studies

Julien Ancel[1], Olivier Massol[2,1], [1]LGI, CentraleSupélec, Paris, France; [2]IFP School, Rueil-Malmaison, France. Contact: julien.ancel.2018@polytechnique.org

Demand Response (DR) is frequently mentioned as a key source of flexibility in renewable-energy-dominated power systems.
This work shows how SDDP, a computationally efficient solution technique designed by (Pereira and Pinto, 1991), may be used to model DR in an efficient way, enabling to bypass tractability issues at the expense of some convexity constraints in the model design. Traditional SDP models fail to account for the temporal granularity and far-off horizons necessary to account for all aspects of DR value.
The estimation of optimal hourly operations of a RES-dominated power system that minimize the expected total system cost over an entire year is proposed. This stochastic model allows several sources of DR from diverse end-uses to be incorporated. It is applied to West European situations, representing existing systems or prospective future systems.

3 Community/Committee'S Choice Submission

Alva J. Svoboda, PG&E, Oakland, CA, Contact: alva.svoboda@gmail.com

Post-transition daily electricity markets will rely on carbon-free energy and dispatchable storage to meet forecast demands. We argue that the California day ahead and real time market designs, although developed for fossil-fuel driven generation resources, may be equally well-suited to a carbon-free resource mix.

Decision Diagrams for Optimization

Community Committee Choice Session

Session Chair: Anthony Karahalios, [1]</sup

1 Domain-Independent Dynamic Programming: Generic State Space Search for Combinatorial Optimization

Ryo Kuroiwa[1], J. Christopher Beck[2], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: jcb@mie.utoronto.ca

We propose Domain-Independent Dynamic Programming (DIDP), a novel model-based paradigm for combinatorial optimization based on dynamic programming (DP). In DIDP, a problem is formulated as a DP model and a generic solver solves it. In recent work, we have introduced Dynamic Programming Description Language (DyPDL), a formalism to define a DP model, and developed a generic solver, CAASDy, based on state space search. In subsequent work, we have also developed anytime solvers, which quickly find a feasible solution and continuously improve it to optimality. Empirical evaluations show that our solvers outperform mixed-integer programming and constraint programming in multiple combinatorial optimization problems.

2 A New Formulation for Parallel Machine Scheduling Using Decision Diagrams

Roel Leus[1], Daniel Kowalczyk[2], Christopher Hojny[3], Stefan Ropke[4], [1]KU Leuven, Leuven, Belgium; [2]University of Leuven, Leuven, Belgium; [3]TU Eindhoven, Eindhoven, Netherlands; [4]Technical University of Denmark, Herlev, Denmark

We present a new formulation for parallel machine scheduling with a regular objective function and without idle time. The formulation is constructed with the help of a decision diagram that represents all job sequences that respect specific ordering rules. These rules rely on a partition of the planning horizon into, generally non-uniform, periods and do not exclude all optimal solutions, but they constrain solutions to adhere to a canonical form. The new formulation has numerous variables and constraints, and hence we apply a Dantzig-Wolfe decomposition in order to compute the linear programming relaxation in reasonable time; the resulting lower bound is stronger than the bound from the classical time-indexed formulation. We develop a branch-and-price framework that solves several instances from the literature for the first time.

3 Column Elimination: Solving Discrete Optimization Problems Using Arc Flow Formulations

Anthony Karahalios, Willem-Jan van Hoeve, Carnegie Mellon University, Pittsburgh, PA, Contact: akarahal@andrew.cmu.edu

Column Elimination is a recently developed method for solving discrete optimization problems. The method has shown competitive results for solving graph coloring and vehicle routing problems when compared to branch-and-cut-and-price. This presentation outlines the general column elimination method. We show how to model a discrete optimization problem as an arc flow formulation that can be solved by column elimination, highlight differences with column generation based methods, and present experimental results for three fundamental combinatorial optimization problems.

4 Network Flow Models for Robust Binary Optimization with Selective Adaptability

Ian Yihang Zhu, Merve Bodur, Timothy Chan, University of Toronto, Toronto, ON, Canada

Adaptive robust optimization problems have received significant attention in recent years. In this talk, we propose a new set of reformulation techniques for two-stage adaptive robust binary optimization problems with objective uncertainty (ARBO). We focus, without loss of generality, on ARBO problems with “selective adaptability”, which describe a common class of linking constraints between first-stage and second-stage solutions. We employ decision diagrams to derive various constrained network flow models that provide exact and approximate reformulations of the ARBO problem. In contrast with existing solution methods, these models are easier to implement and solve with standard mathematical programming solvers. We show through a set of numerical experiments that these models offer a number of computational advantages.

Ride-Share Applications

Contributed Session

Session Chair: Kirit Ghosh, Indian Institute of Management, Calcutta, Kolkata, India

1 Assortment Optimization Under the Generalized Markov Chain Choice Model for Revenue Management of Parking Reservation Service

Pengyu Yan[1,2], Haoyu Xie[2], Sentao Miao[3], Xiaoqiang Cai[4], Kaize Yu[2], [1]Yangtze Delta Region Institute (Huzhou),University of Electronic Science and Technology of China, Huzhou, China; [2]University of Electronic Science and Technology of China, Chengdu, China; [3]McGill University, Montreal, QC, Canada; [4]The Chinese University of Hong Kong, Shenzhen, China. Contact: 202121150122@std.uestc.edu.cn

This paper addresses a revenue management problem for a parking reservation service platform (APP) that offers parking lots to drivers for destinations in surrounding areas. The drivers choose parking lots based on pricing and occupancy rates, and make reservations with certain probabilities, with the option to transfer to another lot with a transferring probability. To model the drivers' comparison and choice behaviors, we adopt a generalized Markov chain choice model. Based on this, we study an assortment optimization problem to maximize the expected revenue of the platform. Unlike existing research on consumers' choice behavior, this study incorporates comparative choices into the model and proposes a polynomial-time algorithm that is proven to be optimal. Numerical experiments demonstrate the effectiveness and efficiency of the proposed model and algorithm.

2 Managing Uberization: Strategies for an Automobile Manufacturer in the Presence of Strategic or Loyal Consumers

Kirit Ghosh, Indian Institute of Management, Calcutta, Kolkata, India. Contact: kiritg19@iimcal.ac.in

'Uberization,' which refers to on-demand services through platforms, has impacted the automobile industry immensely. This paper studies the impact that the firms which offer on-demand ride-hailing or renting services have on a car manufacturer, with consumers being strategic or loyal to the manufacturer. We develop a two-period model with varying usage and show that ride-hailing is more detrimental to the manufacturer under certain conditions. The manufacturer's optimal strategies include collaborating with the uberizing firm or floating its own platform, even with an incentive offered to the users, depending on certain conditions. We propose a fixed fee in addition to revenue sharing based on platform fee, leading to a win-win situation.

2 Driver Persuasion and Fleet Redeployment

Yingda Zhai[1], Andrew B. Whinston[2], [1]National University of Singapore, Singapore, Singapore; [2]University of Texas-Austin, Austin, TX, Contact: yingdazhai@nus.edu.sg

We study optimal information design for efficient fleet redeployment in ride-sharing market. A market designer, who is better informed on the demand distribution, can provide private signal to sway driver's beliefs and induce efficient routing coordination. We characterize the optimal persuasion scheme under a credible persuasion in a repeated Bayesian coordination game. Compared to surge pricing, the information design improves matching efficiency with lower cost.

On Solving Large-scale Optimization on GPU

Community Committee Choice Session

Session Chair: Kibaek Kim, Argonne National Laboratory, Lemont, IL

1 On the Geometry and Refined Rate of Primal-Dual Hybrid Gradient for Linear Programming

Jinwen Yang[1], Haihao Lu[2], [1]University of Chicago, Chicago, IL, [2]University of Chicago Booth School of Business, Chicago, IL, Contact: jinweny@uchicago.edu

Linear programming (LP) is a fundamental class of optimization problems with various practical applications. Recently, there is a new trend of researches on using first-order methods (FOMs) for LP with the goal to further scale up LP by taking advantage of distributed computing. A notable example is the implementation of PDLP, an FOM LP solver that is based on primal-dual hybrid gradient (PDHG). Despite its numerical success, the theoretical understanding of PDHG for LP is far from complete; its existing complexity result depends on the global Hoffman constant of the KKT system, which is known to be very loose and uninformative. In this work, we aim to develop a fundamental understanding of the geometric behaviors of PDHG for LP as well as a refined complexity rate that is not relied on the global Hoffman constant. We show that there are two major stages of PDHG for LP: in Stage I, PDHG identifies active variables and the length of the first phase that is driven by a certain quantity which measures the closeness to degeneracy; in Stage II, PDHG effectively solves a homogeneous linear inequality system, and the complexity of the second stage is driven by a well-behaved local sharpness constant of the system. This finding is closely related to the concept of partial smoothness in non-smooth optimization, and it is the first complexity result of partial smoothness without the non-degeneracy assumption. Our results suggest that degeneracy itself does not slow down the convergence, but near-degeneracy does.

2 Community/Committee'S Choice Submission
François Pacaud, [1</sup]

3 Solving Unit Commitment with ACOPF on GPU
Kibaek Kim, Argonne National Laboratory, Lemont, IL
We present a GPU algorithm for solving unit commitment with alternating current optimal power flow (UC-ACOPF). The algorithm is based on alternating direction method of multiplier that enables our novel decomposition of UC-ACOPF for many small computations on GPU. We compare the numerical results from solving the test problems on CPU and GPU.

4 Solving Large-Scale Nonlinear Optimization on GPU by HiOP
Nai-Yuan Chiang, Jingyi Wang, Cosmin Petra, Lawrence Livermore National Laboratory, Livermore, CA
HiOp is a suite of HPC optimization solvers for some large-scale nonconvex nonlinear programming problems (NLPs). It is a lightweight HPC solver that leverages application's existing data parallelism to parallelize the optimization iterations by using specialized linear algebra kernels. Using RAJA portability abstraction layer, HiOp can solve large-scale NLPs entirely on GPU, i.e., user input model, algorithm, and linear solvers all deal with data on GPU. We will present the latest implementation of HiOp and some numerical studies from power system applications in this talk.

Applications on Individual consumption and financial decision making

Contributed Session

Session Chair: Wenqi Zhou, Duquesne University, Pittsburgh, PA

1 Doing Well by Being Well: Corporate Wellness Programs and Incentives to Exercise
Yongqin Lei, Ivey Business School, Western University, London, ON, Canada. Contact: ylei.phd@ivey.ca
Many employers provide wellness programs that offer financial incentives to employees for exercising, as healthier employees are generally more productive and incur lower health insurance costs covered by employers. However, wellness programs are not always effective because people may renege on their commitments to exercise. We then investigate the optimal design of wellness programs regarding the structure and size of financial incentives.

2 Digital Consumption and Consumer Self-Control
Zheng Wu, Jiong Sun, Purdue University, West Lafayette, IN, Contact: wu1252@purdue.edu
The harmful effects of digital over-consumption become increasingly severe. The goal of our research is to analytically examine how consumers exercise self-control and how for-profit firms' pricing schemes (subscription versus pay-per-use) and product design strategies affect their profit, consumer surplus, and consumers' long-term health. Our findings indicate that firms' pricing schemes and their impact on consumers' long-term well-being are dependent on consumer characteristics and the nature of product category being consumed.

3 Examining Individuals' Retirement Planning Behavior - The Contributions Of Proactive Decision-making
Florian Blösl[1], Johannes Ulrich Siebert[1], Reinhard Erich Kunz[2], Jana Siebert[3], [1]Management Center Innsbruck, Innsbruck, Austria; [2]Bauhaus-Universität Weimar, Weimar, Germany; [3]n/a, Innsbruck, Austria. Contact: florian.bloesl@mci.edu
The influence of financial literacy and numeracy on retirement planning behavior is well-established. A second strand of research focuses on the impact of psychological determinants on retirement planning behavior. Our understanding of which forces lie underneath such psychological determinants still needs to be improved. By considering proactive decision-making, a construct recently developed in behavioral operations research, we intend to provide valuable inputs to the current discourse. Based on hypotheses derived from theory, we expect proactive decision-making to positively impact psychological determinants. These psychological determinants further shape individuals' retirement planning behavior. In conclusion, we contribute to the emerging psychology literature in behavioral finance.

4 The Societal Impact of Ridesharing Through Gig-Economy Employment: Opportunities and Equality
Ayush Sengupta, University of Connecticut, Storrs, CT, Contact: ayush.sengupta@uconn.edu

We investigate the widely debated discussion on the overall social and economic welfare that ridesharing platforms generate through gig-economy employment. The online gig economy may help alleviate financial stressors in the economy and benefit society by providing employment and income with less bias and improving people's financial situation. However, an adverse impact on welfare may arise through a reduction in wages, a stagnation of career growth and income progressions, increasing disparities in the workforce, and reduced job opportunities in the associated traditional industries. We answer this question empirically by examining the impact of Uber's entry on income inequality, geographic migration, and community health. Our findings offer insights for policymakers to devise policies to improve social welfare and alleviate social and economic inequality.

5 Privacy Decisions: The Roles of Individual'S Mindset and the Default Setting

Wenqi Zhou, Georgiana Craciun, Duquesne University, Pittsburgh, PA, Contact: zhouw@duq.edu

Recent privacy scandals have stirred increased interest in understanding consumers' decisions on privacy protection and disclosure. This research compares the privacy decisions of individuals with two different mindsets: *maximizers* who strive for the best possible choice, and *satisficers* who accept a good enough option. An online experiment was conducted to manipulate mindsets and default privacy settings. The results show that individuals lean towards the default privacy setting, particularly maximizers. For example, when asked to choose a privacy option for "post on your private page", satisficers are 3.16 times more likely and maximizers are 8.21 times more likely to choose 'Everyone' when presented with the 'Everyone' default (vs. 'Only Me' default).

Recent Advances in Network Optimization: Theory and Applications

Community Committee Choice Session

Session Chair: Ningji Wei, Texas Tech University, Lubbock, TX

1 Finding the Most Degree-Central Shortest Path in a Weighted Graph

Johnson Phosavanh[1], Dmytro Matsypura[2], [1]The University of Sydney, Sydney, Australia; [2]The University of Sydney, Sydney, Australia. Contact: johnson.phosavanh@sydney.edu.au

The degree centrality of a path, defined to be the number of nodes connected to it, can be used to measure the relative importance of a path in the network. In this study, we consider the problem of finding the most degree central shortest path in a graph with weighted edges. This extends on recently published work studying the unweighted version of this problem. By modifying Dijkstra's algorithm, we show that the weighted version of the problem is solvable in polynomial time, and this new algorithm is more efficient than the existing algorithm for unweighted graphs. We conduct a numerical study of our algorithm on synthetic and real-world networks, and we compare our results to the existing literature.

2 A Human-Trafficking Bilevel Network Interdiction Problem

Daniel Lopes da Silva[1], Thomas Sharkey[2], Yongjia Song[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: dlopesd@clemson.edu

We introduce a human-trafficking based bilevel network interdiction problem where the follower's (trafficker) objective is to maximize network flow whereas the leader's (an anti-trafficking agent) objective is to minimize the number of arcs from a special set with flow on them. We develop single-level reformulations for both, the optimistic and pessimistic cases, and discuss complexity, challenges, and computational results.

3 An Integrated Framework to Improve the Resiliency of Electricity Distribution Systems Exposed to Wildfires

Prasangsha Ganguly[1], Sayanti Mukherjee[2], Jose L. Walteros[3], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo - The State University of New York, Buffalo, NY, [3]University at Buffalo, Buffalo, NY, Contact: prasangs@buffalo.edu

We develop an optimization framework for designing strategic wildfire prevention policies that involve preemptive practices, such as electricity infrastructure hardening and public safety power shutoffs. Unlike existing studies that consider the pre- and post-wildfire event decisions separately, our approach models the interaction between the preemptive strategic actions, the wildfire propagation, and the post-event operational decisions in a unified framework. We propose a tri-level network interdiction model to mitigate the worst possible disruption due to a wildfire. We observed that the hardening strategies are fundamental to improving the resilience of the overall electricity infrastructure, and the public safety power shutoff events are beneficial to reduce the detrimental effects on the electricity infrastructure.

4 Leveraging Decision Diagrams to Solve Two-Stage Stochastic Programs with Binary Recourse and Logical Linking Constraints

Moira MacNeil, University of Toronto, Toronto, ON, Canada

We convexify the second-stage of two-stage stochastic programs (2SPs) with binary recourse using binary decision diagrams (BDDs) in order to use Benders decomposition algorithm. We first generalize an existing BDD-based approach to allow settings where logical expressions of the first-stage solutions enforce constraints in the second stage. We propose a complementary problem where second-stage objective coefficients are impacted by logical expressions of the first-stage decisions, and develop a distinct BDD-based algorithm to solve this novel problem class. We incorporate conditional value-at-risk and propose, to our knowledge, the first decomposition method for 2SPs with binary recourse and a risk measure. We apply these methods to a novel stochastic dominating set problem and present numerical results to demonstrate the effectiveness of the methods.

Infectious disease prevention and control using non-pharmaceutical and/or pharmaceutical interventions

Community Committee Choice Session

Session Chair: Buse Eylul Oruc Aglar, [1</sup]

1 Evaluation of Covid-19 Transmission and the Impact of Mitigation Measures in Cruise Ships Using an Agent-Based Model

Akane Fujimoto Wakabayashi[1], Pinar Keskinocak[1], Sarah Bowden[2], [1]ISyE Georgia Tech, Atlanta, GA, [2]Center for Disease Control and Prevention, Atlanta, GA, Contact: afujimoto@gatech.edu

Cruise ship operations were heavily disrupted during the COVID-19 pandemic. Close quarters and dense populations of domestic and international travelers are an environment where viruses can spread easily. The cruise industry and public health partners continue to develop guidelines to control the spread of disease in this setting.

We developed an agent-based model to simulate COVID-19 spread in cruise ship settings and evaluate the effectiveness of various combinations of mitigation measures, such as masking and routine SARS-CoV-2 testing. We assumed different demographics and social network interactions for passengers and crew. The results provide insights for public health decision-makers and the modeling framework can inform other modeling activities that rely on similar data streams.

2 Model to Estimate Hiv-Care Benefits from Treating Depression in Persons with Hiv in the United States

Md Hafizul Islam, Centers for Disease Control and Prevention (CDC), Atlanta, GA

Depression is prevalent among persons with HIV (PWH) and is associated with poorer adherence and lack of viral load suppression (VLS). Adequate treatment of depression can improve retention in HIV care and medication adherence. However, depression among PWH is not adequately diagnosed or treated. In this work, we describe adaptation of Progression and Transmission of HIV (PATH 3.0), a U.S. agent-based dynamic stochastic simulation model, to incorporate a continuum of depression care. We estimated the impact on VLS of an enhanced depression diagnosis and care scenario compared to a status quo scenario, following assumptions based on the literature. Our findings showed that fully diagnosing and adequately treating depression among all PWH would result in a nearly 5% increase in expected rate of VLS in the United States over ten years, supporting national prevention goals.

3 The Economic Burden of Chronic Hepatitis C Infections in the United States, 2010-2019

Hasan Symum[1], Taiwo Abimbola[1], William Thompson[2], Michelle Van Handel[1], [1]Centers for Disease Control and Prevention, Atlanta, GA, [2]Centers for Disease Control and Prevention, Atlanta, GA

Over 2 million people in the U.S. have hepatitis C virus (HCV) infection, which can lead to serious medical complications and substantial economic burden. This study aims to update the estimated economic burden of hepatitis C in the U.S., including lifetime direct medical costs. Incidence-based cost methods were used to calculate expected lifetime medical cost per case with and without sequelae. Using claims data and the provider perspective, direct medical costs were estimated using inpatient, outpatient, and emergency department encounters. Cost per case of treated and untreated hepatitis C after first medical encounter and diagnosis were followed through disease stages (i.e., fibrosis stage, liver disease, liver transplantation) were produced. Updated costs of hepatitis C can inform resource allocation decisions for the U.S. hepatitis C elimination strategy.

4 Non-Stationary Spatio-Temporal Point Process Modeling for High-Resolution Covid-19 Data

Zheng Dong[1], Shixiang Zhu[2], Yao Xie[3], Jorge M. Mahiques[4], Francisco J. Rodríguez-Cortés[5], [1]Georgia Institute of Technology, Atlanta, GA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Georgia Institute of Technology, Atlanta, GA, [4]Universitat Jaume I, Valencia, Spain; [5]Universidad Nacional de Colombia, Medellín, Colombia. Contact: zdong76@gatech.edu

Most COVID-19 studies commonly report figures of the overall infection at a state- or county-level, which tends to miss out on fine details of virus propagation. In this work, we analyze a high-resolution COVID-19 dataset in Cali, Colombia, that records the precise time and location of every confirmed case. We develop a non-stationary spatio-temporal point process equipped with a neural network-based kernel to capture the heterogeneous correlations among COVID-19 cases. The kernel is carefully crafted to enhance expressiveness while maintaining model interpretability. We also incorporate exogenous influences imposed by city landmarks. Our approach outperforms the state-of-the-art in forecasting COVID-19 cases with the capability to offer vital insights into the spatio-temporal interaction between individuals concerning the disease spread in a metropolis.

5 Modeling the Vaccination Interventions to Control the Spread of Circulating Vaccine-Derived Poliovirus Type 2 Outbreaks

Yuming Sun[1], Pinar Keskinocak[1], Stephanie Kovacs[2], Lauren N. Steimle[1], Steven Wassilak[2], [1]Georgia Tech ISyE, Atlanta, GA, [2]CDC, Atlanta, GA, Contact: ysun608@gatech.edu

Polio is a debilitating disease which can cause paralysis. The global polio eradication program responds to polio outbreaks using oral poliovirus vaccine (OPV). However, the attenuated live virus in OPV can, in rare cases, revert to regain neurovirulence and cause outbreaks in areas with low population immunity. We built a compartmental model to capture dynamics of poliovirus transmission involving OPV virus reversion. We evaluated different outbreak response strategies and quantified the impact of distributing limited vaccines doses across subpopulations considering age groups and geography. We performed a numerical study in northern Nigeria given its ongoing poliovirus transmission.

Humanitarian and Non-Profit Operations

Community Committee Choice Session

Session Chair: Eunae Yoo, Indiana University, Bloomington, IN

1 Fleet Composition Management of Humanitarian Organizations in Response to Armed Conflicts

Telesilla Olympia Kotsi[1], Maria Besiou[2], Alfonso Pedraza-Martinez[3], [1]The Ohio State University, Columbus, OH, [2]Kuehne Logistics University, Hamburg, -, Germany; [3]Indiana University, Bloomington, IN, Contact: kotsi.1@osu.edu

We investigate transportation expenses of a humanitarian organization (HO) that operates in armed conflict settings. We combine a multi-year proprietary data set to study fleet decisions of vehicle rentals and subcontracting. Rentals are relatively expensive but do not permit security breaches because nonprofit authorized staff members drive the rented vehicles. Subcontracting is relatively cheap but permits security breaches because subcontracted drivers outside the nonprofit drive the cars. We use econometric models to find that in areas of armed conflict the HO prefers vehicle rentals to subcontracting.

2 Anti-Corruption and Humanitarian Aid Management in Ukraine

Paola Martin[1], Owen Wu[1], Larysa Yakymova[2], [1]Indiana University, Bloomington, IN, [2]Yuriy Fedkovych Chernivtsi National University, Chernivtsi, Ukraine. Contact: owenwu@indiana.edu

The flow of humanitarian aid in response to Russia's invasion of Ukraine was unprecedented. Regulating aid delivery to prevent loss and misuse due to corruption is crucial. However, strengthening anti-corruption efforts is costly. This cost is part of the total financial aid and it therefore comes at the expenses of people in need. In this study, we analyze this tradeoff in Ukraine's humanitarian aid management. Using game theory, we model the interaction between a government agency and distribution managers. The optimal inspection intensity balances benefits and costs, maximizing the amount of humanitarian aids delivered to the beneficiaries.

3 Sharing the Schedule: Nonprofit Staffing for Volunteers and Employees

Mariana Escallon Barrios, Karen Smilowitz, Northwestern University, Evanston, IL

Recent research in volunteer management has explored how online scheduling platforms can be used to balance volunteer preferences with organizational needs. Strategically assigning staff to the schedule can help to improve supply/demand balance while keeping volunteers engaged. We explore two scheduling strategies, considering organizational and volunteer satisfaction metrics. We present a numerical study to compare the policies under different scenarios of supply, demand, and volunteers' preferences.

4 Crypto Rewards in Fundraising: Evidence from Crypto Donations to Ukraine

Xue (Jane) Tan[1], Yong Tan[2], [1]Southern Methodist University, Dallas, TX, [2]University of Washington, Seattle, WA, Contact: janetanxue@gmail.com

Leveraging the crypto donations to a Ukrainian fundraising plea that accepts Ether (i.e., the currency of the Ethereum blockchain) and Bitcoin (i.e., the currency of the Bitcoin blockchain) over a seven-day period, we analyze the impact of crypto rewards. Separately, we find that crypto rewards have a positive impact on the donation count but a negative impact on the average donation size for donations from both blockchains. Comparatively, we further find that the crypto rewards lead to an 812.48% stronger donation count increase for Ethereum than Bitcoin, given that the crypto rewards are more likely to be issued on the Ethereum blockchain. We also find a 30.1% stronger decrease in average donation amount from Ethereum for small donations (<=$250); the rewards pose similar impacts on the average donation size for the two blockchains for large donations (>$250).

Scheduling in Practice

Community Committee Choice Session

Session Chair: Emrah Cimren, Amazon, Issaquah, WA

1 Optimizing New Hire Event Appointments

Emrah Cimren, Cheng Yuting, Amazon, Seattle, WA

In the hourly job application process at the Amazon's hiring web site, a candidate creates an application, accepts a contingent offer, consents to a background check, and books an in-person office hour called New Hire Event. This study describes the development and evaluation of scheduling system based on mixed-integer optimization for the New Hire Event appointment planning.

2 On-Line Scheduling for the 1-Machine Preempt-Restart Problem

Sheng Guo, Marc E. E. Posner, The Ohio State University, Columbus, OH, Contact: posner.1@osu.edu

A lower bound on the relative error for the online 1-machine sum of completion time preempt-restart problem was found in 1997. While improvements have been made, the competitive ratio is not known. We find a best possible online algorithm. In doing so, we improve the current bound by 0.006.

3 Scheduling for Minimizing the Input Buffer Size

Bertrand Lin[1], Shunji Tanaka[2], [1]National Yang Ming Chiao Tung University, Hsinchu, Taiwan; [2]Kyoto University, Kyoto, Japan

We investigate a single-machine scheduling problem to minimize the size of a finite-capacity input buffer. In this problem, each job is assigned to the machine at its release date and started immediately or sent to the input buffer to wait for processing. The problem in this study is to find a schedule that minimizes the required size of the input buffer. Its strong NP-hardness will be shown first, and next, a pseudo polynomial timedynamic program will be developed for the ordinary NP-hard special case. Three integer programming models are presented using different formulation approaches. Numerical experiments appraise the effectiveness of the formulations.

Service Models for Senior Care

Community Committee Choice Session

Session Chair: Kejia Hu, Vanderbilt University

Session Chair: Yixuan Liu, 1</sup

1 Effectiveness of Telemedicine in Stroke Care: An Empirical Study on a Telestroke Network

Sriram Venkataraman[1], Brandon Lee[2], Lawrence Fredendall[3], Kejia Hu[4], [1]University of South Carolina, Columbia, SC, [2]University of Dayton, Dayton, OH, [3]Clemson University, Clemson, SC, [4]Vanderbilt University, Nashville, TN, Contact: sriram.venkataraman@moore.sc.edu

Using proprietary data from a telestroke network, we study the impact of telestroke on a patient's length of stay (LOS) and patient quality. We find that patients using the telestroke facility have, on average, shorter LOS in the focal hospital and have better quality outcomes. In addition, we explore heterogenous effects.

2 On-Demand Healthcare Platforms: Impact of Q&A Service on Online Consultations and Offline Appointments

Yixuan Liu[1], Ashish Agarwal[2], Guoming Lai[3], Weihua Zhou[4], [1]China Europe International Business School (CEIBS), Shanghai, China; [2]University of Texas at Austin, Austin, TX, [3]The University of Texas at Austin, Austin, TX, [4]Zhejiang University, Hangzhou, China. Contact: yixuanliu@ceibs.edu

The emerging on-demand healthcare platforms connect patients with healthcare practitioners to provide quick access to medical services. These platforms can offer a Q&A service to the patients to seek more information before they seek care online or offline. Using rich panel data from an on-demand healthcare platform in China, we investigate the impact of such a Q&A service on demands for online consultations and offline appointments. Our findings indicate that the Q&A service has a complementary effect on the demand for both channels. Furthermore, we demonstrate that the spillover effects of the Q&A service vary across different medical specialties and among providers of different professional titles. Finally, our results show that the use of the Q&A service reduces the need for future consultations and information-seeking behavior.

3 Does Information Technology Mitigate the Healthcare Geospatial Disparity? an Examination of Healthcare Information Exchange

Yao Zhao[1], Dongwon Lee[2], Hillol Bala[3], [1]HKUST, Kowloon, Hong Kong; [2]HKUST, Kowloon, Hong Kong; [3]Indiana University, Bloomington, IN, Contact: yzhaocq@connect.ust.hk

Healthcare Information Exchange (HIE) enables healthcare providers to share patients' medical information. While HIE is touted as a potential solution to address healthcare geospatial disparities, its impact on reducing inequality between urban and rural hospitals remains unclear. Using data envelopment analysis (DEA) to construct health professionals' productivity measure and applying the difference-in-differences approach, we reveal that hospitals with HIE adoption experience a significant increase in health professionals' productivity. However, this effect is only pronounced in urban hospitals but not rural hospitals, suggesting that HIE adoption might exacerbate healthcare geospatial inequalities. Besides, we find that HIE adoption improves communication and clinical decision-making quality among urban but not rural health professionals.

4 Structural Equation Modeling to Improve the Experience of Kiosk use in the Elderly: A Study Based on Survey Analysis Results

Junho Lee, Hosun Rhim, Korea University Business School, Seoul, Korea, Republic of. Contact: jheric98@korea.ac.kr

With the advent of the information age, many stores are expanding the use of self-ordering machines (kiosks). This study aims to analyze the factors that cause discomfort for elderly people, who are vulnerable to using such machines. A survey will be conducted among the elderly population, and Structural equation modeling (SEM) will be used to identify the fundamental factors that affect their use of kiosks. This will help develop strategies to alleviate the barriers faced by the elderly population in adopting digital technology.

New Business Model Innovation

Community Committee Choice Session

Session Chair: Burcu Tan, University of New Mexico

1 Strategic Investments for Platform Launch and Ecosystem Growth: A Dynamic Analysis

Burcu Tan[1], Edward G. Anderson[2], Geoffrey Parker[3], [1]University of New Mexico, Albuquerque, NM, [2]University of Texas-Austin, Austin, TX, [3]Dartmouth College, Hanover, NH, Contact: btan@unm.edu

We study a two-sided platform startup's optimal new product development investment and pricing decisions over a multi-period life-cycle. We characterize optimal dynamic policies for different monetization models (commission vs 1- or 2-sided subscriptions) and ecosystem regimes including business-to-consumer vs. business-to-business, varying same-side and cross-side externalities, and product development agility.

2 Economic and Environmental Implications of Ride-Hailing and the Vehicle Age Limit Requirements

Vishal Agrawal[1], Ioannis Bellos[2], Natalie Ximin Huang[3], [1]Georgetown University, Washington, [2]George Mason University, Fairfax, VA, [3]University of Minnesota, Minneapolis, MN, Contact: huangx@umn.edu

We study an important decision for ride-hailing platforms, namely, imposing a vehicle age limit. The limit influences not only the price and service quality of ride-hailing, but also its competition with the primary and secondary car sales markets. We explore both the economic and environmental implications of this decision.

Machine Learning Applications in Operational Problems

Community Committee Choice Session

Session Chair: Yaron Shaposhnik, University of Rochester, Chicago, IL

1 Convex Surrogate Loss Functions for Contextual Pricing with Transaction Data

Max R. Biggs, University of Virginia, Charlottesville, VA

We study an off-policy contextual pricing problem where a seller has access to transaction data with historical prices offered and whether individual customers purchased. This contrasts with the well-studied setting in which samples of the customer's valuation (willingness to pay) are observed. We propose convex loss functions, in particular a generalization of the hinge and quantile loss functions adapted to the pricing setting, that provide expected revenue guarantees when optimized. We avoid estimating an intermediate demand function, which aside from being indirect, may lead to a challenging non-linear revenue optimization problem if complex machine learning models are used. In contrast, when linear pricing policies are desired, our proposed loss functions result in a tractable convex revenue optimization problem.

2 Learning to Solve Two-Stage Robust Optimization Problems

Jean Pauphilet, London Business School, London, United Kingdom

Two-stage optimization problems, like the joint inventory placement and shipping problem, are notoriously hard to solve because future decisions depend on the realization of uncertain parameters (e.g., demand). Inspired by the ML paradigm, we use data and unsupervised learning techniques to design provably optimal schemes for two-stage adjustable robust optimization problems that converge orders of magnitude faster than existing schemes.

3 Quantile Regression with a Strictly Convex Objective

Xiaojia Guo, Robert H. Smith School of Business, University of Maryland, College Park, College Park, MD, Contact: xjguo@umd.edu

Some algorithms, such as extreme gradient boosting (xgboost), allow for a customized objective function and require the function to be strictly convex. These algorithms use Newton's method to find point forecasts by minimizing a strictly convex loss function. In this paper, we introduce a strictly convex loss function for quantiles that can be used in these algorithms. The loss function we propose is a (smooth) convexification of any member of the class of proper scoring rule for a quantile, such as the pinball loss function. We demonstrate the use of our loss function on several publicly available datasets. The results suggest that quantiles estimated by xgboost using our convexified loss function may be more accurate than those estimated by other leading methods.

4 Physician Rostering Problem with Downstream Capacity Constraints

Yashi Huang[1], Arik Senderovich[2], Yaron Shaposhnik[1], [1]University of Rochester, Rochester, NY, [2]York University, Toronto, ON, Canada. Contact: yhu126@simon.rochester.edu

We study a physician rostering problem whereby providers are scheduled to weekly sessions during which they examine and consult patients. The sessions serve as a central coordination mechanism which determines the timing of preparatory as well as treatment activities that are scheduled around exams. We collaborate with a large hospital that specializes in cancer treatment, and develop an interactive interface that predicts demand for resources as well as optimizes the roster to improve load-balancing. We conduct numerical experiments to assess the potential improvement that can be obtained by optimizing the roster.

High-Dimensional Tensor Data Analytics

Community Committee Choice Session

Session Chair: Bo Shen, New Jersey Institute of Technology, Newark, NJ

1 Privacy-Preserving Tensor Decomposition for Health Data Analysis

Meng Zhao, University OF Florida, Gainesville, FL

Electronic health records (EHRs) have been one of the most important sources of information about patients. In this paper, we proposed a novel federated tensor factorization model for computational phenotyping from health data without sharing patient-level data. We developed secure data harmonization and federated computation procedures. Using this method, the multiple hospitals iteratively update tensors and transfer secure information to a central server, and the server aggregates the information to generate phenotypes. The evaluation of both simulations and real medical datasets demonstrates that our method resembles the centralized training model (based on combined datasets) in terms of accuracy while respecting privacy.

2 Tensor Gaussian Process with Contraction for Multi-Channel Imaging Analysis

Yang Chen, University of Michigan, Ann Arbor, MI

Multi-channel imaging data is a prevalent data format in scientific fields such as astronomy and biology. The structured information and the high dimensionality of these 3-D tensor data makes the analysis an intriguing but challenging topic for statisticians and practitioners. The low-rank scalar-on-tensor regression model, in particular, has received widespread attention and has been re-formulated as a tensor Gaussian Process (Tensor-GP) model with multi-linear kernel in previous work. We extend the Tensor-GP model by integrating a dimensionality reduction technique with a Tensor-GP for a scalar-on-tensor regression task with multi-channel imaging data. We validate our approach via extensive simulation studies and applying it to the solar flare forecasting problem.

3 Jointly Modeling and Clustering Tensors in High Dimensions

Biao Cai, 1</sup

We consider the problem of jointly modeling and clustering populations of tensors by introducing a high-dimensional tensor mixture model. To effectively tackle the high dimensionality of tensor objects, we employ plausible dimension reduction assumptions that exploit the intrinsic structures of tensors. In estimation, we develop an efficient high-dimensional ECM algorithm that breaks the intractable optimization in the M-step into a sequence of conditional optimization problems. Our theoretical analysis is challenged by both the non-convexity in the EM-type estimation and having access to only the solutions of conditional maximizations in the M-step. We demonstrate that the proposed HECM algorithm, with an appropriate initialization, converges geometrically to a neighborhood that is within statistical precision of the true parameter.

Explainable Artificial Intelligence for Business Analytics

Community Committee Choice Session

Session Chair: Salih Tuntun, 1</sup

1 Understanding Factors Affecting Crash Injury Severities in Multi-Vehicle Crashes Using Explainable Analytics

Ismail Abdulrashid[1], Kazim Topuz[2], [1]The University of Tulsa, Tulsa, OK, [2]The University of Tulsa, Tulsa, OK, Contact:

ismail-abdulrashid@utulsa.edu

Transparent models aid decision-makers in comprehending their judgments and fostering confidence in analytics. This study proposes a comprehensive descriptive, predictive, and prescriptive model to explain the severity of automobile accidents. In addition, we utilize a variety of cutting-edge techniques to address data-related issues, select features, develop predictive modeling, optimize parameters, and separate explanations from models (i.e., model-agnostic interpretation techniques). Our findings provided domain experts with novel insights into accident severity. The output of our model is an understandable representation of crash severity factors. The findings' implications for traffic control stakeholders, policymakers, automakers, the government, and regulators are discussed.

2 Screening Patients for Mental Disorders with New XAI Approach

Salih Tutun[1], Anol Bhattacherjee[2], Kazim Topuz[3], Ali Tosyali[4], Gorden Li[5], [1]Washington University in St. Louis, Chesterfield, MO, [2]University of South Florida, Tampa, FL, [3]University of Tulsa, Tulsa, OK, [4]Rochester Institute of Technology, Rochester, NY, [5]Bosch Center of Artificial Intelligence, Sunnyvale, CA

Mental disorders impact nearly one billion people globally and resulting in significant economic burdens. With a shortage of psychiatrists, experts call for innovative technology to efficiently screen patients. We develop the MDscan, a novel algorithm for screening ten mental disorders using SCL-90-R data. It offers transparency with an explainable, enhancing trust in AI applications for clinical use. Key features include: (1) using proper clinical protocols with psychological data, (2) employing an XAI approach that can not only predict diseases but also explain what features led to that prediction, and (3) generating a full-color diagnostic image that maps ten mental disorders similar to that of radiological images. Field data demonstrates MDscan's 20 percent average improvement, while maintaining high explainability.

Advances in Time Series Data Mining

Community Committee Choice Session

Session Chair: Adam Meyers, University of Miami, Miami, FL

1 Recurrence Plot Quantification Analysis for Time Series Mining

Adam Meyers, University of Miami, Miami, FL, Contact: axm8336@miami.edu

A recurrence plot (RP) visualizes the times at which a dynamical system revisits areas of its phase space, and recurrence quantification analysis (RQA) quantifies the patterns shown in a RP. RQA provides a means of quantitative analysis of highly nonlinear and nonstationary time series while not requiring certain distributional assumptions and reduces the impact of noise on signal analysis through time delay embedding. Despite these advantages, the potential of RQA for time series mining has not been fully explored. This talk will discuss how bivariate RQA methods, which compare two distinct time series, can be utilized for nonlinear temporal similarity assessment. Bivariate RQA, including cross and joint RQA, will be compared against widely used methods such as dynamic time warping, both in terms of methodology and in performance on several time series datasets.

2 Enhancing Bearing Fault Diagnosis in Manufacturing Through Vibration Signal Feature Extraction and 2D Image Embedding with CNN Models

Yongmin Kim, Hyunsoo Yoon, Yonsei University, Seoul, Korea, Republic of. Contact: dsym2894@yonsei.ac.kr

In the realm of manufacturing, a bearing defect can disrupt an entire system. However, recent research employing deep learning for defect diagnosis has faced challenges related to integration of both raw signals and textual information. Moreover, the interpretation of these results has been difficult. To address these limitations, we propose an innovative framework that entails extracting features from vibration signal features, embedding them into 2D images, and leveraging CNN models for analysis. Our method outperforms other competing methods and enhances result interpretation via Grad-CAM. It significantly improves the accuracy and efficiency of bearing fault diagnosis, making it applicable in practical industrial settings.

3 Personalized Choice Model for Forecasting Pricing Scenarios with Observational Data - the Case of Attended Home Delivery

Ozden F. Gur Ali[1], Pedro Amorim[2], [1]Koc University, Istanbul, Turkey; [2]INESC-TEC, Porto, Portugal. Contact: oali@ku.edu.tr

Personalization in discrete choice models substantially increases individual-context level choice prediction accuracy. But naïve personalization with regularization to handle high-dimensional data often results in misleading price sensitivity estimates. Orthogonalization of the outcome and price with respect to confounders avoids the problem. We introduce features that relate an alternative to potential consideration sets to allow non-proportional substitution patterns and improve accuracy. The proposed method avoids positive price sensitivity and is twice as accurate as the non-personalized MNL at the individual-context level in the attended home delivery slot choice.

4 Spectral Clustering with Dependent Excitations for Temporal Networks

Subhadeep Paul[1], Lingfei Zhao[1], Hadeel Soliman[2], Kevin Xu[3], [1]The Ohio State University, Columbus, OH, [2]University of Toledo, Toledo, OH, [3]Case Western Reserve University, Columbus, OH, Contact: paul.963@osu.edu

Temporal networks observed through timestamped relational events data are commonly encountered in applications, including online social media, human mobility, financial transactions, and international relations. Temporal networks often exhibit community structure and strong dependence patterns among node pairs. We combine high-dimensional, mutually-exciting Hawkes processes with the stochastic block model to model community structure and node pair dependence. We obtain an upper bound on the misclustering error of spectral clustering of the event count matrix as a function of the number of nodes and communities, time duration, and a quantity measuring the amount of dependence in the model. The theoretical results provide insights into the effects of dependencies in the mutually-exciting Hawkes processes on the accuracy of spectral clustering.

Information Systems and Consumers

Community Committee Choice Session

Session Chair: Shengjun Mao, University of California-Irvine, Irvine, CA

1 Offline Franchisees Boost Customer Trust on the Onlinebrand: Evidence from Online Retailer Franchiser

Shengjun Mao[1], Fei Ren[2], [1]The University of Hong Kong, Hong Kong, China; [2]Peking University, Beijing, China

This study explores cross-channel effects of adding an offline channel to online retailers via franchising, wherein physical stores are operated under the brand name of the online retailer but are possessed by individual owners. Using a panel dataset from a giant online retailer, we adopt a difference-indifferences (DID) approach to identify the causal effects of opening offline franchisee stores on sales and customer purchase of the online retailer. The results show that opening franchisee stores does not cannibalize sales of the online retailer but increase purchases especially of light buyers. We also inspect the mechanism and find that customers with physical stores opening nearby are more likely to make a payment online in advance, suggesting that simple presence of offline stores boost the credibility of the online retailer.

2 Crowdsourcing Contests: A Choice Among Multiple Contests

Lior Fink[1], Sharon Rabinovitch[1], Ella Segev[2], [1]Ben gurion university of the negev, Beer Sheba, Israel; [2]Hebrew University of Jerusalem, Jerusalem, Israel. Contact: ella.segev@mail.huji.ac.il

Given the proliferation of platforms for crowdsourcing contests, we combine game theoretic and experimental research to determine what affects a solver's decision which of the multiple ongoing contests to participate in and how much effort to exert. In the literature on crowdsourcing contests there are inconsistent findings about the behavioral effects of increasing the prize awarded by the organizer on solvers. We aim to resolve these inconsistencies by analyzing user behavior in a controlled experimental setting in which users can exert real effort in multiple online contests that vary only in their prizes. We show that both participation and effort are non-monotonic with the prize, that the low-prize contest was the most effective for the organizers, and that increasing the prize of the low-prize or high-prize contest actually decreased the benefits for organizers.

3 A Graphical Point Process Framework for Multi-Touch Attribution

Qian Chen[1], Jun Tao[2], James W. Snyder Jr.[2], Arava Sai Kumar[2], Amirhossein Meisami[2], Lingzhou Xue[3], [1]Pennsylvania State University, STATE COLLEGE, PA, [2]Adobe Inc., San Jose, CA, [3]Penn State University, State College, PA, Contact: quc20@psu.edu

Marketers employ various online advertising channels to reach customers and are particularly interested in attribution -- measuring the degree to which individual touchpoints contribute to an eventual conversion. We aim to tackle the problem with finer granularity by conducting attribution at the customer purchase path level. To this end, we develop a novel graphical point process framework to study the direct conversion effects and the full relational structure among numerous types of touchpoints simultaneously. Utilizing the temporal point process of conversion and the graphical structure, we further propose graphical attribution methods to allocate proper path-level conversion credit, called the attribution score, to individual touchpoints or corresponding channels for each customer's path to purchase.

1 Impact of Customer-Initiated Recommendations on Binge Consumption of Digital Content

Hanbing Xue[1], Jinan Lin[2], Natasha Zhang Foutz[3], Yongjun Li[1], [1]University of Science and Technology of China, Hefei, China; [2]UC Irvine, Irvine, CA, [3]University of Virginia, Charlottesville, VA

This research empirically investigates the impact of customer-initiated recommendations on intra-day and inter-day binge consumption of e-book content. Leveraging granular reading records of 142,000 customers, customer-initiated recommendations as natural experiments, and Difference-in-Differences (DiD) analysis, we discover novel heterogeneous impacts of customer-initiated recommendations on binge across time, recommendation types (e.g., popularity- vs personalization-based, human vs AI), and customer segments. The findings offer strategic guidance to digital content platforms regarding for instance how to balance shorter-term engagement and longer-term customer retention.

4 Moviebert: Learning Latent Traits Through Language Models to Tackle the Cold-Start Problem

Ming Gu, UCI, Irvine, CA

Pre-trained language models using large-scale datasets have been proven to have state-of-the-art performance in various downstream natural language processing tasks like text classification, named entity recognition, machine translation, question answering, and sentiment analysis. However, whether they can help with consumer preference understanding remains untapped. This paper tries to bridge this void by developing a MovieBERT model that learns the latent features of movies from public access text data like plots and descriptions from studios and mapping the hidden features with user preference data from Movielens. We validate the model performance on a holdout sample and find this branch of language models capable of predicting movie success in different user groups, suggesting a potential to tackle the cold-start problem in recommender systems.

Digital Platform and AI

Community Committee Choice Session

Session Chair: Shun Ye, George Mason University, Fairfax, VA

1 Negative Emotions, Impoliteness, and Fundraising Success in Educational Crowdfunding

Yasamin Hadavi[1], Xunyi Wang[1], Robin Wakefield[1], Stacie Petter[2], [1]Baylor University, Waco, TX, [2]Wake Forest University, Winston-Salem, NC

We examine the factors impacting crowdfunding success in a donation-based educational crowdfunding context. In particular, we focus on the effects of expressed impoliteness and negative emotions in the crowdfunding project description on fundraising success and the moderating role of a contextual factor, socioeconomic status, on those effects. Using a proprietary dataset from a leading educational crowdfunding platform and survival analyses, we find there is a negative effect of the expressed impoliteness on the likelihood of fundraising success, but the expression of negative emotions is positively associated with fundraising success. Additionally, the school's socioeconomic status positively relates to fundraising success, and it moderates the relationship between impoliteness/negative emotions on fundraising success.

2 Impact of AI on Reviews and Outcomes

Rachit Kamdar, Siva Viswanathan, University of Maryland, College Park, MD, Contact: rkamdar@umd.edu

The importance of online reviews in reducing information asymmetry and disseminating information has been widely acknowledged in the academic literature. However, the under-provision of reviews remains a persistent challenge for online platforms. In this study, we investigate the use of AI technology to facilitate review writing and answer three critical research questions of who uses AI-generated text, how users utilize such text, and the impacts of AI-generated text on review outcomes. Our findings reveal a bias among negative reviewers to adopt AI-generated text. Furthermore, we find that AI-adopting users become more polar in their opinions following the adoption. Our study also demonstrates that reviews with AI-generated text are more diverse and shorter in length. However, the helpfulness of reviews decreases after the usage of AI-generated text.

3 What Makes Successful Entrepreneurs in Online Crowdfunding? Unraveling the Role of Educational and Professional Background

Shuai Zhang[1], Zhiyi Wang[1], Lusi Yang[2], [1]University of Colorado Boulder, Boulder, CO, [2]Georgia State University, Atlanta, GA, Contact: shuai.zhang-1@colorado.edu

Crowdfunding has emerged as a transformative avenue for democratizing entrepreneurship and investment activities through digital platforms. In traditional venture capital, the founder's prior background has consistently been regarded as a crucial factor for entrepreneurship and investment decisions. However, our understanding of how the prior background of founders manifests in online crowdfunding is limited. In this study, we draw on the literature on human and social capital, and examine how founders' educational and professional background affects crowdfunding outcomes. By combining empirical data from the leading crowdfunding platform and professional network, we theorize and empirically test the heterogeneous effects of educational and professional backgrounds and the interplay between them.

4 Examining the Impact of Marketplace Introduction in Crowdsourcing Contest Platforms

Fanshu Li, Pallab Sanyal, Shun Ye, George Mason University, Fairfax, VA, Contact: fli15@gmu.edu

Businesses leverage crowdsourcing platforms as a valuable resource to address challenging problems and fulfill their business needs. While holding contests has long been popular in crowdsourcing platforms, the introduction of the "Marketplace" feature offers an alternative approach by providing instant access to a wide range of readily available solutions. In this study, we examine how the introduction of the Marketplace affects market dynamics and outcomes in a crowdsourcing platform. Our findings show that the introduction of the Marketplace leads to a win-win situation for both solvers and businesses. More experienced solvers are attracted to sell their solutions directly in the Marketplace to address clients' immediate needs; meanwhile, less experienced solvers who remain in contests experience an increase in their winning probabilities.

Financial Frictions and Machine Learning

Community Committee Choice Session

Session Chair: Chen Yang, The Chinese University of Hong Kong, Shatin

Session Chair: Nan Chen, Chinese University of Hong Kong, Shatin N T, NA, Hong Kong

1 Optimal Dividend Strategy with Endogenous Bankruptcy Boundary Under Chapter 11

Steven Kou[1], Jianwei Lin[2], H. Mete Soner[3], Chen Yang[4], [1]Boston University, Boston, MA, [2]Putian University, Putian, China; [3]Princeton University, Princeton, NJ, [4]The Chinese University of Hong Kong, Shatin, China. Contact: kou@bu.edu

The Chapter 11 bankruptcy grants a distressed company a grace period to recover before eventual liquidation. We study Chapter 11 bankruptcy strategies for a company with an endogenous dividend strategy. The model is formulated as a two-stage optimization problem. We show that the optimal dividend strategy is of barrier type and derive its closed-form solution. Compared to the existing Chapter 11 literature with exogenous dividend strategies, we found that while the presence of Chapter 11 bankruptcy still results in higher shareholders' value, it can have the side effects of encouraging more aggressive dividend strategies, which leads to earlier liquidation. Furthermore, such side effects are stronger when Chapter 11 allows for a longer grace period or provides the shareholders with a great incentive benefit.

2 Optimal Investment in the Presence of Limit Order Book

Nan Chen[1], Min Dai[2], Qiheng Ding[3], Chen Yang[4], [1]Chinese University of Hong Kong, Shatin N T, NA, Hong Kong; [2]National University of Singapore, Singapore, Singapore; [3]The Chinese University of Hong Kong, Hong Kong, China; [4]The Chinese University of Hong Kong, Shatin, Hong Kong

We study an optimal investment problem of a CARA investor trading in a market operated with a block-shaped limited order book (LOB), which synergizes three key features of market microstructure: the bid-ask spread, the market depth, and a finite market resilience. Under a Bachelier process for the dynamic of the fundamental value of the asset, we develop explicit characterization on the investor's optimal trading strategy. As an important extension of this model, an asymptotic expansion of the optimal trading strategies in the presence of return-predicting signals are also derived. The theoretical and numerical results unveil how an investor should strike a balance among several competing goals such as achieving the optimal risk exposure currently, incorporating signals about the future, and minimizing trading costs.

3 Non-Concave Utility Maximization with Transaction Costs

Shuaijie Qian, Harvard University, Cambridge, MA, Contact: e0046854@u.nus.edu

We consider the non-concave utility maximization problem, which appears in plenty of areas in finance, with transaction costs. Technically, we propose a proper terminal condition and lay the corresponding theoretical foundation of viscosity solutions. This terminal condition implies that any transaction close to maturity provides a marginal contribution to the target. We find that non-concave utility + transaction costs can prevent the portfolio from unbounded leverage and also result in richer action regions than classical transaction costs problems with concave utilities.

4 Designing Structured Products on Traded Accounts

Zihao Song, The Chinese University of Hong Kong, Hong Kong SAR, China

Structured products on traded accounts are financial products whose payoff depends on a trading account managed by the buyer. In this paper, we study how to design these products from the perspectives of both buyers and sellers, and our model features both the transaction costs in the trading account and the buyer's risk aversion. The buyer's problem is formulated as a singular stochastic control problem with a nonconcave objective, and the seller's contract design strategy is characterized as a Stackelberg game. We design a numerical procedure to study it. We find that the risk-averse buyer's willing price is much smaller than the risk-neutral price in the literature, and the buyer's optimal trading strategy is significantly more complicated. For the seller's perspective, it is optimal to offer a contract to less risk-averse buyers meanwhile with lower market volatility.

Learning and Decision-making for Marketplaces

Community Committee Choice Session

Session Chair: Wanning Chen, University of Washington, Bellevue, WA

Session Chair: Amandeep Singh, 1</sup

1 Optimal Exploration is No Harder than Thompson Sampling

Zhaoqi Li, University of Washington, Seattle, WA, Contact: zli9@uw.edu

This paper proposes an efficient algorithm for pure exploration in linear bandits using sampling and argmax oracles. Given a set of arms in R^d, the pure exploration problem aims to return the arm with the maximum reward through noisy measurements. Existing optimal methods scale in the size of the arm set by requiring either costly projections for each arm or explicitly maintaining an active subset of the arm set at each time. In general, computing projections and maintaining a subset may be expensive and unfeasible in many settings. Our approach overcomes both limitations through *sampling* from an appropriate distribution over parameters combined with an argmax oracle. It achieves computational efficiency similar to Thompson sampling but guarantees the optimal instance-dependent rate asymptotically, unlike Thompson sampling, which is suboptimal for pure exploration.

2 Low-Rank Matrix Recovery with Non-Quadratic Loss: Projected Gradient Method and Regularity Projection Oracle

Lijun Ding, University of Wisconsin -- Madison, Madison, WI, Contact: lijunbrianding@gmail.com

Most low-rank matrix recovery theories focus on quadratic loss, which enjoys favorable properties such as restricted strong convexity/smoothness (RSC/RSM) and well conditioning over all low rank matrices. However, many interesting problems involve more general, non-quadratic losses, which do not satisfy such properties. In this paper, we show that a critical component in provable low-rank recovery with non-quadratic loss is a regularity projection oracle. Accordingly, we analyze an (averaged) projected gradient method equipped with such an oracle, and prove that it converges globally and linearly. Our results apply to various non-quadratic low-rank estimation problems, including one bit matrix sensing/completion, individualized rank aggregation, and more broadly generalized linear models with rank constraints.

3 Algorithmic Governance of Two-Sided Platforms: The Case of Short Video Recommendation

Jinghui Zhang[1], Xuan Bi[2], Qiang Wei[1], Mochen Yang[2], [1]Tsinghua University, Beijing, China; [2]University of Minnesota, Minneapolis, MN

We study how two-sided platforms can tackle governance problems with algorithmic tools (in addition to economic incentives). Taking short video platforms as the context, we design an integer program allowing the platform to achieve two key governance objectives: maximizing ad revenue while mitigating exposure disparity among producers. We conduct evaluations on a public dataset from KuaiShou (a leading short video platform in China), and find that our approach can generate content recommendations that lead to both higher platform revenue and lower producer exposure disparity, as compared to the common practice of greedy recommendation. Further analyses reveal interesting dynamics between recommendation strategies and governance outcomes.

4 Community/Committee'S Choice Submission

Arpit Agarwal, 1</sup

5 The Art of Transfer Learning - An Adaptive and Robust Pipeline

Boxiang Wang[1], Yunan Wu[2], Chenglong Ye[3], [1]University of Iowa, Iowa City, IA, [2]The University of Texas at Dallas, Dallas, TX, [3]University of Kentucky, Lexington, KY, Contact: chenglong.ye@uky.edu

Transfer learning is an essential tool for improving the performance of primary tasks by leveraging information from auxiliary data resources. In this work, we propose Adaptive Robust Transfer Learning (ART), a flexible pipeline of performing transfer learning with generic machine learning algorithms. We establish the non-asymptotic learning theory of ART, providing a provable theoretical guarantee for achieving adaptive transfer while preventing negative transfer. Additionally, we introduce an ART-integrated-aggregating machine that produces a single final model when multiple candidate algorithms are considered. We demonstrate the promising performance of ART through extensive empirical studies on regression, classification, and sparse learning. We further present a real-data analysis for a mortality study.

On the Vehicle Routing Problem

Contributed Session

Session Chair: Merarsylan Meraliyev, SDU University, Almaty, Kazakhstan

1 Accelerating Column Generation via Column Management and Smart Graph Reduction for Solving Vehicle Routing Problems

Qiyao Duan, Mingyao Qi, Tsinghua University, Shenzhen, China. Contact: qimy@sz.tsinghua.edu.cn

Column generation (CG) is a widely used and powerful iterative technique for solving a wide range of combinatorial optimization problems, such as the Vehicle Routing Problem with Time Windows (VRPTW). Two critical difficulties of CG are column management for the Master Problem and the NP-hardness of the Sub Problem. In this paper, we present two novel learning-based approaches to overcome the two aforementioned challenges, thus accelerating CG. We first propose a reinforcement learning column manager to select promising columns from the generated ones to maintain a strong formulation of Master Problem. We then develop a graph neural network driven node selection model that accurately identifies the nodes that are most likely to be included in the optimal solution of the Sub Problem. Experiments demonstrate that the proposed approaches boost the CG significantly.

2 Two-Stage Learning to Branch in Branch-Price-And-Cut Algorithms for Solving Vehicle Routing Problems Exactly

Zhengzhong You, The University of Florida, Gainesville, FL

We propose a novel two-stage learning-to-branch framework for vehicle routing problems (VRPs) within branch-price-and-cut algorithms. Unlike traditional branch-and-cut methods, this framework addresses the challenges of variable generation and indirect variable branching. Stage one utilizes effective features from the graph to identify promising branching candidates. Stage two employs computationally expensive features to predict high-quality final branching decisions. This two-stage learning-based branching (2LBB) strategy outperforms traditional strategies, showing improvements in both speed and efficiency when tested on benchmark CVRP and VRPTW instances.

3 Machine Learning to Solve Vehicle Routing Problems: A Survey

Aigerim Bogyrbayeva, Meraryslan Meraliyev, Taukekhan Mustakhov, Bissenbay Dauletbayev, Suleyman Demirel University, Kaskelen, Kazakhstan. Contact: meraryslan.meraliyev@sdu.edu.kz

This paper provides a systematic overview of machine learning methods applied to solve NP-hard Vehicle Routing Problems (VRPs). Recently, there has been a great interest from both machine learning and operations research communities to solve VRPs either by pure learning methods or by combining them with the traditional hand-crafted heuristics. We present the taxonomy of the studies for learning paradigms, solution structures, underlying models, and algorithms. We present in detail the results of the state-of-the-art methods demonstrating their competitiveness with the traditional methods. The survey indicates the advantages of the machine learning based models that aim to exploit the symmetry of VRP solutions. The paper outlines the future research directions to incorporate learning-based solutions to overcome the challenges of modern transportation systems.

Analysis of Delivery Speed in Online Retailing

Contributed Session

Session Chair: Shuhan Kou, University of Maryland, College Park, College Park, MD

1 To Launch Online Community Group Buying or Not: The Channel Choice of E-Commerce Platform

Jianghua Wu[1], Longdi Chen[2], Yuhong He[3], [1]Renmin University of China, Beijing, China; [2]Renmin University of China, Beijing, China; [3]California State University-Fullerton, Fullerton, CA

In addition to the existing same-day delivery, many e-commerce platforms(e.g, Meituan and Freshhema) have launched online community group buying which reduces last-mile delivery. The platform orders products from suppliers and assigns a leader of the group to promote products in a community. This pre-order strategy may bring up conflict to the current channel with same-day delivery. This study aims to explore how customer acceptance of the group buying, the commission rate for the leader, and the operational cost difference across two channels affect the platform's channel choice and the group leader's effort.

2 Inventory Redistribution for Promotional Products with Demand Learning

Mahsa Abbaszadeh Nakhost[1], Gudrun Kiesmüller[2], Stefan Minner[1], [1]Technical University of Munich, Munich, Germany; [2]Technical University of Munich, Heilbronn, Germany. Contact: mahsa.nakhost@tum.de

We address a lateral transshipment problem among N retailers who sell a promotional product for which historical data is lacking and has a long lead-time. Such products have a single ordering opportunity and exhibit highly uncertain, non-stationary demands. We model the demand with a non-homogeneous Poisson Process with an unknown mean and update the demand distribution before the one-time transshipment using Bayesian methodology. We prove that the expected profit after transshipment is L -Concave in relation to the value of transshipment. Our numerical analysis reveals there is a single time of transshipment that maximizes profit. We evaluated our methodology in a real-world case study and found that it significantly improved profit.

3 Discount or Speed?: An Analysis of Reward Offer in Exchange for No-Rush Shipping

Pavarit Issarathipya[1], Thunyarat (Bam) Amornpetchkul[2,1], [1]National Institute of Development Administration, Bangkok, Thailand; [2]Santa Clara University, Santa Clara, CA, Contact: tamornpetchkul@scu.edu

This research investigates how a no-rush shipping reward program, which offers a discount or a reward to a customer who chooses no-rush shipping for her online purchased items, can be utilized by an online seller to reduce shipping and expediting costs. The seller's optimal decisions regarding whether to offer a no-rush shipping reward program on any items and whether to ship each item separately or together at a normal or expedited speed are characterized. Our results show that the number of items that the seller should offer the no-rush shipping reward program decreases as the amount of reward required to induce a customer opt-in increases. This research suggests that a no-rush shipping reward program can help online sellers reduce operating and shipping costs as well as the environmental impact, while also meeting customers' expectation.

4 The Probabilistic Rural Postman Problem

Shuhan Kou[1], Bruce L. Golden[2], Luca Bertazzi[3], [1]University of Maryland, College Park, College Park, MD, [2]University of Maryland, College Park, College Park, MD, [3]University of Brescia, Brescia, Italy. Contact: shkou@umd.edu

A delivery person is responsible for package deliveries in an area. However, in practice, not all customers require a delivery everyday. Thus, we cast our problem as the probabilistic rural postman problem (PRPP). The aim of this problem is to determine the a priori tour with the minimum expected length for a given set of edges or arcs that may have positive demand. In this work, we formally define the PRPP and discuss several properties, including how it's related to the deterministic counterpart: the rural postman problem (RPP).

Creative Applications of AI

Contributed Session

Session Chair: Nicolas Bustos, University of South Florida, Tampa, FL

1 Automatic Discovery and Generation of Visual Design Characteristics: Application to Visual Conjoint

Ankit Sisodia[1], Vineet Kumar[2], Alex Burnap[1], [1]Yale University, New Haven, CT, [2]Yale School of Management,

New Haven, CT, Contact: ankit.sisodia@yale.edu

Visual design impacts consumer preferences significantly, but quantifying these characteristics is difficult. We offer an automatic method to identify and quantify these features from image data using a disentanglement approach. Our method, unlike others, doesn't require supervision or prior knowledge of design characteristics. It uses structured product characteristics for disentanglement, unveiling human-interpretable and independent attributes. Applied to watches, we discovered six such characteristics. With visual conjoint analysis, we understood consumer preferences for these features. Our method can also generate novel designs to meet various consumer segments' ideal points.

2 Exploring the Impact of AI-Generated Artwork on Learning and Creativity in Online Art Communities

Ahreum Kim, Yingda Lu, University of Illinois-Chicago, Chicago, IL, Contact: akim239@uic.edu

This study examines the impact of AI-generated artwork on online art communities, focusing on learning, collaboration and creativity. The use of prompt engineering in AI artwork shapes its characteristics, enabling artists with varying technical skills to participate and expanding professionalism and stages of artwork sharing. The study investigates how AI-generated artwork affects knowledge sharing in various stages of artwork creation, including learning, creating, discussing, and sharing. Through data-driven analysis, we aim to understand the role of AI in online art communities and provide managerial implications.

3 Will It Be Cost-effective to Automate Human Tasks with AI? Evidence from Computer Vision

Maja S. Svanberg[1], Wensu Li[1], Martin Fleming[2], Brian C. Goehring[3], Neil Thompson[1], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]The Productivity Institute, Glen Ellyn, IL, [3]IBM's Institute for Business Value, New York, NY

If Artificial Intelligence (AI) systems replace job tasks done by human workers too quickly, it could generate substantial unemployment. Previous estimates stating that about half of tasks are at-risk of AI automation have focused on whether these tasks could be done by AI. But just because a task could be automated does not mean it will be. Requiring cost-effectiveness profoundly changes how quickly AI task replacement occurs in the U.S. economy.

For our analysis, we focus on the deployment of AI computer vision systems, where previous work allows us to estimate their cost. We find that, at today's costs, 82% of at-risk vision tasks would not be economical to automate because the benefits for the firm would not justify the development and operations costs of such a system. We explore conditions under which the share of cost-effective task rises.

4 Improving Translation of Visible to Thermal Images Using Gan in Adverse Weather Conditions

Nicolas Bustos[1], Mehrsa Mashhadi[1], Susana Lai-Yuen[2], Sudeep Sarkar[1], Tapas K. Das[2], [1]University of South Florida, TAMPA, FL, [2]University of South Florida, Tampa, FL, Contact: bustos@usf.edu

Under adverse weather conditions, object detection using multimodal imagery and data fusion methods reports better performance than solely using visible images. However, there is limited availability of public datasets that contain multispectral images with weather and time-of-the-day labels. We use CycleGAN, a Generative Adversarial Network, to create aligned image pairs by performing translation from 3-channel RGB to 1-channel thermal images and vice versa. We also transfer missing weather labels in the paired images and use these in fusion algorithms for assessing object detection performance.

Advances in Optimization Under Uncertainty

Contributed Session

Session Chair: David L. Woodruff, University of California-Davis, Davis, CA

1 Adjusted Wasserstein Distributionally Robust Estimator Statistical Learning

Yiling Xie[1], Xiaoming Huo[2], [1]Georgia Tech, ATLANTA, GA, [2]ISyE Georgia Tech, Marietta, GA, Contact: yxie350@gatech.edu

We propose an adjusted Wasserstein distributionally robust estimator---based on a nonlinear transformation of the Wasserstein distributionally robust (WDRO) estimator in statistical learning. This transformation will improve the statistical performance of WDRO because the adjusted WDRO estimator is asymptotically unbiased and has an asymptotically smaller mean squared error. The adjusted WDRO will not reduce the out-of-sample performance guarantee of WDRO. Sufficient conditions for the existence of the adjusted WDRO estimator are presented, and the procedure for the computation of the adjusted WDRO estimator is given. Specifically, we will show how the adjusted WDRO estimator is developed in the generalized linear model. Numerical experiments demonstrate the favorable practical performance of the adjusted estimator over the classic one.

2 On the Conservative Fields of Optimal Value Functions

Chen Jiang[1], Ying Cui[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: jian0649@umn.edu

Understanding the properties of optimal value functions is crucial in developing effective numerical algorithms for various optimization problems, including min-max, two-stage, and bi-level optimization. In this talk, we delve into the examination of first-order variational properties associated with the value functions for bi-parametrized nonlinear optimization problems. We characterize the conservative fields of these optimal value functions while refraining from assuming the uniqueness of optimal solutions or multipliers. The derived results offer a theoretical basis for employing (stochastic) gradient descent methods to tackle intricate hierarchical optimization problems involving varying constrained sets.

3 Software for Data-Based Stochastic Programming Using Bootstrap Estimation

David L. Woodruff, Xiaotie Chen, University of California-Davis, Davis, CA, Contact: dlwoodruff@ucdavis.edu

We describe software for stochastic programming that uses only sampled data to obtain both a consistent sample-average solution and a consistent estimate of confidence intervals for the optimality gap using bootstrap and bagging. The underlying distribution whence the samples come is not required.

Stochastic Models and Networks

Contributed Session

Session Chair: Iaroslav Kriuchkov, Aalto University, Espoo, Finland

1 Stochastic Finite Volume Method for Uncertainty Management of Gas Network Flows

Saif Rahaman Kazi, Sidhant Misra, Anatoly Zlotnik, Svetlana Tokareva, Jake Harmon, Pieter Swart, Los Alamos National Laboratory, Los Alamos, NM, Contact: skazi@lanl.gov

We develop a finite volume representation of uncertainty in solutions of hyperbolic partial differential equation systems on graph-connected domains with nodal coupling and boundary conditions. The representation is used to state the physical constraints in stochastic optimization problems subject to uncertain parameters. The method is based on the Stochastic Finite Volume (SFV) approach, and can be applied for uncertainty management of fluid flow over actuated transport networks. The method is examined for steady-state optimization subject to probabilistic constraints for a single pipe, and is also extended to higher dimensional uncertainty on general network structures.

2 Risk-Averse Stochastic Programming for High-Impact, Low-Probability Events with Applications to Flash Flooding Climate Change Risk

Beau Groom, University of Tennessee, Knoxville, TN, Contact: bgroom1@vols.utk.edu

Traditional stochastic programming (SP) assumes either a known probability distribution or uncertainty set. Both risk-neutral (expected value) and risk-averse (chance-constrained or robust optimization) postures largely ignore low-probability, high-impact events. This work relaxes both assumptions to propose a novel SP model for high-impact, low-probability events and applies it to the projected increase in flash flooding events due to the effects of climate change. The magnitude and location of this flooding is highly uncertain, meaning each road segment has a low flooding probability. However, these events have both short-term (traffic delays) and long-term (road degradation) effects that must be considered in investment planning.

3 A Primal-Dual SDDP Algorithm

Vincent Guigues[1], Vincent Leclere[2], François Pacaud[3], Benoit Tran[2], [1]FGV, Rio de Janeiro, Brazil; [2]Ecole des ponts ParisTech, Champs sur Marne, France; [3]Ecole des Mines, Paris, France. Contact: vincent.leclere@enpc.fr

The Stochastic Dual Dynamic Programming (SDDP) algorithm is a dynamic programming algorithm that iteratively constructs polyhedral approximations of cost-to-go functions for convex multistage stochastic programs. It is widely used in the energy community, especially for hydro-management problems. The primal SDDP algorithm, used since 1991, constructs outer approximations of the cost-to-go functions, while recent works proposed a dual SDDP algorithm constructing inner approximations. Finally, building on level-bundle methods, it has been shown that we can use inner approximation to regularize the SDDP algorithm. Here, we present a primal-dual SDDP algorithm that run both a primal and a dual SDDP algorithm, using dual information to level-regularize and thus improving convergence.

4 Convex Quantile Regression Approach to Fundamental Diagram Estimation

Iaroslav Kriuchkov[1], Timo Kuosmanen[2], [1]Aalto University, Espoo, Finland; [2]University of Turku, Turku, Finland. Contact: iaroslav.kriuchkov@aalto.fi

The fundamental diagram has been a backbone for traffic modeling for almost a century. With the increasing availability of sensor data, stochastic models describing density-flow relation started to draw attention. We introduce a state-of-the-art convex quantile regression with bags (CQRb), a stochastic nonparametric method to estimate the density-flow relationship. The proposed method does not depend on any prior functional form assumptions, and the estimated function conforms to the main properties of the fundamental diagram. We compare the performance of the proposed method with that of a deterministic parametric one and illustrate the application on data from roads in Finland.

Economics and Computation

Contributed Session

Session Chair: John McCarty, The Ohio State University, Columbus, OH

1 Useful PoW Mechanism Design: Economic and Energy Efficiency for Blockchain Systems

Zishuo Zhao, University of Illinois Urbana-Champaign, Urbana, IL, Contact: zishuoz2@illinois.edu

In blockchain systems, Proof-of-Work (PoW) is an essential cryptographical protocol in which miners compete to compute random challenges for writing access of blocks. While a major disadvantage traditional PoW is large overheads of computation and energy consumption with no beneficial use, the Proof-of-Useful-Work (PoUW) introduces PoW challenges that computes useful problems. We study the mechanism design of the PoUW market between challenge providers and miners in order to achieve social efficiency in both cryptocurrency and computational resources.

2 An Entropy-Based Data Reduction Method for Data Preprocessing

Rocco Cassandro, Zhaojun Li, Western New England University, Springfield, MA, Contact: rocco.cassandro@wne.edu

We propose an entropy-based data reduction (EBDR) algorithm for data pre-processing based on information theory. This method aims to explore high-purity dataset subsets in which the values of an attribute are directly linked to specific class labels. Experimental results demonstrate the efficiency of EBDR algorithm on differently-sized datasets. Moreover, to demonstrate EBDR's effectiveness on classification performance, we test it on a wide cross-section of the KDDCUP 1999 dataset using C4.5 Decision Tree (C4.5 DT). The experiment results show that the size of C4.5 DT can be greatly reduced while the accuracy is maintained, and the type II error gets lower.

3 New Algorithms for the Fair and Efficient Allocation of Indivisible Chores

Jugal Garg[1], Aniket Murhekar[2], John Qin[3], [1]UIUC, Urbana, IL, [2]University of Illinois, Urbana-Champaign, Champaign, IL, [3]University of Illinois - Urbana Champaign, Urbana, IL, Contact: johnqin2@illinois.edu

We study the problem of fairly and efficiently allocating indivisible chores among agents with additive disutility functions. We consider the widely-used envy-based fairness properties of EF1 and EFX, in conjunction with the efficiency property of fractional Pareto-optimality (fPO). Existence (and computation) of an allocation that is simultaneously EF1/EFX and fPO are challenging open problems, and we make progress on both. We show existence of an allocation that is (i) EF1+fPO, when there are three agents, (ii) EF1+fPO, when there are at most two disutility functions, (iii) EFX+fPO, for three agents with bivalued disutility functions.

These results are constructive, based on strongly polynomial-time algorithms. We also investigate non-existence and show that an allocation that is EFX+fPO need not exist, even for two agents.

4 Vote Delegation in DAO

Ali Ahmed[1], Brian Lee[2], [1]University of Wisconsin Eau Claire, Eau Claire, WI, [2]Pennsylvania State University, University Park, PA, Contact: ahmeda@uwec.edu

In this paper, we aim to investigate the voting process in Decentralized Autonomous Organization (DAO). Since large token holders can control the voting outcome of a proposal and lead to plutocracy, many DAOs allow vote delegation among community members. We study how the vote delegation serves the interest of the community. More specifically, we analyze if voters with high delegated voting power follow the majority vote on a DAO proposal. By using a dataset from a prominent virtual reality platform, we show that voters with high delegated voting power strategically time their votes and support the leading outcome of a proposal.

5 Using Interpretable AI Methods to Identify Recent Cyber Vulnerabilities with Exploits

John McCarty[1], Amirreza Talebi[1], Theodore T. Allen[2], [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH

We describe the importance of finding "super-critical" vulnerabilities relating to the race between hackers and defenders. Also, the features that predict the existence of exploits and alternative approach are described. Then, we show how optimal classification trees based on a sampling scheme support insights and bounding on a large dataset.

Innovative Operations for Social Goods and Sustainability

Contributed Session

Session Chair: Srinivasa Prasanna, IIIT-Bangalore, Bengaluru, India

1 When Doing Good May Backfire: Smallholder-Farmer Selection into Yield-Improvement Programs

Utku Serhatli[1], Guillaume Roels[2], [1]Nova School of Business and Economics, Lisbon, Portugal; [2]INSEAD, Fontainebleau, France. Contact: utku.serhatli@novasbe.pt

In agricultural-intensive economies, manufacturers often help smallholder farmers improve their yields through training and yield-improvement programs. However, and perhaps paradoxically, some farmers feel that these programs can lower their profit, in part due to a decrease in commodity prices. Using a Cournot model, we show that a) these programs can push prices down, which may indeed decrease the profits of some farmers, b) the objectives of minimizing market prices and protecting farmer well-being might be conflicting, and c) certifying more efficient farmers may perform well in terms of both individual and aggregate farmer well-being.

2 From Efficiency Analysis to Sustainability Identification: A Review, Path Forward and Empirical Application to Belgian Railways

Ahmed-Youssef Oukassou[1], Raluca Parvulescu[2], Marijn Verschelde[2], Nicky Rogge[3], [1]IÉSEG School of Management, Lille, France; [2]IÉSEG School of Management, Lille, France; [3]KU Leuven, Brussels, Belgium. Contact: a.oukassou@ieseg.fr

Data Envelopment Analysis is a widely used method in operations research and management science for evaluating the relative efficiency of decision-making units. A widely recognized downfall is its sensitivity to outliers and extreme observations. To overcome this issue, a large literature has focused on identifying outliers to robustify performance identification. In this paper, we show that outliers provide meaningful information on unsustainable production. This is crucial, given the increasing focus on the downsides of over-performance on employees (e.g., staff sickness and burnouts, safety issues) in the advent of Industry 5.0. We provide an extensive review, path forward, and empirical application on digital railway control rooms to investigate different methods of learning from outlying observations to construct a sustainable frontier.

3 Measuring the Impact of Logistics Development in Cities: A Social Sustainability Approach

Carla A. Tejada, Alison Conway, The City College of New York, New York, NY, Contact: ctejada001@citymail.cuny.edu

The development of logistics infrastructure in cities is growing, intending to meet the expectations of fast demand. In this study, we measure the impact of logistics facilities' proximity to urban areas from a social sustainability approach. We measure the social vulnerability in warehouse permitting areas, analyze the quality of jobs over ten years, and measure the job creation near facilities.

Results show that warehouses are generally located in vulnerable areas. Workforce indicators show a rise in the number of jobs in most industries related to the movement of goods but a limited increase in yearly earnings. Finally, the number of logistics jobs near logistics facilities has not increased significantly. Results are expected to inform future planning for delivery activity at citywide levels and raise awareness of logistics facilities' social impact.

4 Drone Logistics in Agricultural Technology

Srinivasa Prasanna, IIIT-Bangalore, Bengaluru, India. Contact: gnsprasanna@iiitb.ac.in

We discuss logistics of drones used in precision agriculture, in India. Drones enable timely inputs - water, fertilizer, pesticides, ..., timely harvesting, and real time data collection. While road and rail are well matched to bulk transport, drones are well suited for timely crop condition assessment, emergency spraying, transport of perishable items like flowers, ..

We address the problem, by scheduling a heterogeneous fleet of drones to perform these tasks at scale. We handle 1000's of drones, densely packed (trajectory separation < 1 m), under dynamic inter-drone separation constraints. We use a modified MILP formulation for scheduling the drones on airways. respecting Inter-drone separation, flight dynamics and range, and location of charging stations (for electric drones). Results show scalability to 1000's of drones, & GB/s data collection, a first of its kind,

Learning and Operations Management Applications

Contributed Session

Session Chair: Kenichi Shimizu, University of Alberta, Edmonton, AB, Canada

1 A Large Scale Linear Programming Model to Optimize Operational Efficiency of a Semiconductor Fabrication Plant with Multiple Lines

Jinyoun Lee, Junsang Yuh, Kihong Kim, Samsung Electronics/Mechatronics Research, Hwaseong-si, Korea, Republic of

Due to the immense size and re-entrant flow shop characteristics of a semiconductor fabrication plant (FAB), improving efficiency and optimizing productivity of a FAB are becoming ever more important. In this paper, a mathematical model is presented to optimize the operational efficiency of a FAB. Linear programming is used to model a FAB, and the production level is maximized while accounting for realistic constraints such as equipment arrange and work in process. The rolling horizon method is utilized to reduce the computation time for such a large-scale problem. Four experiments are conducted to test the validity and practicality of the model, and the results of the experiments are compared to the actual FAB data. The analysis result also showed that the model can be used for detecting bottlenecks, which is an additional point of improvement from a managerial perspective.

2 The Spread of a Post of an Influencer Viral Marketing on Twitter - a Branching Process Approach

Youhyun Lee[1], Liangfei Qiu[2], Hyungsik Moon[3], [1]UF, Gainesville, FL, [2]University of Florida Warrington College of Business Administration, Gainesville, FL, [3]USC, LA, CA, Contact: youhyun.lee@ufl.edu

This research investigates how an influencer's tweet that promotes a product spread among Twitter users. Once an influencer uploads a marketing tweet, his followers (the first generation) view it, and parts of them can retweet it, and show it to their followers. This process continues until no user in a later generation retweets the tweet. We suggest a branching process model that predicts the number of retweets from each group of followers based on the analyzing data we crawled through the Twitter server. The model let us measure the viral marketing effect on Twitter based on the impression number and viewers' interests, helping firms to expect a return from their expenditure on influencer marketing on the social network service platform.

3 Scalable Estimation Of Multinomial Response Models With Uncertain Consideration Sets

Kenichi Shimizu[1], Siddhartha Chib[2], [1]University of Alberta, Edmonton, AB, Canada; [2]Washington University in St. Louis, St. Louis, MO

Estimation of consideration set models faces a curse of dimensionality because the number of parameters associated with choice set formation processes increases exponentially in the number of available alternatives. In this paper, we propose a scalable estimation while allowing for flexible dependence structure of considerations. We utilize economic reasoning to introduce sparsity into the collection of choice sets. We estimate our model using Markov Chain Monte Carlo (MCMC), for which the sampling algorithm is built on simple and intuitive steps.

Supply Chain Risk Assessment

Contributed Session

Session Chair: Xingyu Li, Ford Motor Company, Dearborn, MI

1 Global Supply Chain Network Analysis and Its Resilience

James (Anxin) Lian[1], lu zhong[1], Ziang Wang[2], Jianxi Gao[1], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]The Hong Kong Polytechnic University, Hong Kong, Hong Kong

Supply chain analysis mainly focuses on a bilateral relationship, a static network, or subnetworks extracted from an industry. This paper examines supply chain networks' resilience based on a worldwide complex dynamic setting. With the 2008 -09 financial crisis as the case study, we identify not only firm-level factors but also network structures that mitigate disaster disruptions.

2 Valuation of Supply Chain Firms with Financially Distressed Retail Partner

Zugang Liu[1], Jia Wang[2], [1]Penn State- Hazleton, Hazleton, PA, [2]Rowan University, Glassboro, NJ

The current asset valuation approaches do not consider dynamic interactions between supply chain firms. However, the interconnections of supply chain firms affect their cash flows which are the fundamental factor determining firm valuations. In particular, supply chain relationships can become critical when there are financially distressed firms. This research develops an asset valuation approach which considers the relationship between supply chain partners as well as the stochastic nature of the credit risk. Our approach analyzes valuations of firms in supply chain networks by integrating game theory with credit risk model and valuation model in finance. We apply the approach to study firms with financially distressed retail partners, and present analytical results as well as numerical examples.

3 Supply Chain Restructuring: Nearshoring in Response to Regional Value Content Requirements

Jonathan Hsu, Washington University in St. Louis, St. Louis, MO

Regional trade agreements (RTAs) have emerged as a prominent trade policy tool, employing requirements on regional value content (RVCs) to enforce the utilization of goods produced within member countries. This paper examines the impact of RVCs within the United States, Mexico, and Canada Agreement (USMCA) on firm sourcing decisions. We show that RVCs incentivize firms to redirect imports from third countries towards USMCA members. Stricter RVCs produce more pronounced shifts in imports, while firms encounter considerably higher overall import costs as a result of these shifts. The most notable nearshoring trends occur in less complex products that are relatively easier to shift within the supply chain. Our findings uncover empirical evidence on the effectiveness of RVCs in promoting supply chain diversification and restructuring.

4 Supply Chain Risk Assessment for Automotive Industry Using Deep Survival Analysis

Xingyu Li, Vasiliy Krivtsov, Don Zhang, Chaoye Pan, Dmitry Snovalnikov, Ford Motor Company, Dearborn, MI

The ever-increasing vulnerability of the supply chain posed the need for automotive manufacturers to closely monitor the risks in their supply base and adjust their sourcing and production decisions accordingly. However, precise information on ongoing supply chain disruptions is often unavailable, making it challenging to evaluate and adapt to risks validly. To address such challenges, we propose a deep survival model to infer the underlying supply chain disruptions from the changes in supplier behaviors, inventory levels, and external stressors. In an application of a large U.S. automotive company, our model successfully predicts time-to-shortage for various auto parts and supports the company in risk-averse and resilient decision-making.

Pharmaceutical Supply Chains and Drug Shortages

Tutorial Session

Session Chair: Ebru Korular Bish, University of Alabama, Tuscaloosa, AL

1 Pharmaceutical Supply Chains and Drug Shortages

Hui Zhao, The Pennsylvania State University, University Park, PA

While pharmaceutical (pharma) industry is vital to the economy and its supply chain efficiency directly affects the quality and cost of patient care, pharma supply chains have been largely under-researched in the healthcare field, compared to the thrived research in medical services/hospital operations by the INFORMS community. At the same time, the pharma industry faces complicated and unique economics and regulation environment. In this tutorial, we aim to provide a base understanding of the very complex pharmaceutical supply chain and present challenges it faces. Using drug shortages (a persistent and significant problem facing the pharma industry, government, and the society) as well as other examples, we demonstrate that the richness and uniqueness of the pharma supply chain provides great opportunities for research with impact.

Technology Tutorial

1 Techno-Economic Analysis with MATLAB: Analyzing the Impact of EV Charging on the Power Grid

Chris Lee, MathWorks, Natick, MA, Contact: chrislee@mathworks.com

With more and more electric vehicles connecting to the power grid every day, there are concerns that existing grid infrastructure will be strained beyond acceptable operational limits. We can address these concerns by bringing operations, pricing, and forecasting into techno-economic models of power systems in MATLAB. Using these models, we can assess feasibility, risk, optimal operations, and profitability of charging infrastructure.

In this tutorial, we consider a scenario where a system operator can command individual electric vehicle battery units to both store and supply electricity while connected to the grid. The operator applies techno-economic optimization in MATLAB to the charging profiles to minimize electricity cost while accounting for system requirements and constraints, such as limits on state of charge, grid supply, and charge/discharge rate. The optimization provides a fast and automated approach for leveraging all of the units connected to the grid for overall system benefit. Charging profiles are then assessed for the impact on voltage and power flow levels using a grid-level simulation.

Data Driven Algorithms: New Paradigms

Community Committee Choice Session

Session Chair: Will Ma, Columbia University, New York, NY
Session Chair: Omar Besbes, Columbia University, New York, NY
Session Chair: Omar Mouchtaki, Columbia University, New York, NY

1 Decision-Aware Data Aggregation

Vishal Gupta, University of Southern California, Los Angeles, CA

Facing multiple stochastic optimization problems each with limited data, data aggregation is a natural approach. For instance, in revenue management, clustering similar products using k-means setting a single price for the cluster is common. Most aggregation heuristics follow an "estimate-then-optimize" paradigm, disregarding the downstream optimization problem's structure.
We propose decision-aware algorithms for data aggregation that adapt to the downstream optimization problem. Our proposals are tractable and outperform estimate-then-optimize approaches. We provide theoretical analysis demonstrating the superior performance of these approaches as the number of problems increases, even when the data per problem is constant.

2 Policy Optimization for Personalized Interventions in Behavioral Health

Jackie Baek[1], Justin J. Boutilier[2], Vivek Farias[3], Jonas Oddur Jonasson[4], Erez Yoeli[3], [1]NYU Stern School of Business, New York, NY, [2]University of Wisconsin - Madison, Madison, WI, [3]MIT, Cambridge, MA, [4]MIT Sloan School of Management, Cambridge, MA

We study the problem of optimizing personalized interventions for patients to maximize some long-term health outcome, in a setting where interventions are costly and capacity-constrained. We present a new algorithm we dub DecompPI that approximates one step of policy iteration. Implementing DecompPI simply consists of a prediction task from offline data, alleviating the need for online experimentation. Theoretically, we show that under a natural set of structural assumptions on patient dynamics, DecompPI surprisingly recovers at least 1/2 of the improvement possible between a naive baseline policy and the optimal policy. Through an empirical case study on a mobile health platform for improving treatment adherence for tuberculosis, we find that DecompPI can provide the same efficacy as the status quo with approximately half the capacity of interventions.

3 On Adaptive Experimentation and Learning

Mohsen Bayati, Stanford University, Stanford, CA

In this talk we study computational, optimization, and statistical challenges of adaptive experiment and learning.

4 From Contextual Data To Newsvendor Decisions: On The Actual Performance Of Data-driven Algorithms

Omar Besbes, Will Ma, Omar Mouchtaki, Columbia University, New York, NY, Contact: om2316@gsb.columbia.edu

We study a data-driven contextual Newsvendor problem and the performance implications of relevance and quantity of data. We consider a model in which demand observed in similar contexts have similar distributions and analyze the performance of a broad class of policies which weigh data according to their similarity in a contextual space. We develop a series of results that lead to an exact characterization of the worst-case expected regret of these policies. This exact analysis enables to unveil new quantitative and qualitative insights on their learning behavior which were not captured by state-of-the-art general-purpose bounds.

Learning Non-parametric Choice Models

Community Committee Choice Session

Session Chair: Antoine Desir, INSEAD, 263 Avenue Daumesnil, France

1 A Nonparametric Stochastic Set Model: Identification, Optimization, and Prediction

Yi-Chun Akchen[1], Dmitry Mitrofanov[2], [1]University College London, London, United Kingdom; [2]Boston College, Chestnut Hill, MA

The identification of choice models is crucial for understanding consumer behavior and informing operational strategies. The identification of parametric choice-based demand models is typically straightforward. However, nonparametric models like ranking-based models, which are highly effective and flexible in explaining customer choice, may encounter the challenge of the dimensionality curse, hindering their identification. In this paper, we develop a new class of nonparametric models that is not subject to the problem of nonidentifiability. Our model assumes bounded rationality of consumers, which results in symmetric demand cannibalization and intriguingly enables full identification. We further show that the proposed model demonstrates competitive prediction accuracy compared to the state-of-the-art benchmarks in a real-world case study.

2 Nonparametric Demand Estimation in the Presence of Unobserved Factors

Sandeep Chitla[1], Srikanth Jagabathula[2], Ashwin Venkataraman[3], [1]New York University, New York, NY, [2]NYU Stern School of Business, New York, NY, [3]University of Texas at Dallas, Richardson, TX, Contact: ashwin.venkataraman@utdallas.edu

In many applications of discrete choice modeling, there exist unobserved factors (UFs) driving the consumer demand that are not included in the model. Ignoring such UFs when fitting the choice model can produce biased parameter estimates and ultimately lead to incorrect policy decisions. Existing approaches such as the classical BLP estimator make strong parametric assumptions to deal with this challenge, and therefore can suffer from model misspecification issues. We propose a novel estimator for dealing with UFs in the mixtures of logit model that is nonparametric, i.e., does not impose any parametric assumptions on the mixing distribution or the underlying mechanism generating the UFs. We theoretically and numerically characterize the benefit of our estimator compared to BLP, and showcase the value of accounting for UFs on real-world grocery sales transaction data.

3 A Mallows-type Model For Preference Learning From (ranked) Choices

Yifan Feng[1], Yuxuan Tang[2], [1]NUS Business School, Singapore, Singapore; [2]National University of Singaporee, Singapore, Singapore. Contact: yuxuan.tang@u.nus.edu

In preference learning, participants choose an ordered list of top k preferred items from different display sets. We develop a distance-based ranking model to represent this choice behavior, similar to the Mallows model but using the Reverse Major Index distance function. The model has a simple closed-form expression for ranked choice probabilities, enabling consistent parameter estimation. We showcase the model's generalization power, robustness, and computational efficiency with real data sets.
We study the link between feedback structure richness (k) and collection efficiency. In a sequential experimental design problem, a company presents display sets and requests customers' top-k ranked choices to identify the top candidate using minimal samples. We find that informational efficiency increases with k, but a small k=2 often achieves near or full optimality.

3 Active Learning for Non-Parametric Choice Models

Fransisca Susan[1], Negin Golrezaei[2], Ehsan Emamjomeh-Zadeh[3], David Kempe[4], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Lexington, MA, [3]Meta Platforms, Inc., Seattle, WA, [4]University of Southern California, Los Angeles, CA, Contact: fransiscasusanwu@gmail.com

We study the problem of actively learning a non-parametric choice model based on consumers' decisions. We present a negative result showing that such choice models may not be identifiable. To overcome this, we introduce a directed acyclic graph (DAG) representation of the choice model, capturing as much information as could information-theoretically be identified. We then design an efficient active-learning algorithm to estimate the DAG representation, which runs in polynomial time when the set of frequent rankings is drawn uniformly at random. We show that our algorithm can better recover a set of frequent preferences on both synthetic and publicly available datasets on consumers' preferences, compared to the corresponding non-active learning estimation algorithms, demonstrating the value of our algorithm and active-learning approaches more generally.

Recent Innovations in E-commerce Fulfillment

Community Committee Choice Session

Session Chair: Linwei Xin, University of Chicago, Chicago, IL

1 Omnichannel Fulfillment at Target

Aravind Govindarajan, Target Corporation, Santa Clara, CA

In this talk, we provide an overview for Target's omnichannel fulfillment, and the various decision systems involved in conducting the fulfillment operations, ranging from inventory placement and positioning, order promise, order allocation, and last mile transportation. We discuss how key simulation systems help improve decision making at scale for the various systems involved in omnichannel fulfillment.

2 Better Round-Robin Matching for Walmart Spark Drivers

Duygu Soylemez[1], Linwei Xin[2], Yuan Zhong[3], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]University of Chicago / Booth School of Business, Chicago, IL, Contact: dsoyleme@chicagobooth.edu

Walmart Spark is a platform where third party drivers deliver online orders. One of the delivery models they use is round-robin. This model tries to match a bunch of orders with drivers before a predetermined time, T, which can be interpreted as the end of round robin before price surging or sent to DoorDash. Every period until T, unmatched orders are sent to unmatched drivers such that every order is sent to at most one driver and a driver receive at most one order in a period. The aim is to determine which order should be sent to which driver in every period to maximize the expected profit considering acceptance probabilities. Current practice is based on solving the weighted bipartite matching problem for a single period. We provide an optimal solution for single order problem under some assumptions and offer algorithms with better performance than the myopic policy that is in use.

3 Inventory Distribution in a Regionalized Network

Xiaoyan Si, Amazon, Bellevue, WA

Amazon's rapid network growth over the last few years has lead it to management complexity and efficiency challenges. In 2023, Amazon rearchitected its US fulfillment to move from a national network to a regionalized network by creating eight interconnected regions in smaller geographic areas. Each of these regions has broad, relevant selection to operate in a largely self-sufficient way, while still being able to ship nationally when necessary. The success of this structural change relies on many aspects of Amazon's supply chain management. In particular, designing a robust inventory distribution network to get the right products into the right region is the key for achieving high degree of self-sufficiency in each region. In this talk, we discuss different designs of Amazon's inventory distribution network in the context of its new regionalized fulfillment network.

4 Real-Time Personalized Order Holding

Mohammad Reza Aminian[1], Will Ma[2], Linwei Xin[3], [1]The University of Chicago, Booth School of Business, Chicago, IL, [2]Columbia University, New York, NY, [3]University of Chicago, Chicago, IL, Contact: linwei.xin@chicagobooth.edu

One common practice in online retailing is to delay real-time order fulfillment decisions to consolidate orders. Instead of immediately dispatching an order to a warehouse for picking/packing, the order is held in a virtual pool for a short amount of time. If the same customer places another order shortly afterward, then a substantial amount of costs can be saved by picking/shipping the orders together. A recent industry innovation is to make personalized order holding decisions based on the estimated chance of order consolidation. In this paper, we study the problem of how to make personalized order holding decisions in real-time. We propose intuitive and practical online algorithms and derive performance guarantees. We also conduct numerical experiments to complement our theoretical results.

Artificial Intelligence in Operations

Community Committee Choice Session

Session Chair: Xiao-Yue Gong, MIT, Cambridge, MA

1 Contextual Bandits and Optimistically Universal Learning

Moise Blanchard[1], Patrick Jaillet[2], [1]MIT, Cambridge, MA, [2]M.I.T., Cambridge, MA, Contact: moiseb@mit.edu

We study learnability for contextual bandits and provide consistent algorithms for large families of data processes. We show that achieving consistency irrespective of the reward function—universal consistency—is possible for large classes of non-i.i.d. processes. For stationary contextual bandits, we give tight characterizations of learnable processes and provide algorithms that achieve universal consistency whenever possible. Hence, if they fail to be universally consistent then no other algorithm would succeed either. In particular for finite action spaces, we show that there is no generalizability cost from standard supervised learning to contextual bandits. For non-stationary bandits, however, such ideal algorithms do not exist: it is impossible to balance population-level fitting and instance-level/personalized fitting with bandit feedback.

2 Regret Distribution in Stochastic Bandits: Optimal Trade-Off Between Expectation and Tail Risk

David Simchi-Levi[1], Zeyu Zheng[2], Feng Zhu[3], [1]Massachusetts Institute of Technology, Cambridge, MA,

[2]University of California, Berkeley, Berkeley, CA, [3]MIT, Cambridge, MA, Contact: fengzhu@mit.edu

We study the trade-off between expectation and tail risk for regret distribution in the stochastic multi-armed bandit problem. We fully characterize the interplay among three desired properties for policy design: worst-case optimality, instance-dependent consistency, and light-tailed risk. We show how the order of expected regret exactly affects the decaying rate of the regret tail risk for both the worst-case and instance-dependent scenario. A novel policy is proposed to characterize the optimal regret tail risk for any regret threshold. Moreover, we discover an intrinsic gap of the optimal tail rate under the instance-dependent scenario between whether the time horizon is known a priori or not. Interestingly, when it comes to the worst-case scenario, this gap disappears. Finally, we show that similar results hold under models with structured non-stationarity.

3 Bandits Atop Reinforcement Learning: Tackling Online Inventory Models with Cyclic Demands

Evelyn Xiao-Yue Gong, Carnegie Mellon University, Pittsburgh, PA

Motivated by a long-standing gap between inventory theory and practice, we study online inventory models with unknown cyclic demand distributions. We design provably efficient reinforcement learning (RL) algorithms that leverage the structure of inventory problems. Our RL policies achieve optimal regret for the lost-sales model and the episodic multi-product backlogging model, matching the regret lower bound that we prove in this paper. Our policies remove the regret dependence on the cardinality of the state-action space for inventory problems, which is an improvement over existing RL algorithms. We conducted experiments with a real sales dataset from Rossmann. Our policy converges rapidly to the optimal policy and dramatically outperforms the best policy that models demand as i.i.d. instead of cyclic.

4 Community/Committee'S Choice Submission

Rui Miao[1], Zhengling Qi[2], Cong Shi[3], Lin Lin[4], [1]UC Irvine, Irvine, CA, [2]The George Washington University, D.C., [3]University of Michigan at Ann Arbor, Ann Arbor, MI, [4]Duke University, Durham, NC, Contact: rmiao2@uci.edu

Pricing based on individual customer's characteristics is a widely used strategy to maximize sellers' revenues. This work studies offline personalized pricing under endogeneity using an instrumental variable approach. We propose a new policy learning method using invalid and continuous instrumental variables that allow direct effects on the outcome. Relying on the structural models of revenue and price, we establish non-parametric identification of an optimal pricing strategy under endogeneity with the help of continuous and invalid instrumental variables. Based on this new identification, we then construct an adversarial min-max estimator and learn an optimal pricing strategy from the offline data. Finally, we demonstrate the effectiveness of the our method via extensive simulation studies and a real data application from a US online auto loan company.

5 Efficient Cloud Server Deployment Under Demand Uncertainty

Konstantina Mellou[1], Rui Peng Liu[2], Evelyn Xiao-Yue Gong[3], Beibin Li[1], Thomas Coffee[2], Jeevan Pathuri[4], David Simchi-Levi[5], Ishai Menache[4], [1]Microsoft Research, Redmond, WA, [2]Amazon, Seattle, WA, [3]Carnegie Mellon University, Pittsburgh, PA, [4]Microsoft, Redmond, WA, [5]Massachusetts Institute of Technology, Cambridge, MA

A main challenge faced by cloud service providers is to ensure that they are ready to accommodate the growing demand for compute resources. Towards that goal, providers need to deploy cloud servers agilely for uncertain future demand under many practical business constraints, without incurring unnecessarily large operational costs. In this talk, we introduce the cloud server deployment problem, formulate the underlying optimization problem as a two-stage stochastic program and develop exact algorithms to efficiently obtain an optimal solution. We test our proposed algorithms with real production traces from Microsoft Azure and demonstrate their effectiveness in cost reductions.

Data-driven Methods for Quality Control

Contributed Session

Session Chair: John Becker, University at Buffalo, Buffalo, NY

1 A Semantic Segmentation Model for Measuring Wire Rod Temperature and Predicting Overall Hardness

SEOKKYU PYO[1], DONGHEE LEE[2], [1]M.S. student / Dept. of Industrial Engineering, SKKU, Seoul, Korea, Republic of; [2]Associate Professor/ Dept. of Industrial Engineering, SKKU, Seoul, Korea, Republic of. Contact: galaxy0521@g.skku.edu

Wire rod hardness is crucial for product quality, with cooling rate being the most significant factor. However, measuring cooling rate is challenging due to the wire rod's shape and conveyor belt noise. To address this issue, a model was developed to extract temperature from thermography. This, along with a hardness prediction model, was used to predict the wire rod hardness. The method can extract the temperature of the entire wire rod automatically, complementing quality inspection relying on sampling. A domestic steel company confirmed its efficacy.

2 Discovering True Optimal Solutions from Response Surface Models with Errors

Hyunho Kim[1], Jong-Seok Lee[2], [1]Sungkyunkwan University, Suwon, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of. Contact: retna319@skku.edu

This research focuses on response surface optimization using a monotonic neural network to estimate the response surface. Because the response surface estimated by training a neural network from data must contain a prediction error, the optimal solution determined from this response surface cannot be considered true optimal. To address this, we propose a method to identify the true optimal solution when there is a monotonic relationship between input factors and the response. By modifying the objective function based on the difference between target and predicted values, our approach iteratively searches for the optimal solution. Numerical experiments on synthetic examples confirmed the effectiveness of our method in finding true optimal solutions.

3 Semi-Supervised Learning for Classification of Transverse Temperature Defects in Hot-Rolled Products

Kyungsoo Kim[1], Seoung Bum Kim[2], [1]Korea university, Seoul, Korea, Republic of; [2]Korea University, Seoul, Korea, Republic of. Contact: kyungsoo@korea.ac.kr

We propose a semi-supervised learning model to classify transverse temperature defects in materials during hot rolling. Thermal imaging cameras are used to measure and store the temperature data during hot rolling process. Typically, classification models are used to classify defects in the thermal images. However, training classification models requires labeled data, which can be time consuming. To address this labeling issue, we propose using a semi-supervised learning model that leverages both labeled and unlabeled data for training. Our experimental results confirm that the semi-supervised learning methods outperform the supervised learning methods for the accurate detection of transverse temperature defects during hot rolling.

4 Nonparametric Adaptive Age-Replacement with Censored Data

Puyao Ge[1], Vidyadhar Kulkarni[2], [1]UNC Chapel Hill, Chapel Hill, NC, [2]University of North Carolina-Chapel Hill, Chapel Hill, NC, Contact: puyao@live.unc.edu

We consider the distribution-free age-replacement problem with censored lifetimes. We first develop a nonparametric adaptive algorithm that is a variant of the stochastic gradient descent method to minimize the expected net cost per machine. Then we combine this algorithm with the Kaplan-Meier estimator to minimize the long run expected cost per unit of time.

5 On Generalizing Information Collection Problems

Nastaran Oladzadabbasabady[1], John Becker[1], Esther Jose[1], Rajan Batta[2], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo (SUNY), Buffalo, NY, Contact: becker6@buffalo.edu

In today's data-driven world, collecting information efficiently is crucial. We generalize this and propose a well-formulated model that can be applied to a wide range of information collection problems. To solve an information collection problem on a graph, we introduce a two-phase approach. In the first phase, we pre-process the graph to determine how much information can be collected at different parts of the graph. In the second phase, we use a mixed-integer linear programming (MILP) model to maximize the amount of valuable information collected by traversing the edges of the graph within a given time limit. Our model has practical applications for any problem where an agent, sensor, or decision maker is collecting information from a space and can accommodate additional assumptions such as information degradation and threat or detection avoidance.

Recent Advances in Stochastic Processing and Matching Networks

Community Committee Choice Session

Session Chair: Siva Theja Magluri, Georgia Tech

Session Chair: Sushil Varma, Georgia Institute of Technology, Atlanta, GA

1 Asymptotically Optimal Matching Policy

Jiankui Yang[1], David D. Yao[2], Heng-Qing Ye[3], [1]Beijing University of Posts and Telecommunications, Beijing, China; [2]Columbia University, New York, NY, [3]Hong Kong Polytechnic University, Hong Kong, China

We study a system with multiple classes of components (jobs, customers, orders, etc.) that arrive following (possibly correlated) renewal processes. Each class has its own matching regime---what jobs from other classes are needed to form a match. The decision is whether to match the jobs that are currently present and hence remove them from the queues, or to wait for further arrivals with the hope to form better matches later. The objective is to minimize a convex holding cost. We propose a matching policy, and show that it is asymptotically optimal: under the diffusion scaling, it achieves the limiting performance of the optimal reflection control of a Brownian motion.

2 Fair Scheduling of Heterogeneous Customer Populations

Justin Mulvany[1], Ramandeep Randhawa[2], [1]University of Southern California, Los Angeles, CA, [2]USC Marshall School of Business, Los Angeles, CA

When managing congested service systems, it is common to use priority rules based on some operational criteria. In this paper, we consider the societal implications of such individual-focused priority policies, when individuals are considered as members of broader population groups. We find that optimal resource allocation policies such as the cμ-rule in scheduling can lead to significant inequity across population groups. We propose policies that can mitigate this inequity and can generate completely equitable outcomes across populations with little, or at times, even no additional system cost. Thus, we find that it can be possible to achieve more equitable outcomes while ensuring operational efficiency.

3 Dynamic Resource Allocation: Algorithmic Design Principles and Spectrum of Achievable Performances

Akshit Kumar[1], Omar Besbes[1], Yash Kanoria[2], [1]Columbia University, New York, NY, [2]Columbia Business School, New York, NY, Contact: akumar25@gsb.columbia.edu

Motivated by online matching markets and network revenue management (NRM) problems with many types (e.g., fulfillment optimization), we study dynamic spatial matching (DSM) in which supply and demand live in d dimensional space and need to be matched with each other dynamically. If demand and supply have different spatial distributions, the matching constraint has bite and greedy matching fails. We introduce a unifying and practical algorithmic principle for NRM and DSM dubbed SOAR: Simulate, Optimize, Assign, Repeat, which repeatedly simulates the future to enable good matching decisions. For particularly challenging NRM and DSM models, SOAR with multiple simulated sample paths at each stage achieves near optimal regret.

4 Care: Resource Allocation Using Sparse Communication

Gal Mendelson[1], Kuang Xu[2], [1]Technion, Haifa, Israel; [2]Stanford Graduate School of Business, Stanford, CA, Contact: galmendelson@gmail.com

We propose a new framework for studying effective resource allocation in a load balancing system under sparse communication using state approximations. We show that using a server-side-adaptive communication protocol, the load balancer can obtain good queue-length approximations using a communication frequency that decays quadratically in the maximum approximation error. Furthermore, we prove that the load balancer achieves asymptotically optimal performance whenever the approximation error scales at a lower rate than the square-root of the total processing capacity. Using simulations, we find that the proposed policies achieve good performance while reducing communication rates by as much as 90%.

Advancements in Service Systems Featuring Queuing Analysis, Parallel Processing, Dynamic Control, and Capacity Allocation

Community Committee Choice Session

Session Chair: Eugene Furman, Alba Graduate Business School, American College of Greece, Toronto, ON, Canada

1 Dynamic Control of Service Systems with Returns

Timothy Chan, Simon Yuxuan Huang, Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

We study a queueing system with returns where at each service completion epoch, the decision maker can choose to reduce the probability of return for the departing customer at a cost that is convex increasing in the amount of reduction in the return probability. We characterize the structure of optimal long-run average and bias-optimal transient control policies for associated fluid control problems. Our results provide insights on the design of post-discharge intervention programs aimed at reducing hospital readmissions.

2 Parallel Server Systems in Extended Heavy Traffic

Rami Atar[1], Eyal Castiel[2], Marty I. Reiman[3], [1]Technion, Haifa, Israel; [2]Georgia Tech, Atlanta, GA, [3]Columbia University, Maplewood, NJ, Contact: rami@technion.ac.il

The standard setting for studying parallel server systems at the diffusion scale is based on the heavy traffic condition, which assumes that the underlying static allocation linear program (LP) is critical and has a unique solution. We argue that the unique solution condition rules out an important class of systems. We introduce the extended heavy traffic condition, where the LP is merely assumed to be critical. Multiplicity of LP solutions dramatically changes the nature of the problem, where, in order to achieve asymptotic optimally at the diffusion scale, the system state must be controlled not only at the diffusion scale but also at the fluid scale.

3 Analysis of Two-Sided Queues with Different Levels of Delay Information

Mehmet Aydemir[1], Mohammad Delasay[2], Siddharth Singh[3], Mustafa Akan[4], [1]Walmart Global Tech, Dallas-Fort Worth Metroplex, TX, [2]Stony Brook University, Stony Brook, NY, [3]University Collage London, London, United Kingdom; [4]Carnegie Mellon University, Pittsburgh, PA, Contact: mohammad.delasay@stonybrook.edu

We model an on-demand platform as a two-sided queueing system and study its delay information disclosure policy when the platform serves two classes of strategic users (consumers and providers) who seek matches to each other using the platform. Users on each side decide whether to join the system or balk based on their expected delay to be matched, conditional on the information provided by the platform to them. We consider different delay information-sharing regimes and compare the matching rates (a proxy for the platform's profit) under these regimes.

4 Capacity Allocation for Clouds with Parallel Processing, Batch Arrivals, and Heterogeneous Service Requirements

Eugene Furman[1], Arik Senderovich[2], Shane Bergsma[3], J. Christopher Beck[4], [1]Alba Graduate Business School, American College of Greece, Athens, Greece; [2]York University, Toronto, ON, Canada; [3]Huawei Cloud, Markham, ON, Canada; [4]University of Toronto, Toronto, ON, Canada. Contact: efurman@alba.acg.edu

Allocating sufficient capacity to cloud services is a challenging task, especially when demand is time-varying, heterogeneous, contains batches, and requires multiple types of resources. We model such system as a multi-class queueing network with parallel processing and multiple types of resources, where arrivals (i.e., virtual machines and containers) follow time-varying patterns and require at least one unit of each resource for processing. We introduce a diffusion approximation of the offered load and investigate its fidelity. Then, we develop a heuristic that leverages this approximation to determine capacity levels that satisfy probabilistic SLAs. Using a data set of cloud computing requests from Huawei Cloud, we show that our heuristic policy results in a 20% capacity reduction and better service quality as compared to a benchmark that reserves resources.

CC-North 124A

Fairness in Decision-Making

Community Committee Choice Session

Session Chair: Sean Sinclair, Cornell University, Ithaca, NY

1 Sequential Fair Resource Allocation Under a Markov Decision Process Framework

Parisa Hassanzadeh[1], Sihan Zeng[2], [1]JPMorgan Chase & Co, Palo Alto, CA, [2]Georgia Institute of Technology, Atlanta, GA

We study the sequential decision-making problem of allocating a divisible resource to agents that reveal their stochastic demands over a finite horizon. Our goal is to design fair allocation algorithms that exhaust the available resource. We propose a new algorithm, SAFFE, that makes fair allocations with respect to all demands revealed over the horizon by accounting for expected future demands at each arrival time. By formulating the problem as an MDP, we show that the allocation made by SAFFE optimizes an upper bound of the Nash Social Welfare fairness objective. We further introduce SAFFE-D, which improves SAFFE by balancing the trade-off between the revealed demands and the future potential demands based on the uncertainty in future demands. We bound its gap to optimality using concentration bounds, and empirically compare SAFFE-D against baseline approaches.

2 Fairness and Budget Flexibility: Advancements in Restless Multi-Armed Bandits for Real-World Planning

Paula Rodriguez Diaz, Harvard University, Cambridge, MA

Restless multi-armed bandits (RMABs) have gained prominence as a model for resource allocation in real-world applications such as anti-poaching patrol scheduling, maternal and child care, and medication treatment adherence. However, existing RMAB models overlook the presence of heterogeneous workers with varying costs, budgets, and intervention effects, limiting their applicability. To overcome this, we propose two advancements: multi-worker restless bandits (MWRMAB) and flexible budget restless multi-armed bandits (F-RMABs). MWRMAB extends the RMAB framework by considering heterogeneous workers, aiming to maximize expected reward while ensuring fairness in workload distribution while F-RMABs introduce flexible budgeting, enabling the distribution of surplus resources across planning steps.

3 Stochastic Online Fisher Markets: Static Pricing Limits and Adaptive Enhancements

Devansh Jalota, Stanford University, Stanford, CA, Contact: djalota@stanford.edu

In a Fisher market, users spend a budget of (artificial) currency to buy goods that maximize their utilities while a central planner sets prices on capacity-constrained goods to clear the market. However, the efficacy of pricing schemes to achieve an equilibrium typically relies on complete knowledge of users' budgets and utilities and requires transactions to happen in a static market where all users are present simultaneously. Thus, we study an online incomplete information variant of Fisher markets, wherein users with privately known utilities and budgets enter the market sequentially. In this context, we study the limits of classical static pricing approaches and develop adaptive pricing algorithms with improved performance guarantees, including one that adjusts prices solely based on observations of user consumption, i.e., revealed preference feedback.

4 Fairness Auditing in Urban Decisions Using Lp-Based Data Combination

Mesrob Ohannessian, University of Illinois Chicago, Chicago, IL, Contact: mesrob@uic.edu

Auditing for fairness in decisions often relies on a secondary source, e.g., the Census, to inform about protected attributes that are missing in the primary source. To avoid assumptions, a recent line of work has suggested finding the entire range of fairness valuations consistent with both sources. We show that, for continuous decisions, this could lead to loose audits, perceived more optimistically than they ought to be. We propose an efficient linear programming formulation to handle continuous decisions, by finding the fairness range based on data and giving it finite-sample guarantees. We apply it to 311 Chicago City Services data to demonstrate its ability to tightly assess fairness. (Joint work with Jingyi Yang and Joel Miller, UIC.)

Advancements in Simulation

Community Committee Choice Session

Session Chair: Henry Lam, Columbia University, New York, NY
Session Chair: Shengyi He, Columbia University, New York, NY

1 Unbiased Gradient Estimation for Intractable Performance Measures

Jeffrey Wang[1], Chang-Han Rhee[2], [1]Northwestern University, Chicago, IL, [2]Northwestern University, Chicago, IL, Contact: xiaotianwang2025@u.northwestern.edu

We propose a new approach to unbiased estimation of the gradients of the stationary means associated with parametrized families of Markov chains. Our new estimators are particularly efficient when the Markov chains have long regeneration cycles. Our estimators are based on constructing coupling which only requires an oracle to evaluate the transition density and its gradient at a given data point without any additional knowledge about the density function itself. Numerical experiments confirm the good performance predicted by the theory.

2 Statistical Optimality in Low-Computation Uncertainty Quantification

Shengyi He, Henry Lam, Columbia University, New York, NY, Contact: sh3972@columbia.edu

The gigantic computation demand of modern simulation and machine learning models has deemed some common uncertainty quantification tools overly expensive. Alternatives that operate under very low computation budgets, such as data splitting and some new resampling approaches, have growing importance in this situation. However, it is open which of these approaches are statistically optimal under computation budgets. We investigate this problem via a large-sample analog of uniformly most accurate unbiased confidence intervals from a dual view of hypothesis testing. We show that standard batching, but also certain schemes using uneven-size batches or overlapping batches, as well as the recently proposed cheap bootstrap method, are optimal. We also discuss these approaches' higher-order properties to understand their behaviors in the smaller-sample regimes.

3 When Can Regression-Adjusted Control Variate Help? Rare Events, Sobolev Embedding and Minimax Optimality

Jose Blanchet[1], Haoxuan Chen[2], Yiping Lu[2], Lexing Ying[3], [1]Stanford University, Stanford, CA, [2]Stanford University, Stanford, CA, [3]Stanford University, Stanford, CA, Contact: haoxuanc@stanford.edu

We study the use of a nonparametric estimator as a control variate for reducing the variance of Monte Carlo (MC) sampling. Specifically, we seek to uncover the key factors that influence the efficiency of control variates by examining a prototype estimation problem that involves simulating the moments of a Sobolev function based on random observations. An information-theoretic lower bound is built for this problem. We also study a specific quadrature rule that uses a nonparametric regression-adjusted control variate to reduce the variance of MC simulation. We demonstrate that such quadrature rule can improve the MC rate and achieve the minimax optimal rate under a sufficient smoothness assumption, which rules out the existence of rare events due to the Sobolev Embedding Theorem. Finally, we show that a truncated version of MC can be minimax optimal when rare events exist.

Optimization and Resilience: Enhancing Community Resilience Against Natural Hazards

Panel Session

Session Chair: Himadri Sen Gupta, University of Oklahoma, Norman, OK

1 Moderator

Himadri Sen Gupta, University of Oklahoma, Norman, OK, Contact: hgupta@ou.edu

This panel session discusses the latest advances in optimization techniques to enhance community resilience against natural hazards. The panelists explore the use of social networks, infrastructure, and multi-objective optimization techniques in disaster response planning, emergency management, and risk analysis. The role of decision analysis in promoting community resilience is also highlighted, emphasizing its integration with optimization techniques for better decision-making. This multidisciplinary approach provides practical recommendations and insights for practitioners, researchers, and policymakers to address complex challenges in community resilience.

Strategic Behavior in Social Operations

Community Committee Choice Session

Session Chair: Manu Goyal, University of Utah, Salt Lake City, UT

Session Chair: Nitin Bakshi, University of Utah, Salt Lake City, UT

1 Fairness in Pollution Regulation

Krishnan S. Anand[1], Francois C. Giraud-Carrier[2], [1]University of Utah, Salt Lake City, UT, [2]Weber State University, Ogden, UT

Fairness in pollution regulation is an important and much-debated question, especially given multiple stakeholders with conflicting objectives, including polluting firms, industry lobby groups, consumers, environmentalists, doctors and the government. While there is a vast literature on the notion of fairness in general, we use the term precisely to mean that the polluter pays for the entire pollution damage it causes, and no more-- the so-called ‘polluter pays’ principle. We develop a novel pollution-control mechanism that we use as a benchmark of fairness. We then assess the fairness of Cap-and-Trade and Taxes against this benchmark.

2 Team Operations and Peer Reporting: Pulling the “Andon Cord” on Loyalty

Nitin Bakshi, Manu Goyal, University of Utah, Salt Lake City, UT, Contact: nitin.bakshi@eccles.utah.edu

Team operations are plagued by shirking (moral hazard) aggravated by free riding. Shirking by peers is not reported by agents who are loyal. Using the framework of dynamic games, we show that if a teammate is loyal even with a tiny probability, shirking becomes rampant and is unreported even by peers who are not loyal. We demonstrate that loyalty, an exalted value, can backfire due to the strategic externalities that it imposes on other members of the team. Interventions that destigmatize peer reporting (e.g., pulling the Andon cord in TPS) can potentially alleviate this problem.

3 The Competition in Online Reputation: A Mean Field Game Approach

Mingwen Yang[1], Vijay S. Mookerjee[2], Cheng Nie[3], Yonghua Ji[4], [1]University of Washington, Seattle, WA, [2]University of Texas- Dallas, Richardson, TX, [3]Iowa State University, Ames, IA, [4]University of Alberta, Edmonton, AB, Canada

Online reputation is critical for the success of a business. Sellers make efforts to improve their online reputation to attract more future customers. In this paper, we model the sellers' competition in product ratings using a mean field game model, where we consider a large number of sellers in a market. Each seller makes an effort to improve the product ratings, and having ratings close to those of other competitors benefits each seller in the market (mutual attraction). Using data from Airbnb, we estimate the parameters in the mean-field game model. We can demonstrate that the proposed model can explain the rating competition in the market.

Role of Forecasting in Operations

Contributed Session

Session Chair: Long Zhao, NUS Business School, Singapore, Singapore

1 A Unified Demand Forecasting Framework for Ecommerce Advertising Products

Zhengchao Yang, Mithun Ghosh, Anish Saha, Darren Xu, Konstantin Shmakov, Kuangchih Lee, Walmart, Sunnyvale, CA

Demand forecast plays a critical role in sales planning and management of advertising business, which requires accurate prediction of the expected advertising product demand at scale for Walmart eCommerce. However, uncertainty in customer behaviors, supply chain disruptions, demand surges and plummets, lack of historical records and patterns can make the forecasts inadequate. In our work, we introduce a framework that incorporates various machine learning modeling methodologies, including statistical models and deep learning-based transfer learning models, etc., as well as evaluation methods to help make robust demand forecasts for all advertising products and accounts in a hierarchical structure. At the end, we also discuss our experimental findings and demonstrate the effectiveness and efficiency of our proposed framework.

2 A Bayesian Framework for Forecasting Spare Part Failures

Firat Kilci[1], Genaro J. Gutierrez[2], Saurabh Bansal[3], [1]The University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]Penn State University, University Park, PA

This study focuses on developing an efficient framework to forecast spare part failures for a global computer manufacturer. Our results show that in addition to the number of computers in use, age, warranty expiration, season, and location-specific factors (like Monsoon season in coastal India) impact the number of failures. Furthermore, using a Bayesian approach, we find that transferring statistical information from an older product significantly improves forecast accuracy. The benefit is most pronounced during the initial 24-month period of the product's life cycle. Lastly, we discuss the implications of this forecasting methodology on the supply chain and inventory management.

3 A Simulated Annealing Approach to Designing Optimal Decision Trees for Classification, Prescriptive, and Survival Analysis

Suleeporn (Yui) Sujichantararat[1], Dimitris Bertsimas[2], [1]MIT EECS, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: ssuji@mit.edu

Binary decision tree is a highly interpretable machine learning model as humans can easily understand how a prediction is made by answering a series of binary questions. Interpretable AI has provided a powerful framework for constructing optimal decision trees by utilizing multiple random warm starts and local search to iteratively improve each warm start until a locally optimal decision tree is found. However, local search does not guarantee global optimality. Hence, we propose to incorporate simulated annealing into decision tree construction as some worse transformations could lead to a better final model. We focus on three problem domains including classification, prescriptive and survival analysis to produce OCT-SA, OPT-SA and OST-SA which further improve on OCT, OPT, and OST by probabilistically allowing a tree to move to a tree with a worse objective value.

4 Getting More Wisdom out of the Crowd: The Case of Competence-Weighted Aggregates

Enrico Diecidue[1], Thomas Langer[2], Michael Goedde-Menke[3], Andreas Jacobs[2], [1]INSEAD, Fontainebleau, France; [2]University of Muenster, Muenster, Germany;

[3]University of Munster, Munster, Germany

This paper shows that group discussions can serve as an instrument to improve individuals' calibration, which in turn strongly increases the accuracy of competence-weighted, statistical aggregates. We conduct an experiment in which participants estimate quantities and report their self-perceived competence for various judgment problems. In addition, they engage in group discussions with other judges on unrelated judgment tasks. We find that prior to participating in the group discussions, judges' self-perceived competence and their estimation accuracy are poorly aligned. However, the information exchange facilitated by the group discussions improved judges' calibration, raising the accuracy of competence-weighted aggregates on subsequent judgment problems to prediction market levels and beyond.

5 Constructing Quantiles via Forecast Errors: Theory and Empirical Evidence

Zhi Chen[1], Long Zhao[2], [1]National University of Singapore, Singapore, Singapore; [2]NUS Business School, Singapore, Singapore. Contact: longzhao@nus.edu.sg

One simple approach to construct probabilistic forecasts is to leverage historical point forecast errors to create quantiles around the point forecast. We develop a theoretical framework to understand how the bias and variance of an estimator affect its overall performance. We find that unbiasedness is not optimal, and the bias towards the center of the distribution is more costly than towards the tails. Besides, higher estimator variance leads to worse performance. These bias-variance insights allow for comparisons among a wide range of estimators. For example, with limited samples, we find that sample quantile is inferior to normal approximation for tail quantiles in both bias (in the more costly direction) and variance. We empirically validate our theoretical findings using the M5 accuracy competition submissions.

Fairness in Optimization Models from Operations Management

Community Committee Choice Session

Session Chair: Anil Aswani, UC Berkeley, Berkeley, CA

Session Chair: Yoon Lee, UC Berkeley, Berkeley, CA

1 Incorporating Fairness into Incentive Design in Principal-Agent Models with Adverse Selection and Moral Hazard

Yoon Lee, Ilgin Dogan, Anil Aswani, Zuo-Jun Max Shen, UC Berkeley, Berkeley, CA, Contact: yllee@berkeley.edu

Existing approaches to incentive design often overlook the important aspect of fairness, which can lead to adverse consequences for certain groups based on race, gender, or other characteristics. In this study, we address this limitation by introducing fairness into optimization problems within principal-agent models. Specifically, we focus on scenarios involving adverse selection and moral hazard. We formulate quantitative definitions of fairness and derive the policy structure for optimal fair contracts. By discussing the underlying intuition behind these contracts, we highlight the impact of fairness on incentive design. Furthermore, we present a numerical case study to illustrate the practical implications of incorporating fairness considerations in the design process.

2 Optimization Hierarchy for Fair Statistical Decision Problems

Anil Aswani[1], Mahbod Olfat[2], [1]UC Berkeley, Berkeley, CA, [2]University of California-Berkeley, Berkeley, CA

A growing literature has begun to develop fair statistical techniques, but these are often specialized to one model context and based on ad hoc arguments. This paper develops an optimization hierarchy, which is a sequence of optimization problems with an increasing number of constraints, for fair statistical decision problems. Because our hierarchy is based on the framework of statistical decision problems, this means it provides an approach for developing and studying fair versions of hypothesis testing, decision making, estimation, regression, and classification. We use tools from variational analysis and random set theory to prove that higher levels of this hierarchy lead to a type of fairness consistency. We demonstrate numerical effectiveness of our hierarchy using several data sets, and we use our hierarchy to fairly perform automated dosing of morphine.

3 The Predictive Power of the Microbiome: Does Learning Translate across Studies?

Giana Cirolia, UC Berkeley, Berkeley, CA, Contact: giana@berkeley.edu

The human gut microbiome is home to trillions of bacteria which play a profound role in host physiology. These natural commensals are essential to human immune regulation, digestion and metabolic health. Disturbances in this complex community have been linked with pathologies such as diabetes, obesity, depression, asthma and inflammatory bowel disease (IBD).However, despite correlations being drawn between microbiome composition and disease status, there are considerable inconsistencies between the observational studies which link specific microbiomes and health conditions. This work aims to address the question: Are species predictive of disease status across multiple studies, encompassing different geographies and social groups.

4 Portfolio Approximations and Fairness in Combinatorial Optimization

Swati Gupta[1], Jai Moondra[2], Mohit Singh[3], [1]ISyE Georgia Tech, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgia Institute of Technology, Atlanta, GA, Contact: jmoondra3@gatech.edu

Inspired by fairness notions, we look at ordered optimization for discrete optimization problems on real vector spaces (such as all path vectors in a graph), where we are given a weight vector and the cost of a vector in the domain is the dot product of the weight vector with the sorted domain vector. This generalizes the classic min-sum (such as shortest path) and the min-max (such as makespan minimization) objectives. We study solution portfolios for ordered optimization where we ask for a small set of vectors in a fixed domain that are approximately optimal for each ordered optimization problem, generalizing the special case when one domain vector is approximately optimal for all ordered optimization objectives. We show various upper and lower bounds for minimum portfolio sizes for various problems including shortest paths, matchings, routing, and parallel scheduling.

5 Redesigning Congestion Pricing for Improving Efficiency and Equity: An Empirical Study of San Francisco Bay Area

Kshitij Kulkarni, UC Berkeley, Berkeley, CA, Contact: kshitijkulkarni@berkeley.edu

Tolling is widely adopted as an effective measure to mitigate traffic congestion. However, two major challenges remain in practice: (i) classical tolling mechanisms such as marginal cost pricing are socially suboptimal when travelers have heterogeneous willingness-to-pay, and when tolls must be constrained; (ii) tolling limits the road accessibility of low income travelers. To tackle these challenges, we present a new tolling mechanism that accounts for travelers' heterogeneous willingness-to-pay and constraints on the tolls. In our empirical study of the San Francisco Bay Area, we estimate the average willingness-to-pay of travelers from real traffic data. We then re-design toll prices and demonstrate that our design improves both efficiency -- by reducing average travel time, and equity -- by reducing the difference in travel time experienced by the populations.

CC-North 127A

Worker Productivity, the Human-Algorithm Connection, and the “Future of Work

Community Committee Choice Session

Session Chair: Ruth Beer, Baruch College, CUNY, New York, NY

1 Is Transparency Enough? the Effect of Historical Pay Information on Negotiations

Xiaoyang Long[1], Hengchen Dai[2], Dennis Zhang[3], [1]University of Wisconsin-Madison, Madison, WI, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]Washington University in St Louis, ST LOUIS, MO, Contact: xiaoyang.long@wisc.edu

A commonly cited cure for pay inequality is pay transparency, because access to peer pay is believed to prompt underpaid individuals to negotiate. We analytically and empirically study how historical peer pay information influences pay negotiations and pay inequality. We show that pay transparency may induce workers with high self-perceived abilities (who are likely already highly-paid) to ask for more, which may in turn exacerbate pay inequality among hired workers. Thus, pay transparency may not always be a panacea for pay inequality. We discuss measures that can be taken along with pay transparency to combat pay inequality.

2 Stopping the Revolving Door: An Empirical and Textual Study of Crowdfunding and Teacher Turnover

Samantha Meyer Keppler[1], Jun Li[2], Andrew Wu[2], [1]University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: srmeyer@umich.edu

Organizations that provide better worker support have better worker retention. In K--12 public education, teachers commonly feel unsupported by their schools and districts as a result of the gap between top-down, one-size-fits-all resource allocation models and teachers' individual resource needs. In this study, we examine whether a recent trend in education ---teacher crowdfunding platforms---effectively fills this gap and improves retention. We find funded projects on DonorsChoose significantly reduce attrition (leaving the public school system) rates of funded teachers by 1.7 percentage points (pp). Resources which more substantially help teachers enact their professional identities as teachers by personalizing their classrooms and/or their teaching pedagogy have the strongest effect.

3 Payment Algorithm Transparency on On-Demand Service Platforms

Swanand Kulkarni[1], Basak Kalkanci[2], Chris Dalton Parker[3], [1]Georgia Tech, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]American University, Washington

On-demand service platforms have been experimenting with algorithms to determine compensation for their workers. While some use commission- or effort-based algorithms that are intuitive to workers, others, in their efforts to better match customer demand, have transitioned to algorithms where pay is not strictly tied to effort, but depends on other, potentially exogenous factors. Platforms have also kept these algorithms opaque. Workers' reactions to such practices, however, are not systematically examined or understood. Through incentivized experiments, we examine how a pay algorithm's intuitiveness to workers, its transparency, and a change that reduces the algorithm's intuitiveness affect workers' engagement with the platform and perceptions of the platform. Results reveal that transparency is highly effective in managing workers' experience.

4 AI Assistance and Service Usage

Yao Cui[1], Zhaohui Jiang[2], Qi Li[3], [1]Cornell University, Ithaca, NY, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Chinese University of Hong Kong, Shenzhen, China. Contact: yao.cui@cornell.edu

As companies continue to incorporate artificial intelligence (AI) into their services, understanding the impact of AI on user behavior becomes increasingly important. In this paper, we investigate how AI assistance affects consumers' service usage, taking into account users' varying skill levels. We partner with an international on-demand car-rental platform and conduct a field experiment through a technology upgrade involving an AI-powered driver monitoring and feedback system. Our findings reveal that users with low or high skill levels increase their service usage due to AI assistance, while users with medium skill levels do not. We further demonstrate that AI creates value in different ways for low-skilled and high-skilled users. These results highlight the need for customized solutions to maximize the value of AI for different segments of users.

Tuesday, October 17, 10:45 AM - 12:00 PM

Operational Challenges in Emergency Transportation and Health Delivery Systems

Community Committee Choice Session

Session Chair: Gonzalo Romero, Rotman, University of Toronto, Toronto, ON, Canada

1 Ambulance Allocation in a Patient-Centered Emergency Medical Service System

Eric Stratman, Justin J. Boutilier, Laura Albert, University of Wisconsin-Madison, Madison, WI, Contact: egstratman@wisc.edu

Changes to U.S. regulations now permit some emergency medical service (EMS) providers to treat patients at the scene of an incident or a destination other than an emergency department. These new treatment pathways prioritize patient-centered care and reduce the cost of emergency care; however, it is unclear how EMS resources should be deployed to support these goals. We bridge this gap. We develop a framework to find the optimal deployment, fleet mix, and allocation strategies for an EMS system with multiple treatment pathways. Our work expands existing facility location research by modeling uncertainty in a patient's condition and the actions taken once a patient's true needs are learned. We summarize managerial insights and demonstrate the importance of adapting EMS strategy for this innovation.

2 Human in the Loop Automation: Ride-Hailing with Remote (Tele-) Drivers

Saif Benjaafar, Zicheng Wang, Xiaotang Yang, University of Minnesota, Minneapolis, MN, Contact: yang4767@umn.edu

By putting the human back "in the loop," tele-driving has recently emerged as a more viable alternative to fully automated vehicles, with ride-hailing (and other on-demand transportation-enabled services) being an important application. We examine the impact of tele-driving on the efficiency of ride-hailing. Among our findings, we show that having fewer (tele-) drivers than vehicles can surprisingly improve performance (mitigating the wild goose chase phenomenon) or stabilize an otherwise unstable system.

3 Operational Challenges in Emergency Service Platforms in Developing Countries

Pieter van den Berg[1], Andre Du Pin Calmon[2], Andreas Gernert[3], Stef Lemmens[4], Gonzalo Romero[5], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Scheller College of Business, Georgia

Institute of Technology, Atlanta, GA, [3]KLU, Hamburg, Germany; [4]Rotterdam School of Management, Erasmus University Rotterdam, Rotterdam, Netherlands; [5]Rotman, University of Toronto, Toronto, ON, Canada. Contact: gonzalo.romero@rotman.utoronto.ca

Many developing economies lack the health-emergency infrastructure of developed countries. Our industry partner Flare (Nairobi, Kenya) coordinates existing ambulance providers through a platform. Flare aggregates the available ambulance capacity and demand for emergency services. Since ambulance platforms make use of independent providers, the ambulance fleet can only be partially controlled.

4 Breaking Silos in Mobile Health Delivery: A Resource Allocation Perspective

Thomas Breugem[1], Tim Sergio Wolter[2], Luk N. Van Wassenhove[3], [1]Tilburg University, Tilburg, Netherlands; [2]INSEAD, Fontainebleau, France; [3]INSEAD, Fontainebleau Cedex, France. Contact: t.breugem@tilburguniversity.edu

We consider a resource allocation problem faced by health and humanitarian organizations deploying mobile outreach teams to serve marginalized communities. These teams can provide a single service or an assortment of services during each visit. Combining services is likely to increase operational efficiency but decrease the relative benefit per service per visit, as operations are no longer tailored to a single service. The aim of this study is to analyze this benefit-efficiency trade-off. Our results show the benefit-efficiency trade-off can be assessed based on high level parameters. We show demand alignment is a key driver of this trade-off. We apply our results to Praesens Care, a social enterprise start-up developing mobile diagnostic laboratories, and verify our insights using real-world data.

5 Design of Community Maternal and Neonatal Health Programs Using the Lives Saved Tool: A Constrained Optimization Approach

Baris Ata[1], Muna Jama[2], Naoko Kozuki[2], Robert Montgomery[3], Elaine Scudder[2], Caitlin Tulloch[2], [1]University of Chicago, Chicago, IL, [2]International Rescue Committee, New York City, NY, [3]University of Chicago, North Pole, AK

We approach the choice of interventions for a community maternal and neonatal health (MNH) program by constructing a constrained optimization model for health program design and applying it to the Somalia setting, identifying the highest-impact combination of interventions in severely resource-constrained environments. After consultations with Somalian stakeholders to establish the resource requirements for 25 MNH interventions we used the Lives Saved Tool (LiST) to calculate the number of projected lives saved. We use optimization techniques to sort through feasible combinations of interventions satisfying the resource constraints to determine the package that leads to the most projected lives saved in Somalia. We include sensitivity analysis to show how the optimal combination of interventions shifts as the resource budgets and other parameters are changed.

Racial and Gender Bias in Healthcare Research

Panel Session

Session Chair: Gian-Gabriel P. Garcia, Georgia Institute of Technology, Atlanta, GA

Session Chair: Behshad Lahijanian, Georgia Institute of Technology, Atlanta, GA

1 Moderator

Gian-Gabriel P. Garcia, Georgia Institute of Technology, Atlanta, GA

Diversity, equity, Inclusion (DEI) is an inherently complex issues, and everyone makes their trade-off between perfect equality and dealing with historical inequality. Researchers always suffer from these biases between different genders, races, and under-represented minorities. This gender bias is more critical in human life. What's missing is an in-depth understanding of how women and men of different races respond differently to medications and other therapies, as well as other variables that profoundly influence human health. In this panel discussion, we will discuss these biases in healthcare research.

Analytics for Healthcare Value Optimization at Mayo Clinic

Community Committee Choice Session

Session Chair: Esma S. Gel, University of Nebraska-Lincoln, Lincoln, NE

Session Chair: Thomas Kingsley, Mayo Clinic, Rochester, MN

1 ICU Datamart: Tool to Support Value Based Practice

Vitaly Herasevich, Mayo Clinic, Rochester, MN

With development of computer science and technology, computer technologies have been widely used in ICU to help providers improve clinical care quality. Adoption of electronic patient information systems in past decade gives hospitals tools to to automate the analysis of clinical data to get valuable insights about practice. Presenter will discuss experience with building a automatic near-real time central database (ICU Datamart) for collection and storing information from heterogeneous and distributed information sources, containing information about ICU patients at Mayo Clinic for purpose of quality improvement, decision support and clinical research.

2 Community/Committee'S Choice Submission

Rajeev Chaudry, Mayo Clinic

3 Community/Committee'S Choice Submission

James Newman, 1</sup

4 Mayo Clinic's COVID-19 Clinical Cohort Knowledge Solution

John O'horo, Mayo Clinic, Rochester, MN

During the COVID-19 pandemic, Mayo Clinic established a series of registries to track patients, care paths and outcomes. Establishing common definitions for research and operational use cases allowed for a unified framework for gathering patient data and implementing new best practices as they became available. This registry allowed for translation of research study eligibility into best practice advisories as new therapeutics and standards of care became available. We describe this approach to a 'clinical cohort knowledge solution,' and advocate for using this framework for agile and efficient responses to future emergencies.

5 Improving Hospital Census Management with Artificial Intelligence

Alex Ryu, Thomas Kingsley, Mayo Clinic, Rochester, MN

Increased hospital bed demand and decreased staff availability have led to unprecedented challenges with hospital overcrowding, particularly since COVID-19. To address these issues, our hospital system began exploring artificial intelligence approaches to forecasting bed demand and expediting patient triage in our emergency department (ED). We explored regularized linear regression and Markov chain modeling to forecast bed demand, and implemented a gradient-boosted tree model to predict patient-level need for hospital admission from the ED. Both tools were associated with specific downstream actions. Our admission prediction model is currently in a randomized, controlled trial to investigate its effect on hospital and ED efficiency.

Analytical Modeling to Inform Health Policy

Community Committee Choice Session

Session Chair: Qiushi Chen, Penn State University, University Park, PA

Session Chair: Yu-Hsin Chen, Pennsylvania State University, University Park, PA

1 Advancing Healthcare Decision-making: Leveraging Data-driven Models for Optimal Insurance Selection and Service Enhancement

Behshad Lahijanian, Georgia Institute of Technology, Atlanta, GA, Contact: blahijanian3@gatech.edu

Selecting an appropriate health insurance plan from a plethora of options can be complex, considering the diverse plans available and their cost distribution throughout the year. In this study, we introduce a stochastic program model to aid in health insurance selection by incorporating different network types. Our model enables individuals to comprehend, compare, and choose the optimal health insurance plan that aligns with their individual needs. Additionally, we propose a solving algorithm to minimize total costs, including both covered and uncovered expenses, over the course of a year. By utilizing this approach, individuals can make informed decisions, resulting in improved financial outcomes and enhanced healthcare coverage.

2 MDP-Based Screening Policy Optimization for Hospital-Acquired Infections: A Case Study of MRSA Surveillance Among Exposed Roommates in Canadian Hospitals

Esma Akgun, F. Safa Erenay, Sibel Alumur, University of Waterloo, Waterloo, ON, Canada. Contact: eakgun@uwaterloo.ca

In this study, we develop an MDP (Markov Decision Process) model to optimize screening strategies for preventing hospital-acquired infections, with a focus on MRSA (Methicillin-Resistant Staphylococcus Aureus) surveillance among exposed roommates in Canadian hospitals. Our model takes into account the spread of MRSA within the hospital room structure and evaluates multiple performance measures, including quality-adjusted life years, cost, the number of colonized patients, and missed MRSA cases. Through our evaluation, we can determine the most effective screening policies to limit MRSA transmission and prevent hospital-acquired infections. Our results offer valuable insights to healthcare professionals to enhance screening protocols and prevent the spread of MRSA in hospital settings.

3 Visiting Nurses Assignment and Routing for Hybrid Telehealth Service Networks

Tan Yu, Yongpei Guan, Xiang Zhong, University of Florida, Gainesville, FL

As telehealth utilization skyrockets, there has been a paradigm shift to a decentralized care delivery modality integrating both in-person and telehealth services provided at different layers of the care delivery network, i.e., central hospital, satellite clinics, and patient homes. The operations of such decentralized care delivery need to take into consideration patients' preferences and satisfaction and rely on multiple types of nurses who can support and facilitate telehealth with physicians in clinics and patient homes. We formulate an optimization problem to simultaneously satisfy patients' care needs and reduce operating costs. We propose a bi-level approximation that exploits the structure of the hybrid telehealth system and develop column generation-based approaches to identify the decision rules for clinic selection and nurse scheduling.

4 Design of Covid-19 Staged Alert Systems with Wastewater Surveillance: A Retrospective Case Study

Guyi Chen[1], Shuotao Diao[2], David Morton[1], [1]Northwestern University, Evanston, IL, [2]University of Southern California, Los Angeles, CA, Contact: guyichen2024@u.northwestern.edu

Community mitigation strategies can reduce transmission of SARS-CoV-2. We seek to derive a COVID-19 mitigation strategy to retrospectively ensure healthcare capacity with minimal closures. Wastewater surveillance is cost-effective and sustainable even during non-pandemic times and can capture symptomatic and non-symptomatic individuals. More importantly, a wastewater signal can precede other signals such as hospital admissions.We use wastewater surveillance to inform toggling between mitigation stages. We propose an optimized staged-alert system with a wastewater signal using Cook County in Illinois as a case study.

5 Optimize Referral Decisions for Early Diagnosis Under Limited Service Capacity: An Application in Autism Screening

Yu-Hsin Chen[1], Qiushi Chen[1], Whitney Guthrie[2], [1]Penn State University, University Park, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA

Early diagnosis is crucial to the treatment outcome of Autism Spectrum Disorder (ASD), a developmental disorder that affects 1 in 44 children in the US. While universal screening has been advocated for early diagnosis of ASD, it has been widely debated concerning the screening tool's poor accuracy and the limited diagnostic service capacity. To improve the early diagnosis of ASD under limited service capacity, we develop a non-convex mixed integer quadratic program that determines the optimal risk-based diagnostic referral decision at different ages. The model is solved to optimality using branch and bound algorithm and McCormick relaxation. Finally, we evaluate the performances of different referral policies with individual-level discrete event simulation, and analyze the impact of service capacity and length of diagnostic waitlist on the early diagnosis outcomes.

Tuesday, October 17, 10:45 AM - 12:00 PM

Recent Advances in Radiation Therapy

Community Committee Choice Session

Session Chair: Kimia Ghobadi, Johns Hopkins University, Baltimore, MD

Session Chair: Masoud Zarepisheh, Memorial Sloan Kettering, New York, NY

1 Low Dimensional Radiotherapy Treatment Planning Using Low-Rank Plus Sparse Matrix Embedding and Wavelets

Masoud Zarepisheh[1], Mojtaba Tefagh[2], [1]Memorial Sloan Kettering, New York, NY, [2]Sharif University of Technology, Tehran, Iran, Islamic Republic of

This study aims to leverage the dimensionality reduction tools to improve the speed and quality of radiotherapy planning. The dimensionality reduction has a rich history in statistics and has recently re-emerged as a powerful tool to deal with the problems arising in the fields of big-data and machine learning. The optimization problems arising in radiotherapy also suffer from the curse of dimensionality (e.g., many machine parameters, voxels). We show how matrix/tensor decomposition, in particular low-rank plus sparse decomposition, and wavelets can be employed to significantly improve the computational efficiency and plan quality. We also propose a novel algorithm for the low-rank plus sparse matrix decomposition and demonstrate the effectiveness of the new algorithm on radiotherapy problems as well as background separation problems in computer vision.

2 Simultaneous Reduction of Number of Spots and Energy Layers in Intensity Modulated Proton Therapy for Rapid Spot Scanning Delivery

Anqi Fu[1], Vicki T. Taasti[2], Masoud Zarepisheh[3], [1]Memorial Sloan Kettering, New York, NY, [2]Maastro, Maastricht, Netherlands; [3]Memorial Sloan Kettering, New York, NY, Contact: anqif@alumni.stanford.edu

We propose a method to improve the delivery efficiency of proton therapy by reducing the number of spots and energy layers using reweighted l_1 regularization. We formulate the treatment planning problem as a convex problem with an objective containing a plan quality term and a weighted l1 regularization term. We iteratively solve this problem, updating the weights to promote sparsity of the spots and layers. We assess the algorithm on four head-and-neck patients and find that reweighted l_1 regularization reduces the number of spots and energy layers by 40% and 35%, respectively, with minimal cost to plan quality. It also provides a better trade-off between delivery efficiency and quality than standard l_1 or group l_2 regularization.

3 PortPy: An Open-Source Python Package for Planning and Optimization in Radiation Therapy Including Benchmark Data and Algorithms

Gourav Jhanwar[1], Mojtaba Tefagh[2], Vicki Trier Taasti[3], Sadegh Alam[4], Seppo Tuomaala[1], Saad Nadeem[1], Masoud Zarepisheh[1], [1]Memorial Sloan Kettering Cancer Center, New York, NY, [2]Sharif University of Technology, Tehran, Iran, Islamic Republic of; [3]Department of Radiation Oncology (MAASTRO), GROW – School for Oncology and Reproduction, Maastricht University Medical Centre+, Maastricht Limburg, Netherlands; [4]Weill Cornell Medicine, New York, NY, Contact: jhanwarg@mskcc.org

Following the success of our in-house automated treatment planning system (called ECHO) which treated more than 7,000 patient to-date, we decided to develop the first open-source python library for *benchmarking*, *reproducibility*, and *community-driven* development of radiotherapy cancer treatment planning optimization algorithms. PortPy is a python codebase currently including: 1) 100 research-ready benchmark dataset for lung patients with pre-calculated influence matrix from an FDA-approved treatment planning system, 2) benchmark optimization algorithms 3) 2D and 3D visualizations, and 4) benchmark evaluation metrics. The PortPy GitHub organization (https://github.com/PortPy-Project) hosts the codebase. PortPy promotes transparency for treatment planning algorithm developments by providing benchmark code and datasets.

4 Automated Vmat Treatment Planning Using Sequential Convex Programming: Algorithm Development and Clinical Implementation

Pinar Dursun, Linda Hong, Gourav Jhanwar, Qijie Huang, Ying Zhou, Jie Yang, Hai Pham, Laura Cervino, Jean M. Moran, Joseph O. Deasy, Masoud Zarepisheh, Memorial Sloan Kettering Cancer Center, New York, NY, Contact: pinar.dursun@boun.edu.tr

This study develops and clinically implements a fully automated treatment planning system for volumetric modulated arc therapy (VMAT). Two constrained optimization problems are solved sequentially using an algorithm that optimizes machine parameters directly and handles non-convexity using sequential convex programming. Two novel convex surrogate metrics improve plan delivery efficiency and reduce plan complexity. Before clinical implementation, the program was tested retrospectively on 60 patients and compared to manual plans, with automated plans found dosimetrically comparable or superior. The program is currently deployed in a clinic and used in daily clinical routine.

Smart Urban Mobility and Logistics: Integration and Optimization

Community Committee Choice Session

Session Chair: Sheng Liu, University of Toronto, Toronto,

ON, Canada
Session Chair: Yiling Zhang, University of Minnesota, Minneapolis, MN

1 Strategic Service Games with Customer-Induced Competition

Lavanya Marla[1], Jungeun Shin[2], Sanyukta Deshpande[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]University of Illinois at Urbana-Champaign Department of Industrial and Enterprise Systems Engineeri, Nottingham, United Kingdom; [3]University of Illinois at Urbana Champaign, Champaign, Contact: lavanyam@illinois.edu

We study decentralized Emergency Medical Services (EMS) in emerging economies, where customers order from multiple providers and choose the one that provides quicker service. In turn, providers strategically define their service regions. We model this as a stylized non-cooperative game with two providers located at each end of a Hoteling line. Providers strategically choose service regions to maximize their utility given the stochasticity and opportunity costs. We analyze provider behavior using renewal theory, to show that the coupling is `limited', resulting in a tractable approximation of the system -- and the existence of an "epsilon"-equilibrium for the original system. We find that customer-utility-maximizing coverages are pareto-improving compared to the provider equilibrium; and are moreover, non-intuitive compared to policymakers' expectations.

2 A Continuum Approximation Approach for Freight-On-Transit System Design Under Spatially Heterogeneous Demand

Shiyu Shen, Yanfeng Ouyang, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: sshen10@illinois.edu

Recent decline in transit ridership and surge in freight demand pose challenges for both sectors. A freight-on-transit (FOT) system is proposed to utilize the available transit vehicle capacities to support freight deliveries. The service region, with spatially heterogeneous freight demand, is divided into disjoint zones each containing a subset of co-modal stations from the transit network. Transit vehicles are used to perform freight line-haul services across zones, while dedicated local vehicles provide intra-zonal and last-mile services. A continuum approximation (CA) approach with an embedded aspatial queuing network model is used to optimize zonal service configurations (including the distributions of zones, co-modal stations, and local fleet sizes). A series of numerical experiments are conducted to demonstrate the applicability of the proposed model.

3 Robust Probabilistic Envelope Constrained Programming for Ultra-Fast Delivery

Xin Wang, Erick Delage, Okan Arslan, Jean-François Cordeau, HEC Montréal, Montréal, QC, Canada. Contact: xin.wang@hec.ca

Ultra-fast delivery is a novel idea for food and grocery delivery service within a matter of minutes. We investigate the arising delivery problem with different service level guarantees, and develop robust probabilistic envelope constrained programming models in which both the travel time distribution and the probability of customer placing order in different time periods are not explicitly known, and the demand depends on the uncertainty and allocation decisions. We then derive equivalent and tractable linear programming models. We compare the performances of period and daily service levels under different protections, and find the profitable ones that yield fast delivery, high demand coverage, and low level of violations. We carry out extensive experiments using a real-world dataset provided by Amazon and Google API, and derive some managerial insights.

4 Packages, Passengers, or Both? The Value of Joint Delivery and Ride-Hailing

Sheng Liu[1], Junyu Cao[2], [1]University of Toronto, Toronto, ON, Canada; [2]The University of Texas at Austin, Austin, TX, Contact: sheng.liu@rotman.utoronto.ca

With the emergence of on-demand platforms, it has become viable for drivers to participate in package delivery and passenger rides operations at the same time. The integration and coordination of the two services, known as co-modality, is considered a promising solution for improving the efficiency of urban logistics and mobility systems. In this work, we propose a simple zoning-based coordination policy and analyze its performance against pure delivery and ride-hailing policies.

Disruptive Technologies and Operations Management

Community Committee Choice Session

Session Chair: Xiangjing Chen, Arizona State University, Tempe, AZ

1 Competitive Pricing in the Presence of Manipulable Information in Online Platforms

Harish Guda, Yuqi Yang, Hongmin Li, Arizona State University, Tempe, AZ

To entice customers to purchase, sellers on online platforms often misrepresent the quality of their goods/services, e.g., by manipulating customer opinions. We analyze an oligopoly where sellers, heterogeneous in their true quality, compete by jointly choosing their prices and the extent of manipulation. We show that when manipulation cost is symmetric across products, higher quality sellers have a greater incentive to manipulate than lower quality sellers, and thereby manipulate by a greater extent. When the manipulation cost is asymmetric, and the marginal manipulation cost is increasing in the quality of sellers, sellers' propensity to manipulate could be either monotone or unimodal in their true quality. In this paper, we describe the dynamics under a wide spectrum of scenarios to explain observations in practice.

2 Data-Driven Delivery Zoning for Equitable Last-Mile Logistics

Han Yu[1], Sheng Liu[2], Stanley Lim[3], John Gunnar Carlsson[1], [1]University of Southern California, Los Angeles, CA, [2]University of Toronto, Toronto, ON, Canada; [3]Michigan State University, East Lansing, MI, Contact: hyu376@usc.edu

Last mile delivery system is in high demand, due to customer expectations for fast deliveries. We propose a novel approach that utilizes the weighted Voronoi diagram to minimize the expected delivery time and sorting time of customer orders and achieve equitable workload distribution among drivers in a stochastic setting. We consider the randomness and general distribution of order locations. Our policy assigns each hub to a specific subregion, and drivers from that hub are responsible for delivering all orders in that region. We combine the sample average algorithm and robust optimization with the weighted Voronoi diagram and also propose a discrete case of the algorithm. We evaluate our algorithm's performance in Thailand and compare it to the current partition approach, demonstrating its potential to improve last-mile delivery systems.

3 Service Recovery via Social Media: The Role of Brand Personality and Competitive Strategy

Pei Xu[1], Lin Lu[2], Sidi Zhao[1], Yen-Yao Wang[1], [1]Auburn University, Auburn, AL, [2]Fairfield University, Fairfield, CT, Contact: pzx0002@auburn.edu

Due to the public nature of the interactions and the ability to foster quicker responses than traditional media, social media has become a powerful channel for both travelers to post their trip-related questions and issues, and airlines to build their brand images. Based on the Signaling theory and Expectations- Confirmation theory, we propose that airline service recovery via Twitter will boost profitability, and such influence is more vital for network airlines than focused airlines and is moderated by brand personality dimensions.

4 Social Media Impersonation and Identity Verification

Zihong Huang, Texas Tech University, Lubbock, TX

In this paper, we study the economics of social media impersonation. Social media impersonation refers to accounts pretending to be someone else by using other people's profile elements such as names, photos, and demographic information. This study is motivated by the observation of social media platforms' efforts to address the social media impersonation problem by introducing the paid identity verification service. we propose questions that should the platform provide the identity verification service, and what's the welfare impact? By incorporating the platform, content creator, and consumers in the signaling game framework, we can examine the platform's optimal decision and the creator's equilibrium behaviors.

Empirical Healthcare Operations

Community Committee Choice Session

Session Chair: Harshita Kajaria-Montag, University of Cambridge, Cambridge, United Kingdom

1 The Role of Peer Familiarity in Shared Service Delivery: An Investigation into Shared Medical Appointments

Nazli Sonmez[1], Kamalini Ramdas[2], Ryan Buell[3], [1]ESMT Berlin, Berlin, Germany; [2]London Business School, London, United Kingdom; [3]Harvard Business School, Boston, Contact: nazli.sonmez@esmt.org

In shared service delivery, a group of customers is served at once. We examine how peer familiarity impacts service outcomes in shared service delivery in the context of shared medical appointments (SMA) - in which patients with similar chronic conditions meet with a doctor at once, and each receives one-on-one care in turn. Using data from the treatment arm of a prior multistage randomized controlled trial at a large hospital in India and an instrumental variable approach, we find that having familiar peers in the group significantly increases patient satisfaction, taking advantage of plausibly exogenous variation in peer familiarity. Our results shed light on an important aspect of how shared medical appointment groups should be formed. The insights obtained could also be valuable when considering delivery innovation in other traditionally one-on-one service settings.

2 The Mediating Effect of Market Competition on Episode-Based Payments

Turgay Ayer[1], Bilal Gokpinar[2], Austin McCandlish[3], [1]Georgia Tech, Atlanta, GA, [2]UCL School of Management, London, United Kingdom; [3]Georgia Institute of Technology, Atlanta, GA, Contact: ayer@isye.gatech.edu

Episode-based payment (EBP) makes health care providers financially liable for meeting cost benchmarks throughout an entire episode of care. We study the effect of an EBP scheme targeting childbirth using a large employer-sponsored claims data set. We find that EBP is associated with a reduction in inpatient spending, driven by lower facility payments. Further, we find EBP only generates savings in competitive hospital markets, and savings are generated by rerouting patients away from high-cost hospitals. We find no evidence of savings in markets with low competition. We also find no evidence providers significantly alter inpatient treatment patterns or use of follow-up. We conclude physicians targeted with EBP focus on reducing use of high-cost hospitals rather than changing treatment patterns, and as such EBP is only effective in competitive hospital markets.

3 Reducing Appointment Delays: The Impact of Standardized EHR Usage on Physician Timeliness

Umit Celik[1], Sandeep Rath[2], Bradley R. Staats[3], Saravanan Kesavan[4], [1]UNC Kenan-Flagler Business School, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of North Carolina-Chapel Hill, Chapel Hill, NC, Contact: umit_celik@kenan-flagler.unc.edu

This paper explores the impact of standardized Electronic Health Record (EHR) usage on physician timeliness and appointment delays. Data from physicians' schedules and detailed EHR timestamps are analyzed. Standardizing EHR work before appointments reduces multitasking, while standardization before and during appointments further reduces multitasking. Increased multitasking during appointments leads to subsequent appointment delays, but increased standardization reduces them. These findings inform healthcare operations strategies for reducing delays by standardizing EHR usage, benefiting healthcare administrators, improving physician timeliness, and enhancing patient satisfaction.

4 Workforce Composition as a Key Determinant of Primary Care Outcomes

Harshita Kajaria-Montag[1], Michael Freeman[2], [1]University of Cambridge, Cambridge, United Kingdom; [2]INSEAD, Singapore, Singapore. Contact: hk437@cam.ac.uk

Primary care practices have responded to the workforce crisis by altering the composition of their workforce, specifically, by hiring more part time and locum physicians. But, this is counterproductive as research suggests that providing continuity of care is productivity-enhancing, which is difficult to offer with such a fragmented workforce. Consequently, the trend suggests that continuity of care has been declining over the past decade. This paper examines this question from an operations management perspective by exploring the relative importance of workforce composition related operational factors that may explain variation in rates of COC between practices and over time

Supply Chain Finance and Operations

Community Committee Choice Session

Session Chair: Christopher J. Chen, Indiana University Kelley School of Business, Bloomington, IN

1 The Endemic Population-Trust and Supply Chain Networks

Ziang Wang[1], Volodymyr O. Babich[2], Gilles Hilary[3], Jing Wu[4], [1]The Hong Kong Polytechnic University, Hong Kong, Hong Kong; [2]Georgetown University, Washington, [3]Georgetown University, Washington, DC, [4]Chinese University of Hong Kong, Hong Kong, Hong Kong

We study the effect of endemic population trust on the formation and dissolution of supply chain links. We apply the matching markets theory from Becker (1973) to analyze supply chain partnerships. Our empirical evidence is consistent with the complementarity of the endemic population trust of supply chain partners. Specifically, using a unique combination of supply chain links with socio-demographic and financial variables, we find a negative relationship between the supply chain durability and the trust distance between the two partners, indicating a positive

assortive matching. We also find that outside of the steady state, after the exogenous shocks to supply chains, the average endemic population trust of supply chain partners increases the durability of supply chain links.

2 Resource Reallocation: Empirical Evidence from Drug Shortages in the United States

Iva Rashkova[1], Panos Kouvelis[2], [1]Washington University in St Louis, St Louis, MO, [2]Washington University in St. Louis, St Louis, MO, Contact: irashkova@wustl.edu

We utilize two drug shortages data sources to study the link between new drug approvals and drug shortages. Drug approvals vary by therapeutic class of the drug and approval type - brand name, generic with or without market exclusivity. We find that the timing of a new drug shortage, in either database, is correlated with a subsequent drug approval for the same firm. Interestingly, the time lag between these events is increasing in the attractiveness of the drug approval's type. With the time lag identified based on the drug approval type, we also find a positive correlation between the time-to-recovery for an individual drug-shortage event and the associated drug approval. Our results potentially offer healthcare providers and policymakers insights into industry-wide capacity and resource allocation trends.

3 Effects of Financial Constraints on Supply Chain Financing Choices and Operational Decisions

Anqi Wu[1], Qi Wu[2], Sridhar Seshadri[3], [1]Florida International University, Miami, FL, [2]Case Western Reserve University, Cleveland, OH, [3]UIUC, Champaign, IL, Contact: anwu@fiu.edu

Bank credit is an important source of financing for firms and can have a significant impact on operational decisions. However, limited OM literature empirically investigates this impact and the mechanisms through which this impact manifest. This study bridges this gap by jointly considering multiple financial and operational factors in a supply chain. We overcome a primary empirical challenge, which arises from the embedded simultaneity between financial and operation decisions, by exploiting a policy intervention that imparted an exogenous shock to bank credit accessibility. We find that the improvement of firms' access to bank credit generates heterogenous effects on their financing choices and operational decisions in terms of different firm sizes and time periods.

Platform Operations

Community Committee Choice Session

Session Chair: Dennis Zhang, Washington University in St Louis, ST LOUIS, MO

Session Chair: Bing Bai, Washington University in St. Louis, Saint Louis, MO

1 Inferring Consideration Sets from Heatmap Data

Zahra Ziaei[1], Adam J. Mersereau[2], Seyed Emadi[3], Vidyaranya Gargeya[4], [1]Kenan-Flagler Business School, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, [3]University of North Carolina-Chapel Hill, Chapel Hill, NC, [4]University of NC-Greensboro, Greensboro, NC, Contact: zahra_ziaei@kenan-flagler.unc.edu

Ignoring consideration sets in modeling customer decisions may lead to biased estimation of customer preferences, yet consideration sets are difficult to infer in brick-and-mortar contexts. We show that the challenge of estimating consideration set models in brick-and-mortar contexts can be overcome with an emerging source of data: heatmap data. In contrast with clickstream data, heatmap data show customer traffic only in the aggregate. Despite this limitation, we show that heatmap data enable us to recover many of the benefits of individual-level data, such as eliminating the need for exclusion-restriction assumption and decreasing finite-sample bias. Finally, we install heatmap sensors in a retail store and find that heatmap data can result in improved predictive accuracy and better-estimated revenues in a product placement decision problem.

2 An Empirical Study of Blockchain-driven Transparency in a Consumer Marketplace

Jane Yi Jiang[1], Kenneth Moon[2], Wedad Jasmine Elmaghraby[3], [1]University of Maryland, College Park, MD, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Maryland, College Park, MD, Contact: jyjiang@umd.edu

Blockchain tracing generates credible transparency into products' supply chains, firms and marketplaces are now asking whether sharing such information with consumers can better convey the quality of their goods and increase consumer trust. We collaborate with a leading online platform in China to study such supply chain transparency's effects in a consumer marketplace. Using synthetic control methods, we find that such transparency significantly increases third-party sellers' average monthly revenues by up to 23.4% but disproportionately benefits products that are handling-sensitive or sold in less trusted markets. We structurally model the consumers' Bayesian learning process regarding quality and find that whereas transparency improves the accuracy of the quality signals that consumers receive, how consumers benefit depends on their sophistication.

3 Green E-Commerce: Environmental Impact of Fast Delivery

Chenshan Hu[1], Xiaoyang Long[2], Jiankun Sun[3], Dennis Zhang[4], [1]Washington University in St. Louis, Saint Louis, MO, [2]University of Wisconsin-Madison, Madison, WI, [3]Imperial College London, London, United Kingdom; [4]Washington University in St Louis, ST LOUIS, MO, Contact: chenshan.hu@wustl.edu

In this paper, we empirically investigate how an increase in delivery speed influences consumer purchasing behavior and evaluate how this would further lead to environmental issues. Then, we develop a model to explain our empirical results and accordingly, propose delivery pricing policies to achieve both environmental benefits and decent company revenue.

4 Externalities of Restaurant Density in Online Food Delivery Platforms

Ruomeng Cui, Emory University, Amazon, Decatur, GA

The rapid growth in sales within the food-delivery industry is driven by platforms striving to increase both the quantity and variety of their partnered restaurants. In this paper, we assess the impact of restaurant density on the operational performance of restaurants partnered with food delivery platforms. By integrating empirical findings with theoretical predictions from a queuing model, we ascertain that the role of delivery becomes more dominant than customer expansion and cannibalization as restaurant density increases.

Data-Driven Methods for Supply Chain Management

Community Committee Choice Session

Session Chair: Yining Wang, University of Texas at Dallas, Richardson, TX

1 Data-Driven Population Tracking in Large Service Systems

Morgan Wood[1], Fernando Bernstein[2], N. Bora Keskin[2], Adam J. Mersereau[3], Serhan Ziya[4], [1]University of North Carolina, Chapel Hill, NC, [2]Duke University, Durham, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]University of North Carolina, Chapel Hill, NC, Contact: smithmor@email.unc.edu

We develop asymptotically optimal policies to track queue lengths under different loss structures in a setting with inaccurate arrival and departure sensor data. By deriving general lower bounds on any policy's expected cumulative loss, we show that tracking the population in real-time is challenging because of the accumulation of tracking errors. We propose a detection policy with provably good performance guarantees that corrects the estimated population count when the system is believed to be nearly empty. Further, we explore the benefits of augmenting the sensor information with periodic queue inspections at a cost. Our model is motivated by queue tracking implemented at a large airport.

2 Assortment Optimization Under the Multivariate MNL Model

Tiancheng Zhao[1], Xin Chen[2], Menglong Li[3], Jiachun Li[4], Yuan Zhou[5], [1]University of Illinois at Urbana–Champaign, Champaign, IL, [2]Georgia Institute of Technology, Atlanta, GA, [3]City University of Hong Kong, Hong Kong, Hong Kong; [4]Tsinghua University, Beijing, China; [5]Tsinghua University, Beijing, China. Contact: tz14@illinois.edu

In this paper, we study an assortment optimization problem in which an assortment consists of products from two categories, and customers are allowed to choose a bundle of at most one product from each category. We allow arbitrary product interaction that determines the utility of each bundle. We show that the problem is NP-hard. Motivated by this, we design a 0.74-approximation algorithm based on an LP relaxation of the problem. This algorithm almost closes the integrality gap of the LP relaxation which is shown to be at most 0.75. Numerical experiments are conducted to demonstrate the quality and efficiency of our proposed algorithm.

3 A Dynamic Learning Policy for Multi-Warehouse Multi-Store Systems with Censored Demands

Sentao Miao[1], Yining Wang[2], [1]McGill University, Montreal, QC, Canada; [2]University of Texas at Dallas, Richardson, TX, Contact: sentao.miao@mcgill.ca

In this paper, we discuss the problem of inventory allocation in a multi-warehouse multi-store system when demand is unknown and we can only observe the censored demand. In particular, two decisions have to be made: replenishment at each store and percentage allocation from warehouses to stores, which depend on each other and make the problem a highly complicated non-convex dynamic programming. We propose a primal-dual learning algorithm based on a robust cutting plane method which decouple these two decisions. Our results show that the proposed algorithm performs near optimal.

4 Unit Commitment without Commitment: A Dynamic Framework for Managing an Integrated Energy System

David Brown[1], James Smith[2], [1]Duke University, Durham, NC, [2]Dartmouth College, Hanover, NH

Renewable energy sources like solar and wind are prone to variability and uncertainty. Although variable and uncertain demand has always been an issue for power systems, the growing reliance on renewable energy increases the need for system operators to manage production systems carefully. In this work, we develop a rigorous, analytical framework based on weakly coupled stochastic dynamic programming to help system operators manage production under uncertainty. We demonstrate our framework using models based on data provided by Duke Energy. Compared to current practice, our approach is computationally efficient and substantially improves operational efficiency, with the efficiency gains increasing in the renewable capacity of the system.

Empirical Examinations of Emerging Topics in Sustainable Operations

Community Committee Choice Session

Session Chair: Natalie Ximin Huang, University of Minnesota, Minneapolis, MN

Session Chair: Wayne Fu, University of Michigan-Dearborn, Dearborn, MI

1 Pooling Carbon Targets

Christian Blanco[1], Oznur Özdemir-Akyildirim[2], Erdinc Akyildirim[2], [1]Ohio State University, Columbus, OH, [2]University of Bradford, Bradford, United Kingdom. Contact: blanco.58@osu.edu

Many corporations now set voluntary direct (Scope 1) and indirect (Scope 2) carbon emissions reduction targets, but low success rates reflect that firms are not very strategic in designing these targets. We examine the design and cost implications of carbon reduction targets.

2 The Role of Waste Management Hierarchy in Sustainable Operations

Dustin Cole[1], Wayne Fu[2], [1]Auburn University, Auburn, AL, [2]University of Michigan-Dearborn, Dearborn, MI, Contact: waynefu@umich.edu

This research aims to understand how waste management hierarchy influences firm environmental performance. Based on the hierarchy, we compare the impact of primary reduction, source reduction, and secondary reduction, waste reduction on firm water usage and carbon emissions. The study results suggest that primary reduction has a stronger impact in general. In addition, a firm's official recognition of corresponding environmental issues leads to an enhanced effect of primary reduction but a diminished effect of secondary reduction, highlighting a potential tradeoff between the two reduction mechanisms.

3 Does Legalizing Marijuana Increase Toxic Waste? Evidence from Manufacturing Facilities in the United States

Suvrat Dhanorkar[1], Suresh Muthulingam[2], In Joon Noh[3], [1]Pennsylvania State University, University Park, PA, [2]The Pennsylvania State University, University Park, PA, [3]Penn State University, University Park, PA, Contact: suresh@psu.edu

We examine whether legalization of marijuana affects the toxic chemical releases at manufacturing facilities. To do so, we leverage a state-level quasi-experimental setting that evolves from the staggered enactment of marijuana legislation by different states in the US. We find that medical marijuana legislation (MML) adversely affects the toxic releases of manufacturing facilities in the state—the average waste released by facilities increased by 5.22% after MML. Further analysis shows that facilities undertake fewer managerial and technical modifications to their operational processes, which clarifies the mechanisms that affect toxic releases. Finally, we find that recreational marijuana legislation (RML), which increases marijuana's access for the general population, leads to further increases in toxic releases—the effect goes beyond the impact of MML.

1 Reaching a Deep-Decarbonization Energy System Under CO_2 Sequestration Uncertainty

Felipe A. Feijoo, Pontificia Universidad Católica de Valparaíso, Valparaiso, Chile. Contact: felipe.feijoo@pucv.cl

Chile seeks a net zero economy by 2050 considering emission reduction and natural sources of CO2 sequestration. However, this target allows further decarbonization of the energy system, particularly in the transport and residential sectors, which could indeed yield to net-negative systems. To assess tradeoffs of net zero or net negative systems, this research uses the Latin American Global Change Analysis Model, a well-known integrated assessment model, and the H2RES model to evaluate deep decarbonization scenarios reaching a net negative system by 2050. Results indicate that deep decarbonization of the energy system results in higher levels of electrification of final demand sectors, reducing dependence of uncertain bio-sources of negative emissions, which have been highly affected by wild-fires in Chile.

2 An Empirical Investigation of Investment Substitutability and Complementarity Between Flexible and Intermittent Electricity Generation

Seyed Amin Seyed Haeri[1], Ahmet Colak[2], Safak Yucel[3], [1]Clemson University, Clemson, SC, [2]Clemson University, Pendleton, SC, [3]Georgetown University, Washington, DC, Contact: sseyedh@clemson.edu

In this study we evaluate the role of the operational flexibility on capacity investment decisions made in electricity grids. We adopt an empirical approach and evaluate this role using a unique granular panel data set of United States electricity grid spanning across 2002-2019. We specifically evaluate how investment in a particular generation technology can influence future investments in other types of generation technologies. We essentially shed light on the evolving nature of the electricity generation portfolio from an operations management perspective while informing policy makers in designing more effective technology-specific policies that facilitate the transition toward renewable generation.

3 High Spatial Resolution Estimates of Residential Heating Flexibility for Power System Planning

Claire Halloran[1], Filiberto Fele[2], Malcolm McCulloch[1], [1]University of Oxford, Oxford, United Kingdom; [2]University of Seville, Seville, Spain. Contact: claire.halloran@eng.ox.ac.uk

Regional variation in housing stock can lead to spatial differences in heating flexibility potential. We introduce a method to evaluate residential thermal energy storage potential at high spatial resolution with low data and computational requirements for power system planning. We leverage high-resolution spatial data on metered gas and electricity annual consumption and weather reanalysis, a more accessible dataset compared to the information required by standard approaches using physics-based building simulations. Incorporating this spatially detailed building stock flexibility potential can significantly benefit bulk power system planning and operation. For instance, we identify regional opportunities in the UK for long-term heat pump flexibility contracting to reduce storage and generation investment requirements, leading to system-wide savings.

4 Evaluating the Impact of Pre- and Post-pandemic Implementation of Flexible Work Policies on Firms' Operational Resilience

Priscilla Rodriguez[1], So Yeon CHUN[2], [1]INSEAD, Fontainebleau, France; [2]INSEAD, Singapore, France

The global shift towards remote and flexible work arrangements, accelerated by the COVID-19 crisis, has notably heightened the importance of flexible work policies (FWP) within organizational strategies. In this research, we explore the drivers behind the adoption of FWP by examining different firm characteristics both prior to and following the pandemic. Additionally, we evaluate how FWP influences firms' performance outcomes

Contributed Session

Session Chair: Hyungjin Kim, Hanyang University, Seoul, Korea, Republic of

1 Incorporating Prior Function Belief into Neural Networks Through Dropout and Negative Correlation Learning

Hyungkwon Lee, Jaesub Yun, Jong-Seok Lee, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: lhk6565@g.skku.edu

The utilization of dropout in neural networks, which is recognized as an ensemble technique, has been linked to Gaussian Process (GP) regression. However, the current dropout method lacks the modeling capabilities of the GP covariance structure found in the original GP model. To address this limitation, we propose a novel dropout training method that incorporates negative correlation learning. Through empirical evaluation, we demonstrate that our approach effectively captures the intended covariance structure of GP within the neural networks model. We believe that our research has important implications for the machine learning field, particularly in enhancing the generalization capability of neural networks.

2 Optimal Regularization of the First Principal Component

Youhong Lee, University of California, Santa Barbara, Santa Barbara, CA, Contact: ylee@pstat.ucsb.edu

In this study, we introduce a novel regularization technique, Direction-Regularized Principal Component Analysis (drPCA), which amalgamates traditional estimators with a structured target, a method widely adopted in high-dimensional data analysis. This method aims to determine the maximum variance direction within the data, while adhering to a pre-specified target direction, thereby offering a solution to the PCA problem. We deploy the high-dimensional, low-sample size framework for an asymptotic analysis of the solution, yielding an optimal tuning parameter that minimizes an asymptotic loss function. As a result, the data rapidly assimilates the estimator corresponding to this optimal tuning parameter.

3 Inexact Bilevel Stochastic Gradient Methods for Constrained and Unconstrained Lower-Level Problems

Griffin D. Kent, Tommaso Giovannelli, Luis Nunes Vicente, Lehigh University, Bethlehem, PA, Contact: gdk220@lehigh.edu

Two-level stochastic optimization formulations have become instrumental in a number of machine learning contexts such as continual learning, neural architecture search, adversarial learning, and hyperparameter tuning. In this paper, we introduce a bilevel stochastic gradient method for bilevel problems with lower level constraints. We also present a comprehensive convergence theory that covers all inexact calculations of the adjoint gradient (also called hypergradient) and addresses both the lower-level unconstrained and constrained cases. To promote the use of bilevel optimization in large-scale learning, we introduce a practical bilevel stochastic gradient method (BSG-1) that does not require second-order derivatives and, in the lower-level unconstrained case, dismisses any system solves and matrix-vector products.

4 Parameter Estimation via Random Search with Surrogate and Simulation Models for Multiple Vectors of Observations

Hyungjin Kim[1], Chuljin Park[2], Heeyoung Kim[3], [1]Hanynag universitiy, Seoul, Korea, Republic of; [2]Hanyang University, Seoul, Korea, Republic of; [3]Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of. Contact: jins731@gmail.com

We consider the parameter estimation for multiple vectors of observations when a simulation model is available. To solve the problem, we first introduce a surrogate model and provide explicit forms of the mean and variance of the least square function between the posterior predictive of the surrogate model and a vector of observations. Then, we propose a framework that iteratively finds the parameters corresponding to a vector of observations using random search with surrogate and simulation models. We show that the framework controls the expected number of simulations as a user-specified value. We test the framework in numerical examples and a case study in semiconductor manufacturing.

Applications of Integer Programming

Community Committee Choice Session

Session Chair: Ashley Peper, University of Wisconsin - Madison, Madison, WI

1 Selecting And Scheduling Cybersecurity Mitigations With Resource Constraints

Ashley Peper, Jim R. Luedtke, Laura Albert, University of Wisconsin-Madison, Madison, WI, Contact: apeper2@wisc.edu

We study the problem of selecting and planning cybersecurity mitigations. Existing models address the problem of selecting a portfolio of security mitigations subject to a budget constraint in order to maximize coverage of vulnerabilities, where covering a vulnerability multiple times exhibits diminishing returns. A key limitation of such models is that they do not consider the limited resources required to deploy the mitigations over time. We introduce a new integer programming model that simultaneously selects mitigations and schedules their deployment while accounting for limited resources. We perform computational experiments that illustrate the benefit of our new model.

2 Solving a Multiple Tethered Autonomous Underwater Vehicle (T-AUV) Routing Problem Toward Entanglement Free Navigation

Jungyun Bae, Abhishek Patil, Myoungkuk Park, Michigan Technological University, Houghton, MI, Contact: bae@mtu.edu

T-AUVs can perform underwater tasks under reliable communication and power supply, which is the most substantial benefit of their operation. Thus, we focus on developing operational strategies that handle multiple T-AUV operations without having tether entanglements while considering workload balancing between the vehicles. The proposed heuristic consists of two main steps, 1) task allocation and routing and 2) re-routing and scheduling. In the first step, the primal-dual technique is applied for initial task allocation and routing while minimizing the maximum travel cost of the vehicles. During the second step, the heuristic confirms if there exists any possible entanglement. A mixed approach has been proposed for those cases to avoid entanglement with time scheduling and sectionalization methods. The algorithm is verified through repeated simulation runs.

3 Optimal Allocation of Chargers at Recharging Stations to Minimize Time Window Violations in Electric Vehicle Routing Problems with Time Windows and Queuing Times

Vamsi Krishna Kunapareddy[1], Rajan Batta[2], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo (SUNY), Buffalo, NY, Contact: vkunapar@buffalo.edu

This talk addresses the impact of queuing times at charging stations on the compliance of time windows for Electric Vehicles (EVs) in a Vehicle Routing Problem with Time Windows (VRPTW). An optimization model is proposed to allocate optimal chargers to maximize the number of customers whose time windows are not violated. The model is tested on a set of instances with varying characteristics, and the results demonstrate the importance of considering queuing times in EVRPTW. The proposed model can be used as a decision-making tool for EV fleet managers to ensure timely and efficient delivery.

4 Helicopter Routing Problem for Cargo and People Transportation

Hernan Caceres[1], Juan Pablo Contreras[2], [1]Universidad Catolica del Norte, Antofagasta, Chile; [2]Universidad Católica del Norte, Antofagasta, Chile. Contact: hcaceres@ucn.cl

The routing problem of helicopters for transporting people and cargo poses a significant challenge in aviation logistics. This work addresses the optimization of helicopter routing to efficiently allocate resources and minimize operational costs while meeting constraints such as passenger and cargo demands, flight distances, fuel consumption, airspace restrictions, and operational time windows. We propose a comprehensive mathematical model integrating route planning, resource allocation, and scheduling. The model incorporates both deterministic and stochastic elements, accounting for uncertainties in demand, weather conditions, and other relevant factors. Additionally, various optimization techniques, including metaheuristics and mathematical programming, are explored to solve the complex routing problem effectively.

Nonlinear Optimization in Machine Learning

Community Committee Choice Session

Session Chair: Hande Benson, Drexel University, Philadelphia, PA

Session Chair: Cassidy Buhler, Philadelphia, PA

1 Decision-Making for Land Conservation: A Derivative-Free Optimization Framework with Nonlinear Inputs

Cassidy Buhler[1], Hande Benson[2], [1]Drexel University, Philadelphia, PA, [2]Drexel University, Philadelphia, PA, Contact: cb3452@drexel.edu

Protected areas (PAs) are designated spaces where human activities are restricted to preserve critical habitats. Decision-makers are challenged with balancing a trade-off of financial feasibility with ecological benefit when establishing PAs. OR tools like simulation and optimization are used to select PAs, but current decision models are primarily linear. We propose a derivative-free optimization framework paired with a nonlinear component, population viability analysis (PVA). Formulated as a mixed integer nonlinear programming (MINLP) problem, our model allows for linear and nonlinear inputs and can be paired with ecological software. Our numerical results serve as a proof of concept, showing our model yields PAs with similar expected risk to that of preserving every parcel in a habitat, but at a significantly lower cost.

2 Effective Weighted Trust-Region Methods for Unconstrained Optimization

Johannes J. Brust[1], Philip Gill[2], [1]Arizona State University, Tempe, AZ, [2]University of California-San Diego, La Jolla, CA, Contact: jjbrust@asu.edu

Unconstrained optimization is essential for many data driven problems. When only gradients of the objective function are available, methods that estimate the Hessian of second derivatives are effective. We develop a trust-region (TR) method that updates a symmetric factorization of the Hessian approximation, and that only requires the matrix factors. The main computational challenge for trust-region methods is the solution of the TR subproblem, which determines the next search direction. In order to overcome this difficulty, the factored matrix can be used to define subproblems in terms of weighted norms, which significantly reduce the costs of a subproblem. We develop two solvers based on a weighted two and a weighted infinity norm. The methods are effective when tested on a vast set of unconstrained optimization problems from the benchmarking CUTEst collection.

Primal-dual Methods for Minimax Problems

Community Committee Choice Session

Session Chair: Serhat Aybat, Penn State University, University Park, PA

Session Chair: Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ

1 Robust Accelerated Primal-Dual Methods for Computing Saddle Points

Xuan Zhang[1], N. Serhat Aybat[2], Mert Gurbuzbalaban[3], [1]The Pennsylvania State University, STATE COLLEGE, PA, [2]Penn State University, University Park, PA, [3]Rutgers University, Piscataway, NJ, Contact: xxz358@psu.edu

We propose a stochastic accelerated primal-dual (SAPD) algorithm for solving strongly-convex-strongly-concave saddle point problems, demonstrating linear convergence to a unique saddle point neighborhood. The neighborhood size depends on the asymptotic variance of iterates. We characterize robustness to gradient noise, optimize SAPD parameters for desired convergence rate-robustness trade-offs, and enable fast convergence with noise robustness. SAPD admits convergence guarantees for the distance metric with a variance term that is optimal up to a logarithmic factor -which can be removed by a restarting strategy. We also discuss how convergence and robustness results extend to the convex-concave setting. Finally, we illustrate our framework on distributionally robust logistic regression.

2 A Stochastic GDA Method with Backtracking for Solving Nonconvex Strongly Concave Minmax Problems

Qiushui Xu[1], Xuan Zhang[2], N. Serhat Aybat[1], Mert Gurbuzbalaban[3], [1]Penn State University, University Park, PA, [2]The Pennsylvania State University, STATE COLLEGE, PA, [3]Rutgers University, Piscataway, NJ, Contact: qjx5019@psu.edu

We propose a stochastic Gradient Descent Ascent method with backtracking (SGDA-B) to solve nonconvex-strongly-concave (NSC) minimax problems min_x max_y sum_{i=1}^N g_i(x_i)+f(x,y)-h(y), where h and g_i for i=1...N are closed convex, f is L-smooth and mu-strongly concave in y. SGDA-B does not require to know L, and using random block-coordinate updates it can compute an eps-stationary point with probability p within O(kappa^2 L eps^{-4} log(1/p)) stochastic oracle calls, where kappa=L/mu. To our knowledge, SGDA-B is the first GDA-type method with backtracking to solve NSC minimax problems. We provide numerical results for SGDA-B on a distributionally robust learning problem.

3 High Probability and Risk-Averse Guarantees for Stochastic Saddle Point Problems

Yassine Laguel[1], Mert Gürbüzbalaban[2], Serhat Aybat[3], [1]Rutgers University, Piscataway, NJ, [2]Rutgers University, Piscataway, NJ, [3]Penn State University, University Park, PA, Contact: laguel.yassine@gmail.com

We investigate the stochastic accelerated primal-dual algorithm for strongly-convex-strongly-concave saddle point problems, common in distributionally robust learning, game theory, and fairness in machine learning. Our algorithm offers optimal complexity in several settings and we provide high probability guarantees for convergence to a neighborhood of the saddle point. We derive analytical formulas for the limit covariance matrix and develop lower bounds to show that our analysis is tight. Our risk-averse convergence analysis characterizes the trade-offs between bias and risk in approximate solutions. We present numerical experiments on zero-sum games and robust learning problems. Collaborators: Mert Gürbüzbalaban and Necdet Serhat Aybat.

4 Recent Advances in Stochastic Primal Dual Algorithms with Applications to Distributionally Robust Learning

Bugra Can[1], Serhat Aybat[2], Mert Gurbuzbalaban[3], [1]Rutgers University, New Brunswick, NJ, [2]Penn State University, University Park, PA, [3]Rutgers University, Piscataway, NJ

We first consider smooth strongly convex strongly concave (SCSC) minimax problems. Such problems arise frequently in machine learning in the context of robust empirical risk minimization (ERM), e.g. distributionally robust ERM (DR-ERM), where partial gradients are estimated using mini-batches of data points. Assuming we have access to an unbiased stochastic first-order oracle we consider the stochastic accelerated primal dual (SAPD) algorithm for SCSC minimax problems as a robust method against gradient noise. We propose efficient bias-reduction strategies for SAPD based on Richardson-Romberg extrapolation and show that our method improves upon SAPD. Second, we present a class of subgradient algorithms with finite-sample complexity guarantees for solving non-smooth non-convex/concave minimax problems that arise in the DR-ERM setting.

Global Optimization

Community Committee Choice Session

Session Chair: Sergiy Butenko, 1</sup

1 Convexification of Nonconvex Compositions with Norms

Anatoliy Kuznetsov, Nikolaos Sahinidis, Georgia Institute of Technology, Atlanta, GA, Contact: akuznetsov3@gatech.edu

Nonconvex optimization problems involving compositions of functions with norms present a challenge for global optimization algorithms based on spatial branch-and-bound since they exhibit a high degree of symmetry, and factorable relaxations of reverse convex constraints and compositions of functions with norms are generally weak. In this work, we introduce novel convex envelopes for common functions composed with norms based on the characterization of their generating sets. The theoretical development exploits the fact that the generating set of these functions is a finite collection of many compact convex sets. We implement our envelopes in the global optimization solver BARON and demonstrate their impact using open problems from the literature as a benchmark.

2 On the Convex Hull of Mixed-Integer Nonlinear Submodular Minimization

Shaoning Han, Andres Gomez, University of Southern California, Los Angeles, CA, Contact: shaoning@usc.edu

We study the mixed-integer epigraph of a convex function which is jointly submodular in continuous and indicator variables. This class of mixed-integer sets appears in many applications such as Markov random fields, value-at-risk minimization and outlier detection. In this talk, we give the recipe of building the convex hull of such sets, based on which we are able to unify the existing results in literature. Beyond that, we discuss more implications of the abstract convexification result in mixed-integer quadratic and conic minimization problems.

3 A Hierarchy of Nonconvex Continuous Reformulations for Discrete Optimization
Miltiades Pardalos, Sergiy Butenko, Mykyta Makovenko, Texas A&M University, College Station, TX
We propose a fundamentally new approach to designing hierarchies of continuous formulations for discrete and combinatorial optimization problems by shifting the focus from convexifying a given formulation to establishing equivalent non-convex reformulations of the original problem. The aim is to move towards an "equi-maximal" reformulation in which every local optimum is global, a property which is eventually achieved at the final level of the hierarchy. The improved quality of local maxima is achieved through an increasing cost of objective function evaluation.

4 On Risk Averse Optimization in Discrete Systems
Masoud Eshghali, Pavlo A. Krokhmal, University of Arizona, Tucson, AZ
We discuss risk-averse stochastic optimization in discrete systems, such as networks or graphs. In particular, we consider identification of minimum-risk structures in graphs with random vertex or edge weights. The discrete setting allows us to obtain new insights into the interplay of risk reduction and diversification, the staple strategy in risk management.

Structuring the Ambiguous: New Perspectives on Distributionally Robust Learning
Community Committee Choice Session
Session Chair: Bahar Taskesen, EPFL, Lausanne, Switzerland

1 Distributional Robustness, Causal Transport, and Time Consistency
Rui Gao, University of Texas at Austin, Austin, TX
Distributionally robust optimization is an emerging paradigm for decision-making under model ambiguity. It hedges against model uncertainty by penalizing the deviation from a reference model. In this talk, we will discuss distributional robustness in a dynamic setting, where the deviation is measured by the bi-causal transport distance between stochastic processes. Such a choice accounts for information evolution, making it hedge against a plausible family of data processes. In spite of the non-convexity of the problem, we develop an equivalent robust Bellman recursion that gives a time-consistent representation.

2 Pessimistic Estimates and Optimistic Decisions for Bandits
Mengmeng Li[1], Bahar Taskesen[2], Daniel Kuhn[3], [1]EPFL, St Sulpice, Switzerland; [2]EPFL, Lausanne, Switzerland; [3]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland. Contact: bahar.taskesen@epfl.ch
We study optimism-pessimism interplay for online bandit problems and propose a general learning principle based on integrating pessimistic estimation with optimistic action selection.
Leveraging recent developments in the offline reduction of online contextual bandits algorithms, we demonstrate that pessimistic evaluations offer valuable out-of-sample disappointment probability bounds, crucial for safety-critical applications, while maintaining the same regret bounds. Our distributional optimism approach, unifies and generalizes existing state-of-the-art (non-)randomized contextual bandit algorithms.
In the finite arm setting, we utilize modern discrete choice theory to suggest an optimistic distribution model, which offers fresh perspectives on existing methods and addresses some challenging problems in the online learning field.

3 Robust Data-Driven Prescriptiveness Optimization
Mehran Poursoltani[1], Erick Delage[2], Angelos Georghiou[3], [1]HEC Montreal, Montreal, QC, Canada; [2]HEC Montréal, Montreal, QC, Canada; [3]University of Cyprus, Nicosia, Cyprus
The emergence of various optimization techniques, which leverage available side information, has motivated the development of a universal measure of performance called the coefficient of prescriptiveness. This coefficient quantifies both the quality of contextual decisions compared to a reference one and the prescriptive power of side information. To identify policies that maximize the former in a data-driven context, we introduce a distributionally robust contextual optimization model where the coefficient of prescriptiveness substitutes for the classical empirical risk minimization objective. We present a bisection algorithm to solve this model and study a contextual shortest path problem to evaluate the robustness of the resulting policies against alternative methods when the out-of-sample dataset is subject to a distribution shift.

4 Distributionally Robust Linear Quadratic Control
Bahar Taskesen[1], Dan Andrei Iancu[2], Cagil Kocyigit[3],

Daniel Kuhn[4], [1]EPFL, Lausanne, Switzerland; [2]Stanford University, Stanford, CA, [3]University of Luxembourg, Luxembourg, Luxembourg; [4]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland. Contact: cagil.kocyigit@uni.lu

The Linear-Quadratic-Gaussian (LQG) involves controlling a system with linear dynamics and imperfect observations, subject to additive noise, with the goal of minimizing a quadratic state and control cost. We consider a generalization of the LQG problem, where the noise distributions are unknown and belong to Wasserstein ambiguity sets centered at nominal (Gaussian) distributions. The objective is to minimize a worst-case cost across all distributions in the ambiguity set, including non-Gaussian distributions. We prove that a control policy that is affine in the observations is optimal for this problem, as in the classical LQG problem. We propose a numerical solution method that efficiently characterizes this optimal policy by using the Frank-Wolfe algorithm to identify the least favorable distributions, and Kalman filter estimation to compute the optimal policy.

Large Scale Optimization with Applications to Machine Learning

Community Committee Choice Session

Session Chair: Haoyue Wang, Massachusetts Institute of Technology, Cambridge, MA

1 Improving the Geometry of (Conic) Linear Optimization Problems for the Primal-dual Hybrid Gradient Method

Zikai Xiong[1], Robert Michael Freund[2], [1]MIT, Cambridge, MA, [2]MIT Sloan School of Management, Cambridge, MA, Contact: zikai@mit.edu

The primal-dual hybrid gradient method (PDHG) (with restarts) has shown significant success in solving huge-scale LP problems. However, current condition measures may take on extreme values and lead to poor performance, which begs the question of whether these condition measures can be improved by transformations of the given instance? In this study we provide a new geometric measure based on the primal-dual level set and show in particular how row and column rescaling can theoretically improve these condition measures. Our theoretical development leads to guidelines for practical implementation of re-scaling based on analytic centers. Moreover, these results could also be extended to conic linear optimization problems. Also, our experiments on LP relaxations of the MIPLIB 2017 dataset demonstrate the impact of rescaling on the actual performance of PDHG.

2 Algorithms for Learning Decision Trees: Optimality and Beyond

Xiang Meng, MIT, Cambridge, MA, Contact: mengx@mit.edu

In this paper, we present a novel branch-and-bound (BnB) based discrete optimization method to obtain optimal decision trees for both regression and classification tasks with continuous features. Our approach splits the search space according to the quantiles of the feature distribution, enabling effective upper and lower bounds evaluation. We provide complexity and error bounds, and leverage our method to design heuristics for building high-quality decision trees. Experiments on benchmark datasets show our optimal tree algorithm achieves up to 10^3 times speedups compared to state-of-the-art methods, and our heuristics improve out-of-sample performance by 5%-80%.

3 On Statistical Properties of Sharpness-Aware Minimization: Provable Guarantees

Kayhan Behdin, Rahul Mazumder, Massachusetts Institute of Technology, Cambridge, MA, Contact: behdink@mit.edu

Sharpness-Aware Minimization (SAM) is a recent optimization framework aiming to improve the deep neural network generalization, through obtaining flatter (i.e. less sharp) solutions. Recent papers have studied the theoretical aspects of the framework and have shown SAM solutions are indeed flat. However, there has been limited theoretical exploration regarding statistical properties of SAM. We directly study the statistical performance of SAM, and present a new theoretical explanation of why SAM generalizes well. To this end, we study two statistical problems, neural networks with a hidden layer and kernel regression, and prove under certain conditions, SAM has smaller prediction error over Gradient Descent (GD). Our results show that SAM is particularly well-suited for non-convex problems.

4 Polycd: A Cyclic Coordinate Descent Method for Convex Optimization on Polytopes

Haoyue Wang, Rahul Mazumder, Massachusetts Institute of Technology, Cambridge, MA, Contact: haoyuew@mit.edu

Coordinate descent (CD) methods are popular for huge-scale optimization problems when the objective is separable across coordinates. In this paper, we propose a new variant of cyclic CD that can handle polyhedral constraints if the polytope does not have too many extreme points. Loosely speaking, our proposed algorithm PolyCD, can be viewed as a hybrid of cyclic CD and the Frank-Wolfe algorithms. We prove that PolyCD has an O(1/k) convergence rate for smooth convex objectives. Furthermore, we propose PolyCDwA, a variant of PolyCD with away steps that has a linear convergence rate when the loss function is smooth and strongly convex. Empirical studies demonstrate that PolyCDwA achieves strong computational performance for large-scale benchmark problems including L1-constrained linear regression, L1-constrained logistic regression and kernel density estimation.

Innovative Solutions for Last-mile Delivery

Community Committee Choice Session

Session Chair: Sarah Powell, 1</sup

1 Underground Freight Transportation for Last Mile Delivery

Sarah Powell[1], Ann Melissa Campbell[2], [1]University of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, IA, Contact: sarah-powell@uiowa.edu

Underground freight transportation (UFT) is an unmanned freight transportation system in which small crates of packages travel through tubes in a network. The use of UFT for last-mile delivery offers many benefits, such as no emissions and reduced traffic congestion. We examine where to build a UFT system along roads in an existing road network. This system will deliver packages to distribution centers that each serve a small area. We present a model to maximize the amount of demand served by UFT while a budget for constructing the network is respected. Strong formulations of this problem can be used to solve realistic instances of the UFT for large cities. We perform a set of experiments using data from New York City and Chicago to weigh the tradeoffs of cost vs. potential impact. Our results show that UFT is a promising alternative for last-mile delivery.

2 Customer Satisfaction and Differentiated Pricing in E-Retail Delivery

Dipayan Banerjee, Alan Erera, Alejandro Toriello, Georgia Institute of Technology, Atlanta, GA, Contact: dipayan.banerjee@gatech.edu

We study a system in which a common delivery fleet serves both same-day delivery (SDD) and next-day delivery (NDD) orders placed by e-retail customers who are sensitive to delivery prices. We develop a continuous approximation model of the system and optimize with respect to two separate objectives. Our model captures the effect that one day's operations have on the next, a novel modeling component not present in SDD-only models; a key technical result is establishing the model's convergence to a steady state. We optimize for customer satisfaction by maximizing the quantity of NDD orders fulfilled one day early given fixed prices. Next, we optimize prices for profit in a two-level scheme with discounts for early-ordering customers. We derive structural insights and efficient algorithms for both objectives. We conduct simulations on a real-world road network for validation.

3 The Driver-Aide Problem in Urban Areas

Mengting Chao[1], Bruce L. Golden[2], Rui Zhang[3], Adriano Masone[4], [1]University of Maryland-College Park, College Park, MD, [2]University of Maryland-College Park, Columbia, MD, [3]University of Colorado Boulder, Boulder, CO, [4]University of Naples, Naples, Italy. Contact: mchao@umd.edu

The exponential growth of package volumes in recent years has presented significant challenges for last-mile delivery, especially in urban areas. Many logistics companies, including FedEx and UPS, have resorted to using a "driver-aide" to assist with deliveries. The aide can be used to assist the driver in two ways. As a "jumper", the aide works with the driver to deliver packages at a given stop. As a "helper", the aide can serve several stops independently, while at the same time the driver serves other stops. Then they meet each other at a later stop. Our goal is to determine both the delivery route and the most effective way to use the aide to minimize the total delivery time. We model this problem as an integer program with an exponential number of variables and an exponential number of constraints, and propose a branch-cut-and-price approach for solving it.

4 Dynamic Routing, Confirmation and Compensation for Combined Urban Transportation of Passengers and Goods

Yilun Wang, Min Xu, The Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: yilun.wang@connect.polyu.hk

Transporting goods with passengers on board can increase profits for Mobility-on-demand companies but may negatively affect travel experience of passengers due to detours for making deliveries along the way. To mitigate this, we investigate the potential of offering on-board passenger compensation as incentives in dynamic and stochastic scenarios, where the requests arrive dynamically and the passengers' acceptance of detour is unknown. We design an anticipatory policy based on a new value function approximation with slide memory and makes integrated routing, confirmation, and compensation decisions. Numerical experiments show that compared to the benchmark policies, the anticipatory policy achieves up to 15% more profits.

5 Time Slot Management for Attended Home Services Using Predetermined Routes

Ehsan Aghamohammadzadeh[1], Niels Agatz[2], Luuk Veelenturf[1], [1]Erasmus University Rotterdam, Rotterdam, Netherlands; [2]Erasmus University, Rotterdam, Netherlands

The timely and convenient delivery of attended home services presents a distinct challenge: customers must be present at home to receive their goods or services. In response, companies offer a selection of service time slots, taking into account both marketing strategies and operational logistics. In our study, we explore a scenario where we have accurate information about customer locations. By using this invaluable information, we investigate the effectiveness of utilizing predetermined routes to streamline the decision-making process for assigning optimal time slots.

Emerging Applications in Transportation and Logistics

Community Committee Choice Session

Session Chair: Julia Y. Yan, University of British Columbia, Vancouver, BC, Canada
Session Chair: Chiwei Yan, University of California-Berkeley, Berkeley, CA

1 A Tale of Two Electric Vehicle Battery Swapping Policies

Wei Qi[1], Mengyi Sha[1], Yuli Zhang[2], [1]Tsinghua University, Beijing, China; [2]Beijing Institute of Technology, Beijing, China. Contact: qiw@tsinghua.edu.cn

Battery swapping is gaining traction in cities. To deal with random service requests and random status of incoming batteries, the literature has assumed a FIFO policy of swapping batteries due to its tractability. We propose models to compare FIFO and HEFO swapping policies. The results demonstrate that HEFO is superior to FIFO in most scenarios, except when all EVs wait for the recharged batteries to reach a target state-of-charge (SOC).

2 A Continuous Approximation Model for Random Stow in Warehouses

John Gunnar Carlsson, University of Southern California, Los Angeles, CA, Contact: jcarlsso@usc.edu

We study the probabilistic behavior of routing optimization problems in which one is given a collection of points and the goal is to find the shortest tour that visits a subset of those points that meets certain criteria. Examples of such problems, which we call "selection routing problems", include the "one-of-a-subset" travelling salesman problem (TSP), and generalized TSP. We derive continuous approximation formulas for several such problems under the assumption that point-to-point distances are Euclidean and all points are independent and identical samples of a probability density on a compact planar region. Numerical simulations demonstrate that our formulas provide pretty accurate estimates of routing costs when a large number of samples are drawn. We also analyze the random stow warehouse model using our results.

3 Robotic Warehousing Operations: A Learn-Then-Optimize Approach to Large-Scale Neighborhood Search

Alexandria Schmid, MIT, Beverly, MA, Contact: aschmid@mit.edu

The rapid deployment of robotics technologies in warehousing requires dedicated optimization algorithms to manage large fleets of autonomous agents. This paper formulates a fleet management problem for parts-to-picker operations to maximize throughput, while managing human workload and congestion in the warehouse. To solve it, we develop a large-scale neighborhood search algorithm with a learn-then-optimize approach to subproblem generation. The algorithm relies on an offline machine learning procedure that attributes objective improvements to subproblem features, and an online optimization routine that generates new subproblems to maximize improvement. In collaboration with a major online retailer, we demonstrate the benefits of our model and algorithm compared to baseline algorithms and heuristics.

4 An Analysis of Batching and Greedy Policies in Dynamic Matching

Myungeun Eom[1], Alejandro Toriello[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Tech ISyE, Atlanta, GA, Contact: myungeun.eom@gatech.edu

Motivated by applications from ride-sharing and freight marketplaces, we study a dynamic non-bipartite matching, where nodes appear following a type-specific independent distribution and wait in the system for a given sojourn time. We analyze the asymptotic properties of two widely used policies, batching and greedy. We show that the batching is asymptotically optimal with respect to the sojourn time □ with an optimality gap of □(1/√□). Similarly, we show that a greedy with a minor modification is asymptotically optimal with a gap of □(1/□). More interestingly, both policies converge exponentially fast to (1-□)-optimality. We prove the convergence by analyzing a single-pair and converting from the single-pair to the general counterpart using a fluid relaxation and randomization. Finally, we present a case study to assess the empirical effectiveness of the policies.

5 Path-Based Formulations for the Design of On-Demand Multimodal Transit Systems with Latent Demand Awareness

Hongzhao Guan[1], Beste Basciftci[2], Pascal Van Hentenryck[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Iowa, Iowa City, IA, [3]ISyE Georgia Tech, Atlanta, GA, Contact: hguan7@gatech.edu

This study investigates capturing the latent demand in on-demand multimodal transit systems, namely the ODMTS Design with Adoptions problem (ODMTS-DA) by proposing a new path-based optimization model, called P-Path. This model addresses the computational difficulties from previous work that utilizes bilevel programs. The key idea of P-Path is to enumerate two specific sets of paths which capture the essence of the choice models associated with the adoption behavior of riders. Then ODMTS-DA can be formulated as a single-level MIP model. P-Path is evaluated on two comprehensive case studies. Results show that P-Path solves the mid-size instances in a few minutes, bringing more than two orders of magnitude improvements compared to previous approach. Moreover, the results show that P-Path can solve large-scale ODMTS-DA instances to optimally in a few hours or in a few days.

Network Modeling and Optimization of Railway Systems

Community Committee Choice Session

Session Chair: Jiateng Yin, 1</sup

1 Operating Plan Development Using a Zero-Based Optimal Blocking Model

Gunnar Feldmann, Mehmet Kolcu, Clark Cheng, Norfolk Southern Corporation, Atlanta, GA

The railroad blocking problem is a large-scale network routing problem that groups shipments into blocks to minimize total shipment cost. It considers various factors, such as the shipment type, business rules, network constraints, and the available yard resources. The blocking problems has two objectives, minimizing distance traveled and handling cost. In this presentation, we will describe how the use of a Zero-based Optimal Blocking Model at Norfolk Southern improves the development of operating plans.

2 Optimizing the Routing of Wagons During Disruptions in Single Wagonload Transport

Maurice Krauth, Daniel Haalboom, Henning Preis, Nikola Besinovic, TU Dresden, Dresden, Germany. Contact: maurice.krauth@tu-dresden.de

In highly utilized rail networks disruptions can quickly have great impact. Dealing immediately with disruptions is important to maintain satisfactory operation level. In this research, we model single wagonload networks and optimize the routing of wagons when a disruption occurs. In particular, wagons can be reassigned to different trains and trains could be rerouted, while minimizing routing costs and delay. The model performance is demonstrated in real life German rail network. A simulation is used that stochastically trigger disruptions. Wagon routing is then optimized while considering the current state of the network. The proposed model enables to evaluate the impact of disruptions on networks and supports dispatchers to optimize real-time network operation performance.

3 A Multi-Task Deep Reinforcement Learning Approach for the Real-Time Traffic Management of High-Speed Trains

Jiateng Yin, Wei Wu, Beijing Jiaotong University, Beijing, China. Contact: jtyin@bjtu.edu.cn

Existing approaches for the real-traffic management of high-speed trains focused on a series of scenario-dependent mathematical formulations, which however requires to solve the model under different disruption scenarios. The traditional deep reinforcement learning (DRL) has similar drawbacks that the model has to be trained under each disruption scenarios. In our study, we develop a multi-task DRL approach for the real-time traffic management of high-speed trains. Our approach only constructs and trains one DRL model, which can be used for different disruption scenarios. We also propose a novel MIP formulation to select the optimal tasks for the training of the DRL model. We test our approach on the real-world data of Beijing-Zhangjiakou high-speed railway network.

4 Modeling Railway Network Resiliency and Derailment Consequences Considering Multi-Yard and Mainline Interactions

Jiaxi Zhao[1], Tyler Dick[2], [1]University of Texas at Austin, Austin, TX, [2]University of Texas at Austin, Austin, TX, Contact: jiaxi.zr@utexas.edu

Safely and efficiently processing longer trains has become necessary as railroads seek to optimize network capacity. Given the interaction and feedback between rail yards and mainlines, once a service disruption occurs, the congestion can promptly spread through the network and deteriorate system performance. Therefore, understanding the resiliency of railway operations to derailments cannot be limited solely to the immediate location of an incident. To further investigate the network-scope impact of a derailment, specifically in classification yards, this paper models and analyzes rail network recovery patterns after abnormal operations between multiple classification yards and connecting mainlines using a mixed micro- and macro-level simulation developed with AnyLogic.

5 Vulnerability Envelopes for Railway Transport Networks

Nikola Besinovic[1], Christopher Szymula[2], [1]Technical University of Dresden, Dresden, Germany; [2]Technische Universität Dresden, Dresden, Germany

In railway networks, multiple disruptions occur causing extreme challenges to both freight and passenger operators. In these cases, the operators need to significantly adjust, reroute or even cancel the existing services, as well as plan additionally extra ones. In this talk, we explore a concept of vulnerability envelopes to describe an expected performance for any given number of disruptions. To model it, three interdependent networks are combined including infrastructure, train operations and freight and passenger flows. We present the initial results on a realistic railway network. Based on the vulnerability envelope of the system, the operator can directly understand the expected level of deterioration in the network. This could help them to take appropriate response and recovery strategies to minimize the impacts and restore the system as soon as possible.

6 Risk-Averse Two-Stage Stochastic Programming Approach for Metro Train Rescheduling Under Uncertain Disturbances

Boyi Su, 1</sup

Taking the uncertainty of the disturbance duration into account, this paper focuses on integrated train timetabling and rolling stock rescheduling for a disturbed metro system. The problem is formulated as a two-stage stochastic programming model, in which the first stage optimizes the dispatching of backup rolling stocks at the occurrence time of disturbance, while the second stage reschedules metro trains. To evaluate the benefits and risks of rescheduling decisions, the mean-conditional value-at-risk criterion is introduced. Then, we reformulate the proposed model as an equivalent mixed-integer linear programming, which can be directly solved using CPLEX software. Finally, numerical experiments are conducted to demonstrate the performance of the proposed method.

Digital Air Traffic Services: Human Performance Perspective

Community Committee Choice Session

Session Chair: Tatiana Polishchuk, 1</sup

1 The Bridge Between Meta-heuristics and Simulation: Application to ATM

Daniel Delahaye, ENAC, Toulouse, France

The bridge between optimization and simulation is more and more efficient due to the CPU (GPU) computation power increase. The talk starts to give a brief overview of the optimization methods and focus on the objective function evaluation. The benefit produced by connecting optimization and simulation is then presented. Such optimization-simulation approach can be also improved by the mean of machine learning. Applications to air traffic management operations are then presented.

2 Human-Centered AI/ML Decision Support for Pre-Departure Trajectory Option Set Reroutes
Jeremy Coupe, NASA, Moffett Field, CA, Contact: william.j.coupe@nasa.gov
This talk will describe NASA's approach to use AI/ML within a human-centered design to augment air traffic management decision making with decision support tools. For NASA's Machine Learning Airport Surface Model this human-in-the-loop requirement guided many design decisions ranging from user interfaces to the selection of the appropriate prediction models. The result of the design decisions is an Airport Surface Model that combines both human input and Machine Learning models to generate predictions that are aligned with Air Traffic Control expectations of traffic flows.

3 Assessment of Remote Pilot Maneuver Taskload Under Multi-Vehicle Control Schemes
Husni Idris, CA
Multi-vehicle control schemes where a number of remote pilots (m) supervise a number of uncrewed vehicles (N>m) are desired to enable scalability of operations, such as air cargo delivery, in the face of pilot shortage and other constraints. We use queuing models derived from historical track data to assess the increased task load on a remote pilot due to maneuvering demands as the number of supervised vehicles increase. We quantify metrics such as the probability that the inter-maneuver time and inter-communication time is under certain values. We discuss the use of digital communication to mitigate the increased demand on the remote pilot.

4 Digitalization Within Airspace Management: Opportunities and Barriers for Risk Assessment
Billy Josefsson, LFV, Norrköping, Sweden
How can we validate ML / AI support to define efficient, the proper objective understandable methods to identify risks in the coming highly automated ATM / UTM systems.?These systems team up with a human and their task will be to manage the Air-Space from ground to heaven, vehicles performance will vary accordingly but needs to be considered together. The overall challenge from an Air Navigation Service Provider or an UTM Service Provider in the future will be to manage the airspace usage in terms of access, safety, efficiency and follow up assisted with automation. Opportunities and barriers for digitalization within Air Space management will be discussed at the presentation

Tuesday, October 17, 10:45 AM - 12:00 PM

Session Chair: Ruiyun Xu, The University of Hong Kong, Hong Kong, Hong Kong

1 Can Earning Calls Tell? A Multimodal Attentive Network for Financial Misstatement Detection
Wei Du[1], Qi Lu[2], Wei Xu[2], [1]Renmin University of China, Beijing, China; [2]Renmin University of China, Beijing, China. Contact: ahduwei@ruc.edu.cn
Deceptive signals extracted from the text (i.e., verbal cues) and audio (i.e., non-verbal vocal cues) in earning calls help detect financial misstatements. However, prior studies either treat the earning calls as a whole or simply superpose the multimodal features. We hereby propose a multimodal attentive network that deeply learns the deceptive signals from the multi-round dialogues in earnings calls by systematically integrating verbal and vocal features. The attention mechanism helps provide interpretative results by capturing abnormal information in detecting misstatements. Experimental results on a real-world dataset from SeekingAlpha and the Securities and Exchange Commission (SEC) demonstrate the outperformance and interpretability of our model compared to baselines.

2 Determinants of the Inequality in Non-Fungible Tokens Markets
Wei Hu, Tongji University, Shanghai, China
Non-fungible token (NFT) is a unique digital identifier recorded on a blockchain to certify ownership and authenticity. Due to high inequality, most of the population has little to no economic mobility, leading to increased transaction costs and criminal activities. In this study, we collect the NFT projects from NiftyGateway and the transaction data from Ethereum. We construct dynamic trader networks with a sliding time window and measure the inequality using the Gini index and the coefficient of power-law distribution. Ethereum underwent an upgrade process known as “the Merge” on September 15, 2022, switching from proof-of-work (PoW) to proof-of-stake (PoS). In this study, we validate that “the Merge” process can exacerbate the inequality of NFT transactions. By employing econometric analysis, we analyzed the economic mechanisms.

3 Towards Ubiquitous Ultraefficient Deep Learning

Yanzhi Wang, MA
We present our recent work CoCoPIE, representing Compression-Compilation Codesign, to overcome this limitation towards the best possible DNN acceleration on edge devices. We propose novel fine-grained structured pruning schemes, including pattern-based pruning, block-based pruning, etc. They can simultaneously achieve high hardware performance (similar to filter/channel pruning) while maintaining zero accuracy loss, with the help of compiler, which is beyond the capability of prior work. Through the CoCoPIE framework, we are able to achieve real-time on-device execution of a number of DNN tasks, including object detection, pose estimation, activity detection, speech recognition, just using an off-the-shelf mobile device, with up to 180X speedup compared with prior work.

4 The Power of Visualization on Making High-Quality Business Analytical Reports: A Multi-Dimensional Analysis

Wenping Zhang, Zhiyuan Liu, Yanan Liu, Zhiting Yan, Zhihong Yi, Renmin University of China, Beijing, China. Contact: wpzhang@ruc.edu.cn

Visualization techniques have been deeply developed and widely used in various domain. Nevertheless, there are many improper utilizations, which is harmful instead of helpful for information transmission. We conducted a study on the usage of visualization in analyst reports with the hope to reveal the proper utilization of visualization techniques, more specifically exploring the problem that what kinds of visualization help to make a successful analyst report. Based on visualization theories, we proposed a model to assess the quality of visualization. Five aspects, namely originality, aesthetics, clarity, standardization and understandability, were defined and measured based on multimodal data anlytical techniques. Our study found that these aspects have significant impacts on the success of analyst reports.

5 Geotagged Echoes: Deciphering the Impact of Location Disclosure Policy on Online User Interactions

Yizhi Liu[1], Qili Wang[2], Xingchen Xu[3], Liangfei Qiu[4], [1]University of Maryland, College Park, MD, [2]University of Florida, Gainesville, FL, [3]University of Washington, Seattle, WA, [4]University of Florida Warrington College of Business Administration, Gainesville, FL

Amidst the debate surrounding the extent of identity disclosure on social media, this study empirically investigates the impact of group identity disclosure on user posting behavior. Leveraging a natural experiment arising from the province-level location disclosure policy implemented on Chinese social media platforms in April 2022, we uncover notable changes in user posting patterns and the dynamics of online discussions. Our exploration of the underlying mechanisms reveals various effects on different user groups and a tendency towards group polarization in discussions. Our study sheds light on the impact of group identity disclosure and its implications for online behavior and discussions, contributing valuable insights to the broader identity disclosure debate.

Social Good

Community Committee Choice Session

Session Chair: Elisabeth Paulson, Harvard Business School, Somerville, MA

1 Enhancing Early Childhood Education Outcomes Through Personalized Behavioral Nudges in Resource-Constrained Settings: A Data-Driven Approach

Divya Singhvi[1], Alex Akira Okuno[1], Somya Singhvi[2], [1]New York University, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA

Early Childhood Education (ECE) is one of the most cost-effective investments that countries can make to eradicate poverty, boost prosperity, and ensure the creation of human capital needed for sustainable and diversified growth. However, low- and middle-income countries worldwide struggle to support childhood education. In this study, we collaborate with one of India’s leading non-profits focused on catalyzing ECE. We run a series of large-scale experiments to evaluate the impact of personalized behavioral nudging using WhatsApp messages. Our results demonstrate the significant positive effect that data-driven techniques can have on parents’ engagement on these platforms.

2 Survival Bandits

Arielle Elissa Anderer[1], Hamsa Sridhar Bastani[2], John M. Silberholz[3], [1]Cornell University, Ithaca, NY, [2]Wharton School, Philadelphia, PA, [3]University of Michigan Ross School of Business, Ann Arbor, MI, Contact: aea68@cornell.edu

This project adapts online learning techniques to scenarios with time-to-event data, where there is a delay between choosing an arm and observing feedback that is endogenous to the quality of the arm. We posit a multi-armed bandit algorithm that uses a cox-proportional hazards estimator. We theoretically analyze and prove guarantees on the regret under this algorithm. Lastly, we examine its performance on a dataset of metastatic breast cancer clinical trials, and compare it to that of other adaptive allocation schemes.

3 Robust, Balanced Dynamic Matching and Its Application to Refugee Resettlement

Kirk Bansak[1], Soonbong Lee[2], Vahideh Manshadi[3], Rad Niazadeh[4], Elisabeth Paulson[5], [1]University of California, Berkely, Berkely, CA, [2]Yale university, New Haven, CT, [3]Yale University, New Haven, CT, [4]Chicago Booth School of Business, CHICAGO, IL, [5]Harvard University, Cambridge, MA, Contact: soonbong.lee@yale.edu

Motivated by the refugee resettlement process in the U.S., we study a dynamic allocation problem that involves two types of resources, static (e.g., housing) and dynamic (e.g., processing). The goal is to maximize the matching reward (the employment outcomes) while respecting the capacity constraints for static resources and balancing congestion for the dynamic ones. To address large variations in the composition of refugee pools across the years, we take a robust approach and develop a primal-dual algorithm that minimally relies on data from past years. Despite having high-dimensional dual variables, we show that our algorithm has a sub-linear regret. Further, it outperforms existing ones when tested on data from a major resettlement agency, making it a viable candidate for replacing the current practice upon experimentation.

4 Learning and Planning Under Uncertainty for Wildlife Conservation

Lily Xu, Harvard University, Cambridge, MA

Wildlife poaching fuels the multi-billion dollar illegal wildlife trade and pushes countless species to the brink of extinction. To aid rangers in preventing poaching in protected areas around the world, we have developed PAWS, the Protection Assistant for Wildlife Security. We present technical advances in multi-armed bandits and robust sequential decision-making using reinforcement learning, with research questions that emerged from on-the-ground challenges. We also discuss bridging the gap between research and practice, presenting results from field deployment in Cambodia and large-scale deployment through integration with SMART, the leading software system for protected area management used by over 1,000 wildlife parks worldwide.

Computation Services in Cyber Physical Systems

Community Committee Choice Session

Session Chair: Yingyan Zeng, Virginia Tech, Blacksburg, VA

1 Investigating Dielectric Spectroscopy and Soft Sensing for Nondestructive Quality Assessment of Engineered Tissues

Yingyan Zeng[1], Shohanuzzaman Shohan[2], Xiaoyu Chen[3], Ran Jin[4], Rohan A. Shirwaiker[5], [1]Virginia Tech, Blacksburg, VA, [2]North Carolina State University, Raleigh, NC, [3]University of Louisville, Louisville, KY, [4]Virginia Tech, Blacksburg, VA, [5]Assistant Professor, Raleigh, NC

This study explores a non-destructive dielectric spectroscopy (DS) soft-sensing approach for inline quality monitoring of tissue engineered medical products (TEMP). The performance of DS was evaluated using gelatin methacrylate (GelMA) constructs containing human adipose-derived stem cells and compared to traditional biochemical assays. A key metric (Δ?) related to cellular metabolic activity was assessed, considering photocrosslinking duration and growth media volume. To minimize cytotoxicity risks, a bilinear basis mixed model (BBMM) was developed as a soft sensor for accurate quality prediction. The BBMM outperformed state-of-the-art vector prediction methods, demonstrating its potential as an inline monitoring tool for scaled-up TEMP production systems.

2 Synthetic Data Generation and Sampling for Online Training of Dnns in Manufacturing Supervised Learning Problems

Prithivrajan Thiyagarajan, Virginia Tech, Blacksburg, VA, Contact: prithivrajant@vt.edu

The Industrial Internet provides passive manufacturing data for data-driven modeling with DNNs. However, data class imbalance, shifting distribution, and multi-modality variables impede DNN performance. To solve this, the SIDES framework proposes a bi-level Hierarchical Contextual Bandits to integrate active DoE data generation and passive data sampling to enhance the DNN's online learning performance. SIDES employs a Multimodality-Aligned Variational Autoencoder to transform predictors into a shared low-dimensional space for effective data generation and sampling. The benefits of SIDES are shown in a printed electronics case study, which improved DNNs' learning performance. We integrate SIDES with Chat GPT to improve the usability.

3 Change Point Estimation, an Evaluation Tool for Computational Detection Algorithms

Vasileios Pavlopoulos, University of Alabama in Huntsville, Huntsville, AL, Contact: vasilis.pavlopoulos7@gmail.com

A rich literature on detection algorithms is trying to capture change points in the distribution of time series data. However, applying those algorithms to the same dataset, we find different estimates, thus creating confusion for practitioners. We propose an estimation methodology as a tool to evaluate different computational algorithms. We test methodologies from change point estimation to evaluate the detected estimates. We provide inferences about the effectiveness of each algorithm and their estimates. The aim is to minimize the randomness associated with the detected estimates. We focus on change points in the covariance matrix of multivariate time series data. Finally, we provide a comparison of detection algorithms.

Reliability Modeling and Maintenance Optimization

Community Committee Choice Session

Session Chair: Yili Hong, Virginia Tech, Blacksburg, VA

1 Remaining Useful Life Prediction Based on Forward Intensity

Peihong Xiao, National University of Singapore, Singapore, Singapore. Contact: xiaopeihong@u.nus.edu

This study proposes a new RUL prediction method using a novel tool called forward intensity to overcome the challenge of finding fixed failure thresholds for degradation signals in existing methods. The degradation signals of the product of interest are treated as time-varying covariates for its forward intensity, with regression coefficients estimated using smoothing splines under the reproducing kernel Hilbert space framework. The proposed method enables RUL prediction without a fixed failure threshold, providing satisfactory prediction accuracy and interpretable covariate effects. Prediction intervals for the RUL are also developed. Three real examples demonstrate the effectiveness of the proposed method, outperforming existing methods in terms of prediction accuracy.

2 Robust Condition-Based Production and Maintenance Planning for Degradation Management

Qiuzhuang Sun, National University of Singapore, Singapore, Singapore. Contact: q_strong@163.com

We study the robust production and maintenance control for a production system subject to degradation. Different from the existing literature that posits aparametric stochastic degradation process, we suppose the degradation increment during a decision epoch lies in an uncertainty set. We derive closed-form solutions for production planning that facilitate the real-time implementation of our model on IoT-enabled production systems.

3 Optimal Sensor Placement for Linear Inverse Problems with Nonnegativity Constraints

Xinchao Liu[1], Dzung Phan[2], Youngdeok Hwang[3], Levente Klein[2], Xiao Liu[1], Kyongmin Yeo[2], [1]University of Arkansas, Fayetteville, AR, [2]IBM Research, Yorktown Heights, NY, [3]Baruch College, City University of New York, New York, NY

To optimally deploy sensors for atmospheric inverse modeling based on Gaussian plume model, closed-form designs (e.g., A or D-optimal) do not exist due to the nonnegativity constraint of emission rates. A bi-level optimization framework is proposed with a stochastic outer objective (i.e., estimation loss) and a constrained inverse model with regularization at the inner level. We solve this bi-level problem by implicit gradients considering the inner KKT system. Finally, two first-order iterative algorithms are investigated and compared using two numerical examples. The scalability of the SGD-based approach is demonstrated.

4 Vehicle Battery Life Modeling with Two Failing Stages and Partially Observed Covariates

Qingyu Yang[1], Yili Hong[2], [1]Wayne State University, Detroit, MI, [2]Virginia Tech, Blacksburg, VA

Recent years have seen a significant increase in the development of vehicle batteries. This paper investigates the impact of the length of time a vehicle spends on a dealership lot or in a manufacturing facility on the durability of its battery. The unique conditions under which a vehicle battery operates in idle mode in these environments can result in different degradation and failure modes compared to when the vehicle is in use. To address this, the paper presents a new two-stage reliability model for vehicle battery modeling that considers partially observed covariates. The methodology is validated through a real-world case study, providing practical evidence for its effectiveness in understanding and predicting battery durability.

Recent Advances in Collaborative Data Analytics and Its Applications

Community Committee Choice Session

Session Chair: Seokhyun Chung, University of Michigan, Ann Arbor, MI

Session Chair: Xubo Yue, University of Michigan, Ann Arbor, Ann Arbor, MI

1 Addressing Data Heterogeneity in Collaborative Fault Diagnosis via Clustered Federated Learning

Manan Mehta, Chenhui Shao, University of Illinois Urbana-Champaign, Champaign, IL, Contact: mananm2@illinois.edu

Federated learning (FL) has received significant attention for collaborative training of deep learning models across devices while preserving privacy. Industrial big data in applications like healthcare, robotics, and smart manufacturing is inherently non-IID and heterogeneous, which deteriorates the quality of the learned FL model. To address this, we present a clustered FL framework called Federated Learning via Agglomerative Client Clustering (FLACC). FLACC greedily agglomerates clients or groups of clients after each server round. FLACC allows clients with similar underlying distributions to benefit by training together and restricts negative information transfer between dissimilar clients. We demonstrate its efficacy through extensive experiments on three benchmark FL datasets and a real-world case study for industrial mixed fault classification.

2 Causal Representation Learning with Structured and Unstructured Data: Neural Bayesian Machine

Yan Xue, Hao Yan, Yongming Liu, Arizona State University, Tempe, AZ, Contact: yxue37@asu.edu

A novel causal representation learning integrating Neural Networks for unstructured data representation learning and Bayesian causation structural learning is proposed to handle structured and unstructured data simultaneously. The proposed method addresses the discovery of high-level causal factors from low-level unstructured data. The proposed model also achieves continuous gradient optimization and outperforms benchmark methods/models for handling heterogeneous structured and unstructured data. The effectiveness of the proposed model is demonstrated and verified with numerical toy problems and with two real-world problems, i.e., melanoma diagnosis and material failure with random microstructure.

3 Process Defects Knowledge Modeling in Laser Powder Bed Fusion Additive Manufacturing: An Ontological Framework

Nazmul Hasan[1], Md Habibor Rahman[1], Andrew Wessman[2], Timothy Smith[3], Mohammed Shafae[4], [1]University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ, [3]NASA Glenn Research Center, Cleveland, OH, [4]University of Arizona, Tucson, AZ

A lack of a structured approach to representing knowledge of defects in the laser powder bed fusion (LPBF) process hinders its industrial adoption for metal additive manufacturing (AM). This study addresses this issue by proposing an ontological framework that systematically structures and represents knowledge of LPBF defects. The implementation of the proposed LPBF defect ontology is demonstrated in web ontology language using the Protégé software. The framework captures the intricate network of relationships among defects and causal factors, providing a sustainable and reusable knowledge base for tutoring researchers, assisting in defect root cause identification, and guiding practitioners in defect-controlled process planning.

Impact of Variability and Extremes of Weather in Energy Systems

Community Committee Choice Session

Session Chair: Aleksander Grochowicz, 1</sup

Session Chair: Jacqueline Dowling, California Institute of Technology, Pasadena, CA

1 Improving System Reliability in Wind- and Solar-Dominated Electricity Systems via Capacity Investment

Natasha Reich, California Institute of Technology, CA

In this study, we examined wind- and solar-dominated electric power systems using a capacity expansion model to analyze cost-effective investments to improve system reliability. We used over 40 years of U.S. weather data to evaluate the performance (i.e. ability to meet demand) of systems planned with a single year of data when operated on the full dataset. Then, additional investments in each technology were made and the system's performance was re-evaluated to determine the impact of the investment on system reliability. Our findings suggest that wind power is a more cost-effective investment than solar power, indicating that expanding wind power capacity over solar power capacity could increase the adequacy of an energy system at a lower cost.

2 Multi-Scale and Multi-Resource Analysis of Increased Adoption of Renewable Energy Sources

Elnaz Kabir[1], Vivek Srikrishnan[2], Vivienne Liu[2], Scott Steinschneider[2], Lindsay Anderson[2], [1]Texas A&M, College Station, TX, [2]Cornell University, Ithaca, NY

The variability and intermittency of renewable energy sources pose several challenges for power systems operations, including energy curtailment and price volatility. In power systems with considerable renewable sources, co-variability in renewable energy supply and electricity load can intensify these outcomes. In this study, we examine the impacts of renewable co-variability across multiple spatial and temporal scales on the New York State (NYS) power system, which is undergoing a major transition toward increased renewable generation. Our results demonstrate that renewable energy resources can vary considerably, where the variability is substantially greater in shorter time scales. For the case of NYS, this results in a 9% variation in annual average electricity prices and up to a 56% variation in the frequency of price spikes.

3 Identifying Weather Stress Events from Power System Optimisation Outputs

Koen van Greevenbroek[1], Aleksander Grochowicz[2], Hannah Bloomfield[3], [1]UiT The Arctic University of Norway, Tromsø, Norway; [2]University of Oslo, Oslo, Norway; [3]University of Bristol, Bristol, United Kingdom. Contact: koen.v.greevenbroek@uit.no

The shift toward renewable generation increases the impact of weather and climate on the energy sector and can introduce new risks if not accounted for properly. However, the characteristics of large compound events leading to potential lost load are still poorly understood. In this work, we apply a high-resolution optimization model for a decarbonized European electricity system to the question. Dual variables of this model are used to identify difficult weather periods, understood as periods that drive system design and total cost. We then characterize the meteorological conditions during these periods. This interdisciplinary approach combining meteorology and energy systems modeling enhances our understanding of weather resilience.

4 Firming Electricity Systems Reliant on Wind and Solar Generation

Ken Caldeira, Carnegie Institution for Science, Stanford, CA

Wind and solar electricity generation is variable in time, as is electricity demand. Matching electricity generation with electricity demand depends on the deployment of technologies or approaches that can supply electricity at times when demand exceeds generation by wind or solar. These firming technologies could involve dispatchable generation or dispatchable energy storage devices. Load management can also contribute. There are many technologies that could potentially play this firming role. However, uncertainties in future costs precludes determination of which technologies might comprise future least-cost electricity systems. However, a large number of such technologies could potentially play a firming role at acceptable cost levels. Rather than looking for least-cost solutions, it may suffice to find low-cost solutions.

5 How the Combination of Space Heating Electrification and Climate Change Could Impact Seasonal Peaking and Reliability of the Texas Power Grid

Henry Ssembatya, North Carolina State University,

Raleigh, NC
Texas typically experiences peak electricity demand in the summer. Around 60% of households rely on electricity for space heating, but as decarbonization efforts surge, more households could switch from using natural gas to electricity, thus significantly increasing winter electricity demand. Simultaneously, climate change will increase summer temperatures and the potential for heat waves. Uncertainty regarding the timing and magnitude of these simultaneous changes raises questions about how they will jointly affect seasonal generation requirements and the firm capacity needed. In this study, we investigate long-term patterns in electricity demand driven both by space heating electrification and climate change using an open-source nodal power system model. The results will help system planners to better plan for adequate supply capacity.

Wild Fire Mitigation and Forest Harvest Planning

Contributed Session

Session Chair: Fatemeh Rezaei, Mississippi State University, Starkville, MS

1 Restoration of Forest Linear Disturbances from Oil-And-Gas Exploration: How Can Network Models Help?

Denys Yemshanov[1], Mackenzie Simpson[1], Ning Liu[1], Aaron Petty[2], Frank H. Koch[3], Cynthia Chand[2], George Duffy[2], Vita Hoyles[2], Chris Mallon[2], [1]Natural Resources Canada, Sault Ste. Marie, ON, Canada; [2]Alberta Environment and Parks, Edmonton, AB, Canada; [3]USDA Forest Service Southern Research Station, Research Triangle Park, NC, Contact: denys.yemshanov@nrcan-rncan.gc.ca

We propose a two-tier network optimization model for restoration of linear forest disturbances in areas of oil-and-gas extraction. The model delineates a contiguous set of coarse-scale regions for restoration and then uses this solution to warm start a fine-scale forest patch-level network optimization model that allocates restoration activities to maximizing the access of wildlife species to undisturbed habitat, maintain human access to unrestored sites and keep restoration in meaningful clusters. We applied the approach to develop forest restoration scenarios in the Red Rock caribou range in the northwestern Alberta, Canada.

2 Application of Machine-learning Models for Wildfire Prediction in South Korea

Chanjung Lee[1], Yohan Lee[2], [1]Seoul National University, Seoul, Korea, Republic of; [2]Seoul National University, Seoul, Korea, Republic of. Contact: gtano@snu.ac.kr

This study aims to develop a model that predicts domestic forest fire occurrences during fire outbreaks using machine learning techniques. For the modeling methods, logistic regression analysis and ensemble techniques, such as gradient boost and random forest, were used while the oversampling technique was utilized to address the imbalance problem of the forest fire data. The model developed in this study predicted 239 out of 333 forest fire occurrences during the nationwide forest fire period in 2020 with a prediction accuracy of approximately 0.71. We found that forest fire occurrences are not just influenced by climate factors, such as temperature, humidity, and precipitation, but also by farmland density and stem volume per hectare as human-associated factors in the minimum level of administrative regions of the Repulic of Korea.

3 A Stochastic Model for Forest Harvest Planning Problem

Fatemeh Rezaei[1], Bruno Kanieski da Silva[1], Jesse D. Henderson[2], Mohammad Marufuzzaman[1], Shaun Tanger[3], [1]Mississippi State University, Starkville, MS, [2]USDA Forest Service, Southern Research Station, Research Triangle Park, Durham, NC, [3]University of Arkansas at Monticello, Monticello, AR, Contact: fr277@msstate.edu

The forest harvest planning problem consists of the maximization of landowners' goals within a complex combination of biological, economic, and social variables. In the US South, the uncertainties related to tornados and hurricane occurrences have a major impact on forest planning and economic profitability. In this paper, we develop a stochastic multi-stage model to investigate the optimal harvest planning policy.

Keywords: Harvest planning, Uncertainty, Climate events

Carbon-centric Power System Operation and Transaction

Community Committee Choice Session

Session Chair: Yunhe Hou, The University of Hong Kong, Hong Kong, Hong Kong

Session Chair: Yue Chen, The Chinese University of Hong Kong, Sha Tin

1 An Energy Market with Carbon Emission Allocation Enabling Real-Time Energy Storage Participation

Rui Xie, Yue Chen, The Chinese University of Hong Kong, Hong Kong, China. Contact: yuechen@mae.cuhk.edu.hk

This paper proposes an energy market with a carbon emission allocation mechanism. The emission is allocated among generators, electric demands, and energy storage based on Aumann-Shapley prices. A novel multi-parametric linear programming-based algorithm is developed to calculate the allocations more accurately. Furthermore, to fully cultivate the potential of ES in reducing carbon emissions, a real-time ES bidding method is established based on Lyapunov optimization. Case studies demonstrate the effectiveness and advantages of the proposed method compared to some existing approaches, e.g., the carbon emission flow method.

2 Commercial Building Hvac Demand Response for Low-Carbon Power Systems: Theoretical Energy Efficiency Analysis and Data-Driven Flexibility Estimation

Shunbo Lei, Weimin Wu, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China

Demand response from commercial building heating, ventilation, and air conditioning (HVAC) systems, which sometimes is treated as a virtual battery, possesses a significant potential to accommodate the uncertainty and variation of renewable energy, thereby expediting the transition to low-carbon power grids. This talk introduces our investigation into the impact of HVAC demand shifting on building energy efficiency. Based on a general thermodynamics model, we analyze the influence of both thermodynamics and control strategies on HVAC energy efficiency, and propose a method for efficiency improvement. We also propose a data-driven method to quantify the demand flexibility of HVAC systems. By combining it with the theoretical energy efficiency analysis and adjusting control signals, we aim to enhance HVACs' energy efficiency in providing services to power grids.

3 Robust Dispatch with Demand Response Under Decision-Dependent Uncertainty

Yifan Su, Tsinghua University, Beijing, China. Contact: suyf19@mails.tsinghua.edu.cn

Demand response is recognized as a promising solution to reducing operation costs and alleviating system risks by encouraging end-users to participate in system regulation. In practice, demand response will inevitably introduce uncertainty to decision-making due to volatile weather and complicated social behaviors. The decisions, conversely, may affect the uncertainty itself on parameters or information structures. This kind of uncertainty is the decision-dependent uncertainty (DDU), which has not been explored in demand response. We propose a novel two-stage robust economic dispatch model with demand response under DDU, where the uncertainty set of demand response varies with respect to its set-point determined by the decision. To solve this problem, we propose an improved column and constraint generation (C&CG) algorithm with a scenario mapping embedded.

4 A Submodularity-Based Interpreting Scheme for Generalized Forward Scenario Selection: A Case of Wind Power Generation

Qinfei Long[1,2], Yunhe Hou[3], [1]The University of Hong Kong, Hong Kong, China; [2]HKU Shenzhen Institute of Research and Innovation, Shenzhen, China; [3]The University of Hong Kong, Hong Kong, Hong Kong

The generalized forward scenario selection is important in scenario-based technologies, such as stochastic programming. However, as a combinatorial optimization, forward scenario selection typically lacks an approximation guarantee for the solution, and the selected number cannot be scientifically predetermined. This study reports a new approach to interpret generalized forward scenario selection. First, the process submodularity ratio (PSR) is proposed to measure the process submodular degree. Then a PSR-based approximation guarantee is theoretically derived to quantitively assess the performance of the selection process. Finally, the tail cost is established via power-law exponent, which can dynamically estimate the selection cost and indicate when the selection should be stopped. Its performance is verified by a wind power generation case.

5 Zoning Ordinances: Implications for Rural Utility-Scale Pv Deployment and Power System Decarbonization

Papa Yaw Owusu-Obeng, Michael Craig, University of Michigan, Pinckney, MI

Power system planning models overlook the influence of zoning ordinances on utility-scale PV investment. We present advances in two fronts: 1) we estimate the extent to which zoning ordinances influence the capacity value and competitiveness of large-scale utility-scale PV projects. 2) we determine whether renewable energy portfolio standards can drive the deployment of utility-scale PV investment amidst zoning ordinances.

Environmental and Sustainability Issues across Different Product Life-Cycle Stages

Community Committee Choice Session

Session Chair: Arda Yenipazarli, Georgia Southern University, Statesboro, GA

1 From Transparency to Transformation: Causal Effects of CDP's Supply Chain Program

Jury Gualandris[1], William Diebel[2], Robert Klassen[1], [1]Ivey Business School at Western University, London, ON, Canada; [2]Ivey Business School, London, ON, Canada

This study investigates the causal effect of supply chain transparency driving sustainable change. Using data from CDP's supply chain program, coarsened exact matching, and panel data analysis, we examine how increased transparency enables to identify and report on environmental supply chain issues more effectively. This research underscores the importance of embracing transparency as vital tool in the pursuit of more sustainable supply chains.

2 Environmental Strategies for Building Competitive Advantage: When Does It Pay to Be "Green"?

Arda Yenipazarli, Georgia Southern University, Statesboro, GA, Contact: ayenipazarli@georgiasouthern.edu

In this paper, we focus on competing firms' incentives to pursue product-oriented differentiation-based environmental strategies associated with high technological risk, delayed payoffs (if successful) and substantial research and development (R&D) investments in lieu of lower-risk, short-term and low-cost process-oriented environmental strategies, and vice versa. Drawing on a two-period game-theoretic model, we characterize how the presence of strategic rivals who potentially pursue an environmental strategy in dynamic markets, competition intensity, product development capabilities, technology trajectories and customer concerns govern the environmental strategy priorities and choices of firms, and identify under what supply and market conditions these strategic choices provide competitive advantage and thereby result in win-win outcomes.

3 Inventory Disclosure with Product Returns

Tolga Aydinliyim, Ceren Gultekin, Baruch College, CUNY, New York, NY, Contact: tolga.aydinliyim@baruch.cuny.edu

We study whether selective-inventory-disclosure, which can mitigate the adverse profit implications of consumers' strategic purchase deferrals, remains effective when product returns are allowed. Using a price- and refund-setting newsvendor framework with availability-dependent demand, we show consistent-inventory-disclosure to be optimal. Furthermore, equilibrium refund relative to consistent-inventory-masking can be higher or lower.

4 Sustainable Bioleaching of Lithium-Ion Batteries for Critical Materials Recovery

Majid Alipanah[1], Hongyue Jin[1], Qiang Zhou[1], Caitlin Barboza[2], David Gazzo[3], Vicki Thompson[2], Yoshiko Fujita[2], Jiangping Liu[4], Andre Anderko[4], David Reed[2], [1]University of Arizona, Tucson, AZ, [2]Idaho National Lab, Idaho Falls, ID, [3]University of Notre Dame, Notre Dame, IN, [4]OLI Systems, Parsippany, NJ, Contact: hjin@arizona.edu

Recycling spent lithium-ion batteries could alleviate supply risks for critical metals such as lithium, cobalt, and nickel, and be less harmful to the environment compared to new production. This study aimed to optimize a recycling technology called bioleaching for maximum economic competitiveness through design of experiments assisted by thermodynamic modeling. The optimal condition was identified as 2.5% pulp density in 75 mM gluconic acid biolixiviant at 55°C for 30 h which could recover 57%-84% of nickel, 71%-86% of cobalt, and 100% of lithium and manganese, yielding a 17%-26% net profit margin. The recommended pulp density and acid concentrations, together with the observed metal solubilization, were supported by thermodynamic modeling predictions.

Optimization Modeling Software I

Community Committee Choice Session

Session Chair: Susanne Heipcke, FICO, Birmingham, United Kingdom

Session Chair: Robert Fourer, AMPL Optimization Inc., Evanston, IL

1 New Modeling and Programming Features in Xpress Mosel 6

Susanne Heipcke, FICO, Birmingham, United Kingdom

This talk presents examples of recent new features of FICO Xpress Mosel. On the mathematical modeling side, these include support for the new global solver of Xpress, handling of multiple objectives and extension of Irreducible Infeasible Sets (IIS) to nonlinear constraints. Many new programming features, in particular new forms of data input from different text formats including JSON, rely on the concept of union types, a container holding an object of one of a predefined set of types. Support for reflection, that is, inspection of the currently executing program itself, particularly helps for the implementation of testing systems. New mechanisms for library compatibility and depreciation markup ease the maintenance of large-scale projects over longer periods of time.

2 Model Building with Gurobipy-Pandas

Robert Luce, Gurobi Optimization, Berlin, Germany. Contact: luce@gurobi.com

Gurobipy-pandas is a Python project that allows you to connect pandas with gurobipy. It enables you to easily and efficiently build mathematical optimization models from data stored in DataFrames and Series, and to read solutions back directly as pandas objects. We will walk through the basic API and discuss best practice model building patterns.

3 Modeling for Optimisation over Trained Graph Neural Networks

Shiqiang Zhang, Juan Campos, Calvin Tsay, Ruth Misener, Imperial College London, London, United Kingdom

Our open-source software OMLT (Optimization and Machine Learning Toolkit, https://github.com/cog-imperial/OMLT) translates machine learning models into Pyomo formulations and thereby enables optimization over already-trained models. This presentation discusses extending the OMLT framework to incorporate graph neural networks and discusses effective modelling for these optimization problems.

4 MAPL: A New Modeling Program Language for Optimization Problems

Cheng Yang, Alibaba

Modeling complex systems has always been a challenging task in science and engineering. A new modeling language called MAPL (MindOpt Algebraic Modeling Language) has been developed to address this challenge. MAPL provides a concise syntax similar to mathematical expressions and supports vectorized numerical computing syntax, making it easier to model complex systems more efficiently without sacrificing accuracy. MAPL also supports multiple solvers, including the self-developed MindOpt solver, capable of handling large-scale optimization problems and providing quick solutions to large problems. In addition, the integration of MAPL with AI technology leverages Alibaba's large language model to assist developers in the modeling process.

Mechanism of Matching Demand for Sharing Economy

Contributed Session

Session Chair: Peash Saha, Queen's University, Kingston, ON, Canada

1 Modeling a Hybrid On-Demand Meal Delivery System in a Link-Node-Based Network Setting with Dynamic Choice Behaviors

Rui Ma, Zohre Noormohamadzade, University of Alabama in Hunstville, Huntsville, AL, Contact: rui.ma@uah.edu

This paper presents an optimization framework with dynamic user equilibrium describing the choice behaviors of the delivery drivers. The framework can be utilized to reveal how to maximize operators profit or the overall social benefit in such an on-demand meal delivery system. The network model is based on a link-node network representation that considers road network topology, time-varying demand and dispatched drivers, restaurant strategies and a matching mechanism to connect waiting drivers with pending orders. In this model, restaurants have two strategies to serve their demands by either using their own vehicles in house or delegating tasks to a third party platform. Various competing strategies that restaurants can adopt in response to different network setup, demand profiles and background traffic scenarios are analyzed under the proposed framework.

2 The Impacts of Ride-Hailing on Car Ownership Under Individual Choice Endogeneity

Yuliu Su[1], Ying Xu[2], Shih-Fen Cheng[3], Costas Courcoubetis[4], [1]Siemens, Beijing, China; [2]Singapore University of Technology and Design, Singapore, Singapore; [3]Singapore Management University, Singapore, Singapore; [4]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China. Contact: xu_ying@sutd.edu.sg

With the emergency of ride-hailing platforms, individuals with travel needs face a new tradeoff: either purchase a car and provide ride-hailing service or use the ride-hailing service. We aim to quantitatively evaluate the impact of ride-hailing on individuals' car demand and usage. We adopt an equilibrium choice model to study a heterogeneous population's choices on car ownership and transportation modes. We evaluate how driving costs and platform pricing schemes affect car ownership, platform profits, and environmental impacts.

3 Demand Seasonality Driving the Value of Information Sharing

Vladimir Kovtun[1], Avi Giloni[1], Clifford Hurvich[2], Noam Shamir[3], [1]Sy Syms School of Business, New York, NY, [2]Stern School of Business, New York, NY, [3]Coller School of Management, Tel Aviv, Israel. Contact: vladimir.kovtun@yu.edu

We explore the impact of demand seasonality on the value of information sharing between retailer and supplier in supply chains. By using spectral analysis to view several types of demand-generating ARMA models we uncover several key results. Information sharing is found to be valuable when retailer demand is "seasonal enough" unless the retailer's leadtime is a multiple of the seasonal period. This is true for simple ARMA models such as AR(1) and AR(2), as well as several Seasonal ARIMA models commonly used to study seasonal data. In studying an extremely-seasonal SARIMA model we note that seasonality causes the supplier's demand to be equal to the sum of a negligible shock and retailer demand occurring some time in the past. That is, current demand observed by the retailer drives future demand observed by the supplier thereby making this information valuable to the supplier.

4 Popular Matching Under Boston School-Choice Mechanism and Its Applications

Peash Saha, Salimur Choudhury, Kai Salomaa, Queen's University, Kingston, ON, Canada. Contact: p.saha@queensu.ca

Boston mechanism is a long-established model for two-sided matching problems with strict preferences on one side and rough priorities on the other. The model focuses on the welfare of the agents with the preferences. We analyze the popularity of the matching produced using the Boston mechanism and provide a characterization of the popular matching and the maximum cardinality popular matching in the model. A popular matching is the one preferred by the maximum number of agents among all matchings. Our proposed polynomial time algorithm finds a popular matching if there is any in such a setting. There exist many corresponding applications of popular matching under the Boston mechanism such as volunteer and food rescue tasks matching.

Energy-aware Business Practices

Contributed Session

Session Chair: Kumar Saurav, IBM Research Labs, Bangalore, India

1 Navigating the Bitcoin Boom: Assessing the Impact of Mining on Power Generation Expansion

Fargol Nematkhah[1], Andrew Lu Liu[2], Yihsu Chen[1], [1]University of California, Santa Cruz, Santa Cruz, CA, [2]Purdue University, West Lafayette, IN, Contact: fnematkh@ucsc.edu

Texas has welcomed an influx of Bitcoin miners seeking affordable energy resources. However, the presence of miners has raised debates about their impact on the carbon footprint of the power grid and new-generation investments. In this work, we study the impact of Bitcoin mining on generation expansion in ERCOT as a two-stage stochastic cost minimization problem which we further analyze using a progressive hedging approach to tackle the large problem size.

2 Computing Equilibrium Automotive Technology Decisions Under Regulation

Johnathan Vicente[1], Jeremy J. Michalek[1,2], Kate S. Whitefoot[1,2,3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]Carnegie Mellon University, Pittsburgh, PA

Computational equilibrium models of the automotive industry are used to inform vehicle technology strategies and policies by understanding the impact of particular regulations on automaker costs and technology use. However, the use of these models in practice has been hindered by (1) high computational time and (2) unknown properties governing when the model will successfully solve for valid equilibria. By exploiting properties of automakers' profit-maximization problem and deploying a multi-stage solution approach, this work identifies improvements that accelerate solutions and guarantee valid equilibrium solutions given sufficient time.

3 The Impact of Corporate Responses to Environmental Shareholder Proposals on Financial Performance

Marilyn Lucas, Thomas Noordewier, University of Vermont, Burlington, VT

Shareholder-sponsored proposals that petition publicly held companies to adopt environmental initiatives have become commonplace in recent years. The way in which firms respond to such proposals plays a key role in explaining the diversity of observed relationships between corporate environmental behavior and corporate financial performance. This study, which focuses on withdrawn proposals, builds upon the resource-based view (RBV) and stakeholder management theory. We merge information from multiple sources to assemble a comprehensive data set, and empirically investigate this relationship, highlighting the contingent role of the firm's R&D and advertising activities.

4 Carbon-Aware Data Center Management: Towards Sustainable and Efficient Operations

Kumar Saurav[1], Ayush Jain[2], [1]IBM Research Labs, Bangalore, India; [2]IBM Research Labs, Delhi, India. Contact: kr.saurav.010@in.ibm.com

With the proliferation of data centers worldwide, their environmental impact has become a pressing concern. As a result, carbon-aware operation for a group of data centers has emerged as a strategic approach to minimize emissions and improve efficiency across multiple facilities. This abstract presents a carbon-aware operation for a group of data centers to reduce their carbon emission by 10% without any significant increase in operational costs by exploring strategies such as geo-shifting of loads, renewable energy integration, etc. By adopting carbon-aware practices at the group level, data centers can achieve significant reductions in carbon emissions, enhance energy efficiency, and contribute to a more sustainable digital infrastructure.

Quantum Computing and Optimization III

Community Committee Choice Session

Session Chair: Rodolfo Alexander Quintero Ospina, 1</sup

Session Chair: Brandon Augustino, Lehigh University, Landing, NJ

1 A Quantum Framework for Topological Data Analysis

Bernardo Ameneyro Rodriguez[1], Vasileios Maroulas[1], George Siopsis[2], Rebekah Herrman[3], [1]University of Tennessee, Knoxville, TN, [2]University of Tennessee, Knoxville, TN, [3]University of Tennessee, Knoxville, TN, Contact: bameneyr@vols.utk.edu

TDA methods capture the shape of data, which can be useful for classification problems. First they extract topological features from the data via persistent homology, tracking them across different scales or resolutions. The topological features are then displayed in persistence diagrams that show the birth and death of each feature. These diagrams are a great way to summarize data before performing machine learning algorithms. But to do this one must compute distances between persistence diagrams, such as the Wasserstein distance. To estimate these one needs to minimize a cost function over all possible ways to match points from two persistence diagrams. We present a quantum algorithm for persistent homology, as well as a QAOA approach for estimating the distance between persistence diagrams.

2 Quantum Semidefinite Programming with the Hadamard Test and Approximate Amplitude Constraints

Iria Wang, Harvard Griffin Graduate School of Arts and Sciences, Cambridge, MA, Contact: iriawang@g.harvard.edu

While semidefinite programs (SDPs) yield favorable scaling behavior in exchange for a quantifiable loss of accuracy, classical SDPs remain intractable for high-dimensional problems. Our proposed solution is a variational algorithm for Quantum SDPs using the Hadamard Test and Approximate Amplitude Constraints (HTAAC-QSDP), which approximates SDPs with up to 2^n variables using n+1 qubits, O(1) quantum measurements, and O(poly(n)) classical approximations. The Hadamard test enables optimization by estimating an expectation value on an ancilla qubit, and with O(poly(n)) Pauli string amplitude constraints, allows approximate enforcement of the SDP contraints. We extend its original implementation (Goemans-Williamson algorithm for MaxCut) to other instances of Karp's 21 problems and demonstrate specific bounds for solution quality and unitary complexity.

3 Polyhedral Structure of Penalty Constants in Quadratic Unconstrained Binary Optimization and Applications to Quantum Computing

Rodolfo Quintero Ospina, Lehigh University, Bethlehem, PA

Quadratic Unconstrained Binary Optimization (QUBO) problems have resurged, offering a unified framework for solving combinatorial optimization problems (COPT). Quantum computing algorithms like QAOA, VQE, and quantum annealing effectively address QUBO models. We present a polyhedral characterization of penalty constants in penalization-based reformulations of linear and quadratic integer programs as QUBO problems. Our approach recovers prior techniques and establishes a bijective correspondence between optimal solutions of QUBO constructions and the original problem. Moreover, for inequality-constrained combinatorial optimization problems, we characterize QUBO formulations that eliminate binary slack variables, albeit with challenging computation of penalty constants. Computational experiments exemplify the efficacy of these ideas.

4 Quantum State Estimation from a Dynamical System Perspective

Muqing Zheng, Xiu Yang, Lehigh University, Bethlehem, PA

The presence of noise significantly limits the complexity and capabilities of model quantum devices, while nature prevents us from accurately recording the actual evolutions in real devices. In this research, we propose a data-driven approach to viewing quantum circuits from a dynamical system perspective, enabling the application of the classical tool, Kalman smoother. By using time-series measurement data, we iteratively infer the state evolution process without introducing additional quantum noise. Promising results are obtained through experiments on backend noise simulators and real quantum backends.

5 Semidefinite Programming Using Thermal Pure Quantum States

Oscar Watts, Quantinuum, London, United Kingdom. Contact: Oscar.Watts@quantinuum.com

We propose a modification of the quantized MMW algorithm introduced by Brandao and Svore, replacing the Gibbs sampler with thermal pure quantum (TPQ) states. Our approach relies on Quantum Signal Processing and extending Jaynes Principle to TPQ states. While our methodology incurs an additional problem-dependent error, which reduces as the problem size grows, it avoids the explicit preparation of (purified) Gibbs states and shows a similar quantum speedup saturating the theoretical Õ(sqrt(N)+sqrt(m)) lower bound. We numerically verify the algorithm for the Hamiltonian learning problem for sizes of up to N=2^10 variables.

Optimization in Healthcare Treatment and Resource Allocation

Contributed Session

Session Chair: Eunbi Kim, Korea University., Seoul, Korea, Republic of

1 Intelligent CT-Scanner Parameter Selection Using AI-Powered Recommender System

Neda Sayahi, Wayne State University, Detroit, MI

In this study, a Machine Learning-based recommender system for CT-scanner parameter selection is proposed for recommending optimal scan parameters. As predicting scan feasibility using machine learning methods is at the heart of the proposed recommender system, the accuracy of four ML methods in predicting scan feasibility is compared. The results indicate that multi-layer perceptron predicted scan feasibility with higher accuracy and outperformed the other methods. Furthermore, a game theoretic approach was utilized to explain the predictions provided by the model.

2 Joint Scheduling of Automated External Defibrillators and First Responders with Coordination in Out-of-hospital Cardiac Arrests

Kexin Cao, Xinglu Liu, Mingchuan Yang, Wai Kin (Victor) Chan, Tsinghua University, Shenzhen, China. Contact: kexincao5@gmail.com

A one-minute delay in the treatment of out-of-hospital cardiac arrest (OHCA) reduces a patient's chance of survival by 10%, making the treatment extremely time-sensitive. However, timely real-time access to automated external defibrillators (AED) remains a challenge. This research focuses on the joint scheduling problem of AEDs and first responders for AED delivery. To guarantee a very short time limit as well as the accuracy and robustness of decisions, our research also considers the coordination between multiple-type first responders and some other detailed factors. A mixed integer programming model is constructed for this problem and is solved by Gurobi. The experimental results reveal that a significant decrease in response time is achieved through our optimization and the improvement in coordination consideration is effectively verified.

3 Spatiotemporal Analysis of Volunteer First Responders Effectiveness

Michael Khalemsky[1], Yuval Hadas[2], Janna Ataiants[3], Stephen Lankenau[3], Anna Khalemsky[1], Alexis Roth[3], Gabriela Marcu[4], David G. Schwartz[5], [1]Hadassah Academic College, Jerusalem, Israel; [2]Bar-Ilan University, Ramat Gan, Israel; [3]Drexel University, Philadelphia, PA, [4]University of Michigan, Ann Arbor, MI, [5]Bar-Ilan University, Ramat Gan, Israel

Rapid first aid is vital for reducing mortality and improving long-term prognosis during medical emergencies. One approach to achieving faster response times is through smartphone-based Volunteer First Responder (VFR) networks.

VFR effectiveness is measured by factors such as arrival time, relevant intervention, and medical outcomes. Geographic coverage is a commonly used measure of emergency medical service effectiveness. This study presents a novel analytical technique for analyzing VFR network effectiveness in terms of geographic coverage using real-world data from a field study. The analysis considers the unpredictable location and availability of VFRs during an emergency event, aiding decision-making for recruitment and retention efforts and improving collaboration with EMS. Findings can enhance VFR network administrators' efforts to save lives.

4 EMS Location-Allocation Problem Under Uncertainties

Wei Wang[1], Shuaian Wang[1], Lu Zhen[2], Xiaobo Qu[3], [1]The Hong Kong Polytechnic University, Hong Kong, Hong Kong; [2]Shanghai University, Shanghai, China; [3]Tsinghua University, Beijing, China

Emergencies pose great threats to health, life, and property. Immediate response and treatment are crucial in mitigating these threats. This research optimizes the locations of ambulance stations, deployment of ambulances, and dispatch of vehicles under demand and traffic uncertainty to improve the response speed. The research problem is formulated as a dynamic scenario-based two-stage stochastic programming model with the goal of minimizing total costs while responding to as much demand as possible. Two solution methods, i.e., sample average approximation and a two-phase Benders decomposition solution scheme, are proposed to solve the problem. Numerical experiments using real-world emergency data are conducted to validate the performance of the solution methods and derive constructive managerial insights for the EMS system.

5 Enhancing the Emergency Rescue System: An Analysis of Incorporating Drone Ambulances

Eunbi Kim[1], Joonyup Eun[2], Taesu Cheong[1], [1]Korea University, Seoul, Korea, Republic of; [2]Korea Univeristy, Seoul, Korea, Republic of

Performing immediate cardio-pulmonary resuscitation within 4 minutes of cardiac arrest is crucial to achieve a survival rate of 50% or above. However, paramedics' median arrival time is 7 minutes in Korea, which exceeds patients' "golden time". According to this issue, we come up with an idea to use human-crewed drone ambulances that can transport paramedics to patients rapidly. This study aims to determine the optimal location of a human-crewed drone ambulance station to minimize the average dispatch time during cardiac arrest emergencies. We expect that this study provides a way to improve the patients' survival rate by enabling paramedics to respond promptly (within 4 minutes) to cardiac arrest cases.

Methodological Advancements in Multiobjective Optimization I

Community Committee Choice Session

Session Chair: Margaret M. Wiecek, Clemson University, Clemson, SC

1 Pareto Leap: An Algorithm for Biobjective Mixed-Integer Optimization

Philip de Castro, Clemson University, Clemson, SC, Contact: pdecast@clemson.edu

We present an algorithm for solving biobjective mixed-integer optimization problems which exploits the structure of the nonconvex outcome set. The algorithm "leaps" between subsets of the outcome set, correctly identifying those that contribute to the global Pareto set. The leaps are performed using tabu constraints (also known as "no-good" constraints) and convex approximations of the nonconvex region dominated by the subsets. We discuss theoretical results, detail the algorithm, and apply it to test instances for demonstrations of the results.

2 Decision-Space Decomposition for Multiobjective Programs

Emma Soriano, Clemson University

We present a decomposition theorem for computing the efficient set of multiobjective programs (MOPs). The entire efficient set can be computed as the intersection of efficient sets of lower-dimensional subproblems. The approach is inspired by the parametric decomposition theorem for MOPs of Cuenca Mira and Miguel Garcia (2017), and by the block-coordinate descent for single objective programs. Preliminary results allowing for a decomposition implementation are included.

3 Identifying Alternative Stops for First and Last Mile Urban Travel Planning

Thomas Horstmannshoff[1], Michael Redmond[2], [1]Otto-von-Guericke-Universität Magdeburg, Magdeburg, Germany; [2]University of Iowa, Iowa City, IA

As we move into an increasingly connected world for urban travel planning, we need to expand our concept of itinerary planning to meet the multimodal and diverse needs of today's traveler. Our approach provides travelers with a set of optimal nearby stops that presents a number of traveler preferences in an easily comprehensible and quickly calculable manner. We display first and last mile stops that fall on a Pareto front based on multiple criteria such as travel time, number of transfers, and frequency of service. This tool combines both stop and route based information, and we incorporate free-floating scooters to investigate the impact on decision making with multiple transportation modes. This tool can greatly help in offering diverse itineraries for travelers based on their preferences.

Diversity, Equity, and Inclusion Research in Information Systems and Operations Management

Community Committee Choice Session

Session Chair: Lanfei Shi, Virginia University, VA

Session Chair: Lu Kong, University of South Florida, Tampa, FL

1 Hiding Behind Complexity: Supply Chain, Oversight, Race, and the Opioid Crisis

Jorge Mejia, Indiana University, Bloomington, IN

The opioid crisis has ravaged the United States taking 69,000 lives in 2020, with prescription opioids accounting for 98% of opioid abuse. Though nationally, this epidemic is often considered a White public health crisis, overdose deaths have doubled among people of color from 2017-2019. We find evidence that the scope of the blame goes beyond individual actors to include the very structure of supply chains, where complex supply chains fueled the crisis by dispensing significantly more opioids. We show evidence that supply chain complexity allowed mass quantities of opioids to escape detection by the Drug Enforcement Administration (DEA).

2 Online Education's Impact on Teaching Evaluations: The Role of Instructors' Gender and Race in a Digital Learning Era

Lu Kong[1], Kejia Hu[2], Lanfei Shi[3], [1]University of South Florida, Tampa, FL, [2]Vanderbilt University, Nashville, TN, [3]University of Virginia, Charlottesville, VA, Contact: kongl@usf.edu

The growing prevalence of online education necessitates a deeper understanding of potential biases in teaching evaluations within the context of diversity, equity, and inclusion (DEI). Using the teaching evaluation dataset from a public website, we assess the impact of DEI initiatives on online education. Our findings reveal significant disparities in evaluations, with non-white male instructors experiencing a 27.03% decline in ratings after transitioning to online classes. Our study contributes to the understanding of online education's effectiveness and highlights the need for more equitable evaluation methods that consider the unique challenges and opportunities of online learning. By providing valuable insights to educators and university leadership, we emphasize the importance of fostering an inclusive environment for instructors and students alike.

3 Equitable Data-Driven Assignments of Workers to Tasks

Cagla Keceli, Daniel Adelman, University of Chicago, Booth School of Business, Chicago, IL, Contact: ckeceli@uchicago.edu

Managers may be cautious of using individuals' innate characteristics when allocating workers to tasks to prevent discrimination. We develop a practical algorithm to predict task completion times, which obscures workers' (innate) performance information and only uses the task familiarity of individual workers, i.e., the "equitable" policy. We compare the emerging steady-state predictions against the policy that doesn't obscure worker-specific performance, i.e., the "full-information" policy. We study the ramifications of using the equitable policy.

Dynamic Resource Allocation in Public Sector Settings

Community Committee Choice Session

Session Chair: Hamid Reza Zarei, Northeastern University, Somerville, MA

1 Sublinear Time Algorithm for Online Weighted Bipartite Matching

Zhaozhuo Xu, Rice University, TX

Online bipartite matching is a critical problem in online algorithms, where two sets of vertices need to be matched for optimal edge weight sum. In recommendation systems and search engines, these weights depend on the inner product of deep user and item representations. Traditional online matching involves linearly scanning and computing weights for all items, resulting in a time complexity of nd. However, real-world scenarios like online e-commerce platforms often have an extremely large number of items (n). Hence, enhancing weight computation efficiency becomes crucial. Our research introduces randomized data structures enabling sublinear time computation of weights while maintaining the competitive ratio of the matching algorithm. This work establishes a theoretical foundation for approximate weight computation, addressing its practical significance.

2 A Data-Driven Approach for Matching While Learning with Two-Sided Arrivals

Hamid Reza Zarei[1], Ozlem Ergun[2], [1]Northeastern University, Somerville, MA, [2]Northeastern University, Newton, MA, Contact: zarei.h@northeastern.edu

In this study, we design a service platform that matches dynamically arriving workers to jobs inspired by the experience of matching workers to long-term care facilities during the COVID-19 outbreak in Massachusetts. Workers and jobs arrive randomly over time with different characteristics. The outcome of a match is not known before matching and by using data from outcomes of previous matches, the platform finds the probability of success for a match. By matching workers to jobs, the platform aims to maximize the total probability of success considering future expected outcomes subject to job availability. We examined the performance of the service platform using real-world data that we obtained from the COVID-19 matching framework in MA.

3 Quantification of Social Metrics for Solid Waste Management Optimization

Jenny Gutierrez-Lopez[1], Ronald G. McGarvey[2], James Noble[1], Christine Costello[3], Damon Hall[4], [1]University of Missouri, Columbia, MO, [2]IESEG School of Management, Lille, France; [3]The Pennsylvania University, University Park, PA, [4]University of Missouri, Columbia, MO, Contact: jg9z9@umsystem.edu

This study presents a methodology for quantifying a social metric for integrated solid waste management (SWM) using Life Cycle Assessment - based optimization. SWM workers are exposed to a high demand for manual material handling activities during their work-shift, which is observed to contribute to high employee turnover. The social metrics proposed capture: 1) a worker's physical exposure to the job, considering activities such as lifting, carrying, placing, emptying, and sitting, 2) turnover of employees including loss of productivity, hiring and replacement costs, and quit rate. These metrics are used as a multi-criterion decision-making framework for SWM, extending the traditional economic and environmental objective functions. Results illustrate the trade-offs among these conflicting criteria and provide insights of diverse waste management strategies.

4 Dynamic Matching for Cloud Manufacturing Platforms Based on Model-Based Deep Reinforcement Learning

Pengyu Yan[1,2], Liu Yang[2], Sentao Miao[3], Kaize Yu[2], [1]Yangtze Delta Region Institute (Huzhou), University of Electronic Science and Technology of China, Huzhou, China; [2]School of Management and Economics, University of Electronic Science and Technology of China, Chengdu, China; [3]Desautels Faculty of Management, McGill University, Montreal, QC, Canada

Cloud manufacturing platform is a service-oriented platform connecting the supply and demand sides of manufacturing resources and services. However, matching the two sides can be challenging due to the incomplete information and uncertain environment. This study focuses on how to dynamically match the sequentially arriving manufacturing orders with available production services while learning the unknown information, aiming to maximize the long-term revenue of the platform. Such a matching-while-learning problem is formulated as a Markov decision process and solved by a model-based deep reinforcement learning algorithm(MDRL). The MDRL alleviates the issue of low-sample efficiency by allowing the agent to interact with a learned environment model. The numerical experiments validate that the MDRL can obtain a better and more interpretable matching policy.

5 On a Combinatorial Algorithm for the Correct Parity Matching Problem

Hitoshi Murakami, Yutaro Yamaguchi, Osaka University, Osaka, Japan. Contact: hitoshi.murakami@ist.osaka-u.ac.jp

The Exact Matching problem is a constrained variant of the matching problem, in which we are required to find a perfect matching that contains a specified number of specified edges. There exists a randomized polynomial-time algorithm for this problem, and it is open whether it can be derandomized. El Maalouly et al. (2022) proposed a deterministic polynomial-time algorithm for an easier variant, called the Correct Parity Matching problem, using a linear algebraic technique. In this research, we try to design a more direct, combinatorial, deterministic polynomial-time algorithm for this problem.

Scheduling Applications

Community Committee Choice Session

Session Chair: Rodrigo A. Carrasco, Pontificia Universidad Catolica de Chile, Santiago, Chile

1 Improving Exoplanet Observations Through Mathematical Optimization

Constanza Lorca[1], Rodrigo A. Carrasco[2], [1]University of Virginia, Charlottesville, VA, [2]Pontificia Universidad Catolica de Chile, Santiago, Chile. Contact: wrk2pp@virginia.edu

Several approaches have been used to tackle the observation scheduling problem in astronomy observatories. However, many observatories still schedule observations manually or using greedy algorithms, making it difficult to predict the impact certain decisions will have in the future. When making daily decisions analyzing multiple exoplanet candidates, the task of choosing the ones to observe manually in a limited timeframe can be time-consuming, providing suboptimal results. This work proposes a combinatorial optimization model, derived from the Vehicle Routing Problem (VRP), adjusted to the exoplanet transits observations scheduling problem. We provide an approach maximizing observational efficiency, aligning the resulting schedule with the observatory's objectives and prioritizing observation constraints in the discovery of exoplanets.

2 An Approximation Algorithm for Resource-Constrained Project Scheduling Applied to Strategic Planning in Undergroundmining

Rodrigo A. Carrasco[1], Diego Fuentes[2], Eduardo Moreno[2], [1]Pontificia Universidad Catolica de Chile, Santiago, Chile; [2]Universidad Adolfo Ibanez, Santiago, Chile

The resource-constrained project scheduling problem (RCPSP) is central to many planning applications; hence, it has been thoroughly studied in many different settings. This work focuses on the underground mining strategic planning problem, which can be formulated as an RCPSP instance. We present a new approximation algorithm for computing solutions in this setting, computing approximation bounds for specific settings and showing that this approach can solve very large instances to a high degree of accuracy.

3 Scheduling Limited Initiation Cues (SLIC): A Novel Combinatorial Scheduling Formulation for Adaptive Machine Learning and Cybersecurity Applications

Nouri (Nourhan) Sakr[1], Ojas Parekh[2], Cynthia Phillips[3], Cliff Stein[4], [1]American University in Cairo, Giza, Egypt; [2]Sandia National Labs, Albuquerque, NM, [3]Sandia National Laboratories, Albuquerque, NM, [4]Columbia University, New York, NY, Contact: n.sakr@columbia.edu

Inspired by adaptive machine learning theory and cybersecurity games, we develop a combinatorial framework to optimize on resources of a given system. We introduce a novel scheduling problem where each of a set of parallel machines has a specific set of jobs that must be executed on that one machine in a specific order. We must select a limited set of global start times. Upon completing a job, a machine must wait to the next global start time to begin its next job. We wish to maximize the total work completed before a given global deadline. This problem comes from a stochastic-programming version of a probabilistic game that models moving-target defense in cybersecurity. This game also has an interpretation in adaptive machine learning. We motivate and define the scheduling problem and give the hardness results, algorithms for special cases, and initial approximations.

Advances in Planning and Managing Services

Community Committee Choice Session

Session Chair: Felix Papier, Essec Business School, Cergy Pontoise Cedex, France

1 Asymmetries of Service: Interdependence and Synchronicity

Andrew Daw[1], Galit Bracha Yom-Tov[2], [1]University of Southern California, Marshall School of Business, Los Angeles, CA, [2]Technion - Israel Institute of Technology, Haifa, Israel

We propose and analyze a Hawkes cluster model of service interactions that captures two (a)symmetries between the customer and agent: co-production vs self-production, synchrony vs asynchrony. We analyze the stochastic process through a novel decomposition in terms of objects from probabilistic combinatorics. This model reveals connection to the behavioral operations literature, such as non-monotonic system performance from monotonic agent-load slowdown, which we prove will exist under customer-agent asynchrony. Given this existence, we can prescribe an optimal concurrency, or level of multi-tasking, for the service agents. However, the efficiency of such operational improvements is limited by symmetry in interdependence: the more co-productive the service, the less opportunity there is to improve.

2 Socially Responsible Operations for Medical Devices

Zumbul Atan[1], Yeqing Zhou[2], Ayten Beyza Emre[2], [1]Eindhoven University of Technology-Industrial Engineering &Innovation Sciences, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: z.atan@tue.nl

Underserved communities lack essential medical devices. We propose a business model, where a manufacturer refurbishes and rents medical devices to these communities. The devices are originally owned by hospitals. Given that the medical devices have limited lifetimes, we develop a decision support tool to determine the optimal timing of taking the machines from original hospitals and renting them to underserved communities. This business model leads to higher profit and increases the accessibility of healthcare.

3 The Operational Data Analytic (ODA) for Service Speed Design

Qi Annabelle Feng[1], Zhibin Jiang[2], J. George Shanthikumar[3], Yang Yang[4], [1]Purdue University, West Lafayette, IN, [2]Shanghai Jiao Tong University, Shanghai, China; [3]Purdue University, WEST LAFAYETTE, IN, [4]Purdue University, West Lafayette, IN

We develop the operational data analytics (ODA) framework for the classical service design problem of G/G/c/k systems. Validating the data-integrated decision model against the long-run average service reward leads to a uniformly optimal service rate for any given sample size. We further derive the ODA-predicted reward function based on the data-integration model, which gives a consistent estimate of the underlying reward function. We demonstrate that the ODA framework can lead to an efficient design of service rate and service capacity, which is insensitive to model specification.

4 Scheduling Customer-Preference-Based Field Appointments Under Uncertainty

Yanlu Zhao[1], Felix Papier[2], [1]Duham University Business School, Durham, United Kingdom; [2]Essec Business School, Cergy, France. Contact: felix.papier@gmx.de

Motivated by sales force operations of a B2B services company in Belgium, we develop a data-intensive model for scheduling field appointments at the customer sites. The appointments are made by an outbound call center and subject to uncertain customer approval. The objective of the model is to maximize the number of sales appointments by minimizing the the agent's travel and idle times. We formulate the model as MDP, derive analytic properties of the problem, and develop time-efficient scheduling policies that dynamically decide which clients to call and which time slots to propose. We use a real data set to perform numerical experiments to test the policies, and we find that the policies are an effective way to achieve a trade-off among field force effectiveness, efficiency, and reactivity that best fits the company's strategy.

Topics on Social Media Engagement

Contributed Session

Session Chair: Frances Wang, Cornell University, Ithaca, NY

1 Effect of Deception in Influence Maximization and Polarization on Social Networks: A Sheaf Laplacian Approach

MEHMET EMIN AKTAS, Georgia State University, Atlanta, GA, Contact: maktas@gsu.edu

This study investigates the effects of deception on information diffusion, specifically focusing on influence maximization and polarization in social networks. We start with modeling deception among users within social networks. Building upon the sheaf Laplacian diffusion model derived from algebraic topology, we examine opinion dynamics in the presence of deception. Moreover, we redefine the Laplacian centrality to quantify the influence of deception in influence maximization. We further model polarization in networks and investigate the impact of deception on polarization. Our findings suggest that deceptive individuals wield more influence than honest users within social networks. Furthermore, we demonstrate that deception amplifies polarization in networks, with influential individuals playing a significant role in deepening the polarization.

2 What are the Motivations of Finfluencers? Evidence from Tiktok

Alexander Kupfer, University of Innsbruck, Innsbruck, Austria

Policymakers and researchers have recently become aware of the importance of financial literacy in empowering individuals to make informed decisions about their money. In this context, social media influencers who “cover” financial aspects in their social media posts (so-called finfluencers) have recently become very popular. Although recent studies suggest that those born between the late 1990s and early 2010s (i.e., the so-called Generation Z) follow their advice, little is known about finfluencers’ motives and the actual content of their posts. This study focuses on finfluencers on TikTok and examines their profile pages for indicators of financial motives, such as affiliate links or links to their own premium subscription services.

3 Is an Emoji Worth a Thousand Engagements? Empirical Evidence from a Peer-to-Peer Digital Payment Platform

Ying Gu[1], Panteleimon Loupos[2], [1]Univesity of Washington, Seattle, WA, [2]University of California, Davis, Davis, CA

Emojis are becoming an ever-increasing tool in every marketer’s toolbox, but does this strategy lead to a favorable customer engagement outcome? This work examines the effect of emoji usage on customer engagement in peer-to-peer platforms where network effects are also present. We leverage a large panel dataset from Venmo and use a dynamic linear-in-means model to causally identify the effect of emoji usage and its peer effects on customer engagement. To achieve identification of the dynamic network peer effects, we exploit the introduction of the emoji auto-complete keyboard feature. We find that both individual emoji usage and its contextual peer effects are positively associated with customer engagement. Our findings offer substantive guidelines to marketing practitioners who wish to use emoji-driven marketing tactics to engage with their audience.

4 Free or Paid: Profit Maximizing Pay-Per-Click Advertising

Frances Wang, Christopher Anderson, Cornell University, Ithaca, NY

Using a switchback experiment, we investigate the impact of PPC advertising on consumer channel choice and firm profitability. A group of 26 hotels are cycled on and off Google’s hotel platform. Through the use of a matched control group, we are able to measure the incremental demand created through display on Google. We model consumer channel choice (direct versus third-party) as a function of display on Google (both organic and PPC advertising) in an effort to develop profit-maximizing advertising policies.

Community Committee Choice Session

Session Chair: Harish Guda, Arizona State University, Tempe, AZ

1 Combating Excessive Overtime in Global Supply Chains

Chuanya Jiao[1], Anyan Qi[2], Jiayu Chen[3], [1]University of Science and Technology of China, Hefei, China; [2]The University of Texas at Dallas, Richardson, TX, [3]University of Calgary, Calgary, AB, Canada. Contact: cyjiao@ustc.edu.cn

Workers in developing economies may be forced by suppliers to work excessive overtime, resulting in severe mental and physical issues for the workers and possible significant damage to the brand of multinational enterprises (MNEs) if exposed in public. In this paper, we develop a game-theoretic model of a dyadic supply chain to analyze a manufacturer’s strategies to combat these excessive overtime issues of a supplier, including a *stick* strategy of auditing the supplier’s practice and a *carrot* supplier-development strategy of cross-training the supplier’s workers to increase their versatility. We show that, (i) cross-training may be either complement or substitute to the auditing; (ii) cross-training may backfire and increase the degree of excessive overtime; (iii) cross-training may Pareto improve the manufacturer’s and the supplier’s profits.

2 When Doing Good May Backfire: Smallholder-Farmer Selection into Yield-Improvement Programs

Utku Serhatli[1], Guillaume Roels[2], [1]Nova School of Business and Economics, Fontainebleau, France; [2]INSEAD, Fontainebleau, France

In agricultural-intensive economies, manufacturers often help smallholder farmers improve their yields through training and yield-improvement programs. However, and perhaps paradoxically, some farmers feel that these programs can lower their profit, in part due to a decrease in commodity prices. Using a Cournot model, we show that a) these programs can push prices down, which may indeed decrease the profits of some farmers, b) the objectives of minimizing market prices and protecting farmer well-being might be conflicting, and c) certifying more efficient farmers may perform well in terms of both individual and aggregate farmer well-being.

Big Data Applications in Global Operations and Management

Community Committee Choice Session

Session Chair: Xiaojin Liu, Virginia Commonwealth University, Richmond, VA

Session Chair: Pankaj Kumar, Virginia Polytechnic Institute and State University, Blacksburg, VA

1 Automatic Analysis and Adaptive Learning for Continuous Chemical Manufacturing

Yanjun Qian, Virginia Commonwealth University, Richmond, VA

In continuous chemical manufacturing, the slug-flow process plays a vital role in crystallization synthesis and provides better process control and reproducibility. However, it is challenging to maintain the uniformity of the crystal size when scaling-up slugs. Thanks to the advances in in-line imaging technologies, we can develop analyzing methods to improve flow control for better crystallization quality. Incorporating image processing and statistical learning tools, we propose an in-line monitoring and modeling framework for the slug-flow process. This will lead to a controller to scale up the process without sacrificing slug and crystal size uniformity.

2 Detecting Earnings Management from Earnings Calls

Xinran Wang[1], Lee Spitzley[2], [1]Colorado State University, Fort Collins, CO, [2]State University of New York at Albany, Albany, NY, Contact: xinran.wang@colostate.edu

Companies frequently adopt earnings management (e.g., changing accounting estimates and policies) to manipulate financial reports, and earnings management is misleading and deceptive in nature. Current approaches to identifying earnings management rely on the availability of financial reports and are limited in their timeliness. To address this limitation, we propose to detect earnings management in a timelier manner by analyzing executives' behaviors during earnings calls. Using a unique dataset of earnings calls held by S&P 500 companies provided by Alpha Street, we study the relationships between earnings management and executives' verbal and vocal behaviors and examine the moderating role of preparation. We also build predictive models with executives' behavioral cues to detect earnings management.

3 Semiparametric Bayesian Joint Models for Proportion Outcomes and Informative Observation Times: A Scalable Approach for Electronic Health Records

Ya Su[1], Dipankar Bandyopadhyay[1], Sanvesh Srivastava[2], [1]Virginia Commonwealth University, Richmond, VA, [2]University of Iowa, Iowa City, IA, Contact: suyaf@vcu.edu

Electronic health records (EHR) data when thevisiting process is informative gains much attention recently. This paper considers a Bayesian joint modelingapprooach for proportion outcomes via a semiparametric mixed effectmodel and informative observation times via a counting process with asemiparametric intensity function with frailty. The EHR data couldinclude a large number of patients and this together with theintrinsic high dimension of the parameter space poses a challengingtask for any MCMC sampler to function well. We adopt a divide andconquer approach with a simple adjustment on the likelihood in eachsubset followed by an easy combination step to approximate theposterior samples based on the original posterior. Simulation and realdata analysis reveal the efficiency the algorithm achieves whilemaintaining accuracy.

4 Take It or Not? Impact of Investments from Tech Giants on It-Startups' Future Funding

Linmei Huang, Baruch College, City University of New York, New York, NY, Contact: linmei.huang@baruch.cuny.edu

While tech giants have become important external equity financing sources, it remains unclear whether IT-startups should take investments from tech giants. In this study we empirically examine how taking investments from tech giants influences future funding of IT-startups. Our results indicate that taking investments from tech giants significantly reduces the amount of funding IT-startups could obtain in the following rounds. Additionally, we find that social ties between IT-startups' regions and locations with substantial capital will attenuate such negative impact of taking investments from tech giants. We further explore the mechanisms. Results suggest that when tech giants make investments in IT-startups, they predominate the new technologies by applying for more patents in the relevant fields and crowd out new investors.

1 Resiliency of Energy and Power Grids with Multi-Modal Interdependencies on Other Critical Infrastructures

Massoud Amin, Lindsay Lien Amin, Energy Policy & Security Associates, Minneapolis, MN

This presentation covers energy and power infrastructure resiliency and its interconnectedness with other critical infrastructures. The reliability, security, and efficiency of power and energy infrastructures are critical for crucial economic and social functions. We will present recent advances in distributed sensing, modeling, and control, with case studies, and address short to long-term technologies, training, policies, and protocols needed to protect power systems. Key themes include a systems-based approach to resilience and the use of big data and data science to tackle the challenges of interconnected critical infrastructures.

2 Estimating Tropical Cyclone Induced Power Outages in Future Climate Scenarios

Zaira Pagan Cajigas[1], Seth Guikema[1], Brent Boehlert[2], Charles Fant[2], [1]University of Michigan, Ann Arbor, MI, [2]Industrial Economics Inc, Cambridge, MA, Contact: zpagan@umich.edu

The occurrence of natural disasters, such as tropical cyclones, frequently disrupts the energy system, leading to power outages. Climate change projections indicate hazards will become more frequent and severe, prolonging the duration of outages. Our research uses a power outage statistical model to examine how tropical cyclones affect power outages in the Atlantic and Gulf Coasts regions at the census tract level, considering future climate projections from seven distinct climate models. This study provides a basis for understanding future climate scenarios' impact on the frequency and duration of outages. Our findings can inform the development of strategies to mitigate the risks associated with climate change and ensure the resilience of the energy system.

3 Modeling Policy Interventions to Reduce Losses for Low Income Households from Hurricanes

Cen Guo[1], Dahui Liu[1], Linda Karen Nozick[1], Meghan Millea[2], Jamie Kruse[2], Caroline Williams[3], Rachel Davidson[3], Joseph Trainor[3], [1]Cornell University, Ithaca, NY, [2]East Carolina University, Greenville, NC, [3]University of Delaware, Newark, DE, Contact: dl742@cornell.edu

Regional hurricane losses are escalating with significant impacts on the economy alongside ever-increasing burdens to homeowners. We applied a multi-year computational framework to examine how insurance subsidies, retrofit grants, and buyouts can elevate the recovery prospects of low-income homeowners. We introduce policy interventions as means- and risk-adjusted to improve efficacy and equity. As a result, when insurance subsidies, retrofit grants, and buyouts are integrated and low-income homeowners are supported, insurance prices fall, GDP recovers more quickly and completely, and household recovery is more consistent across income groups.

Machine Learning Assisted Biomarker Discovery in Medical Research

Community Committee Choice Session

Session Chair: Jay Shah, Tempe

1 An Improved Saliency Map that Shows Trustworthiness for Localizing Abnormalities in Medical Imaging

Nolan Skelly, Air Force Institute of Technology, Dayton, OH

Saliency maps are a widely used methodology to make deep learning models more interpretable by providing post-hoc explanations through identification of the most pertinent areas of an input medical image. These techniques have been assessed on the basis of 1) localization utility, 2) sensitivity to model weight randomization, 3) repeatability, and 4) reproducibility. No tested saliency map technique has been able to pass all of the criteria. The neural networks used to predict and read medical information require a reliable solution to provide medical practitioners intelligible results. Using the information of two large publicly available radiology datasets, we look to quantify and posit a solution to this problem, so that the usage of saliency maps in the high-risk domain of medical imaging will require less scrutiny and can hold a more trustworthy base.

2 ExpertRNA: A New Framework for RNA Secondary Structure Prediction

Menghan Liu, Arizona State University, Tempe, AZ, Contact: mliu126@asu.edu

Ribonucleic acid (RNA) is a fundamental biological molecule that is essential to all living organisms, and we want to study RNA folding problem for RNA function discovery. RNA folding problem is, given the sequence of nucleotides, a probable list of base pairs are returned, referred to as the secondary structure prediction. There are many existing algorithms solving RNA folding problem and the two main categories are minimum free energy algorithms and data-driven algorithms. In this work, we introduce the new ExpertRNA algorithm that provides a modular framework that can easily incorporate an arbitrary number of rewards (free energy or non- parametric/data driven) and secondary structure prediction algorithms. We argue that this capability of ExpertRNA has the potential to balance out different strengths and weaknesses of state-of-the-art folding tools.

3 Using Ai to Predict Treatment Response in Leukemia Patients

Kevin Leder, University of Minnesota - Industrial and Systems Engineering, MINNEAPOLIS, MN

Multiple Myeloma is a blood cancer with a median survival time of 6 years. The disease is characterized by recurrent episodes of remission and relapse under treatment. Failure to predict treatment response leads to wasted time and resources, and often adverse side effects of failed treatments. In this work, we aim to predict treatment response in advance by linking baseline observations and treatment history to treatment response using a Hierarchical Bayesian framework that combines a mechanistic model of tumor growth with statistical learning methods. Preliminary work has shown that the method works in simple simulated situations. If successful in real clinical scenarios, this approach may help clinicians choose more effective treatments, prolonging the lives of patients and easing their disease course.

4 Accurate Prediction of Post-Traumatic Headache Persistence Using One Week of Headache Diary Data

Gina Dumkrieger, Todd Schwedt, Catherine Chong, Mayo Clinic, Phoenix, AZ

Currently, there is no accurate way of predicting which patients will recover quickly from post-traumatic headache (PTH) and which patients will continue to have PTH months or years after mild traumatic brain injury (mTBI). Here we utilized daily headache diary data over 7 days to predict headache resolution after 3 months. Individuals with acute PTH due to mTBI completed a daily headache e-diary beginning 1-59 days post mTBI. Features generated from diary data were used to create a prediction model. Recovery status after three months was predicted with 78% leave-one-out cross validation accuracy using the features generated from the first 7 days of diary data. This model achieved 73% accuracy on an unseen sample. Despite simple models and simple features high accuracy is achieved. This approach could be used to set patient expectations and guide decisions on interventions.

5 Predicting Rna Sequence-structure Likelihood Via Structure-aware Deep Learning

You Zhou, Arizona State University, Tempe, AZ, Contact: yzhou253@asu.edu

Machine learning method was used to evaluate RNA sequence, secondary structure pair. However, several challenges arise: Firstly, whether the features from existing machine learning model can thoroughly encode the sequence-structure pairs is uncertain. Secondly, the design of the features could rely on subjective choice. Thirdly, the RNA level feature could not encode all base pairing information. We propose a deep learning approach including two models to evaluate sequence-structure pair. The first one is NU-ResNet which uses ResNet18 as the primary architecture. This model solves the challenges by explicitly encoding the sequence-structure pair into a 3D matrix. The second one is NUMO-ResNet, which extends NU-ResNet with added information from the characterizations of the 2D shape of the folding, motifs. We also developed an automatic way to extract motifs.

Theory and Applications of Active Learning

Community Committee Choice Session

Session Chair: Ashif Iquebal, Arizona State University, Tempe, AZ

1 Active Learning for Classification with Imperfect Labels

Pouya Ahadi, Kamran Paynabar, ISyE Georgia Tech, Atlanta, GA, Contact: pouya.ahadi@gatech.edu

In an active learning problem, query samples will be annotated using some oracles. In most cases, these labels include noise due to the noisy oracles. Moreover, uncertain samples are more likely to receive imperfect labels from those labelers. Learning with highly imperfect labeled data points will result in an inaccurate classifier. We propose a novel method for active learning problems to construct a robust classification model by minimizing the noise level. Our approach includes an assignment model to optimally assign query points to labelers in order to minimize the highest possible noise in a cycle. Moreover, we propose a new sampling approach for finding the best query points in order to mitigate the effect of label noise on the classifier's performance.

2 Consistent Exploration-Exploitation Trade-Off in Active Learning Regression with Dirichlet Process Prior

Upala Junaida Islam, Ashif Iquebal, Arizona State University, Tempe, AZ, Contact: uislam@asu.edu

Approaches of active learning usually focus on either exploration or exploitation in the design space. Methods considering exploration-exploitation simultaneously employ fixed or ad-hoc measures to control the trade-off that may not be optimal. We develop a Bayesian hierarchical approach with Dirichlet process prior to dynamically balance the trade-off as more data are queried. We subsequently formulate an approximate Bayesian computation approach based on the linear dependence of data samples in the feature space to sample from the posterior distribution of the trade-off parameter obtained from the model. Our approach performs better or at least as well as either pure exploration or pure exploitation. Using theoretical results, we prove that our methodology achieves posterior consistency as well.

3 Dispersion-Enhanced Sequential Batch Sampling for Adaptive Contour Estimation

Yiming Che, Binghamton University, Vestal, NY

The issue of near duplicates poses tremendous quandary for sequential learning. Near duplicates severely diminish the computational efficiency as they barely contribute extra information towards update of the surrogate. To address this issue, we impose a dispersion criterion on concurrent selection of sampling points, which essentially forces a sparse distribution of critical points in each batch, and demonstrate the effectiveness of this approach in adaptive contour estimation. Specifically, we adopt Gaussian process surrogate to emulate the simulator, acquire variance reduction of the critical region from new sampling points as a dispersion criterion, and combine it with the modified expected improvement (EI) function for critical batch selection.

4 A Faster Upper Confidence Bound for Point-Based Value Iteration to Approximate Finite-Horizon Pomdps

Siqiong Zhou[1], Ashif Iquebal[1], Esma S. Gel[2], [1]Arizona State University, Tempe, AZ, [2]University of Nebraska-Lincoln, Lincoln, NE, Contact: siqiong.zhou@asu.edu

We present the algorithm Approximating with Upper Confidence Bound(AUCB), an active learning approach for approximating upper bounds in point-based value iteration for solving finite-horizon Partially Observable Markov Decision Processes (POMDPs). AUCB utilizes the upper confidence bound of a Gaussian Process Regression (GPR) fit to efficiently approximate value function upper bounds. AUCB enables estimation for any point in the belief space, providing an effective solution for large-scale problems. Experimental evaluation demonstrates the effectiveness of AUCB in improving the performance of solving finite-horizon POMDPs over state-of-the-art algorithms. Specifically, AUCB achieves 2.5 times more iterations and a 30% improvement in the value function gap between upper and lower bounds within a limited time of 3000 seconds for large-scale examples.

Information Systems Research in the Era of New Technologies

Community Committee Choice Session

Session Chair: Sameer Borwankar, Purdue University, West Lafayette, IN

1 The Impact of Political Polarization on Restaurant Reviews: Evidence from Yelp.Com

Rajan Mishra[1], Wreetabrata Kar[2], Sugato Chakravarty[1], [1]PURDUE UNIVERSITY, WEST LAFAYETTE, IN, [2]Krannert School of Management, Purdue University, West Lafayette, IN, Contact: mishra92@purdue.edu

By examining a large sample of Yelp restaurant reviews during the 2016 national election cycle, this study examines the influence of party ideology on the tone of restaurant reviews, focusing on Yelp as a leading online platform for user-generated reviews. The findings of our study reveal compelling insights into the relationship between political polarization and restaurant reviews. Following a national election, when a region undergoes a political shift from Democratic (BLUE) to Republican (RED) affiliation, we observe significant changes in the characteristics of restaurant reviews: 1) These reviews tend to be shorter in length. 2) A decrease in the number of compliments provided indicates a shift towards more critical evaluations. 3) A higher proportion of "simpler" words, suggesting a shift towards less sophisticated language usage.

2 Collaboration Network Dynamics in Technology Standardization Platforms

Rushikumar Pandya, Purdue University

Technology standardization platforms have emerged as unique innovation communities to design interoperability standards. Domain experts strategically collaborate with others to develop standards that benefit complex technology ecosystems. This study explores social network ties formation, i.e., collaboration patterns within open standards development organization (SDO) for internet technology. Large-scale co-authorship data shows active SDO participants adopt exploration vs. exploitation strategy choices for partner selection. Participants' firm affiliation, influence within the network structure, and domain expertise significantly impact their strategy selection. The study contributes to understanding SDO network dynamics and offers insights into tie formation strategies adopted by the participants.

3 Book Bans in American Libraries: Impact of Politics on Inclusive Content Consumption

Naveen Basavaraj[1], Uttara Ananthakrishnan[2], Sabari Rajan Karmegam[3], Ananya Sen[1], Michael D. Smith[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Washington, Seattle, WA, [3]George Mason University, Gaithersburg, MD, Contact: nthotada@andrew.cmu.edu

Banning of books has become increasingly prevalent and politically polarizing in the United States. While the primary goal of these bans is to restrict access to books, conversations about the bans have garnered attention on a wider scale. This increased attention to bans can influence consumers' choices to either consume or boycott banned books, depending on their political and moral concerns around the ban. In this study, we use a novel, large-scale dataset of US library book circulations and evaluate the impact of book bans on the consumption of banned books. Using a staggered difference-in-differences design, we find that the circulations of banned books increase by 12% on average compared to comparable non-banned titles in the period after the ban. We also find that banning a book in a state leads to increased circulation in states that do not observe any bans. We show that the increase in consumption is driven by books from lesser-known authors suggesting that new and unknown authors stand to gain from the increasing consumer support. Additionally, our results demonstrate that books with higher visibility on social media following the ban see an increase in consumption, suggesting a link between social media and political consumerism. We also find that book bans have a tangible political impact through campaign donations - Democratic Party candidates attract significantly more donations following the ban events.

4 Elections and Hate Speech on Twitter

Indulekha Guha, 1</sup

This paper studies the impact of presidential and gubernatorial election timing on the level of toxicity present on social media platforms such as Twitter. We empirically determine the extent to which the toxicity of Twitter content changes during election times as compared to non-election times. We randomly sample Twitter users and collect all tweets made by this sample around election time. We use a difference-in-differences identification leveraging election and non-election years. We further focus on toxic content that is motivated by political polarization and examine various bias-motivation categories that come up in this content as well as the variation in intensity of toxicity between national and local election times.

5 Using Consumer Wearable Sensor Data to Understand Covid-19 Experience

Shiyang Sima, Alok R. Chaturvedi, Hossein Ghasemkhani, Purdue University, West Lafayette, IN, Contact: ssima@purdue.edu

The emergence of the novel SARS-CoV-2 virus has resulted in a significant disease burden on both individuals and society at large. The virus has caused substantial mortality and disability, while also impacting productivity and incurring substantial healthcare, societal, and economic costs. Notably, certain social groups have been disproportionately affected, experiencing higher disease rates and inferior outcomes, despite being underserved. This paper leverages routinely collected passive sensor data from wearable devices to understand the COVID-19 experience. Furthermore, we attempt to use change point detection to infer the symptom onset date. Lastly, we contrast the changes in daily health measurements using the diagnosis dates and estimated symptom onset dates.

6 Information Warranties - A Game Theoretic Approach to Addressing Fake News

Michael Lewis, University of Houston, Houston, TX

Social media platforms and smart phones, while reducing barriers to generate news content, can facilitate the spread of false information and erode prospects for collective sensemaking. Previous approaches to combatting fake news are subject to claims of biased application or fail to change the incentives for fake news producers. In this paper, we study the effects of information warranties on the production and distribution of verifiable news content. We model these processes as Stackelberg games, with the news producer as the game's leader and the consumer as the follower. The implications of news veracity, warranty adjudication, and news verification costs are discussed, and the resulting equilibria presented. We find that the key drivers of outcomes are the benefit-to-loss ratio of the consumer that propagates information and the nature of the verification costs.

Competitive Strategies

Community Committee Choice Session

Session Chair: Xia Zhao, University of Georgia, Athens, GA

1 Quality Control of Transaction Platform for Trading Experience Goods

Xinlin Tang, Florida State University, Tallahassee, FL

The success of transaction platforms depends on effective quality control on both complementors (sellers) and complements (products). Due to the large volume of complements traded on the platform, the current quality control is distributed between the platform owner and customers: the platform owner controls the quality of complementors, but leaves that of complements to the customers. Technology advances make it possible for the platform owners to control the quality of the complements. We assess the effectiveness of this new quality control mechanism on promoting product change and the market response using the recent move of ctrip.com to assign quality grade to package tours sold on the platform. This study enriches our knowledge on a novel mechanism of quality control and demonstrates the benefits of shared control on a transaction platform trading experience goods.

2 Keep Your Friends Close and Your Enemies Closer? the Role of Competitive Intelligence

Mariana Andrade-Rojas, University of Georgia, Athens, GA

This study uses a network multiplexity perspective to explore the effects of two complex networks: competition and collaboration networks. While collaboration and competition networks are two important sources of strategic information, in the current information age, firms do not only rely on information from partners and competitors, but also on information obtained via information technology. Two IT-enabled capabilities that allow the firm to obtain information are competitive intelligence and enterprise social media. In this study, we develop a conceptual model to investigate whether IT-enabled competitive intelligence and enterprise social media influence how firms benefit from the information they obtain from collaboration and competition networks.

3 Antecedents and Consequences of Digital Resource Redeployment in Mergers and Acquisitions in the Healthcare Industry

Chengxin Cao, Baruch College, NY

Despite the surging hospital consolidations, the effects of how health information technology (HIT) contributes to the value creation of hospital M&A remain mixed. Against this backdrop, this paper examines (1) how digital resources of the acquirer and target affect the likelihood of hospital consolidation, and (2) the role of digital resource redeployment from the target to the acquirer in the performance of the acquiring hospitals after M&A. Using a sample of over 3,000 US hospital systems and 5,000 hospitals, our empirical analysis suggests that M&A served as a means for acquiring hospitals to obtain new resources and capabilities from targets, i.e., digital resource redeployment occurred from target to acquiring hospitals. Furthermore, the digital resources gained from target hospitals helped improve the care quality of the acquiring hospitals.

4 Can Information Sharing Reduce Diagnostic Bias? Evidence from a Health Information Exchange

Minghong Yuan[1], Indranil R. Bardhan[2], Wen Wen[1], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Bee Cave, TX

Prior literature has documented evidence of bias in physician diagnosis, which negatively impacts some minority groups. Such implicit bias can contribute to disparities in healthcare delivery, patient perceptions of care, and health outcomes. By leveraging a quasi-experimental approach, our study offers a new perspective on the identification and measurement of racial bias against racial minority patients in physician diagnoses. We find health information sharing may help to reduce the level of such bias. We also find the effect is stronger among physicians with low prior case experience with racial minority patients. Our study suggests significant potential of using Health Information Exchange (HIE) systems to address disparities in the treatment and care of ethnic minority groups, thereby promoting health equity.

5 An Empirical Investigation of the Bidirectional Effects Between Online Reviews and Offline Business Performance

Xue Guo[1], Kexin Zhao[2], Sam Lee[3], [1]University of North Carolina-Charlotte, Charlotte, NC, [2]University of North Carolina-Charlotte, Charlotte, NC, [3]Texas State University, San Marcos, TX, Contact: xue.guo@uncc.edu

Our study focuses on the dual role of consumers in both creating and consuming online reviews simultaneously and explores the bidirectional interaction between consumers' online-offline behaviors. Specifically, we employ the panel vector autoregression (PVAR) methodology to explore the dynamic relationship among multiple time series variables. We find significant bidirectional effects between online reviews and offline visits in the short term but not long term. We also find the above bidirectional effect varies for different restaurants' characteristics (i.e., younger vs. older restaurants and chain vs. independent restaurants). Our study provides rich theoretical contributions and practical implications for platforms and business owners.

Electronic Commerce and Consumer Behavior

Community Committee Choice Session

Session Chair: Han-Fen Hu, University of Nevada, Las Vegas, Las Vegas, NV

1 Factors Affecting Polarization in Online Communities: Insights from Five Online Platforms

Le Kuai[1], Rajiv Sabherwal[2], [1]University of Arkansas, Fayetteville, AR, [2]University of Arkansas - Sam M. Walton College of Business, Fayetteville, AR, Contact: LKuai@walton.uark.edu

Online communities enable individuals to offer their opinions, but can also create echo chambers and group polarization. This study uses sentiment analysis to examine how group polarization in online communities is influenced over time by the nature of focal topics and the addition and deletion of related posts. It is based on data downloaded every six hours from 9-2021 to 2-2022 from 40 online communities on five platforms across U.S. and China. The results suggest that more active discussions, non-IT-related online communities, and intense topics like work, money, or religion involve greater group polarization, but relaxed topics like leisure or home do not. The time of day when a discussion takes place affects polarization. Overall, this study provides insights into the factors that could intensify or alleviate group polarization in discussions on online communities.

2 Anonymous vs. Timely Transactions: Impact of Real Name Regulation in Crypto-Asset Investment Market

Jaeho Myeong[1], Miyeon Jung[2], JaeHyeon Ahn[1], [1]Korea Advanced Institute of Science and Technology, Seoul, Korea, Republic of; [2]University of Nevada, Las Vegas, Las Vegas, NV, Contact: mwogh96@kaist.ac.kr

Our research investigates how failure to comply with government regulations at the national level affects the performance of international cryptocurrency exchanges and the behavior of global investors. By employing synthetic control methods and unique on-chain data, we examine how digital assets move between international exchanges by individual investors. Our analysis reveals that non-compliant exchanges experienced substantial declines in asset reserves. When regulatory grace periods were implemented, investors shifted their assets from foreign exchanges to domestic ones. During enforcement periods, investors moved their assets to unregulated domestic exchanges to reduce their risk. Additionally, our findings offer useful insights for market participants regarding the risk-averse actions of global customers in the context of international business.

3 Does Black Music Also Matter? the Effect of the George Floyd Incident on Hip-Hop Music Streaming in the United States

Yifei Wang[1], Gorkem Turgut Ozer[1], Anandasivam Gopal[2], [1]University of New Hampshire, Durham, NH, [2]Nanyang Technological University, Singapore, Singapore. Contact: ywang269@umd.edu

This study explores the role of music, particularly hip-hop, in promoting awareness and discourse related to race-based social justice following the death of George Floyd. Using Spotify's streaming data, we found a significant increase in hip-hop consumption, particularly in less racially diverse cities, and consumption shifts towards black artists across all genres. These findings suggest that hip-hop may act as a means of participating in discussions related to Floyd's death, and music made by black artists can serve as a source of information and sense-making in the context of anti-black police violence and racial inequality in the United States.

4 ASIC, Hodl, Sats: New Language, Common Ground, and the Diffusion of Innovation

Jesse-Burton Nicholson[1], Sharon A. Alvarez[2], Arielle Badger Newman[3], Narayan Ramasubbu[4], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh,

Pittsburgh, PA, [3]Syracuse University, Syracuse, NY, [4]University of Pittsburgh, Pittsburgh, PA, Contact: jesseburton@pitt.edu

For new-to-the-world innovations to diffuse, new language—the creation of new words, the co-opting of existing words into a new context, new meanings being ascribed to existing words, and/or the combination of existing words in a new way—must be created in order to make meaning and to build a common ground of shared beliefs, knowledge, language, and values. In this paper, we explore how the creation of new language reduces the uncertainty surrounding an innovation by allowing tensions associated with the unknown or unanticipated aspects of the innovation to be lessened or resolved. We follow a computational grounded theory approach and develop a theoretical model that illustrates this process. We find that new language is often essential to the creation of meaning and understanding that enables a new-to-the-world innovation to diffuse.

Quantitative Methods in Finance and Risk Management

Community Committee Choice Session

Session Chair: Dohyun Ahn, The Chinese University of Hong Kong

1 Efficient Tail Risk Estimation Under Distributional Uncertainty

Dohyun Ahn, Lewen Zheng, The Chinese University of Hong Kong, Shatin, Hong Kong. Contact: lwzheng@se.cuhk.edu.hk

We study the problem of efficiently estimating tail risk when the distribution of risk factors is unknown. While tail risk estimation has been a central problem in finance, most existing studies either develop efficient tail risk quantification methods assuming the data-generating model is fully known or address the issue of distributional uncertainty without providing efficient estimation techniques. Our research aims to bridge this gap. Specifically, we devise a novel simulation method that approximately minimizes errors in both determining the uncertainty set for risk factor distributions and estimating the worst-case bound for tail risk given the uncertainty set. We prove the efficacy of our approach both theoretically and numerically.

2 Generalized Importance Sampling for Nested Simulation

Amber Qingyuan Chen[1], Ben Mingbin Feng[2], [1]Cornell University, Ithaca, NY, [2]University of Waterloo, Waterloo, ON, Canada. Contact: ben.feng@uwaterloo.ca

Importance sampling (IS) is a classical variance reduction technique as one often seeks variance-minimizing optimal sampling distribution. IS has success in many applications such as engineering, operations research, and finance. In some applications such as enterprise risk management and input uncertainty quantification, complex simulation designs such as nested simulation arises naturally: The outer-level simulation generates a set of risk factors, i.e., the scenarios, which are used as inputs for inner-level simulations. In this study, we propose, analyze, and test a generalized importance sampling technique for nested simulation. Our generalized IS approach reuses one set of inner simulation outputs across different outer scenarios. Numerical experiments show that our proposal is orders of magnitudes more efficient than the standard procedure.

3 Resampling Stochastic Gradient Descent Cheaply

Zitong Wang, Henry Lam, Columbia University, New York, NY

Stochastic gradient descent has been widely used in model training and stochastic optimization. Inference on the obtained solutions from SGD has only been recently studied, yet is important due to the growing need for uncertainty quantification. We investigate two easily implementable resampling-based methods to construct confidence intervals for SGD solutions. One uses multiple, but few, SGDs in parallel via resampling with replacement from the data, and another operates this in an online fashion. Our methods can be regarded as enhancements of established bootstrap schemes to substantially reduce the computation effort in terms of resampling requirements, while at the same time bypasses the intricate mixing conditions in existing batching-type methods. We achieve these via a recent cheap bootstrap idea and Berry-Esseen-type bound for SGD.

4 Systemic Risk Adjustments for Term Structures

Zachary Feinstein[1], Andreas Sojmark[2], [1]Stevens Institute of Technology, Hoboken, NJ, [2]London School of Economics and Political Science, London, United Kingdom

In this talk, we introduce a dynamic Gai-Kapadia interbank network to study the yield curve of bank debt under a network valuation adjustment. Such a dynamic system requires a forward-backward approach in which the future probability of default is required to determine the present value of debt. In this way, the systemic model presented provides the network valuation adjustment to the term structure for free without additional steps required. Time permitting, we present this problem in two parts: (1) a single maturity setting that closely matches the traditional interbank network literature and (2) a multiple maturity setting to consider the full term structure.

5 Accelerating Risk-Sensitive Reinforcement Learning via Forecasting

Ju-Hyun Kim, Seungki Min, Korea Advanced Institute of Science and Technology, Daejeon, Korea, Republic of. Contact: vgb8111@kaist.ac.kr

We consider a decision maker (DM) who wants to enhance robustness of his policy by adopting conditional value-at-risk (CVaR) as an objective. Some reinforcement learning algorithms offer a means to find the CVaR-optimal policy. However, they often suffer from slow convergence since they only utilize the worst q-fraction of the outcomes. We accelerate the convergence using convex representation and time decomposition of the CVaR objective. Our main idea is to introduce a "forecaster" that actively predicts the probability that a current sample path belongs to the worst q-fraction. We utilize this forecast sequence, which is a martingale, to reduce the variance in learning. We demonstrate its effectiveness via theoretical analyses and numerical experiments.

Pricing in Combinatorial Auctions

Community Committee Choice Session

Session Chair: Benjamin Lubin, Boston University, Boston, MA

Session Chair: Robert Day, University of Connecticut, Bergen, Norway

1 Combinatorial Auctions for Truckload Transportation

Mohsen Emadikhiav[1], Robert Day[2], [1]Florida Atlantic University, Boca Raton, FL, [2]University of Connecticut, Storrs, CT, Contact: memadikhiav@fau.edu

We present a combinatorial auction/exchange market for a truckload transportation system where carriers can use a compact bid language to express their preferences to participate in the market. We present a dual-pricing mechanism that finds (epsilon-)competitive equilibrium prices and evaluate market outcomes under consideration of different practical constraints.

2 Machine Learning-Powered Combinatorial Clock Auction

Ermis Nikiforos Soumalias[1], Jakob Weissteiner[1], Jakob Heiss[2], Sven Seuken[3], [1]University of Zurich, Zurich, Switzerland; [2]ETH Zurich, Zurich, Switzerland; [3]University of Zurich, Zuerich, Switzerland

In this work, we introduce a machine learning-powered combinatorial clock auction. Our main technical contribution is a novel method for training ML models on demand query observations and a theoretically motivated and efficient ML method for determining the next price vector. We evaluate our new auction design compared to the well-known combinatorial clock auction (CCA). Compared to the clock phase of the CCA, our approach achieves up to 9% points higher efficiency and significantly higher clearing potential.

3 Single Price Path Vickrey Auctions

Sébastien Lahaie[1], Benjamin Lubin[2], [1]Google Research, New York, NY, [2]Boston University, Boston, MA

Iterative auctions typically converge to market clearing (i.e., competitive equilibrium) prices, where demand balances supply. However, to induce truthful bidding during the auction process, it is understood that VCG payments need to be charged upon auction completion. The naive approach to achieve this is to either re-run the auction as many times as there are bidders, or run auctions in parallel using multiple price paths. In this work, we present an auction that computes VCG payments using just a single price path, where the pricing structure (e.g., linear, anonymous) remains flexible.

4 Walrasian and Price-Match Equilibria via Primal Cuts in Combinatorial Auctions

Robert Day[1], Benjamin Lubin[2], [1]University of Connecticut, Storrs, CT, [2]Boston University, Boston, MA, Contact: robert.day@uconn.edu

In a combinatorial auction, there is often no vector of prices for the items being auctioned that constitutes a Walrasian equilibrium, in which all bidders prefer their allocated bundle and excess supply items are priced at zero. We use valid inequalities (cuts) of the binary integer program for winner determination as "artificial items" that can be interpreted intuitively and priced to generate an artificial Walrasian Equilibrium. We show that the lack of an integer programming gap is not a sufficient stopping criterion for cut generation to arrive at a "price-match equilibrium" and provide examples where this refinement differs from Walrasian equilibrium.

Emerging Topics for Electric Vehicles

Contributed Session

Session Chair: Hyeong Suk Na, University of Missouri, Columbia, MO

1 The Impact of Electric Vehicle Sharing on Automaker's Electric Vehicle Charging Infrastructure

Tania Saha[1], Prasenjit Mandal[2], [1]SP Jain Institute of Management & Research (SPJIMR), Mumbai, India; [2]NEOMA Business School Reims Campus, Reims, France. Contact: tania.saha@spjimr.org

Carbon emissions cause global temperature to rise, contributing to climate change. The adoption of electric vehicles (EVs) is an effective way of reducing carbon emissions. Building EV charging stations can elevate EV adoption among customers but is capital-intensive for a manufacturer. In recent years, the sharing economy is getting more and more popular. Instead of having exclusive ownership, the consumer-to-consumer (C2C) sharing service enables the accessibility of products to consumers. In this study, we understand the impact of C2C sharing service on a manufacturer's strategic decision in developing EV charging infrastructure.

2 A Linear Program Model for the Electric Vehicle Routing Problem: A Case Study in a Swiss Network of Supermarkets

Reinaldo Crispiniano Garcia[1], Bruno Souza Nunes[2], André Gonçalves Corrêa Pereira[3], [1]University of Brasilia (UnB) - Director ORLaB (www.orlab.com.br), Brasília - DF, Brazil; [2]University of Brasilia (UnB), Brasília - DF, Brazil; [3]University of Brasilia (UnB), Brasília - DF, Brazil. Contact: rcgar@yahoo.com

The use of electric vehicles by companies is a reality in the world since there is an incentive to replace the vehicles powered by fossil fuels to mitigate carbon dioxide emissions. However, the electric vehicles are a challenge for the logistic systems because its related vehicle routing problem depends not only on the distance travel and the vehicle load capacity but also on the battery life. This work implements a model taking into account the electric vehicles distance travel and their load capacity besides their battery life, the working hours and the stores demand, among other factors. The implemented model minimizes then the distance travel by the electric vehicles being applied to a network of a Swiss supermarket stores.

3 Sustainability and Accessibility of Electric Vehicles in Disaster Management

Olusola Ogungbeje[1], Joon-Yeoul OH[2], [1]Texas A & M University-Kingsville, Kingsville, TX, [2]Texas A&M University-Kingsville, Kingsville, TX, Contact: olusolaogungbeje@gmail.com

The rapid proliferation of electric vehicles market in the United State is revolutionizing the transportation sector. There is little evidence of the sustainability, and accessibility of the electric vehicle charging stations during an evacuation from disasters. This research is to investigate the sustainability and accessibility of electric vehicle during natural disasters and propose the way of the increasing the sustainability and accessibility in the South Texas area. The results of this study help the stakeholders to design electric vehicles systems in terms of a social infrastructure.

4 Electric Vehicle Charging Behavior Optimization in Congested Network Environments

Nastaran Tork[1], Alireza Khani[2], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, MInneapolis, MN, Contact: tork0100@umn.edu

The rapid expansion of electric vehicles (EV) makes their role more prominent in transportation networks. The majority of the existing literature overlooked the interconnection between charging and route choice behavior of EV drivers. The objective of this study is to devise charging pricing mechanisms to influence the rational decision-making of individual EV drivers. This strategy is intended to simultaneously alleviate traffic congestion and prevent the overloading of power distribution across the network.

5 Stochastic Evacuation Route Planning for Electric Vehicles

Hyeong Suk Na[1], Sang Jin Kweon[2], [1]University of Missouri, Columbia, MO, [2]Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of. Contact: hyeongsuk.na@missouri.edu

The increasing demand for fuel-efficient and low-emission vehicles has driven significant expansion of the global electric vehicle (EV) market. However, EVs still face drawbacks such as long charging times and restricted operational ranges. Furthermore, the growing adoption of EVs for evacuations has highlighted the need for robust charging infrastructure to effectively manage long-distance EV evacuations. To address these challenges, this study focuses on the stochastic evacuation route planning for EVs, considering the limited availability of EV charging facilities during evacuations. Accordingly, we propose a resilient evacuation plan that strategically allocates mobile EV charging stations along evacuation routes. A case study on a hurricane evacuation in Florida is presented to validate the applicability and the practicability of our proposed model.

Assortment Planning with Multiple Warehouses

Contributed Session

Session Chair: Hongyuan Lin, National University of Singapore, Singapore, Singapore

2 Shall We Only Store Popular Products? Warehouse Assortment Selection for E-Companies

Xiaobo Li[1], Hongyuan Lin[2], Fang Liu[3], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore; [3]University of Chinese Academy of Sciences, Beijing, China. Contact: lin_hongyuan@u.nus.edu

We study the single-warehouse assortment selection problem, with the aim to minimize order fulfillment cost under cardinality constraints, considering spillover fulfillment and order-splitting costs. Despite the problem's inherent complexity, we formulate Mixed Integer Linear Programs (MILPs) and put forward a feasible Marginal Choice Indexing (MCI) policy that primarily stores popular products. The MCI policy proves optimal under conditions common in both classic and many multi-purchase discrete choice models. Through extensive analysis of a real-world dataset, the MCI policy is demonstrated to be near-optimal and robust, significantly enhancing the fill rate, thereby asserting its practical value.

1 Assortment Planning of Pharmaceutical E-Commerce Platform Considering Drug Substitution and Complementarity

Yingying Wang, Huazhong University of Science and Technology, Wuhan, China. Contact: yingying_wang@hust.edu.cn

Assortment planning across multiple warehouses is a challenge for pharmaceutical e-commerce platforms. A fixed assortment plan may lead to inventory crises for enterprises. This study focused on optimizing assortment planning in pharmaceutical e-commerce platforms under demand uncertainty. Taking into account the substitutability, we also consider the complementarity of drugs, which means drugs need to be used in combination. We use transaction data from pharmaceutical e-commerce platform to estimate parameters and apply the sample average approximation method to approximate the model. Our study shows that the platform should focus on assortment depth when demand for a particular product increases significantly. The platform can increase profits by broadening categories when demand is stable.

Session.Location:CC-West Lecture Hall

Applications of Deep Learning for Predictive Modeling

Contributed Session

Session Chair: Sorouralsadat Fatemi, University of Illinois, Chicago, IL

1 Individualized Location Prediction Using Autoencoders and Long-Short Term Memory Networks

Gerald Onwujekwe[1], Manfred Zibo Men[2], Joseph Eyo Duke[3], [1]Washington University in St. Louis, St. Louis, MO, [2]Washington University in St. Louis, St. Louis, MO, [3]University of Calabar, Calabar, Nigeria

Predicting an individual's future location is a challenging task that has significant implications for a variety of real-world applications. In this paper, we present a novel location prediction algorithm based on an autoencoder using Convolutional Neural Network and Long-Short Term Neural Network. Our approach aims to predict an individual's future location rather than a generalized prediction for everyone's next location. The experiments were conducted using the GeoLife dataset. The autoencoder model effectively learned the underlying features of the input data, while the LSTM model showcased great ability to learn from the input features, achieving a validation loss of 0.0643 (mean squared error). These results demonstrate the potential of the proposed approach for individualized location prediction in real-life scenarios.

2 Clustering Morphological Properties of Cells Using Neural Network-Basedimage Segmentation Models

Hyemin Lim[1], Geonhee Jang[1], Wonkeun Jo[1], Yeongjun Koh[1], Dongil Kim[2], [1]Chungnam National University, Daejeon, Korea, Republic of; [2]Ewha Womans University, Daejeon, Korea, Republic of. Contact: lim960516@o.cnu.ac.kr

Image-based cell profiling is a method that extracts features from cell images to quantify cell information. With recent advancements in CNN-based research, recognition of small objects such as microscope images has become feasible. In this paper, we propose a method for clustering cells using a combination of neural network-based segmentation and clustering models by utilizing a pretrained model on the LiveCell dataset. Experimental results demonstrated that the proposed method showed superior performance compared to existing clustering models.

3 Graph Koopman Operator for Traffic Forecasting

Weiheng Zhong, Hadi Meidani, University of Illinois Urbana Champaign, Champaign, IL, Contact: weiheng4@illinois.edu

Traffic forecasting is a crucial part of traffic management. While graph neural networks (GNNs) have been successful in predicting traffic, their complex model architectures make them impractical for use in large networks due to high computing and memory costs. To overcome this barrier, we propose a novel linear model, named Graph Koopman Operator, which encodes the graph topology into the Koopman Operator to capture graph-based dynamics. Using real-world traffic data from the entire California highway network with over 37,000 nodes, we demonstrate that this proposed simple linear method, compared to all the existing nonlinear GNN forecast models, surprisingly can achieve higher prediction accuracy and is more efficient by around two orders of magnitude.

4 Graph Neural Network for Estimating Bond Returns

Dan Zhou[1], Ajim Uddin[1], Xinyuan Tao[1], Dantong Yu[1], Jiang Lei[2], [1]New Jersey Institute of Technology, Newark, NJ, [2]Tsinghua University, Beijing, China. Contact: dz239@njit.edu

Networks are ubiquitous in financial systems. Holding similar portfolios forms implicit network connections between assets. This paper turns the institutional bond holding (eMAXX) into this type of network and develops an advanced Temporal Bipartite Graph Neural Network (TBGNN) model to capture valuable information from connections for corporate bond pricing. Our bond networks and associated model have two advantages: demonstrate the networks of common bond holdings explain excessive returns and predict the future bond returns. Results show that our model can explain about 90% of the in-sample return variation, with at least 70% improvement compared to benchmarks. Overall, our finding strongly suggests that incorporating network economically and highly statistically improves future bond return prediction and such impacts are above and beyond pricing factors.

5 Stock Market Movement Prediction Utilizing LLMs

Sorouralsadat Fatemi[1], Yuheng Hu[2], [1]University of Illinois-Chicago, Chicago, IL, [2]University of Illinois-Chicago, Chicago, IL, Contact: sfatem6@uic.edu

In recent times, significant advancements have been observed in the performance of large language models (LLMs) across diverse tasks in natural language processing (NLP). Nonetheless, their potential in the financial sector, particularly in the prediction of stock market trends, has yet to be thoroughly investigated. This study undertakes a comprehensive examination of the abilities of LLMs such as ChatGPT in the context of predicting changes in stock movements using a multimodal approach, incorporating both stock-related news and technical indicators. Our experimentation encompasses zero-shot and few-shot inference, employing advanced models such as gpt-3.5, as well as smaller, instruction-based LLMs like Flan-T5. Our results indicate that LLMs demonstrate comparable performance when compared to the state-of-the-art models.

First Order Methods, Machine Learning, and Beyond

Community Committee Choice Session

Session Chair: Bart Paul Gerard Van Parys, Massachusetts Institute of Technology, Cambridge, MA

Session Chair: Shuvomoy Das Gupta, MIT, Cambridge, MA

1 BnB-PEP: A Unified Methodology for Constructing Provably Fastest Optimization Methods

Shuvomoy Das Gupta, MIT, Cambridge, MA, Contact: sdgupta@mit.edu

As the data revolution continues to unfold, the pressing demand for provably fastest first-order methods has become increasingly apparent, given their key role in large-scale optimization and machine learning. To address this issue, we present BnB-PEP, the first unified methodology for constructing provably fastest first-order methods for both convex and nonconvex optimization. BnB-PEP poses the problem of constructing the fastest method as a nonconvex but practically tractable quadratically constrained quadratic optimization problem and solves it to certifiable global optimality using a customized branch-and-bound algorithm. We apply BnB-PEP to various practically relevant setups, yielding methods that surpass previous state-of-the-art results. Finally, we demonstrate how BnB-PEP can be used to systematically generate analytical convergence proofs.

2 Computer-Assisted Design of Accelerated Composite Optimization Methods: OptISTA

Ernest Ryu[1], Shuvomoy Das Gupta[2], Uijeong Jang[3], [1]Seoul National University, Department of Mathematical Sciences, Seoul, Korea, Republic of; [2]MIT, Cambridge, MA, [3]Seoul National University, Seoul, Korea, Republic of. Contact: ernestryu@snu.ac.kr

In this work, we present a novel double-function stepsize-optimization PEP methodology that poses the optimization over fixed-step first-order methods for composite optimization as a finite-dimensional nonconvex QCQP, which can be practically solved through spatial branch-and-bound algorithms. We utilize this methodology to design the exact optimal method OptISTA for the composite optimization setup, which outperforms the state-of-the-art accelerated composite optimization method FISTA (Beck, Teboulle 2009) by a factor of 2. We then establish the exact optimality of OptISTA with a novel lower-bound construction based on the extension of semi-interpolated zero-chain construction. By establishing exact optimality, our work concludes the search for the fastest first-order methods for the proximal, projected-gradient, and proximal-gradient setups.

3 A First-Order Approach to the Product Replacement Problem with Cross-Item Effects in Retail

Manuel Moran-Pelaez[1], Georgia Perakis[2], Tamar Cohen-Hillel[3], [1]MIT Operations Research Center, Cambridge, MA, [2]Sloan School of Management, MIT, Cambridge, MA, [3]UBC Sauder School of Business, Vancouver, BC, Canada. Contact: mmoranp@mit.edu

Assortment optimization is an important problem in the retail sector with the retailer deciding on which products to display in the stores. In this work we deviate from the usual first-choice model approaches where customers purchase their preferred available option. We model demand by capturing substitution (cannibalization) and complementarity cross-item effects. Although the original problem is NP-hard, we develop efficient and near-optimal first-order methods to compute assortments. We show the scalability and optimality of our approach in synthetic experiments. Our methods compute solutions within a 2% optimality gap for thousands of items in minutes. We also show a 6-8% revenue improvement of these methods in a real setting.

KINFORMS Special Issue

Community Committee Choice Session

Session Chair: Chang Won Lee, Hanyang University, Seoul

1 Understanding the Concept of Proactive Quality Management and Its Impact on Firm Value

Yejee Kim, Hosun Rhim, Korea University Business School, Seoul, Korea, Republic of. Contact: gkrdus8279@naver.com

Most customers do not complain the inconvenience of a product or service, but rather decide to stop using it. To address this issue, we define the concept of proactive quality management and classify it into three types; guarantee program, preventive quality management, and forecasting-

based quality management. We conduct the event study method to examine the impact of proactive quality management on firm value.

2 Creating Sustainable Metaverse Business Models in Korea Healthcare Industry: Strategic Map Perspectives

Chang Won Lee[1], Kwangjum Kim[2], Jae Byung Chae[3], Ji Eun Kim[4], [1]Hanyang University Business School, Seoul, Korea, Republic of; [2]The Catholic University of Korea, Seoul, Korea, Republic of; [3]SK Telecom Metaverse Co, Seoul, Korea, Republic of; [4]Korea Health Industry Development Institute (KHIDI), Seoul, Korea, Republic of. Contact: leecw@hanyang.ac.kr

Metaverse is an emerging issue in the recent era. This study is to explore some cases and applications in the metaverse. Korean cases in the healthcare industry are discovered and presented in 4 different types of metaverse models. This study will provide important insights for decision-makers and policy-makers to create and implement sustainable metaverse business models and ecosystems.

3 Is Supply Chain (SC) Resilience a Critical Factor for Every Business?: Mitigation for the Sustainable Supply Chain Including SC Vulnerability

Da-sol Lee[1], Minjeong Oh[2], Sungyong Choi[3], [1]Hanyang University, Seoul, Korea, Republic of; [2]Yonsei University, Wonju, Korea, Republic of; [3]Hanyang University Business School, Seoul, Korea, Republic of. Contact: dslee1006@hanyang.ac.kr

This study aims to identify the critical factors that enhance the supply chain (SC) resilience in organizations, by taking into account their vulnerabilities, and provide empirical evidence to support the improvement of SC resilience, performance, and sustainability. The study examines the impact of key SC resilience competencies on the SC resilience phase and extends it to investigate the effects on sustainability. The study finds that the factors contributing to SC resilience vary depending on the SC vulnerability of each company. The study's findings can assist organizations in developing SC resilience strategies, and provide empirical results to support the enhancement of resilience and performance, ultimately contributing to the improvement of the entire supply chain's resilience.

4 Optimal Inventory Policy for Upstream when Downstream Follows (S,S) Policy

Byung Kwon Lee, Jeongwook Lim, Kun Soo Park, Seoul National University, Seoul, Korea, Republic of. Contact: kunsoo@snu.ac.kr

We consider a decentralized supply chain with one upstream firm and one downstream firm. The downstream firm faces customer demand with a fixed ordering costs, and it uses (s,S) policy to make its order to the upstream firm. The upstream firm in this decentralized supply chain does not know the downstream firm's inventory level, and it only knows the distribution of customer demand. By actively analyzing the downstream's order features, we propose a novel approach to optimize the upstream firm's optimal inventory policy.

5 Building Numeracy by Playing with Toys

James J. Cochran, The University of Alabama, Tuscaloosa, AL

Numeracy is an important and elusive component of literacy. We show how to use Legos pieces and operations research to quickly develop students' skills in modelling, demonstrate the real-world relevance of algebra and geometry, and demonstrate connections between these two sometimes intimidating areas of mathematics. By doing so, we demonstrate how to rapidly improve our students' numeracy and make them see that they are *very* capable of working with abstract mathematical concepts (and so also expand our students' literacy).

1 Automated Benchmarking for High-Performance Computing Workloads in Life Sciences

Rostislav I. Markov[1], Matthew Noyce[2], [1]Amazon Web Services, Inc., New York, NY, [2]Amazon Web Services, Inc., Nashville, TN, Contact: rmarkov@amazon.com

Running high-performance computing workloads such as genomics workflows requires large pools of compute instances that process data at a petabyte scale. Benchmarking helps evaluate workflow performance and discover faster and cheaper ways of running them. In practice, performance evaluations happen irregularly because of the associated heavy lifting. Using action research, we build a prototype based on cloud computing services of Amazon Web Services to help life-science research teams automate such evaluations. Our automated benchmarking solution measures performance on timing and pricing dimensions and provides: 1) more accurate enterprise resource planning by performing historical analytics, 2) lower cost to the business by comparing performance on different resource types, and 3) cost transparency to the business by quantifying periodical chargeback.

2 Supervised and Unsupervised Deep Learning for Workload Classification

Bing Hu[1], Andrew N. Mason[2], Karl Kempf[2], [1]Intel Corp., Chandler, AZ, [2]Intel Corporation, Chandler, AZ, Contact: bing.y.hu@gmail.com

A recuring decision in any data center involves optimally matching the computational requirements of an arbitrary workload with the computational capabilities of the available servers and their specific provisioning. As a first step in this decision process to utilize the full potential of a software/hardware system and obtain scalable performance improvements, a set of meaningful and accurate workload classifiers is essential. This paper proposes supervised and unsupervised deep learning workload analysis tools to capture complex workload dynamics. Our experiments show that these tools can precisely classify workloads by using latent feature representations from deep learning models.

3 Adaptive Federated Learning with Auto-Tuned Clients

J. Lyle Kim[1], Mohammad Taha Toghani[2], Cesar A. A. Uribe[3], Anastasios Kyrillidis[3], [1]Rice University, Houston, TX, [2]Rice University, HOUSTON, TX, [3]Rice University, Houston, TX

Federated learning (FL) is a distributed machine learning framework where the global model of a central server is trained via multiple collaborative steps by clients, without sharing their own data. While being a flexible framework where the distribution of local data, client participation rate, and computing power of each client can greatly vary, such flexibility gives rise to plethora of challenges, especially in terms of the hyperparameter tuning of the optimization routines used by the server and the clients. We propose a simple step size rule, that not only enables each client to use its own step size, but also adapts to the local smoothness of the function each client is optimizing. We provide both theoretical and empirical results where the benefit of the client adaptivity is shown in various FL scenarios.

4 Parameter Optimizer for Cloud Resource Forecasting

Albert Shyn Kwan Tan[1], Mohammadreza Samadi[1], Prashanth Mohan[2], Juan Li[3], [1]Google, Mountain View, CA, [2]Google, Sydney, Australia; [3]Google, New York, NY

Cloud services typically need to support Service Level Objectives (SLO) of less than 1% of downtime despite the variability in the demand and unplanned events. In Cloud resource planning, meeting the availability SLO is a hard constraint. However, different demand structures (e.g. ordering frequency, degree of fungibility across workloads, etc.) require different capacity levels to meet the availability SLO given the volatility of the demand. In this work, we present a statistical backtest simulation framework where we simulate capacity paths based on backtests under different demand structure assumptions, and compare them to actual demand to obtain efficiency and availability metrics. With that, the efficiency-availability tradeoff can be fully evaluated for decision makers.

Machine Learning Methods in Healthcare - 2

Contributed Session

Session Chair: Oscar Rincon Guevara, 1</sup

1 Recognition of Super-Agers and Cognitive Decliners with fMRI and sMRI - Classification Study on ADNI

Parvin Mohammadiarvejeh, Mohammad Fili, Guiping Hu, Auriel Willette, Iowa State University, Ames, IA

The decline in multiple cognitive domains is considered the normal part of the aging process. However, older individuals show variation in the cognitive trajectories' patterns in their lifetime. Furthermore, adults aged 80 years or older, called "Super-Ager", showed cognitive functions at least as good as middle-aged adults. In this study on the ADNI database, we developed classification models to distinguish Super-Agers from normal Cognitive Decliners using Structural brain Magnetic Imaging Resonance (sMRI) and Functional Magnetic Imaging Resonance (fMRI) features. Understanding the differences in neurobiological features provides the knowledge to resist cognitive decline in healthy people and mitigate Alzheimer's disease.

2 The Effect of COVID-19 on COPD Patient's Readmission and Its Predictors

Behrad Barghi, Nasibeh Azadeh-Fard, Rochester Institute of Technology, Rochester, NY, Contact: bb3412@rit.edu

Chronic obstructive pulmonary disease (COPD) is a progressive lung disease among the top three causes of death in the US. Identifying risk factors for COPD patients' readmission and reducing it has become even more critical since the start of the COVID-19 pandemic. In this study, we use a nationwide dataset and machine learning techniques to develop a novel readmission prediction model, and the Bayesian optimization method is used to find the most optimal hyperparameters in each model.

3 Deep Learning Classification in Presence of Uncertain Predictors for Medical Decision Making

Maryam Kheirandish Borujeni, Shengfan Zhang, University of Arkansas, Fayetteville, AR, Contact: mkheiran@uark.edu

Deep learning classification models are becoming increasingly applicable in healthcare but are also significantly challenging due to the inherent uncertainties in clinical and laboratory test data. These errors are usually presented as sensitivity and specificity measures and do not follow a normal but some discrete distribution. We demonstrate the impact of these uncertainties on predictions and develop a framework to handle and quantify these uncertainties in medical decision-making problems.

4 Identifying Early Mpox Symptoms in Clinical Notes Using Natural Language Classification

Oscar Rincon Guevara, Mukesh Hamal, Lara Bull-Otterson, Centers for Disease Control and Prevention, Atlanta, GA

Natural language processing models trained on clinical notes can support extraction of critical features associated with emerging conditions of public health importance. In this study, a pretrained transformer model was applied to clinical notes within American Board of Family Medicine PRIME Registry data (April 2022 to January 2023) to identify potential early symptoms of monkeypox virus infection (i.e., occurring before rash onset or diagnosis) among patients with sexually transmitted disease-related outpatient visits. The transformer model identified differential symptoms between patients with and without mpox diagnoses; a random forest classifier was used to identify symptoms having the strongest association within each subgroup. These findings could support early diagnosis of mpox to aid prevention and treatment efforts.

Stochastic Models on Part Failures

Contributed Session

Session Chair: Xiao Chen, University of New Hampshire, Dunham, NH

1 Servicizing Models with Product Remanufacturing Regarding Uncertain Collection Quality

Qidong He[1], Nengmin Wang[2], [1]Southwest Jiaotong University, Chengdu, China; [2]Xi'an Jiaotong University, Xi'an, China. Contact: heqd@outlook.com

Servicizing business models have been widely adopted by manufacturers to provide maintainable service especially when products are not fully functional. But the uncertain quality of collected cores reduces the economic benefit of remanufacturing process. To investigate the influence of quality uncertainty on servicizing, first, we propose new collection functions with customers heterogeneously prioritizing maintainable service in a two-period model, in which the manufacturer choose to provide servicizing, purchasing, or leasing business. Second, the collection rates and profits of manufacturers choosing different business models are compared under quality uncertainty and remanufacturing of wasted products. We find out the best business model choice under different quality scenario and impact of uncertain quality on servicizing efficiency.

2 Enhancing Semiconductor Equipment Failure Detection Using Correlation Analysis and Data Augmentation

Minjae Baek, Seoung Bum Kim, Korea University, Seoul, Korea, Republic of. Contact: minjae7306@korea.ac.kr

Traditional control charts and machine learning methods have been used to detect equipment failures in semiconductor processes. However, detecting failures and identifying their root causes can be challenging because of the complexity of the process and structural characteristics of the equipment. Moreover, the anomaly sections for each part can be imbalanced, which can hinder classification performance. In this study, we propose a method to detect failures using the correlation of variables and data augmentation. We demonstrate the effectiveness and applicability of the proposed method using real-world multivariate time series data obtained from ashing process equipment.

3 Manufacturing Rescheduling After Crisis or Disaster-Caused Supply Chain Disruption

Hongguang Bo[1], Xiao Alison Chen[2], Qian Luo[3], Wenpeng Wang[4], [1]Dalian University of Technology, Dalian, China; [2]University of New Hampshire, Durham, NH, [3]Xi'an Jiaotong-Liverpool University, Suzhou, China; [4]Dalian University of Technology, Dalian, China. Contact: alison.

chen@unh.edu

In this paper, we address the rescheduling challenges faced by a repair shop following major supply disruptions. These disruptions cause delays in production and order delivery, necessitating the rescheduling of unfinished parts. Our study considers the holding costs associated with finished and unfinished parts, as well as setup costs when switching between part types. We formulate the rescheduling problem as an integer program, aiming to minimize total tardiness, setup cost, and holding cost. Then, we propose a two-stage genetic algorithm that incorporates an estimation of distribution algorithm for enhanced search. We evaluate the algorithm using data from a heavy machinery maintenance provider. Results show that our approach outperforms the initial schedule and other benchmark algorithms without sacrificing computational time.

Models for Supply Chain Resilience and Disruption

Contributed Session

Session Chair: Ashesh Kumar Sinha, Kansas State University, Manhattan, KS

1 Cognitive Digital Twins for Supply Chain Resilience Enhancement

Mahmoud Ashraf[1,2], Islam Ali[1,2], Amr B. Eltawil[1,2], [1]Egypt-Japan University of Science and Technology, Alexandria, Egypt; [2]Alexandria University, Alexandria, Egypt. Contact: mahmoud.ashraf@ejust.edu.eg

Given the adverse impact of local and global crises on global supply chains, building resiliency is vital to mitigate such adverse impacts. Therefore, a cognitive digital supply chain twin is developed to enhance supply chain resilience through improved decision-making support, driven by the growing digital transformation efforts. The cognitive digital twin adopts a set of machine learning-based modules, enabling disruption detection, disrupted component identification, disruption duration prediction, and time-to-recovery prediction. Additionally, a disruption extrapolation module is developed to predict the future supply chain performance trajectory under a disruptive event and test recovery actions. Obtained information from the cognitive digital twin helps decision-makers make appropriate decisions based on real-time disruption detection data.

2 A Coverage Procurement Approach Does Not Pay: Empirical Evidence of the Cost of Flexibility

Angela Acocella, Tilbrug University, Tilburg, Netherlands. Contact: a.j.acocella@tilburguniversity.edu

Market uncertainty can drive procurement decisions that favor flexibility and delayed decision-making to mitigate financial risk. However, we empirically demonstrate that doing so can lead to higher costs and lower supplier performance. In the full truckload transportation services industry, buying firms (shippers) establish non-binding contracts with trucking companies (carriers) that function as options to avoid price escalations and volatility in a spot market. We build a set of empirical models of shippers' and carriers' strategic and operational behaviors to test the effects of shippers' choices to establish contracts but ultimately not exercise them. Despite firms' intentions to reduce costs and mitigate risks, we find that the strategy has tangible costs. We add to the by exploring a context in which these tactics are unfavorable and quantify the costs.

3 Exploring the Interplay of Agile Methodologies, Resilience, and ESG in Supply Chains: A Bibliometric Review and Qualitative Analysis

Angelica Alebrant Mendes, Susan Meireles Christiano Dantas, Federal University of ABC, Santo André, Brazil. Contact: angelica.alebrant@ufabc.edu.br

The importance of agile methodologies and resilience has increased due to competitiveness and the risk of value chain disruption. ESG frameworks in investment decision-making are gaining momentum, but implementation across industries is limited, and its relationship with functions such as supply chain, and logistics is understudied. The impact of ESG and agility on supply chain resilience is still being explored, resulting in a lack of extensive research. A bibliometric review and qualitative analysis of 58 articles from 2013 to 2022 revealed a 32.98% growth in scientific production on the topic. The study emphasizes the interdependence between resilience and agility, focusing on financial and operational performance in the supply chain regarding ESG. Identified gaps in the literature provide insights for future research.

4 Option Contract in the Air Cargo Industry Under Limited Capacity and Multiple Forwarders

Jiyong Kim[1], Byeongkwon Lee[1], Kunsoo Park[1], Kwanghun Chung[2], [1]Seoul National University, Seoul, Korea, Republic of; [2]Hongik University, Seoul, Korea, Republic of

The outbreak of COVID-19 has imposed restrictions on international travel, which has posed significant challenges for airlines managing their operations. In this context, the air cargo industry has played a crucial role in sustaining the airlines. Furthermore, as global logistics continue to expand, cargo industry is expected to grow steadily in the future. Consequently, our research aims to analyze the overbooking decisions of a carrier, as well as the reservation decision of forwarders, who are the key stakeholders within the air cargo industry. To achieve this, we employ option contracts and the stackelberg game model. Diverging from prior literature, which assumes a single carrier and forwarder or a carrier with unlimited capacity, our analysis focuses on the scenario involving multiple forwarders and a carrier with limited capacity.

5 Data Driven Decomposition Approach for Drone Battery Swapping in Last Mile Logistics

Ashesh Kumar Sinha, Kansas State University, Manhattan, KS, Contact: ashesh.sinha24@gmail.com

Supply chain disruptions have been a challenging issue worldwide, leading to losses of over several million dollars. The need for a resilient supply chain has led to the rise of technology-driven logistics, especially using e-commerce. In recent years, drones have become a low-cost, efficient, and less polluting alternative to land transportation for delivering packages in last-mile logistics, even in rural and hard-to-reach areas. One of the substantial operational challenges in using drones in the supply chain network is the limited flight coverage since they have limited flight range. The research goal of this proposal is to improve resiliency in the last-mile logistics of drones through a novel data-driven battery swapping/charging model that utilizes realistic charge and discharge cycles.

Mining Nonlinear Dynamics in Operational Data for Process Improvement

Tutorial Session

Session Chair: Hari Balasubramanian, University of Massachusetts, Amherst, Amherst, MA

1 Nonlinear Dynamics Modeling and Control of Operational Data for Process Improvements

Hui Yang, Pennsylvania State University, University Park, PA

Whenever multifarious entities cooperate, compete, or interfere in manufacturing or service operations, there will be the rise of nonlinear and nonstationary dynamics. As complex systems evolve in time, operational dynamics deal with change. Whether the system settles down to the steady state, undergoes incipient changes, or deviates into more complicated variations, it is dynamics that help analyze system behaviors. Effective monitoring, modeling and control of nonlinear dynamics will increase system quality and integrity, thereby leading to significant economic and societal impacts. For example, manufacturing processes will make products with better quality and higher throughput. Gaining a deeper understanding of nonlinear dynamics of complex diseases will help improve the delivery of healthcare services, reduce the healthcare cost, and improve the health of our society. However, nonlinear dynamics pose significant challenges for operations engineering. Particularly, nonlinear dynamical systems defy understanding based on the traditional reductionist's approach, in which one attempts to understand a system's behavior by combining all constituent parts that have been analyzed separately. In order to cope with system complexity and increase information visibility, modern industries are investing in advanced sensing modalities such as sensor networks and internet-of-things technology. Real-time sensing gives rise to rich datasets pertinent to operational dynamics. Realizing the full potential of such operational data for process improvements requires fundamentally new methodologies to harness and exploit complexity. Nonetheless, there is a critical gap in the knowledge base that pertains to integrating nonlinear dynamics research with operations engineering. The theory of nonlinear dynamics has been primarily studied in mathematics and physics. There is an urgent need to harness and exploit nonlinear dynamics for creating new products (or services) with exceptional features such as adaptation, customization, responsiveness, and quality in unprecedented scales.This tutorial presents a review of nonlinear dynamics methods and tools for real-time system informatics, monitoring and control. Specifically, we will discuss the characterization and modeling of recurrence dynamics, network dynamics, and self-organizing dynamics hidden in operational data for process improvements. Further, we contextualize the theory of nonlinear dynamics with real-world case studies and discuss future opportunities to improve the design, monitoring, and control of manufacturing and service operations. We posit this work will help catalyze more in-depth investigations and multi-disciplinary research efforts in the intersection of nonlinear dynamics and data mining for operational excellence.

Theory and Practice of Revenue Management in Service Systems by Jeunghyun and Xu

Community Committee Choice Session

Session Chair: Xu Sun, University of Florida, Gainesville, FL
Session Chair: Jeunghyun Kim, Korea University, Seoul, Korea, Republic of

1 Multichannel Advertising: Budget Allocation in the Presence of Spillover and Carryover Effects

Huijun Chen[1], Ying-Ju Chen[2], SUNGHYUK PARK[3], Dongwook Shin[4], [1]HKUST, Hong Kong, Hong Kong; [2]The Hong Kong University of Science and Technology, Kowloon, Hong Kong; [3]KAIST College of Business, Dongdaemun-Gu, Korea, Republic of; [4]HKUST Business School, Clear Water Bay, Hong Kong. Contact: hchenby@connect.ust.hk

This paper investigates how the presence of the spillover and carryover effects in the multi-channel ad campaign affects the budget allocation decisions of a marketing agency. The dynamic customer response to the advertisement is modeled by a hidden state Markov process. We first characterize the state in-attentive budget allocation problem, where the decision maker solves a static optimization iteratively. Second, we study the state attentive budget allocation problem and find the optimal budget remains most of the time close to an optimal steady state. Finally, we show that when channels are very different, the gap between them is not negligible.

2 Consistent Assortment Optimization Under Uncertainty

Carlos Henrique Cardonha[1], Aritanan Gruber[2], [1]University of Connecticut, Storrs, CT, [2]Federal University of ABC, Santo André, Brazil

This work investigates a dynamic version of the Assortment Optimization Problem (AOP) under the Multinomial Logit (MNL) choice model, where the firm relies on exogenous observations from multiple sources (competitors) to identify an optimal assortment. More precisely, we assume that all customers follow an MNL choice model, but the utility components of the parameters are unknown to the firm. Instead, the firm knows the assortments offered by its competitors. Additionally, the firm can derive the factor indicating how much the utility of the products differs from the utilities used by its competitors. We present preliminary structural, algorithmic, and complexity results for constrained and unconstrained versions of the problem and address some extensions and further applications of the model.

New Models in Digital Platforms

Community Committee Choice Session

Session Chair: Rim Hariss, McGill University, Montreal, QC, Canada
Session Chair: Setareh Farajollahzadeh, University of Toronto, Toronto, ON, Canada

1 Responsible Revenue Sharing Models in Streaming Platforms

Rim Hariss[1], Shreyas Sekar[2], [1]McGill University, Montreal, QC, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: rim.hariss@mcgill.ca

Recently, there has been a growing concern that the adopted policies by online platform can exacerbate the biases present in the data and lead to outcomes that favour specific groups of popular users. This can affect the long-term health of the marketplace by endangering users' trust in the platform and lead to lopsided growth.This work tackles the problem of designing data-driven policies for online platforms that lead to diverse/fair outcomes. We focus on one lever used by the platform: pricing/revenue sharing. We adopt a two-pronged approach: 1) Use publicly available data from platforms such as Spotify to quantify how current policies lead to undesirable outcomes that only benefit some users; 2) Design policies for revenue sharing that benefit a broad spectrum of users operating on the platform.

2 An Operational Perspective on Microfinancing in Developing Countries

Opher Baron, Elaheh Rashidinejad, Gonzalo Romero, Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: e.rashidinejad@rotman.utoronto.ca

We compare two microfinancing structures in developing countries where an entrepreneur with zero initial budget borrows a loan to operate a business. The entrepreneur faces a Newsvendor problem with financing and effort framework. We characterize conditions under which a community bank, which can apply social pressure on the entrepreneur to pay all of its debt back, improves individual and social welfare in comparison with a social bank, which has no such mechanism. We study the banks under profit maximization or zero profit objectives. Our theoretical model provides

practical guidelines on how to improve the design of microfinancing structures to maximize social impact and help alleviate poverty in a financially sustainable fashion.

3 Sequential vs. Simultaneous Product Release

Setareh Farajollahzadeh[1], Ningyuan Chen[2], Ming Hu[3], Hojat Abdollahnejad[2], [1]McGill University, Montreal, QC, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]University of Toronto, Minneapolis, MN, Contact: setarefarajollahzade@gmail.com

We study the release strategy of media content where the content creators, such as authors or producers of series, are uncertain about the level of consumer interest in their products. They must decide whether to release all the content at once or release it in sequential episodes. With each episode release, a buzz is generated in the market, which attracts consumers to the product but fades away in the following period. During each period, consumers may learn about the content's attractiveness through direct experience (private learning), reading other users' reviews (social learning), or reading expert opinions (public learning). We determine the optimal pricing and release strategy for the seller under different learning settings.

4 Offline-Online Retail Collaboration via Pickup Partnership

Zahra Jalali[1], Maxime Cohen[2], Necati Ertekin[3], [1]McGill University, Vancouver, BC, Canada; [2]McGill University, Montreal, QC, Canada; [3]University of Minnesota, Minneapolis, MN

We study an popular retail practice called pickup partnership that allows online retailers to offer an in-store pickup service by partnering with a physical store. In practice, online retailers use two policies for such partnerships: (i) paying a fixed fee for each pickup order to the offline partner, or (ii) offering a coupon with each pickup order to customers to be redeemed at the offline partner's store. Our goal is to examine each policy and identify the best approach for online retailers. We develop a stylized model that captures the key features of a pickup partnership. We find that the coupon policy allows the online retailer to gain greater market coverage compared to the fixed fee policy, but it does not always increase the online retailer's profit. We characterize when an online retailer should establish a pickup partnership using the fixed fee versus the coupon policies.

Multi-Armed Bandits and Their Applications

Community Committee Choice Session

Session Chair: Arpit Agarwal, Columbia University, New York, NY

1 Batched Algorithms for the Dueling Bandits Problem

Rohan Ghuge[1], Arpit Agarwal[2], Viswanath Nagarajan[1], [1]University of Michigan, Ann Arbor, MI, [2]Columbia University, New York, NY

In this work, we study the K-armed dueling bandits problem, which has applications in a wide-variety of domains like search ranking, recommendation systems and sports ranking where eliciting qualitative feedback is easy while real-valued feedback is not easily interpretable; thus, it has been a popular topic of research in the machine learning community. Previous works have only focused on the sequential setting where the policy adapts after every comparison. However, in many applications, it is preferable to perform comparisons in a limited number of parallel batches. We introduce and study the batched dueling bandits problem under two standard settings: (i) existence of a Condorcet winner, and (ii) strong stochastic transitivity and stochastic triangle inequality. For both, we obtain algorithms with a smooth trade-off between the number of batches and regret.

2 Improving Efficacy and Data Utility of Generalized Linear Contextual Bandits via Doubly Robust Method

Wonyoung Kim[1], Kyungbok Lee[2], Myunghee Cho Paik[2], [1]Columbia University, New York, NY, [2]Seoul National University, Seoul, Korea, Republic of

We propose a novel algorithm for generalized linear contextual bandits (GLBs) with an $\tilde{O}(\sqrt{\kappa^{-1} \phi^{-1} T})$ regret over T rounds where ϕ is the minimum eigenvalue of the covariance of contexts and κ is a lower bound of the variance of rewards. In several identified cases of $\phi^{-1}=O(d)$, where d is the dimension of contexts, our result is the first regret bound for GLBs achieving the order $\sqrt{d}$ without discarding the observed rewards. Our algorithm achieves the bound by incorporating contexts from all arms in our double doubly-robust (DDR) estimator. We also provide an $O(\kappa^{-1} \phi^{-1} \log (NT) \log T)$ regret bound for N arms under a probabilistic margin condition. We conduct empirical studies using synthetic data and real examples, demonstrating the effectiveness of our algorithm.

3 Diversified Recommendations for Agents with Adaptive Preferences

Arpit Agarwal, Wiliam Brown, Columbia University, New York, NY

When an Agent visits a platform recommending a menu of content to select from, their choice of item depends not only on immutable preferences, but also on their prior engagements with the platform. The Recommender's objective is to encourage content consumption which optimizes some reward, such as ad revenue. We formalize this problem as an adversarial bandit task. At each step, the Recommender presents a menu of k (out of n) items to the Agent, who selects one item in the menu according to their unknown preference model, which maps their history of past items to relative selection probabilities. The Recommender then observes the Agent's selected item and receives bandit feedback of the item's reward. Our main result is to show that low regret algorithms are possible if the Recommender ensures that the total distribution of chosen items has sufficiently high entropy.

4 Langevin Thompson Sampling with Logarithmic Batches

Siddharth Mitra, Yale University, New Haven, CT

Thompson sampling is widely used for sequential decision making due to its ease of use and strong performance. Two core challenges faced by Thompson sampling, however, are that it requires the posterior distributions to have closed form solutions, and that it is classically studied for fully sequential decision making, which is unable to factor in any delay in obtaining reward. In this talk, we will jointly address these problems with the aim of further strengthening Thompson sampling. We will then discuss this improved Thompson sampling algorithm for stochastic multi-armed bandits and reinforcement learning.

Game Theoretic Models of Supply Chain

Community Committee Choice Session

Session Chair: Aadhaar Chaturvedi, University of Auckland, AUCKLAND, New Zealand

1 Supply Chain Model Under Common Agency

Aadhaar Chaturvedi, University of Auckland, AUCKLAND, New Zealand

We look at a supply chain model under common agency setting and show how it applies towards investigating impact of upstream yield correlation on a buyer's profit.

2 Supplier Allocation in Collaborative Product Development with Internal Competition

Timofey Shalpegin[1], Svenja C. Sommer[2], Christian van Delft[3], [1]Univeristy of Auckland, Auckland, New Zealand; [2]HEC Paris, Jouy-En-Josas, France; [3]Groupe HEC, Jouy Enjosas, France

This study examines how internal competition affects supplier collaboration and firm profits in a development process where a firm deploys multiple competing internal teams to explore alternative approaches for a single product. We propose a tournament model with two suppliers, who differ in expertise and development costs, and identify cost savings resulting from the similarity between different development efforts. Our analysis suggests that increasing supplier competition by increasing the number of teams per supplier can increase supplier efforts. The optimal allocation of internal teams to potential suppliers depends on their expertise and cost-effectiveness. Allocating more teams to the stronger supplier generally undermines their incentives to exert high levels of effort.

3 A Game-Theoretic Analysis of Pollution Tax, Partial Privatization/Nationalization, and Greening Technologies in a Mixed Oligopoly

Subhamoy Ganguly[1], Vinay Ramani[2], [1]University of Auckland, Auckland, New Zealand; [2]Indian Institute of Technology Kanpur, Kanpur, India. Contact: s.ganguly@auckland.ac.nz

We consider a mixed oligopoly where a (partially) privatized firm competes with one or more private firms. The production process of the firms causes some environmental damage through pollution. Firms have options to make investments (e.g., green technologies) that will reduce pollution. The partially privatized and the private firms differ not only in the cost of production and the greening technology, but also in their objectives. While the private firm maximizes profit, the partially privatized firm maximizes a weighted average of profit and consumer welfare. Using game-theoretic models, we investigate how government can use pollution tax and the degree of privatization/nationalization to maximize social welfare and control environmental damage caused by industrial production.

4 Promotion Incentives for Customer Retention: Field Experiment with a Subscription Meal Kit Service

Aysun Mutlu, Sanjith Gopalakrishnan, Mehmet Gumus,

Saibal Ray, McGill University, Montreal, QC, Canada. Contact: aysun.mutlu@mail.mcgill.ca

Customer retention is a challenging problem in retail management. Companies employ a variety of incentives to retain or re-acquire customers. However, their effectiveness needs to be better understood. Via field experiments carried out with a subscription meal kit service, we estimate the impacts of various incentives on customer retention and lifetime value. Furthermore, analyzing these incentives facilitated the exploration of personalized promotions and promotion timing optimization as strategies to enhance customer retention. The research findings provide valuable insights for retail businesses aiming to improve customer retention by implementing personalized promotions and optimizing promotion timing based on the effects of incentives.

Advances in Revenue Management and Pricing

Community Committee Choice Session

Session Chair: Rene A. Caldentey, The University of Chicago, Chicago, IL

1 Fluid Approximations of Network Revenue Management Under General Demand Model

WEIYUAN Li[1], Huseyin Topaloglu[1], Paat Rusmevichientong[2], [1]Cornell Tech, New York, NY, [2]USC Marshall School of Business, Los Angeles, CA, Contact: wl425@cornell.edu

In revenue management literature, a popular demand model divides the selling horizon into time periods where at most one customer arrival is allowed per period. This discretized demand model is equivalent to a Poisson process approximation, but has a drawback: if the mean number of customer arrivals is high, then the variability of arrivals must be low. This limits the ability to handle both large demand volume and variability. This talk explores a generalized revenue management model that overcomes this limitation. The aim is to determine the fluid approximation under a general demand model.

2 Near Optimal Pricing for Nor1 eStandby Upgrades

Farbod Ekbatani[1], Andrew Vakhutinsky[2], Natalia Kosilova[3], [1]Chicago Booth School of Business, Chicago, IL, [2]Oracle Labs, Burlington, MA, [3]NULL, State College, PA, Contact: fekbatan@chicagobooth.edu

The eStandby upgrade is one of the prominent offering from Nor1. With this product, hotels have the ability to enhance a customer's experience by providing the option to upgrade from a standard room to a premium one at a reduced price. This approach brings advantages to hotels on two fronts: firstly, it serves as a revenue-generating tool, and secondly, it assists in redirecting bookings from overbooked standard rooms to available premium accommodations. In this presentation, we introduce a simple pricing strategy that is nearly optimal, interpretable, and easily implementable.

3 Bundling and Pricing Decisions for Ancillary Products

Tong Xie, Rene A. Caldentey, The University of Chicago, Chicago, IL

We study ancillary revenue management in the presence of consumer risk aversion. We characterize the firm's optimal pricing and bundling decisions in settings where there is a lag between the time of purchase and the time of consumption of the products or services. We consider both myopic and strategic purchasing behavior from the part of consumers.

Algorithm Design for Causal Inference

Community Committee Choice Session

Session Chair: Christopher Harshaw, UC Berkeley, Berkeley, CA

1 Clip-OGD: An Experimental Design for Adaptive Neyman Allocation in Sequential Experiments

Jessica Dai, UC Berkeley, Berkeley, CA, Contact: jessicadai@berkeley.edu

Though adaptive sequential designs have become increasingly popular for causal inference, the extent to which adaptive designs can improve precision is not well understood. In this work, we study Adaptive Neyman Allocation (ANA) in a design-based potential outcomes framework. The goal is to construct an adaptive design that is nearly as efficient as the optimal but infeasible non-adaptive Neyman design. Motivated by online learning, we propose Neyman Regret, a performance measure of adaptive designs for ANA. We present Clip-OGD, an adaptive design which achieves $\tilde{O}(T^{1/2})$ Neyman Regret, recovering the optimal Neyman variance in large samples. Finally, we construct a conservative variance estimator to develop asymptotically valid confidence intervals. We also conduct simulations using data from a microeconomic study. Joint work with Chris Harshaw and Paula Gradu.

2 New Problems and Future Directions at the Interface of Nonconvex Optimization and Causal Inference

Bryon Aragam[1], Kevin Bello[2], [1]Chicago Booth, Chicago, IL, [2]Carnegie Mellon University, Pittsburgh, PA

Interpretability and causality are key desiderata in modern machine learning systems. Graphical models, and more specifically DAGs (aka Bayesian networks), are an established tool for representing interpretable causal models. Unfortunately, estimating the structure of DAGs from data is a notoriously difficult combinatorial problem, and existing approaches rely on various local heuristics. Recently, we proposed NOTEARS, a fundamentally different strategy that re-formulates the problem as a smooth but nonconvex optimization problem that avoids combinatorial constraints entirely. Although deceptively simple, many open questions---some elementary---remain regarding the properties of this class of problems. After reviewing this framework and recent progress in understanding its properties, we will discuss some future directions and open problems.

3 Fast Computation of Exact Confidence Intervals for Randomized Experiments with Binary Outcomes

Patrick Lopatto, Brown University, Providence, RI

Given a randomized experiment with binary outcomes, exact confidence intervals for the average causal effect of the treatment can be computed through a series of permutation tests. This approach requires minimal assumptions and is valid for all sample sizes, as it does not rely on large-sample approximations such as the central limit theorem. We show that these confidence intervals can be found in O(n log n) permutation tests in the case of balanced designs, where the treatment and control groups have equal sizes, and $O(n^2)$ permutation tests in the general case. Our results improve on prior work of Li and Ding (2016) and Rigdon and Hudgens (2015), and facilitate exact inference as a viable option for randomized experiments far larger than those accessible by previous methods. This is joint work with P. M. Aronow and Haoge Chang.

4 Off-Policy Evaluation Beyond Overlap: Partial Identification Through Smoothness

Samir Khan, Stanford University, CA

Off-policy evaluation (OPE) is the task of estimating the value of a target policy using data collected under a logging policy. OPE methods often assume overlap, enabling solutions based on reweighting or imputation. In this work, we approach OPE without overlap by partially identifying the off-policy value under weak assumptions on the expected outcome, such as Lipschitz smoothness. Under such assumptions, we formulate linear programs whose values bound the contributions of the no-overlap region. We show that these linear programs can be solved efficiently and that their solutions converge to the sharp partial identification bounds. We also show that the rate of convergence is optimal, up to log factors. We deploy our methods on two semi-synthetic examples, and obtain informative and valid bounds that are tighter than those possible without smoothness assumptions.

Learning and Scheduling in Stochastic Systems

Community Committee Choice Session

Session Chair: Fiona Slothaak, Eindhoven University of Technology, Eindhoven, Netherlands

1 Learning While Scheduling in Multi-Server Systems with Unknown Statistics: Maxweight with Discounted Ucb

Zixian Yang[1], R. Srikant[2], Lei Ying[3], [1]The University of Michigan, Ann Arbor, Ann Arbor, MI, [2]University of Illinois, Urbana, IL, [3]The University of Michigan, Ann Arbor, Ann Arbor, MI, Contact: zixian@umich.edu

We consider a multi-server system with multiple servers and multiple types of jobs, where different job types require different amounts of processing time at different servers. The goal is to schedule jobs on servers without knowing the statistics of the processing times. To fully utilize the processing power of the servers, it is known that one has to at least learn the service rates of different job types on different servers. We propose a new algorithm, which combines the MaxWeight scheduling policy with discounted upper confidence bound (UCB), to simultaneously learn the statistics and schedule jobs to servers. We obtain performance bounds for our algorithm that hold for both stationary and nonstationary service rates. Simulations confirm that the delay performance of our algorithm is several orders of magnitude better than previously proposed algorithms.

2 Integrated Learning and Decision Making for Cumulative Shock Degradation

Collin Drent[1], Melvin Drent[1], Joachim Jacob Arts[2], Stella Kapodistria[1], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]University of Luxembourg, Luxembourg City, Luxembourg. Contact: c.drent@tue.nl

We study maintenance optimization for a system whose condition deteriorates according to a compound Poisson degradation with a fairly general compounding distribution, where the parameters of both the Poisson process and the compounding distribution are unknown. We propose a Bayesian framework to learn these unknown parameters independently from each other and embed this into a Markov decision process, so that learning and decision making are integrated. We establish the optimality of a control limit policy that depends on the entire historical deterioration path of the individual system. We demonstrate the effectiveness in practice with a case study on interventional x-ray machines.

3 Optimal Stopping Policies when Assessing Students' Mastery

Sandjai Bhulai, Androniki Sapountzi, Jaap Storm, Martijn Meter, Vrije Universiteit Amsterdam, Amsterdam, Netherlands. Contact: s.bhulai@vu.nl

Assessing learning outcomes and determining mastery of a skill from a sequence of responses is a significant challenge. The difficulty lies in a reliable diagnosis with minimal student responses while offering an adaptive length assessment personalized for the learner online. This paper introduces a three-component solution to this challenge. Firstly, a Markov reward model is proposed in which the value function represents the student's mastery level. Secondly, a combination of reinforcement learning and machine learning techniques is utilized to evaluate the value function. Lastly, stopping policies based on the value function are introduced to balance accuracy and efficiency in mastery assessment. These policies are user-friendly and intuitive, even for teachers. The effectiveness is demonstrated using both synthetic and historical student response data.

4 Regret Analysis for Routing Policies in Matching Queues with Uncertain Payoffs

Sanne van Kempen, Eindhoven University of Technology, Eindhoven, Netherlands. Contact: s.f.m.v.kempen@tue.nl

We consider queueing in call centers, where customers classified by problem subject need to be matched to agents with suitable expertise. We model this as a multi-class multi-server queueing system with a fixed matching topology in the form of a bipartite graph. To capture the uncertainty in customer classification and heterogeneity of customers and servers, we introduce customer-server dependent random rewards associated to each allocated service. We aim to learn an optimal routing policy in a system where the rewards are sampled from unknown probability distributions. Such a routing policy is constrained by the stability conditions of the queueing system. We introduce a model that combines decision making with queueing dynamics and formulate the regret of a routing policy. By exploiting the structure of this problem, we are able to extend known results on regret bounds.

Bayesian Optimization

Community Committee Choice Session

Session Chair: Raul Astudillo, California Institute of Technology

1 Knowledge Gradient Policy for Multi-Objective Bayesian Optimization with Decoupled Evaluations

Jack Buckingham[1], Sebastian Rojas Gonzalez[2], Juergen Branke[3], [1]Warwick University, Coventry, United Kingdom; [2]Data Science Institute, Leuven, Belgium; [3]Warwick University, Coventry, United Kingdom

Multi-objective Bayesian optimization aims to approximate the set of Pareto-optimal solutions with different trade-offs between a set of expensive objectives, while collecting as few samples as possible. In some cases, it is possible to evaluate the objectives separately. This presents an opportunity to learn the Pareto front more effectively by evaluating the objectives in a decoupled fashion, especially if they have different latencies. We propose a scalarization based knowledge gradient acquisition function which accounts for the different evaluation costs of the objectives. We prove consistency of the algorithm and show empirically that it significantly outperforms a benchmark algorithm which always evaluates all the objectives.

2 Class Bo: Bayesian Optimization for Heterogeneous Functions

Mohit Malu[1], Giulia Pedrielli[2], Gautam Dasarathy[1], Andreas Spanias[1], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: mmalu@asu.edu

In standard Bayesian Optimization method with Gaussian Process prior, we typically assume the function to be optimized is stationary (homogeneous) over the domain, but in many real-world applications we often deal with heterogeneous functions that can be divided into locally stationary functions over the partitions of input space. In this work, we propose a novel tree-based optimization technique dubbed as Class-BO (Class Bayesian Optimization), with information sharing across the non-contiguous partitions that belong to the same homogeneous class. This method uses a novel acquisition function dependent on the partitions of the input space. We also show the superior performance of Class-BO via extensive empirical evaluations.

3 Latent Space Preference Exploration for Bayesian Optimization with Many Outcomes

Yujia Zhang[1], Jelena Markovic-Voronov[2], Jerry Z. Lin[2], Ryan-Rhys Griffiths[2], Qing Feng[2], Peter Frazier[3], Eytan Bakshy[4], [1]Cornell University, Ithaca, NY, [2]Meta, Menlo Park, CA, [3]Cornell / Uber, Ithaca, NY, [4]Meta, New York, NY

Bayesian Optimization (BO) is a sample-efficient black-box optimization method when direct queries of the objective are possible. In many real-world problems, however, information about the objective is only available through a human decision maker who voices binary preferences over vector-valued outcomes from expensive experiments. Bayesian optimization with preference exploration (BOPE) partially addresses this challenge by modeling both the outcome and preference functions. However, it struggles computationally and statistically with high dimensional outcomes. To overcome this limitation, we introduce preference exploration over a latent subspace to jointly model the outcomes and user's preference. Our approach enables faster computation, efficient preference learning, and improved optimization performance.

4 Optimizing Value-at-Risk and Conditional Value-at-Risk of Black-Box Functions

Quoc Phong Nguyen, Massachusetts Institute of Technology, Boston, MA, Contact: qphongmp@gmail.com

Value-at-risk (VaR) and conditional VaR (CVaR) are established measures to assess risks in critical real-world applications with random environmental variables. In this talk, we present two Bayesian optimization (BO) algorithms with theoretical performance guarantee to maximize VaR and CVaR of a black-box function which are based on the well-established principle of optimism in the face of uncertainty. The BO of VaR is constructed by proving the existence of values of environmental random variables (to be selected to achieve no regret) such that the confidence bound of VaR lies within that of the black-box function evaluated at such values. Then, we utilize a connection between CVaR and VaR to derive a variant of our BO algorithm for the optimization of CVaR.

New Business Models for Socially Responsible Operations

Community Committee Choice Session

Session Chair: Luyi Gui, The Paul Merage School of Business, UC Irvine, Irvine, CA

Session Chair: Xiaoyang Long, University of Wisconsin-Madison, Madison, WI

Session Chair: Yixin Lu, George Washington University, Washington, DC

1 Managing Returns: Economic and Environmental Impact

Yulan Amanda Wang[1], Xin Wang[2], Kanglin Chen[3], [1]The Hong Kong Polytechnic University, Kowloon, Hong Kong; [2]The Hong Kong University of Science and Technology, Kowloon, Hong Kong; [3]Southern University of Science and Technology, Shenzhen, China. Contact: yulan.wang@polyu.edu.hk

In this study, we discuss some innovative return management means adopted by the platforms and study their economic and environmental impacts.

2 Spatial Competition of High-Performance Charging Stations

Philipp Kienscherf[1], Yixin Lu[2], Long He[2], Wolfgang Ketter[1], [1]University of Cologne, Cologne, Germany; [2]George Washington University, Washington, DC

Many countries have launched ambitious policy initiatives to foster adoption of electric vehicles (EV). In this paper, we study the competition of high-performance EV charging stations in a network, where the profitability of each charging station depends on its ability to extract monopolistic or oligopolistic rents via pricing. We model the interaction between operators of charging stations and consumers as a networked Stackelberg game. We then apply our modeling framework to analyze the recently proposed national EV charging network in Germany. Our study provides timely insights into the competitive landscapes of real-world EV charging networks.

3 Self-Targeting in Social Assistance Programs: How to Harness Data's Power?

Yuanzheng Ma[1], Guodong Lyu[2], Chung Piaw Teo[3], Huan Zheng[4], [1]Shanghai Jiao Tong University, Shanghai, China; [2]The Hong Kong University of Science and Technology, Hong Kong, China; [3]National University of Singapore Business School, Singapore, Singapore; [4]Shanghai Jiao Tong University, Shanghai, China. Contact: joan_myz@sjtu.edu.cn

Proxy-Means-Test (PMT) is often used in Social Assistance Programs (SAPs) to predict the consumption levels of individuals using big data. Self-Targeting is another approach developed to identify beneficiaries because the people living in poverty will more likely come forward to claim the benefit. Can we predict the shift in the sub-population coming forward based on the big data collected for PMT and use it to develop a more accurate targeting method? A simple model characterizing the effect in emerging self-enrolling SAPs using the Bayesian approach is proposed. Real data from Sierra Leone was used to evaluate the efficacy of the proposed method.

4 The Impact of Ride-Sharing Transportation on Patient No-Shows: Evidence from a Quasi-Experiment

Saif Benjaafar[1], Jason Chan[1], Nathaniel Witte[2], Shihong Xiao[3], [1]University of Minnesota, Minneapolis, MN, [2]University of Minnesota, Rochester, MN, [3]Fudan University, Shanghai, China. Contact: shihongxiao@fudan.edu.cn

We investigate the extent to which access to healthcare services can be improved through programs providing free ride-sharing transportation to medical appointments for patients. Specifically, we examine the impact of such a program on no-show rates using a quasi-experiment that contrasts treated patients with control patients. We find that the program is effective on average, but its effectiveness tends to dwindle over time, except that its effect sustains only for patients with low clinic attending frequency. Moreover, we find that among treated patients, primary care appointments enjoy a larger no-show reduction with the ride-sharing service than other types of appointments. Also, we find that the ride-sharing service reduces patients' visits to emergency departments, which implies that ride-sharing services can generate substantial impact on patient health.

Supply Chain Risk and Obsolescence Management

Community Committee Choice Session

Session Chair: Hugh Medal, University of Tennessee, Knoxville, TN

1 Understanding the Key Factors Associated with Obsolescence Risk in Critical Supply Chains

Michael Sherwin, Duquesne University, Pittsburgh, PA

All supply chains are impacted by diminishing manufacturing sources and material shortages (DMSMS). However, critical supply chains are uniquely susceptible to DMSMS risks. In particular, the obsolescence of products and suppliers poses a substantial risk to the continuinity of supply. In addition to ordinary risks that affect the longevity of a company, irregular procurement cycles, qualification barriers, and strict requirements pose additional risks in the supply chain network of manufacturers. This research is focused on gaining valuable information for strategic and tactical decision-making by identifying key factors that assure continuity of supply. As such, we pose and test hypotheses pertaining to key variables that may affect the continuity of supply within critical supply chains and present results with the purpose of improving decision-making.

2 A Reliability Approach for Prediction and Management of Part Obsolescence

Christina Mastrangelo, University of Washington, Seattle, WA

Accurate prediction of part obsolescence is critical to maintaining system health, especially for the long-lived systems that typically exist in aerospace and naval domains. These environments are often characterized by decreasing product life (dynamic probability distribution parameters), incomplete data (highly censored), and relatively few predictor variables (but large sample size). This work describes a Weibull-based conditional probability method for the prediction of part-level obsolescence risk. Practical implementation solutions are discussed with respect to oversampling for small datasets, uncertainty estimation, and operational rationale/assumptions.

3 Optimizing the Selection of Resolutions to Part Obsolescence over a Time Horizon

Chad Uhles[1], Hugh Medal[2], [1]University of Tennessee, Knoxville, TN, [2]University of Tennessee, Knoxville, TN, Contact: cuhles@vols.utk.edu

Diminishing manufacturing sources and material shortages (DMSMS) is a significant issue in many industries such as aerospace, defense, and nuclear power. Problems caused by DMSMS can arise when crucial systems are extended well beyond their initially anticipated lifetimes and parts become obsolete. To combat this issue, it is important to develop a plan to buy, replace, and refresh parts over time to sustain the system. Indeed, a well-crafted sustainment plan can yield significant cost savings. In this work, we develop a mixed-integer programming model for selecting resolutions of DMSMS issues over time. Possible resolutions include, but are not limited to, part substitutions, lifetime buys, or a full refresh of the current part or system design. We demonstrate our model on a hypothetical system that is subject to obsolescence.

Equity-promoting Optimization: Theory and Applications

Community Committee Choice Session

Session Chair: Karmel Shehadeh, 1</sup

1 Reducing Disparities in Transportation Distance in a Stochastic Facility Location Problem

Karmel S. Shehadeh, Lehigh University, Bethlehem, PA, Contact: karmelshehadeh@gmail.com

Uneven distributions of service-providing facilities across different regions lead to disparity in accessibility and transportation distance to essential services. To mitigate such disparities, we propose equity-promoting stochastic programming (SP) and distributionally robust optimization (DRO) models for the stochastic fixed charge facility location problem. Our results show, for the first time, how different methods of modeling equity under uncertainty can result in different location decisions with varying impacts on equity. Notably, the proposed equity-promoting DRO models lead to a more diverse distribution of facilities and better mitigate disparities in transportation distance than their SP counterparts and equity-neutral models

2 Equity-Promoting Integer Programming Approaches for Medical Resident Rotation Scheduling

Shutian Li[1], Karmel S. Shehadeh[1], Beth Hochman[2], Jacob Krimbill[2], Alexander P. Kossar[2], [1]Lehigh University, Bethlehem, PA, [2]Columbia University Medical Center, New York, NY, Contact: shl919@lehigh.edu

Newly graduated physicians from medical schools often join certified residency programs to fulfill specialty board certification requirements. Residents rotate through various clinical settings during their residency to gain the necessary training. Manually constructing the annual rotation schedule is challenging and laborious. Moreover, manual methods often produce inequitable schedules. To address these challenges, we propose new equity-promoting integer programming approaches for rotation scheduling. Numerical experiments based on a case study from a residency program illustrate the potential of the proposed approaches in automating the resident-to-rotation scheduling process and improving equity among residents and their satisfaction.

3 A Unified Framework for Analyzing and Optimizing a Class of Convex Inequity Measures

Man Yiu Tsang, Karmel S. Shehadeh, Lehigh University, Bethlehem, PA

We present a unified framework for analyzing a new parameterized class of convex inequity measures suitable for optimization contexts. We provide theoretical analyses and derive a dual representation of these measures. Importantly, this dual representation renders a unified mathematical expression and an alternative geometric characterization for convex inequity measures. Moreover, we present generic solution approaches for equity-promoting optimization problems with a convex inequity measure objective or constraint. Finally, we provide stability results on the choice of convex inequity measures in the objective of optimization models. Our numerical results show the computational efficiency of our approaches over existing approaches.

4 Fairness Regulation and Market Collusion

Zongsen Yang[1], Xiao Lei[2], Pin GAO[3], [1]Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]University of Hong Kong, Hong Kong, Hong Kong; [3]The Chinese University of Hong Kong, Shen Zhen, Shenzhen, China. Contact: zongsenyang@link.cuhk.edu.cn

The regulation of price discrimination due to fairness concerns has drawn significant attention recently. While previous literature has focused on price fairness in a monopoly setting, its impact under a competitive market is not clear. We consider the impact of price fairness regulation under a duopoly market and examine its interplay with price collusion, another important topic in market regulation. Our findings suggest that strict fairness regulation can facilitate collusion, leading to reduced consumer surplus. To remedy this drawback, we propose the use of randomized regulation, which can effectively deter price collusion while maintaining the benefits of fair pricing. Our study highlights the need for a nuanced approach to price fairness regulation and provides important insights for policymakers and market regulators.

Discrimination and System Design in Admissions and Career Advancement

Community Committee Choice Session

Session Chair: Jordan D. Tong, University of Wisconsin Madison, Madison, WI

Session Chair: Xiaoyang Long, University of Wisconsin-Madison, Madison, WI

1 Application Mistakes and Informations Frictions in College Admissions

Ignacio Rios[1], Tomas Larroucau[2], Anais Fabre[3], Christopher Neilson[4], [1]The University of Texas at Dallas, Richardson, TX, [2]Arizona State University, Tempe, AZ, [3]Toulouse School of Economics, Toulouse, France; [4]Yale University, New Haven, CT, Contact: ignacio.rios.u@gmail.com

We study application mistakes in a centralized college admissions system. We use data from Chile and exploit institutional features to identify four types of mistakes: admissibility, over-confidence, under-confidence, and ordering. We identify that biases in students beliefs about their admission chances and information frictions explain a large fraction of these mistakes. We use these insights to design and implement a large-scale information policy to reduce application mistakes. We find that showing personalized information about admission probabilities significantly reduces the risk of not being assigned to the centralized system and the incidence of application mistakes. Our results suggest that information frictions play a significant role in affecting the performance of centralized college admissions systems.

2 Dropping Standardized Testing for Admissions Trades off Information and Access

Faidra Monachou, Harvard University, Cambridge, MA

We study the role of information and access in capacity-constrained selection problems with fairness concerns. Using theory and UT Austin data, we develop a framework with testable implications that formalizes the trade-off between the informativeness of a feature and its exclusionary nature when members of different social groups have unequal access to this feature. Our framework finds a natural application to policy debates on dropping standardized testing in college admissions. Our primary takeaway is that dropping a feature may exacerbate disparities by decreasing the amount of information available for each applicant, especially those from non-traditional backgrounds. However, in the presence of barriers, we show that the interaction between the informational environment and the effect of access barriers on the applicant pool size becomes highly complex.

3 Gender Bias in Job Assignment: Evidence from Retail Frontline Managers

Ruoran Chen[1], Susan F. Lu[2], Lauren Xiaoyuan Lu[3], Simin Huang[4], [1]Southwest Jiaotong University, Chengdu, China; [2]Purdue University, West Lafayette, IN, [3]Dartmouth College, Hanover, NH, [4]Tsinghua University, Beijing, China. Contact: lauren.x.lu@tuck.dartmouth.edu

While anecdotes suggest that workplace gender disparities widely exist, the current literature has not provided sufficient causal evidence due to two deficiencies. First, because most gender studies rely on surveys and laboratory experiments, causal evidence of gender disparities in the field is rare; Second, because most empirical gender studies focus on individual workers or C-suite executives, research on low-level managers using real-world personnel data is also rare. In this study, we aim to address these deficiencies by empirically studying the effect of gender on the job assignment of frontline managers in a large sportswear retail chain using personnel, sales, and operational data. Our estimation strategy is a two-step panel estimation framework, which separately identifies manager and store fixed effects by exploring manager switches across stores.

4 Funnels and Favoritism: How Recruiting Structures Shape Diversity and Quality

Jordan Tong, Xiaoyang Long, University of Wisconsin-Madison, Madison, WI, Contact: jordan.tong@wisc.edu

Behavioral research has uncovered several biases that evaluators display when judging quality. How do these biases impact the diversity and quality of hires? We examine this question using a stylized model of recruiting structures, i.e., the funnel shape from the candidate pool to the final hire(s), and the hiring committee composition. We show that the impact of judgment biases depends critically on the recruiting structure. Whereas a basic model of taste-based discrimination leads to intuitive dynamics, incorporating other established biases like outgroup homogeneity and judgment noise can lead to surprising results. We deliver insights into what combinations of judgment biases and recruiting structures most (dis)advantage minorities, and how organizations can change their recruiting structure to improve both quality and diversity.

Applied Models and Empirics in Healthcare

Community Committee Choice Session

Session Chair: Joel Goh, NUS Business School, Singapore, Singapore

1 Wheels on the Bus: Impact of Vaccine Rollouts on Demand for Public Transportation

Huaiyang Zhong[1], Tinglong Dai[2], Guihua Wang[3], [1]Virginia Tech, Blacksburg, VA, [2]Johns Hopkins University, Baltimore, MD, [3]The University of Texas at Dallas, RICHARDSON, TX, Contact: hzhong@vt.edu

The COVID-19 pandemic caused a decline in public transit ridership, impacting vulnerable riders without alternative transportation. This study examines the relationship between COVID-19 vaccination progress and public transportation demand, focusing on vulnerable populations. To estimate the impact, we use a unique instrumental variable by merging US vaccination and county-level mobility data. Results show that higher vaccination rates lead to increased demand for public transport, particularly in uninsured and non-college-educated communities. These findings highlight the need for targeted efforts to increase vaccination coverage and restore public transit infrastructure for an equitable recovery.

2 Should Doctors and Patients Decide Together? An Analytical Framework for Shared Decision-Making

Feray Tuncalp[1], Rouba Ibrahim[1], Song-Hee Kim[2], Jordan D. Tong[3], [1]University College London, London, United Kingdom; [2]Seoul National University, Gwanak-gu, Korea, Republic of; [3]University of Wisconsin Madison, Madison, WI, Contact: f.tuncalp@ucl.ac.uk

In recent years, shared decision-making (SDM), where doctors and patients jointly decide on appropriate treatment options, has drawn a lot of attention in the healthcare domain. Despite the documented benefits and limitations of SDM, there are no clear guidelines that identify when to involve patients in treatment decisions, and when to rely solely on the doctor's medical expertise. To provide insights into when to do SDM, we study the decision-making process between two treatments using a stylized model where we account for both patients' and doctors' bounded rationality in decision-making, as well as doctors' insufficient metacognition about these errors. Contrary to the common medical belief which advocates using SDM for all conditions, we find that there is no one-size-fits-all policy for the healthcare decision-making process.

3 Dynamic Physician Staffing During a Pandemic:
Yvonne Huijun Zhu[1], Joel Goh[2], [1]National University of Singapore, Singapore, Singapore; [2]NUS Business School, Singapore, Singapore
We study a dynamic model of healthcare service provider staffing in the context of an infectious disease pandemic. In the model, physicians are split into two teams, a "hot" team that serves patients who have the infectious disease, and a "clean" team that serves regular patients. A unique feature of the model is that service providers can themselves be infected with the disease, which takes them out of service for a period of recovery. Through the model, we analyze the structure of dynamic optimal policies for staffing these two teams.

4 Adaptive Design of Clinical Trials
Zhengli Wang[1], Stefanos Zenios[2], [1]University of Hong Kong, Hong Kong, Hong Kong; [2]Stanford University, Stanford, CA
: Adaptive design of clinical trials hold great promise for reducing the cost of clinical trials. In this paper, we propose a tractable Bayesian framework where the clinical trial designer can either choose among different experiments with different information, or to terminate the trial. There are rewards associated with making the correct decision and penalties from incorrect ones. We present solutions to the resulting asymptotic stochastic control problem.

1 On Reducing Medically Unnecessary Cesarean Deliveries: The Design of Payment Models for Maternity Care
Emily Z. Fainman[1], Beste Kucukyazici[2], TING WU[3], [1]Texas State University, San Marcos, TX, [2]Queen's University, Kingston, ON, Canada; [3]Nanjing University, Nanjing, China. Contact: c_z88@txstate.edu
This data-driven study focuses on the design of financial incentives to reduce unnecessary C-sections, resulting in enhanced birth quality with alleviated economic burden for healthcare systems. We first use semi-supervised learning methods to classify pregnancy women into low- and high-risk groups. Then we validate the optimal delivery methods for two risk groups through post-delivery variables in the dataset. We propose easily implementable and robust pay-for-performance models, resulting in risk sharing between payer and physicians, and coordination among any group of physicians.

2 Improving Health Outcomes with Less Cost? Provision of Mobile Clinic in Developing Economics
Fang Liu[1], Pengfei Guo[2], Yulan Amanda Wang[3], Yuejuan Xi[1], [1]University of Chinese Academy of Sciences, Beijing, China; [2]City University of Hong Kong, Hong Kong, Hong Kong; [3]The Hong Kong Polytechnic University, Hung Hom, Hong Kong. Contact: yuejuanxi@ucas.ac.cn

Consider a public healthcare system consisting of a hospital, a mobile clinic (MC), and a population of potential patients. The government is concerned about the system's healthcare spending and the population's health outcomes. It needs to decide whether and how to provide the MC service to maximize the social welfare that consists of two terms: the system's long-run average healthcare cost and the population's average quality-adjusted life year (QALY). We model the population's natural disease progression and derive both the average healthcare cost and the average QALY for a given MC delivery cycle. We show that the MC service is provided only when the setup cost is below a certain threshold under both disease types. Once the MC service is provided, we show that if the disease is fast-progressive, the MC service is provided either every or every other period.

3 Managing Incentives for Medical Care Services Under Competition and Imperfect Quality Information

Linggang Qi[1], Zhan Pang[2], [1]City University of Hong Kong, Hong Hong, China; [2]Purdue University, West Lafayette, IN, Contact: lingganqi2-c@my.cityu.edu.hk

Our paper investigates how to design performance-based incentives in a healthcare market with imperfect quality information. We adopt a three-stage game to model the system: the payer first designs a payment contract, hospitals then decide their quality levels and last patients choose hospitals. We first characterize hospitals' quality decisions under a given bonus contract, and also characterize the optimal contracting decision in a class of bonus contracts. We find that the fee-for-service reimbursement should be set as small as possible to reduce payments to the hospitals and improving quality information can lower bonus reimbursement. Moreover, the system under the optimal bonus contract can reach the social optimum under some certain conditions. Our results also show that competition intensity and performance-based incentives are substitutes to each other.

Data-Driven Decision Making in Healthcare I

Community Committee Choice Session

Session Chair: Agni Orfanoudaki, Oxford University, Oxford, United Kingdom

1 Automated Data Extraction for Clinical Databases Using Natural Language Processing

Dimitris Bertsimas[1], Robert Habib[2], George Margaritis[1], Agni Orfanoudaki[3], Periklis Savvas Petridis[4], David Shahian[5], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Society of Thoracic Surgeons, Chicago, IL, [3]Oxford University, Oxford, United Kingdom; [4]Massachussetts Institute of Technology, Cambridge, MA, [5]Massachusetts General Hospital, Boston, MA, Contact: geomar@mit.edu

Across the U.S., 97% of adult cardiac surgery programs transfer their patient data to the STS National Database for quality improvement and risk assessment. However, this involves substantial manual human effort, as most patient records are unstructured text reports. Utilizing recent advances in Natural Language Processing, we propose a flexible, end-to-end ML pipeline that automates this data-extraction process. Preliminary results from Massachusetts General Hospital and Brigham and Women's Hospital are promising, demonstrating high accuracy in predicted outcomes. The benefits of this approach include reduced operational costs, improved data consistency and quality, and a unified framework for medical predictions from diverse patient data.

2 Integrated Planning and Control of Drone Networks for Emergency Medical Response

Jamal Chu[1], Sheng Liu[1], Wei Qi[2], Timothy Chan[1], [1]University of Toronto, Toronto, ON, Canada; [2]Tsinghua University, Beijing, China. Contact: jamal.chu@mail.utoronto.ca

Drones have been proposed as a supplemental response to medical emergencies such as cardiac arrest and anaphylactic shock through the delivery of time-critical supplies. Recent work has focused on separate drone base placement and heuristic dispatch policies via two-stage models, which may lead to performance loss compared to an integrated model. We first propose a new dispatch policy and prove that it is optimal under the assumption that drones have non-overlapping coverage zones. We then propose a novel stochastic integer program to jointly optimize base placements and dispatch policies for both p-median and max coverage objectives. We show that our integrated placement-dispatch model can have substantial improvements over a two-stage model on out-of-sample data.

3 Interpretable Framework for Optimal Sepsis Treatment Under Limited Resources

Lien H. Le[1], Angela Lin[2], Dessislava Pachamanova[3], Georgia Perakis[2], Omar Skali Lami[4], [1]Newton-Wellesley Hospital, Newton, MA, [2]Massachusetts Institute of

Technology, Cambridge, MA, [3]Babson College, Wellesley, MA, [4]MIT / McKinsey & Company, Cambridge, MA, Contact: aglin@mit.edu

Sepsis is a life-threatening response to infection responsible for 250K deaths per year and the largest portion of hospitalization costs in the US. Deciding which treatments to give sepsis patients in intensive care units (ICU) with limited resources is challenging, as sepsis is broad and heterogeneous, and timely treatment is critical to patient outcomes. In this work, we propose a clinical decision-making framework for treating sepsis patients: we learn a concise Markov Decision Process (MDP) model from observed data, propose novel value iteration algorithms for finding optimal policies, and formulate a tractable optimization problem for allocating scarce resources. Upon testing our framework on an ICU dataset, we see a 14% increase in number of patients successfully discharged, 8% decrease in number of deaths, and over two-fold decrease in length of ICU stay.

4 Improving Stability in Decision Tree Models

Vassilis Digalakis[1], Dimitris Bertsimas[2], [1]MIT/HEC Paris, Cambridge, MA, [2]MIT, Cambridge, MA

Owing to their inherently interpretable structure, decision trees are commonly used in applications where interpretability is essential. Recent work has focused on improving aspects of decision trees, including their predictive power and robustness; however, their instability has been addressed to a lesser extent. We take a step towards the stabilization of decision tree models through the lens of real-world healthcare applications. We introduce a distance metric for decision trees and use it to determine a tree's level of stability. We propose a methodology to train stable decision trees and investigate the existence of trade-offs between stability, predictive power, and interpretability. We show that, on average across six healthcare applications, a 4.6% decrease in predictive power can improve the model's stability by as much as 38%.

5 Efficient Estimation for the Transportability Index Using Neural Networks

Jiwei Zhao, University of Wisconsin, Madison, WI

We consider estimating some quantity of interest on the target population, via efficiently leveraging information from a different but relevant source. In the literature, such transportation is possible after imposing assumptions on source and target. This type of assumption is, unfortunately, made partially on unobserved data and hence unverifiable empirically. To assess the impact of its violation, we adopt a sensitivity analysis framework indexed by a sensitivity parameter. We propose a new measure, transportability index, that quantifies the sensitivity to change in quantity of interest with respect to a small perturbation to the underlying assumption. Estimating the transportability index involves two nuisances, both of which are conditional expectations. We validate and demonstrate our proposal via experiments on synthetic and real-world datasets.

Optimization Models in Medical Decision Making with Uncertainty

Community Committee Choice Session

Session Chair: Kimia Ghobadi, Johns Hopkins University, Baltimore, MD

1 A Geometric Approach to Beam Angle Optimization in Radiation Therapy

Danielle Ripsman, University of Waterloo, Waterloo, ON, Canada

Beam angle optimization (BAO) is a difficult component of planning radiation therapy treatments. Despite the wealth of proposed methodologies for selecting beam-angles in the literature, in practice, clinicians often opt for a fixed number of equidistant beams, or manual iterative planning. This is due in part, to the requirement for a secondary fluence map optimization (FMO) to validate any BAO selections and the resource-intense calculations needed to calculate the parameters for such a model at each iteration. In this talk, the BAO problem is modeled using a geometrical abstraction, allowing it to be considered in a single-stage column generation-driven set-covering framework. This novel abstraction allows for a reduction in the reliance of BAO modeling on sophisticated dose calculators, as well as eliminating the need for time-consuming BAO-FMO iteration.

2 Achieving Financial Sustainability in Chilean Healthcare: A Stackelberg Model Approach

Diego A. Martínez, Luis Lillo, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile. Contact: luis.lillo@pucv.cl

According to the World Bank´s universal healthcare index, Chile is among the best-ranked countries in Latin America. However, Chile´s health system is fragmented and unfair, affecting vulnerable urban and rural populations. Social and political actors are debating the future of the Chilean health system with a long-term focus on equity and financial sustainability. Considering the stochastic longitudinal dynamics inherent in two-tiered healthcare systems, we propose a Stackelberg model to support this debate. We discuss the model insights and provide actionable information to re-design the current pay model (volume- vs. value-based).

3 Inventory System Optimizing Under Endogenous and Exogenous Uncertainty

Jing Liu[1], Cassandra Thiel[2], Kimia Ghobadi[3], [1]Johns Hopkins University, Baltimore, MD, [2]NYU Langone Health, New York, NY, [3]Johns Hopkins University, Baltimore, MD, Contact: jliu254@jhu.edu

Medical supply inventories have been under stress in recent years with a combination of unstable markets, global supply chain challenges, and increased demand, e.g., during the pandemic. In this talk, we propose a robust inventory optimization model that considers exogenous demand uncertainty and endogenous shipping lead time uncertainty that are captured through a set of order-dependent uncertainty subsets. We demonstrate the efficacy of our methods using data from New York University Healthcare System and showed our robust model achieves more resilient inventory over the nominal model and lower costs than a state-of-the-art model under uncertain settings.

Sustainable Transportation: Modeling and Reality

Community Committee Choice Session

Session Chair: Yudai Honma, The University of Tokyo, Meguro-Ku, Japan

1 Location Analysis of In-Motion Wireless Power Transfer System for Trips in Urban-Scale Region by Electric Vehicle

Yudai Honma[1], Daisuke Hasegawa[2], Katsuhiro Hata[1], Takashi Oguchi[1], [1]The University of Tokyo, Meguro-Ku, Japan; [2]The University of Tokyo, Bunkyo-Ku, Japan. Contact: yudai@iis.u-tokyo.ac.jp

The popularization of electric vehicles (EVs) is limited by their driving range and long charging times. To address this, in-motion wireless power transfer systems (WPTSs) are currently attracting attention as a new power supply system. This study aims to propose a new mixed integer programming (MIP) model to determine the optimal locations of WPTSs in urban-scale area. Specifically, we calculate the amount and locations of WPTS necessary and sufficient to achieve substantially zero consumption of energy in urban areas. We also present an numerical example by real data of a typical medium-sized city in Japan.

2 Strategic Planning for EV Charging Networks by Integrating Demand and Supply Dynamics Through Continuous-Time Models

Xuesong Zhou[1], Xiangyong Luo[2], Michael Kuby[1], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: xzhou74@asu.edu

By using continuous-time models, it considers the demand and supply dynamics, taking into account the long-term perspective required for effective resource planning. The study recognizes the emergence of EVs as a sustainable and cost-effective option, emphasizing the importance of considering innovation diffusion and predicted adoption curves.

3 An Inverse Shortest Paths Problem Model for Evaluating Urban Facilities Using Visit Data

Hiroyuki Hasada[1,2], Yudai Honma[1], Takashi Oguchi[1], [1]The University of Tokyo, Meguro-Ku, Japan; [2]The Institute of Behavioral Sciences, Shinjuku-ku, Japan. Contact: hasada-hiroyuki649@g.ecc.u-tokyo.ac.jp

Despite few visitors, some inaccessible public facilities are nonetheless attractive. We propose an evaluation method that estimates the utility value and consumer surplus of each facility based on visitor's travel costs, rather than visitor numbers. We implement a linear integer programming model to maximize the surplus of the visited facility among those of other facilities. This model also classifies visitors into segments sharing the same estimated utility value, forming a novel inverse shortest paths problem model. We apply this method to Japan's "Michi-no-Eki" roadside stations, utilizing ETC2.0 vehicle probe data. The evaluation identifies valuable, remote stations used by truck drivers. Our method contributes to the accurate evaluation and optimal placement of facilities beneficial to logistics operators.

4 Modelling and Piloting Emerging Transportation Technologies

Shuyao Hong, Arizona State University, Tempe, AZ, Contact: shuyao.hong@asu.edu

Emerging transportation technologies have the potential to lead us to a safer, more sustainable and equitable transportation system. However, they also present uncertainty and risk to the society. Piloting and modelling are two important tools to understand the impact of emerging technologies as they evolve rapidly: the widespread testing of autonomous vehicles, the acceleration of vehicle electrification, the commercialization of AI-based traffic control technologies, the proliferation of connected vehicle data, just to name a few. This presentation will discuss some of these efforts that's happening locally here in Phoenix, Arizona.

5 The Fundamentals of Optimum Coordination Control of Traffic Signals

Takashi Oguchi, The University of Tokyo, Tokyo, Japan. Contact: takog@iis.u-tokyo.ac.jp

How to optimize traffic signals along with a route with series of adjacent intersecions? Because the existence of counter directional traffic flow, providing a green wave for both directions for the simplest case with a link with two adjacent intersections is determined by several parameters. They are the displacement of two adjacent intersections, vehicle running speed, traffic signal cycle time duration, green time duration, and traffic demands for both directions. The theory introduction is followed by the discussion for increase of number of intersections on the same route. Finally the effects of area wide or road network on the traffic signal coordination are also outlined.

Emerging topics on OM/Marketing Interface

Community Committee Choice Session

Session Chair: Rachel Rong Chen, University of California-Davis, Davis, CA

Session Chair: Xuying Zhao, Texas A&M University, College Station, TX

1 Vertical Competition with Common Attributes

Xiaojuan Puyang[1], Jane Gu[2], Juan Li[3], Rachel Rong Chen[4], [1]Sichuan Normal University, ChengDu, China; [2]University of Connecticut, Stors, CT, [3]Nanjing University, Nanjing, China; [4]University of California-Davis, Davis, CA, Contact: rachen@ucdavis.edu

Vertically differentiated products in a competitive market often share common attributes (e.g., location value, infrastructure, or technologies) provided by third-parties. In this study, we characterize how common attributes affect high- and low-quality firms in their offerings of individual attributes and pricing, and consequently affect market competition and social welfare. First, we disentangle three distinctive effects of common attributes on vertical competition, and identify a "bottom-up" influence through which common attributes affect the firms. Second, we contrast how common attributes affect vertical competition in different product markets. Finally, we examine a retail platform's commission policy when its infrastructure constitutes common attributes for vertically differentiated vendors.

2 How Does the Best Seller Recommendation Shape the Ecosystem of an Online Marketplace?

Yi Xu[1], Farzad Fathi[1], Bo Zhou[2], [1]University of Maryland, College Park, MD, [2]University of Maryland, College Park, College Park, MD, Contact: yxu1@umd.edu

This paper studies the impact of the best seller recommendation, a widely used popularity-based system, on consumers, sellers, and the online marketplace. We show that the best seller recommendation intensifies competition among sellers, resulting in a lower equilibrium price and potentially decreased profits for sellers and the marketplace. Our results highlight the importance of accounting for the strategic response of the sellers before an online marketplace implements the best seller recommendation system.

3 Behavior-Based Pricing Under Informed Privacy Consent

Yunhyoung Kim[1], Tony H. Cui[2], Yi Zhu[2], [1]Carlson School of Management, University of Minnesota, Twin Cities, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: kim01073@umn.edu

The implementation of recent privacy protection regulations requires firms to obtain privacy consent from consumers before collecting their information. Informed privacy consent has significant implications for behavior-based pricing, with which firms practice third-degree price discrimination based on consumers' purchase history. Consumers' ex ante endogenous privacy decisions are affected by two components: cost of risk from privacy breaches and avoidance to unfavorable discriminative price in the following period. We find that consumers give privacy consent only if there is a monetary incentive for opting in, and that consumers' sophisticated privacy decisions lead to higher profits for firms even with the cost of compensation. It is found that this also holds when there is an additional utility from opting in (e.g. personalization, ease of ordering, etc.).

4 Opaque Product in a Decentralized Supply Chain

Xuying Zhao[1], Lifei Sheng[2], Ashutosh Prasad[3], [1]Texas A&M University, College Station, TX, [2]University of Houston Clear Lake, Houston, TX, [3]University of California-Riverside, Riverside, CA, Contact: xzhao@mays.tamu.edu

We study whether or not a retailer should offer an opaque product to consumers, considering the interaction between the manufacturer and the retailer in a decentralized supply chain. We show that a retailer is less likely to offer an opaque product in a decentralized supply chain than in a centralized supply chain. We find that the ratio of the product's profit potential to the consumers' strength of product preference is a critical factor in whether the retailer should offer an opaque product. The retailer should sell an opaque product if and only if the ratio is not too low or too high. Furthermore, we explore how the retailer can further improve the profit when selling an opaque product. We find that the retailer should preemptively communicate the product inclusion probability before wholesale prices are decided.

5 Buy Now, Pay Later: Independent Versus Integrated Consumer Installment Plans

Buqing Ma[1], Bo Zhou[2], Ying-Ju Chen[3], [1]University of Science and Technology of China, HeFei, China; [2]University of Maryland, College Park, College Park, MD, [3]The Hong Kong University of Science and Technology, Kowloon, Hong Kong

This paper investigates the impact of the installment model on the firms' profits and consumer surplus when the product and the installment plan are offered by one firm (i.e., integrated model) or two independent firms (i.e., disintegrated model). By building a two-dynamic period, we find several insights. First, the installment plan induces the seller to increase the price, which prevents consumers from buying the product. Put differently, the adoption of installment plans can lead to lower market coverage and leave out consumers who may, ironically, need the service more. Second, the disintegrated model leads to a higher interest rate but a lower retail price than the integrated model. Third, the installment plan can benefit consumers regardless of the installment plan structure, and the disintegrated model can lead to a higher consumer surplus than the integrated model.

Tuesday, October 17, 12:45 PM - 2:00 PM

Analytics for Social Good

Community Committee Choice Session

Session Chair: Pengyi Shi, Purdue University, West Lafayette, IN

1 Estimating Prevalence of Opioid Use Disorder at County Level Using Public Available Data: A Bayesian Hierarchical Modeling Approach

Zixuan Feng[1], Qiushi Chen[1], Le Bao[2], Paul Griffin[1], [1]The Pennsylvania State University, University Park, PA, [2]The Pennsylvania State University, University Park, PA, Contact: zixuan.feng@psu.edu

Understanding the prevalence of opioid use disorder (OUD) is crucial for shaping health policies and resource allocation strategies to address the opioid crisis. While there exist OUD prevalence estimates at national and state levels, county-level estimates are lacking for most states. To fill this gap, we developed a Bayesian hierarchical model that only relied on publicly available sources such as county-level socioeconomic, healthcare, criminal justice, and opioid-related outcome metrics to estimate OUD prevalence. Using Massachusetts' data, our model showed good performance with an average absolute percentage error of 8.8% from the leave-one-out cross-validation. We further applied our method to generate OUD prevalence estimates in other states and demonstrated its generalizability.

2 Combining Machine Leaning And Queueing Theory For Data-driven Incarceration-diversion Program Management

Bingxuan Li[1], Antonio Castellanos[2], Pengyi Shi[1], Amy R. Ward[2], [1]Purdue University, West Lafayette, IN, [2]The University of Chicago Booth School of Business, Chicago, IL, Contact: li3393@purdue.edu

Incarceration-diversion programs are proven effective in reducing recidivism. Accurately predicting the number of program participants with varying characteristics is vital since this prediction guides program size determination and staffing needs. However, due to the diverse outcomes and lengths-of-stay in these programs, this task is complex. Collaborating with an Illinois government agency, we develop a framework that integrates machine learning and queueing model simulation, yielding accurate forecasts for program census and offering insights into program dynamics and decision impact in counterfactual scenarios. Additionally, we introduce a user-friendly beta version of a web app for visualization and demonstrate two use cases: altering program admission criteria and introducing similar initiatives in new counties.

3 Pooling Physical and Virtual Services with Application to Telehealth

Omer Berk Olmez, Alex Mills, Baruch College, City University of New York, New York, NY

Healthcare services can be offered both in-person and virtually by the same providers. We study a clinic's decision of whether to pool the resources of both channels or to have dedicated resources for each channel, where patients decide which channel to join (or whether to balk) while observing the expected waiting time for both channels and the distance to the in-person facility. Contrary to the consensus in the classical pooling literature, our findings indicate that patients' expected waiting times and net utilities do not necessarily improve with pooling. We highlight that pooling the two channels yields benefits for the providers only when the net profit generated from the virtual channel is substantially similar to that of the physical channel.

4 Machine Learning Based Health Status Prediction and Development of Food-Health Vulnerability Index for Us Counties

Surya Ramachandiran, Tasnia Biswas, Harshita Ayala, Soundar Kumara, Pennsylvania State University, State College, PA, Contact: harshitaa45@gmail.com

Food insecurity is a growing public health concern in the United States. In this study, we investigate the relationship between health risks and food insecurity-related factors across 2953 US counties. We propose a machine learning-based US county-level health risk prediction model using food vulnerability and socio-economic data. A robust food-health vulnerability index based on integrating six health outcomes, such as life expectancy and % of adults with various chronic diseases like diabetes and obesity, is developed. Further, we achieve both global and local interpretability in the trained model using SHAP. The results indicate that the three most highly responsible factors affecting the proposed robust health index are % food insecure, % enrolled in free lunch, and median household income. Thus the government should enable targeted interventions in these areas.

Supply Chain Finance and Risk Management

Community Committee Choice Session

Session Chair: Qi Zhang, [1</sup]

Session Chair: gangshu Cai, [1</sup]

1 Gold or Cash? Analyzing the Operational and Financial Value of Tokens on the Tokenized Commodity Market

Yunzhe Qiu, Dongwei Xie, Peking University, Beijing, China

With the development of blockchain technology, tokenomics have gradually emerged by virtue of tokens' operational value as cryptocurrency and financial value as investments. We model the firm's dynamic inventory on a tokenized commodity market in the presence of a token trading platform. The firm counteracts the risk of stochastic demand for goods, and price fluctuations through the transformation of commodity and token stocks. We discuss the operational and financial value of tokens in a stationary model with i.i.d. prices and a dynamic model with a stochastic evolution token market, separately. We find that the tokens' operational and financial values depend on the characteristics of the token, commodity, and market, e.g., user base, demand pattern, and platform productivity.

2 Financing a Capital-constrained Supply Chain: Equity or Debt

Xiuli He[1], Suresh P. Sethi[2], Xun Xu[3], Nina Yan[4], [1]UNC Charlotte, Charlotte, NC, [2]The University of Texas at Dallas, Richardson, TX, [3]California State University, Dominguez Hills, Carson, CA, [4]Central University of Finance and Economics, Beijing, China

Many small or medium retailers often have limited access to capital to fund their operations. Here, we consider a supply chain consisting of a capital-constrained retailer (she) and a manufacturer (he) and examine the effect of equity and debt financing schemes on their operational decisions. Using a game theoretical approach, for the risk-neutral scenario, we take expected profit maximization as the participants' objective to examine the equilibria of their operational and financing decisions.

3 Carrot and Stick: When to Offer Trade Credits and Encroach on the Downstream Market

Qiaohai Hu[1], Wenhui Zhao[2], Hao Wang[3], [1]colorado school of mines, Golden, CO, [2]Shanghai Jiao Tong University, Shanghai, China; [3]Shanghai Jiaotong University, Shanghai, China. Contact: JOICE.HU@GMAIL.COM

This paper explores the relationship between an upstream supplier's decision to encroach on its downstream market and its decision to offer trade credits to its downstream retailer under market uncertainty. Different from the existing literature, we allow the parties to adopt revenue management strategy when their total supply exceeds the level of of a Cournot equilibrium.

4 Calibrated Recommendations with Sponsored Items

Shaojie Tang[1], Jing Yuan[2], Shuzhang Cai[3], Yao Wang[4], [1]University of Texas-Dallas, Richardson, TX, [2]University of North Texas, Denton, TX, [3]The University of Texas at Dallas, Richardson, TX, [4]Xi'an Jiaotong University, Xi'an, China

Calibrated Recommendation Systems (CRS) surpass traditional models by factoring in user preferences along with diversity, fairness, and novelty. These systems deliver personalized and inclusive suggestions. Businesses increasingly utilize sponsored slots in these systems to engage customers. However, existing CRS studies often overlook the influence of sponsored content. Our work addresses this by examining CRS within sponsored contexts, treating it as a combinatorial optimization challenge. The objective is to generate a recommendation list that optimizes utility and integrates sponsored items. We introduce constant-factor approximation algorithms for this purpose.

Incentive and Information in Service Operations

Community Committee Choice Session

Session Chair: Shouqiang Wang, The University of Texas at Dallas, Richardson, TX

Session Chair: Qiong Chen, Southwestern University of Finance and Economics, Chengdu

1 Impact of Emerging Technology on Online Healthcare Platforms

Zhi Cao[1], Meng Li[2], Qiang Li[3], [1]University of Electronic Science and Technology of China, Sugar Land, TX, [2]University of Houston, Houston, TX, [3]Wilfrid Laurier University, WATERLOO, ON, Canada. Contact: zcao@std.uestc.edu.cn

Our study applies the difference-in-differences methodology with CEM to identify the causal relationship between the adaptation of real-time video-based communication technology and the volume of follow-up online consultations for physicians. The results show that the adoption of this technology significantly increases physicians' follow-up online consultations by approximately 36.8%.

2 Enhancing Resilience in Services During the Post-Covid Era: An Analysis of the Restaurant Industry

Hongli Ye[1], Aleda Roth[2], [1]Clemson University, clemson, SC, [2]Clemson University, Seneca, SC, Contact: hongliy@clemson.edu

Our research focuses on building resilience in the high customer contact services in the Post-COVID Era. We develop new measurements for assessing pandemic service resilience strategies applied to dine-in restaurants. Then we apply these unique measurements to test the service resilience strategies, as there are no valid and reliable measurements for service operation resilience strategies. Using experiments, we assess the underline service resilience strategy mechanisms that motivate customers' return to in-restaurant dining and underlying mechanisms. We show that certain customers value these restaurants, while others may be indifferent.

3 Strategic Role of Service Quality Monitoring

Shouqiang Wang[1], Aleda Roth[2], Qiong Chen[3], [1]The University of Texas at Dallas, Richardson, TX, [2]Clemson University, Seneca, SC, [3]Southwestern University of Finance and Economics, Chengdu, China. Contact: chenqiong@swufe.edu.cn

This paper examines a firm that delegates service delivery to a service provider, such as a contractor or an employee. We examine the strategic role played by the firm's commitment to a service quality monitoring program. The quality monitoring program audits users' opinions of the quality of service provided by a service provider. Our analytical results demonstrate the conditions under which commitment becomes more valuable, and a third-party quality monitoring program should be employed.

Supply Chains, Operations, and ESG Outcomes

Community Committee Choice Session

Session Chair: Niyazi Taneri, Cambridge Judge Business School, Cambridge, United Kingdom

1 Can Tax-Subsidies for Charitable Donations Foster Accessibility to Fresh Goods?

Armagan Ozbilge[1], Saif Benjaafar[2], Elkafi Hassini[3], Mahmut Parlar[3], [1]Dalhousie University, Halifax, NS, Canada; [2]University of Minnesota, Minneapolis, MN, [3]McMaster University, Hamilton, ON, Canada. Contact: ozbilgea@dal.ca

Leveraging government tax incentives to prompt corporate charitable giving has gained considerable popularity over the last decade. This paper sheds light on the broader consequences of the U.S. government's enhanced tax deduction policy for charitable food donations. We incorporate the enhanced tax deduction into a food retailer's after-tax profit function in a two-period model. She makes a purchase prior to the selling season and (possibly) donates at the end of period 1. We develop the retailer's optimal policy and characterize conditions under which she donates some, all, or none of her unsold inventory. Our study reveals that contrary to conventional wisdom, charitable donations have a non-monotone relationship with both quality and tax-subsidy. Hence, when implemented inadequately, tax-subsidies may undermine societal objectives and squander public funds.

2 Improving Labor Outcomes: The Role of Operations and Supply Chains

Niyazi Taneri[1], Wei Kiat Lim[2], Hsiao-Hui Lee[3], Sameer Hasija[4], [1]Cambridge Judge Business School, Cambridge, United Kingdom; [2]National University of Singapore, Singapore, Singapore; [3]National Chengchi University, Taipei, Taiwan; [4]Insead, Singapore, Singapore. Contact: n.taneri@jbs.cam.ac.uk

We develop and test hypotheses that can help firms make operational decisions to prevent the incidence of labor controversies. Our analysis of a panel of 9,484 observations reveals two core results and a mitigation strategy: (i) higher sales volatility increases a firm's involvement in labor controversies, (ii) supplier controversies spill over to the focal firm, (iii) supplier spillovers are moderated by inventory buffer. Our results are robust to various model specifications and accounting for potential endogeneity with instrumental variables external to the focal firm's decision-making. Together, these results suggest that the operations and supply chain functions of the firm need to be at the heart of efforts to improve labor outcomes.

3 Plastic Recycling in Agriculture Industry

Yinping Mu[1], Wenli Xiao[2], Feifei Shan[3], Qiong Chen[4], [1]University of Electronic Science and Technology of China, Chengdu, China; [2]University of San Diego, San Diego, CA, [3]University of Science and Technology of China, Hefei, China; [4]Southwest University of Finance and Economics, China

In thisstudy, we compare three prevailing forms of agricultural film recycling:Penalty Scheme, Reward Scheme and Service Scheme. Our results suggest thesocial planner should set a sufficiently high penalty if the manufacturer isresponsible for collection and a moderate penalty if the farmer is responsiblefor collection.

Incentives and Mechanism Design with Social Considerations

Community Committee Choice Session

Session Chair: Iva Rashkova, Washington University in St Louis, St Louis, MO

1 Trust-And-Evaluate: A Dynamic Non-Monetary Mechanism for Internal Capital Allocation

Shivam Gupta[1], Saurabh Bansal[2], Milind Dawande[3], Ganesh Janakiraman[4], [1]University of Nebraska Lincoln, Lincoln, NE, [2]Penn State University, University Park, PA, [3]The University of Texas at Dallas, Richardson, TX, [4]University of Texas-Dallas, Richardson, TX, Contact: sgupta7@unl.edu

To stay competitive, firms regularly invest in innovation by supporting internal capital projects (funded and executed in-house) that explore new products and operational improvements. Each year managers from different functional units submit proposals for such projects. Managers, due to their domain knowledge and expertise, are naturally better informed about the costs and benefits of their projects, and can use this information strategically to secure funding. An example of such behavior is the under-reporting of the cost estimate of a project and subsequently requesting additional funding during the execution phase. Such strategic behavior not only affects the firm's ability to fund the best projects but is also costly. We propose a dynamic non-monetary mechanism that is both provably near-optimal and guarantees truthful reporting from managers.

2 Optimal Investment of Farming Mechanization

Ying Zhang[1], Jayashankar M. Swaminathan[2], [1]Santa Clara University, Santa Clara, CA, [2]University of North Carolina Chapel Hill, Chapel Hill, NC

Adopting mechanization in farming is a fundamental and sustainable approach to increase agricultural productivity. In this paper, we study the seeds and farm mechanization procurement of a farmer for a single crop in a cropping season under land and budget constraint, where a farmer's budget is dependent on her land size. We explore the optimal procurement policy in the monopoly model and Cournot competition model. Our results show that the optimal total expenditure follows a tiered threshold-type policy. We further explore the impact of government subsidies on the mechanization level, farmers' welfare and social welfare.

3 Information Disclosure for Perishables: Profit and Food Waste Implications

Fan Zhou[1], Ekaterina Astashkina[2], Ravi Anupindi[3], [1]Ross School of Business, University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, [3]University of Michigan, Ann Arbor, MI, Contact: fanzhou@umich.edu

The freshness of produce often varies and may be unobservable to consumers, particularly in online grocery retail settings. This study aims to investigate how the visibility of produce freshness impacts profitability and waste generation.

Job Market Candidate Showcase

Community Committee Choice Session

Session Chair: Yuanyuan Ding, University of Minnesota, Minneapolis, MN

1 Essays on Social Sustainability in Operations Management

Soh Hyun Chu, The Ohio State University, Columbus, OH, Contact: chu.589@osu.edu

My dissertation is driven by an overarching problem: Socially Sustainable Operations are important, yet organizations have potentially conflicting priorities or operational motives. In the first essay, I explore the impact of different Social Sustainability issues on a firm's financial performance over three decades. I compare the severity of the impact of social misconducts whether they arose in focal firms or supply chains. In the second essay, I explore one dimension of Social Sustainability, worker safety. This essay explores whether safety and completion time in warehouse operations trade off differently under alternative performance evaluations or training conditions. In the third essay, I explore whether firms' Social and Environmental Sustainability efforts tradeoff as well as create potential synergies on their operational performance.

2 Managing Operational Design within Innovative Retail Contexts

Yuanyuan Ding, University of Minnesota, Minneapolis, MN

My research centers on behavioral operations within the context of retailing, with a focus on utilizing behavior insights to help retailers improve their operational design decisions. I examine two design decisions that have emerged in recent years: (i) introduction of open-box products to the assortment, and (ii) a new subscription-based online retailing service. For both contexts, I develop theories to inform the appropriate design decisions and then test them using empirical evidence from experiments. In the first context, I explore how to design the display of open-box products along with corresponding new products. In the second context, I focus on the design of two features (i.e., collection transparency and customer involvement) within a subscription-based service. The presentation today will mainly focus on the second project.

3 The Whiplash Effect: Congestion Dissipation and Mitigation in a Circulatory Transportation System

Ming Hu[1], Chaoyu Zhang[2], [1]University of Toronto, Minneapolis, MN, [2]University of Toronto, Toronto, ON, Canada. Contact: cyu.zhang@rotman.utoronto.ca

We build an analytical fluid model to investigate how disruptions at one port can affect the disrupted port and its counterpart in another country. Our analysis reveals two main effects of port disruption: the inbound backlog and the outbound backlog. We provide an analytical expression for the recovery time of two ports and track the evolution of backlogs of goods and ships. In addition, we identify a whiplash effect that occurs in the outbound backlog level at two ports, resembling the commonly known "bullwhip effect". Furthermore, we extend our analysis to a network of ports and show that the key findings still hold in the multi-port system. Finally, we apply machine learning techniques to predict the time vessels spend in the Shanghai port and show that our proposed model reduces prediction errors compared to the benchmark, indicating the application potential of our model.

4 Inventory Productivity and Stock Returns in Manufacturing Networks

Deepak Agrawal[1], Nikolay Osadchiy[2], [1]Emory University, Atlanta, GA, [2]Emory University, Atlanta, GA

We provide a novel, supply network-based perspective on inventory productivity. Using data from 2003 to 2019, we find that inventory productivity is lower for firms located upstream in the supply network, and higher for high degree and more central firms. Firms with high inventory productivity show high equity valuations and abnormal returns, with both valuations and abnormal returns amplified for upstream, low degree, and peripheral firms. Moreover, the difference in valuations and abnormal returns between best and worst performing firms is greater upstream, suggesting that financial markets offer outsized rewards for improving inventory productivity to upstream firms. We show that the information about firm's upstreamness and centrality in the supply network is a valuable predictor of its inventory productivity and financial performance.

Freestyle OR Supreme

Community Committee Choice Session

Session Chair: Carrie Beam, UC Davis, Walnut Creek, CA

1 Freestyle OR Supreme

Carrie Beam, UC Davis, Walnut Creek, CA

Calling all students, early-career professionals and anybody else who wants to build a resume! Freestyle O.R. Supreme Expo is our fast-moving live game show, in which teams frame a real-life problem and present a solution in real time. This is a great opportunity to participate in the conference without having to write a paper or make a poster. An industry "client" will present a 10 - 15 minute overview of a real-world problem to solve. Your team will have a 30 minute break out session to craft your 3 - 5 minute O.R. presentation with recommendations for methodology for an implementable solution. The client will listen to each team and give feedback on their presentations, and will select a winner from the presentations. Fame and glory can be yours.

Amazon Last Mile Warehouse Operations

Community Committee Choice Session

Session Chair: Chinmoy Mohapatra, Amazon, Bellevue, WA

1 Optimized Resource Task Planning for Warehouse Operations

Chinmoy Mohapatra[1], Rohit Malshe[1], Gah-Yi Ban[2], Mahdieh Allahviranloo[3], [1]Amazon, Bellevue, WA, [2]Imperial College Business School, London, United Kingdom; [3]The City College of New York, New York, NY, Contact: cmohapat@amazon.com

We develop a joint optimization and machine-learning based model to determine the optimal assignment and prioritization of pick activities in a warehouse to available associates. The objective is to minimize the overall completion time of all tasks while also satisfying several time-based operational constraints. We present novel formulations for the problem and show performance improvements with respect to heuristic approaches.

2 Optimizing Rack Types in Delivery Stations

Gah-Yi Ban[1], Kyoung Yoon Kim[2], Rohit Malshe[2], Sourabh Puri[2], Liron Yedidsion[3], [1]Imperial College Business School, London, United Kingdom; [2]Amazon, Bellevue, WA, [3]Amazon, Redmond, WA, Contact: kyounkim@amazon.com

In Amazon Logistics, delivery stations contain two types of racks to handle processing of non-oversized and oversized packages in a 50:50 ratio. We consider optimizing this ratio and introducing fungible racks to delivery stations. We propose stochastic optimization models to address these problems and show that they can be solved using data-driven mixed-integer linear programs. We carry out a real-data case study and find that (i) having a 50:50 ratio of standard racks is not at all optimal, (ii) introducing fungible racks by a small amount (just 2-4% of the total capacity) can allow the station to serve peak demand even with a low tolerance for spillover, and (iii) optimizing the rack volumes of OV, NOV, and fungible racks can increase the station's capacity by 13 to 19% during off-peak and 14 to 24% during peak, which translates to an annual saving potential of $0.7B-1B.

3 Volume Allocation Using the Layout of Warehouses

Sourabh Puri[1], Kyoung Yoon Kim[2], [1]Amazon, Bellevue, WA, [2]Amazon.com, Bothell, WA, Contact: purisour@amazon.com

We consider the problem of volume (packages and bags) allocation for Amazon Last Mile Warehouses, aka delivery stations. Currently, when the operation allocates the packages and bags to delivery station floor, the process relies on manually generated static configurations that are not agnostic of demand, cube, layout of the station, and on-road capacity fluctuations. This leads to inefficiencies in the pick and stage operations, congestion of aisles, and safety incidents. The paper addresses the inefficiency of the current planner and proposes a dynamic allocation scheme using dynamic programming and MILP that utilizes the station layouts and optimally allocates incoming packages to the floor. Finally, we share the results for walk time savings, aisle cube variation, and other metrics from the two planners, leading to over $60M combined annualized savings for Amazon.

4 Applications of 2D Renewal Theory to Last Mile Operations

Abhilasha Katariya[1], Natarajan Gautam[2], Rohit Malshe[3], [1]Amazon, Issaquah, WA, [2]Syracuse University, Syracuse, NY, [3]Amazon, Bellevue, WA

Given forecasted demand and capacities across different dimensions like time and space, last mile planning systems need to predict operational metrics like rates and throughputs. These are then input to downstream planning systems to plan and optimize use of available resources. To this end, we applied a combination of 2D renewal theory, machine learning and optimization to improve Amazon's planning processes. This has reduced costs and improved on-time delivery metrics.

Bilevel Optimization

Community Committee Choice Session

Session Chair: Federico Battista, Bethlehem, PA

1 Data-Driven Bilevel Optimization of Integrated Planning and Scheduling Problems with Mixed-Integer Nonlinear Lower-Level Formulations

Hasan Nikkhah[1], Vasileios M. Charitopoulos[2], Styliani Avraamidou[3], Burcu Beykal[1], [1]University of Connecticut, Storrs, CT, [2]University College London, London, United Kingdom; [3]University of Wisconsin-Madison, Madison, WI

Planning and scheduling are critical components in supply chain management. The interconnected relationship between the two can be mathematically realized through bilevel programming, but this poses algorithmic challenges such as NP-hardness. This work proposes using data-driven optimization, specifically the DOMINO framework, to overcome these difficulties. The framework is tested on an MINLP scheduling model for a multiproduct continuous manufacturing process formulated as a traveling salesman problem, and the results show that the production targets are achieved for the entire planning period with scheduling levels solved to global optimality.

2 Parametric Inequalities in Mixed Integer Linear Optimization

Ted K. Ralphs, Lehigh University, Bethlehem, PA, Contact: ted@lehigh.edu

Parametric inequalities are valid inequalities that are parameterized such that they remain valid when (some of) the problem data are perturbed. The so-called Benders cuts that arise in Benders decomposition can be viewed as a kind of parametric inequality, but the notion arises in a number of other contexts and such inequalities are useful/necessary in a range of methodological applications, such as in warm-starting, the solution of bilevel/multilevel optimization problem, multiobjective optimization, etc. In this talk, we present a brief overview of the theoretical underpinnings and discuss a general approach to generating such inequalities.

3 Exploiting Dual Functions in Mixed Integer Bilevel Linear Programs

Federico Battista, Ted K. Ralphs, Lehigh University, Bethlehem, PA, Contact: feb223@lehigh.edu

Mixed integer bilevel linear problems (MIBLPs) involve the optimization of the strategy of a leader (upper level) and the subsequent reaction of a follower (lower level). One of the time-consuming steps in MIBLPs algorithms is the resolution of numerous (yet related) mixed integer linear problems (MILPs) as a subroutine to check the feasibility of a solution and/or to generate cuts, e.g. in a branch-and-cut framework. Instead of optimizing these MILPs each time from scratch, in this talk we discuss how building iteratively refined dual functions of such MILPs value functions can both improve the solution process at each subproblem and provide information to extract violated cuts. Preliminary results are presented using open-source solver MibS.

Advances in Nonlinear Stochastic Optimization II

Community Committee Choice Session

Session Chair: Alberto Solomon Berahas, University of Michigan, Ann Arbor, MI

Session Chair: Raghu Bollapragada, The University of Texas at Austin, Austin, TX

1 Adaptive Sampling Mechanisms for Stochastic Constrained Optimization

Raghu Bollapragada, The University of Texas at Austin,

Austin, TX
In this talk, we discuss adaptive sampling mechanisms for solving stochastic constrained optimization problems.

2 On the Optimization Landscape of Low-Rank Matrix Recovery: When Do Global Solutions Correspond to Ground Truth?
Salar Fattahi, Jianhao Ma, University of Michigan, Ann Arbor, MI, Contact: fattahi@umich.edu
Low-rank matrix recovery is typically solved via a nonconvex method called Burer-Monteiro factorization (BM). If the rank of the ground truth is known, BM is free of sub-optimal local solutions, and its true solutions coincide with the global solutions--that is, the true solutions are identifiable. When the rank of the ground truth is unknown, it must be over-estimated, giving rise to an over-parameterized BM. In the noiseless regime, it is recently shown that over-estimation of the rank leads to progressively fewer sub-optimal local solutions while preserving the identifiability of the true solutions. In this work, we show that with noisy measurements, the global solutions of the over-parameterized BM no longer correspond to the true solutions, essentially transmuting over-parameterization from blessing to curse.

3 An Adaptive Sampling Augmented Lagrangian Method for Stochastic Optimization with Deterministic Constraints
Cem Karamanli[1], Raghu Bollapragada[1], Brendan Keith[2], Boyan Lazarov[3], Socratis Petrides[3], Jingyi Wang[3], [1]The University of Texas at Austin, Austin, TX, [2]Brown University, Providence, RI, [3]Lawrence Livermore National Laboratory, Livermore, CA, Contact: cem.karamanli@utexas.edu
We provide an efficient solution algorithm based on the augmented Lagrangian framework for optimization problems with a stochastic objective function and deterministic constraints. Our main contribution is combining the augmented Lagrangian framework with adaptive sampling. To improve efficiency, we consider inexact solutions for the augmented Lagrangian subproblems. We show sublinear convergence for convex objectives and linear convergence for strongly convex objectives with affine equality constraints. We also present the worst-case sample complexity of the resulting algorithm, under different assumptions. Finally, we test the performance of our adaptive sampling augmented Lagrangian framework in machine learning optimization and engineering design problems, including topology optimization of a heat sink with environmental uncertainty.

4 An Interior Point Algorithm for Solving Nonlinear Optimization Problems with Noise
Shima Dezfulian, Andreas Waechter, Northwestern University, Evanston, IL, Contact: shimadezfulian2023@u.northwestern.edu
We propose and analyze a modification of the interior point algorithm for solving bound-constrained nonlinear optimization problems in which the objective and gradient evaluations are affected by non-diminishing and bounded noise. These modifications include a relaxation of the Armijo line search, a novel stop test for the barrier problem, and a new barrier parameter update. Given a fixed barrier parameter, we establish global convergence to a neighborhood of stationary points. We further show the local convergence of the iterates to a neighborhood of stationary points. This neighborhood, defined in the space of decision variables, is narrower for decision variables whose optimal value is at the boundary of the feasible region. This result suggests that noise does not impact the identification of active constraints and is confirmed by our numerical experiments.

Recent Developments on Bilevel and Semi-Infinite Programs

Community Committee Choice Session

Session Chair: Qihang Lin, University of Iowa, Iowa City, IA

1 Primal-Dual Hybrid Gradient Methods for Smooth Semi-Infinite Programming with Applications in Machine Learning with Fairness Constraints
Yao Yao[1], Qihang Lin[1], Tianbao Yang[2], [1]University of Iowa, Iowa City, IA, [2]Texas A&M University, College Station, TX, Contact: yao-yao-2@uiowa.edu
We consider a convex smooth semi-infinite problem where the constraint functions continuously depend on parameters from a convex compact domain. We propose a primal-dual method where, in each iteration, decision variables, Lagrangian multiplier and constraint parameters are updated by a gradient step using hybrid gradients. We analyze its iteration complexity for finding an �-optimal solution with and without strong convexity and when the gradient oracles are deterministic and stochastic. Compared

to existing approaches, our methods do not require sampling constraints, have a lower iteration complexity and less computational cost per-iteration. We also present the applications of our methods in fairness-aware machine learning with multiple outputs, including multi-class learning, multi-label learning and multi-task learning.

2 Efficient Bilevel Optimization and Application in Continual Learning

Kaiyi Ji, University at Buffalo, Buffalo, NY

Bilevel optimization (BO) has received increasing attention in modern machine learning (ML), and has become a theoretical foundation for designing efficient computational tools for various ML areas such as meta-learning, autoML, fair ML, continual learning, and etc. In the first part of this talk, I will briefly introduce several recent BO applications in hyperparameter optimization and rehearsal based continual learning. In the second part, I will propose a novel stochastic bilevel optimization algorithm named stocBiO, which features a sample-efficient hypergradient estimation via Hessian-vector computations and automatic differentiation. I will then present the convergence analysis for stocBiO and discuss its application in coreset selection for rehearsal based continual learning by proposing a new bilevel problem formulation.

3 A Fully First-Order Algorithm for Stochastic Bilevel Optimization

Jeongyeol Kwon, University of Wisconsin-Madison, Madison, WI, Contact: jeongyeol.kwon@wisc.edu

We consider Bilevel Programming (BP) when only the first-order stochastic gradient oracles are available. Existing optimization methods either tend to require possibly expensive calculations regarding Hessians of lower-level objectives, or lack rigorous finite-time guarantees. We first study the landscape of BP through the lens of penalty-methods. Then, we propose a Fully First-order Stochastic Approximation (F2SA) method, and study its non-asymptotic convergence properties. For unconstrained BPs with strongly-convex lower-level objectives, we show that F2SA converges to an ⍰-stationary solution of the original BP in poly(1/⍰) iterations with each iteration using O(1) samples. We also discuss how our results can be extended to more general settings when the lower-level problem consists of non-convex objectives and convex constraints.

4 Bome! Bilevel Optimization Made Easy: A Simple First-Order Approach

Bo Liu, University of Texas at Austin, Austin, TX, Contact: bliu@cs.utexas.edu

Bilevel optimization (BO) is useful for solving many important machine learning problems. Conventional BO methods need to differentiate through the low-level optimization process with implicit differentiation, which requires expensive calculations related to the Hessian matrix. There has been a recent quest for first-order methods for BO, but the methods proposed to date tend to be complicated and impractical for large-scale applications. In this work, we propose a simple first-order BO algorithm that depends only on first-order gradient information, requires no implicit differentiation, and is practical and efficient for large-scale non-convex functions in deep learning. We provide a non-asymptotic convergence analysis of the proposed method to stationary points for non-convex objectives and present empirical results that show its superior performance.

Recent Advances in Mixed-integer Nonlinear Programming

Community Committee Choice Session

Session Chair: Shaoning Han, University of Southern California, Los Angeles, CA

1 Constrained Optimization with Indicator Variables

Soroosh Shafieezadeh Abadeh[1], Fatma Kilinc-Karzan[2], [1]Cornell University, Ithaca, NY, [2]Carnegie Mellon University, Pittsburgh, PA

Optimization problems involving minimization of a convex function over constraints modeling restrictions on the support of the decision variables emerge in various machine learning applications. These problems are often modeled with indicator variables for identifying the support of the continuous variables. In this paper we investigate compact extended formulations for such problems through perspective reformulation techniques. In contrast to the majority of previous work that relies on support function arguments and disjunctive programming techniques to provide convex hull results, we propose a constructive approach that exploits a hidden conic structure induced by perspective functions. We illustrate the efficacy of our results on sparse nonnegative logistic regression problems.

2 Shortest Paths in Graphs of Convex Sets

Tobia Marcucci, MIT, Cambridge, MA, Contact:

tobiam@mit.edu
Given a graph, the shortest-path problem requires finding a sequence of edges of minimum cost connecting a source vertex to a target vertex. In this talk we introduce a generalization of this classical problem in which the position of each vertex in the graph is a continuous decision variable, constrained to lie in a corresponding convex set, and the cost of an edge is a convex function of the positions of its endpoints. Problems of this form arise naturally in motion planning of autonomous vehicles, robot navigation, and even optimal control of hybrid dynamical systems. The price for such a wide applicability is the complexity of this problem, which is easily seen to be NP-hard. We discuss this novel problem along with different solution approaches, including a strong mixed-integer convex formulation based on perspective functions.

3 On Lagrangian Cuts For Stochastic Integer Programs

Haoyun Deng, Weijun Xie, Georgia Institute of Technology, Atlanta, GA
Stochastic integer programs (SIPs) are optimization problems that involve making decisions over stages under uncertainty realized by a set of scenarios. Recently, by dualizing the nonanticipativity constraints, Lagrangian cuts have been successfully applied to solve SIPs. To understand the strength of Lagrangian cuts, we first prove that the Lagrangian cuts are sufficient to describe the convex hull of the local recourse problems. Next, to compute the Lagrangian cuts, the existing method, however, is subgradient-based and often unstable and rather slow. We propose closed-form Lagrangian cuts and an efficient routine to strengthen them to achieve “partial Pareto optimal.” We numerically demonstrate the performances of the proposed approach.

4 Regression Problems with Outliers: Strong Conic Formulations

Andres Gomez, University of Southern California, Los Angeles, CA
We study regression problems with outliers. Such problems can be naturally modeled as mixed-integer quadratic optimization problems, where binary variables control which observations are flagged as outliers and discarded, and continuous variables correspond to the regression coefficients. The problems studied corresponds to the least trimmed squares in statistics, which has been studied in depth but is widely regarded as intractable, with few exact methods proposed. Indeed, the natural mixed-integer quadratic formulation relies on big-M constraints, and performs poorly in practice. We close this gap in the literature by proposing strong conic formulations, which avoid big-M constraints altogether.

Theory and Applications of Distributionally Robust Optimization

Community Committee Choice Session

Session Chair: Nan Jiang, Georgia Tech, Atlanta, GA
Session Chair: Weijun Xie, Georgia Institute of Technology, Atlanta, GA

1 A Decomposition Algorithm for Distributionally Robust Two-Stage Convex Quadratic Programs

Nazlican Arslan, David Morton, Northwestern University, Evanston, IL
Distributionally robust optimization is a framework to model stochastic optimization problems in which the distribution of the random variables is uncertain. The uncertain distribution is assumed to come from an ambiguity set that contains plausible distributions. The goal is to find decisions that can hedge against the worst distribution in the ambiguity set. This study focuses on a two-stage stochastic program with convex quadratic recourse under distributional ambiguity. We assume uncertainty only in the right-hand side vector. We consider data-driven distributional ambiguity sets based on the Wasserstein distance and an optimal quadratic transport distance. For the latter, we derive decomposition algorithms, and present computational results for a capacity expansion problem.

2 Robust Optimization with Moment-dispersion Ambiguity

Li Chen[1], Melvyn Sim[1], Chenyi Fu[2], Fan SI[3], Peng Xiong[4], [1]National University of Singapore, Singapore, Singapore; [2]Natinonal University of Singapore, tianjin, China; [3]National university of Singapore, Singapore, Singapore; [4]National University of Singapore Business School, Fairfax, Contact: chen_l@u.nus.edu
We introduce the moment-dispersion ambiguity set enabling independent characterization of a random variable’s central location, dispersion, and support. We propose the dispersion characteristic set as the input format for representing dispersion ambiguity in algebraic modeling tools. We also introduce the independence propensity hyper-parameter

to foster joint ambiguity set creation for multiple random variables, enhancing our model's real-world applicability and facilitating varying independence characterization without needing a correlation matrix. We develop safe tractable approximations for assessing risks linked with affine and convex piecewise affine cost functions over moment-dispersion ambiguity sets, accommodating varying risk tolerances. We show two numerical case studies involving appointment scheduling and portfolio optimization.

3 Data-Driven Stochastic Dual Dynamic Programming: Performance Guarantees and Regularization Schemes

Hyuk Park[1], Zhuangzhuang Jia[2], Grani Adiwena Hanasusanto[3], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]University of Illinois Urbana-Champaign, Champaign, IL, [3]University of Illinois Urbana-Champaign, Austin, TX, Contact: hyukp2@illinois.edu

We present a data-driven approach for multistage stochastic linear programming with Markovian random parameters, using an extended stochastic dual dynamic programming (SDDP) algorithm. Our method uses historical trajectories and evaluates cost-to-go functions empirically using kernel regression. This eliminates the need for scenario trees which can be computationally expensive. However, if the training data is sparse, the SDDP algorithm may suffer from poor out-of-sample performance. To address this, we use distributionally robust optimization, which replaces empirical expectation with worst-case expectation over an ambiguity set. We derive theoretical out-of-sample performance guarantees and demonstrate polynomial sample complexity on the number of time stages. Our numerical experiments show the superiority of our approach over existing schemes.

4 Value of Stochastic Solution with Right-Hand Side Uncertainty

Haoming Shen[1], Ruiwei Jiang[2], [1]University of Arkansas, Fayetteville, AR, [2]University of Michigan, Ann Arbor, MI

We revisit the value of stochastic solution (VSS) in the context of distributional ambiguity. When the uncertainty arises from the right-hand side of a two-stage stochastic program, we consider upper and lower bounds of VSS using distributionally robust and optimistic optimization. We discuss the computation of these bounds and demonstrate them through numerical examples.

5 Hedging Against Black Swans in Renewable Energy Markets via Distributionally Robust Optimization

Liviu Aolaritei, Boubacar Bangoura, Nicolas Lanzetti, Saverio Bolognani, Florian Dörfler, ETH Zurich, Zurich, Switzerland. Contact: aliviu@ethz.ch

A black swan is an event that (i) is an extreme outlier, (ii) has a catastrophic effect, and (iii) is impossibly difficult to predict. While such events are unavoidable in financial and energy markets, it remains widely unclear how to make robust decisions in their presence. In this work we argue that in many cases black swans can be efficiently captured by Optimal Transport ambiguity sets with properly designed transportation costs. Consequently, the decision-making amounts to an Optimal Transport-Based Distributionally Robust Optimization, which we show to have a finite dimensional convex reformulation. We validate this reasoning in renewable energy markets, on real data from a wind farm in Finland.

Structured and Tame Optimization

Community Committee Choice Session

Session Chair: Lexiao Lai, Columbia University, New York, NY

1 The Complexity of First-Order Optimization Methods from a Metric Perspective

Tonghua Tian, Cornell University, Ithaca, NY

A central tool for understanding first-order optimization algorithms is the Kurdyka-Lojasiewicz inequality. Standard approaches to such methods rely crucially on this inequality to leverage sufficient decrease conditions involving gradients or subgradients. However, the KL property fundamentally concerns not subgradients but rather "slope", a purely metric notion. By highlighting this view, and avoiding any use of subgradients, we present a simple and concise complexity analysis for first-order optimization algorithms on metric spaces. This subgradient-free perspective also frames a short and focused proof of the KL property for nonsmooth semi-algebraic functions.

2 Survey Descent and It's Initialization

X.Y. Han, Cornell University, Ithaca, NY

The recent work of Han and Lewis (2023) proposed a Survey Descent method for blackbox, nonsmooth optimization --- proving its local, linear convergence when the unseen objective is max-of-smooth given the right initialization. In this talk, I will review the Survey Descent method and discuss a potential heuristic for its initialization.

3 A Unified Complexity Metric for Nonconvex Matrix Completion and Matrix Sensing in the Rank-One Case

Haixiang Zhang[1], Baturalp Yalcin[2], Javad Lavaei[2], Somayeh Sojoudi[3], [1]UC Berkeley, Berkeley, CA, [2]University of California, Berkeley, Berkeley, CA, [3]University of California, Berkeley, El Cerrito, CA, Contact: haixiang_zhang@berkeley.edu

We develop a new complexity metric for an important class of low-rank matrix optimization problems, where the metric aims to quantify the complexity of th nonconvex optimization landscape and the success of local search methods. The existing literature has focused on two complexity measures, namely the RIP constant and the sampling rate in terms of the incoherence. The proposed complexity metric has the potential to unify these two notions and applies to a much larger class of problems. We illustrate the usefulness of the new complexity metric from three aspects, and we establish theoretical results to provid conditions on the existence of spurious solutions in terms of the proposed complexity metric.

4 Global Stability of First-Order Methods for Coercive Tame Functions

Cedric Josz, Lexiao Lai, Columbia University, New York, NY, Contact: lexiao.lai@columbia.edu

We consider first-order methods with constant step size for minimizing locally Lipschitz coercive functions that are tame in an o-minimal structure on the real field. We prove that if the method is approximated by subgradient trajectories, then the iterates eventually remain in a neighborhood of a connected component of the set of critical points. Under suitable method-dependent regularity assumptions, this result applies to the subgradient method with momentum, the stochastic subgradient method with random reshuffling and momentum, and the random-permutations cyclic coordinate descent method.

Topics in Facility Logistics

Community Committee Choice Session

Session Chair: Jennifer A. Pazour, Rensselaer Polytechnic Institute, Troy, NY

1 Warehouse Order-Picking Operations with Human-Drone Coordination

Juan Pablo Morande, Daniel F. Silva, Alice E. Smith, Auburn University, Auburn, AL, Contact: jpm0112@auburn.edu

The focus of this exploratory work is the implementation of drones for order-picking inside warehouses. Specifically, we explore how drones can be used to reduce the time required to collect a set of orders and return them to a specific point in the warehouse. We consider a human worker and a set of drones, either of which can pick orders, working in coordination, with drones dropping items at either their base or handing them off to the human picker. We model the system as a mixed-integer linear program, run computational experiments, and evaluate the results to assess the effectiveness of this application.

2 Zone-Based Approach to Dynamic Facility Layout with Embedded Input/Output Points

Sadan Kulturel-Konak, Penn State Berks, Reading, PA, Contact: sadan@psu.edu

Solving the unequal area Dynamic Facility Layout Problem (DFLP) using a zone-based structure will be presented. The unequal area DFLP is modeled and solved using a zone-based structure, referred to as ZDFLP, where the dimensions of the departments and material handling system input/output (I/O) points are decision variables. A two-phase matheuristic, which directly operates on Problem ZDFLP without requiring an encoding scheme of the problem, is proposed to solve the ZDFLP with promising results.

3 Expected Value and Variance of Picking Travel Distance Under Three Routing Policies

Carlos Morel Figueroa, Hector J. Carlo, Noel Artiles-León, University of Puerto Rico Mayagüez Campus, Mayagüez, Puerto Rico

Order picking from storage bins is one of the functional areas of an E-Commerce Distribution Center. In this area, workers retrieve their assigned order lines (products) using a picking cart according to a routing policy. This work derives the expected travel distance and variance to retrieve a random order with a fixed number of lines under three routing policies (Return, S-Shaped, and Mid-Point). A Monte Carlo simulation is used to validate the resulting formulas. Due to the multivariate nature of the problem, the resulting equations are not closed-form.

4 Modelling and Solving Grid-Based Dynamic Facility Layout Problems with Unequally Shaped Facilities and Obstacles Using a Genetic Algorithm

Felix Rauscher, Karlsruhe Institute of Technology, Karlsruhe, Germany. Contact: felix.rauscher@kit.edu

Achieving high levels of flexibility and adaptability in modern production systems requires optimizing facility layout across various time periods, considering transportation and rearrangement costs. One approach is the application of the dynamic facility layout problem (DFLP). This study explores a method to solve the grid-based DFLP, which involves objects (e.g., facilities) and obstacles with arbitrary (grid-based) shapes connected by feasible transportation paths. The implementation of a genetic algorithm is demonstrated as a viable solution approach. Additionally, the investigation explores significant influencing factors and identifies best strategies for attaining improved solution outcomes.

5 Multi-Load Handling Devices in Multi-Deep Storage Systems: An Investigation of Their Impact on Throughput

Timo Lehmann[1], Martin Bamesberger[2], Johanna Pothmann[2], David Schwär[2], Jakob Hußmann[2], [1]Karlsruhe Insitute of Technology, Karlsruhe, Germany; [2]Karlsruhe Insitute of Technology, Karlsruhe, Germany. Contact: timo.lehmann@kit.edu

Multi-deep storage systems as well as storage systems with multi-load handling devices are widespread in the industry. Multi-Load handling devices can transport several unit loads at the same time and allow several storages and retrievals of these unit loads in the same command cycle. Thus, the throughput of storage systems can be improved compared to single load handling devices. We investigate different operating strategies for such multi-deep systems with multi-load handling devices and compare the different strategies with each other and with strategies for single load handling devices. We present analytic models for each strategy, validate them with discrete event simulation and evaluate the impact of multi-load handling devices.

1 Dynamic Traffic Assignment with Physics-Informed Deep Learning

Shakiba Naderian, Ohay Angah, Yiran Zhang, Xuegang Ban, University of Washington, Seattle, WA, Contact: naderian@uw.edu

Dynamic traffic assignment (DTA) is a challenging problem in transportation science, having distinct mathematical components that often require significant computational time. Recent DTA advances are featured by applying learning methods, like neural networks (NN), to ease this computational burden. Our study uses a physics-informed deep learning (PIDL) framework to approximate traffic dynamics in DTA. Using Ma et al.'s DTA model as the physical component, our PIDL framework incorporates two neural networks. The first one calibrates DTA parameters based on real-world scenarios, while the second one estimates DTA variables that are difficult to be solved mathematically. Our PIDL approach bridges the gap between mathematical complexity and practical application in DTA, giving insights for improving the use of DTA models in transportation planning and management.

2 Leveraging Connected and Automated Vehicles for Participatory Traffic Control

Minghui Wu[1], Ben Wang[2], Yafeng Yin[1], Jerome P. Lynch[3], [1]University of Michigan, Ann Arbor, MI, [2]Univerisity of Michigan, Industrial and Operations Engineering Department, Ann Arbor, MI, [3]Duke University, Durham, NC, Contact: minghuiw@umich.edu

In the future, traditional physical controllers like traffic signals may be complemented by connected and autonomous vehicles (CAVs) as mobile actuators. This research aims to establish the theoretical foundation for this novel participatory traffic control scheme. In this approach, CAVs exert indirect influence over the day-to-day traffic dynamics of other vehicles, aiming to redistribute traffic demand across various time periods and transportation facilities. To address this challenge, we model the problem within the major-minor mean field control (M3FC) framework and leverage reinforcement learning algorithms to compute the optimal control policy. Our model offers broad applicability, accommodating various commute choices such as departure time and route choices, and is adaptable to different levels of CAV penetration rate.

3 Optimal Information Perturbation for Traffic Congestion Mitigation: Gaussian Process Regression and Optimization

Lili Du, Stephen Spana, University of Florida, Gainesville, FL

Information perturbation is an information provision strategy that strategically alters the traffic information sent to drivers, aiming to mitigate network congestion caused by selfish routing decisions. Previous works have integrated information perturbation into coordinated routing mechanisms and proved the system performance improvement but did not give direct guidance on optimal perturbation levels, considering the competing effects of system performance improvement and user optimality loss. This work aims to uncover this optimal perturbation under general network conditions. The relationships used in the optimization models are obtained through Gaussian process regression, which is trained using the output of computer experiments. We demonstrate the merit of our methodology through a sensitivity analysis using the Sioux Falls network as a test case.

4 Stabilization of Nash Equilibrium for Mixed Traffic

Richard Lee[1], Jeffrey Scruggs[1], Yafeng Yin[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: leerich@umich.edu

The transition from human driven vehicles (HDVs) to connected-autonomous vehicles (CAVs) raises the question of how mixed traffic interactions will affect overall network performance. This research frames this problem in the context of a population game, where each origin-destination pair constitutes a population. We assume that the evolutionary dynamics are governed by the Impartial Pairwise Protocol with the travel time as the payoff. Due to distinct headways between HDVs and CAVs, the link travel time is dependent on the population proportion of each link. System-theoretic passivity methods are then used to propose a controller that guarantees global asymptotic stability of the system to Nash equilibrium.

5 On the Relocation Game of Ride-Hailing Platforms with Non-Atomic Drivers
