Yi-Neng Wang[1], Xi Lin[2], Fang He[1], Zhengtian Xu[3], Zuo-Jun Max Shen[4], [1]Tsinghua University, Beijing, China; [2]Tsinghua University, beijing, China; [3]The George Washington University, Washington, [4]University of California Berkeley, Berkeley, CA, Contact: yn-wang19@mails.tsinghua.edu.cn

Vacant drivers spontaneously relocate to mitigate the supply-demand imbalance embedded in ride-hailing services. We aim at addressing two fundamental questions. (i) To what extent can drivers' spontaneous relocation resolve the supply-demand imbalance? (ii) How does a ride-hailing platform subsidize drivers to cope with the platform-optimum goals? We propose a leader-follower game theoretical framework, where the platform as the leader designs relocation subsidies and idle drivers as followers form a multistage driver equilibrium. After proving the existence of the equilibrium, we depict the non-empty subsidy strategy for the platform. We derive the analytical conditions so that the platform does not need to subsidize drivers to achieve platform goals. For other cases, we prove that the gaps compared with platform goals are bounded by constant discounts.

Network Design : New Techniques and Approaches

Community Committee Choice Session

Session Chair: Pushpendra Singh, Dartmouth College, Hanover, NH

Session Chair: Vikrant Vaze, Dartmouth College, Hanover, NH

1 A Reinforcement Learning (Rl) Approach to Mixed Integer Non Convex Network Design Problems

Pushpendra Singh, Vikrant Vaze, Dartmouth College, Hanover, NH, Contact: pushpendra.singh.th@dartmouth.edu

Numerous transportation applications such as shared micromobility systems, & bus transit systems, all involve discrete choice network design. Network design captures various salient features of planning such as strategic, tactical, & operational decision making that arise in transportation systems. We define a new class of mixed integer non-convex programs (MINCP) problems, which are practically important across many fields and their mathematical similarity motivates this joint study. We provide compact & general formulation for this class of problems & design an algorithm based on RL to solve this problem. We use a model based on attention layers & implement REINFORCE to train our model with baseline greedy rollout. Our algorithm provides better results & runtime, than the existing state of art methods, such as adaptive discretization, to solve these problems.

2 Community/Committee's Choice Submission

Lilly Yang, Vikrant Vaze, Laurens G. Debo, Dartmouth College, Hanover, NH, Contact: lilly.yang.th@dartmouth.edu

Food waste in landfills is an avoidable source of methane emissions responsible for global warming. While composting offers a greener alternative increasingly mandated by governments, cost & ability to compost in one's backyard varies unevenly & inequitably across households. Customer dropoffs & curbside pickups enable a centralized composting alternative with lower processing cost due to economies of scale. But it incurs additional transportation cost & raises the question how to minimize total systemwide costs. Mathematically, this amounts to multivehicle pickup routing with a distributed disposal option. We use continuum approximation for a stylized circular city to underscore peculiar discontinuous tradeoff curves unique to this problem. Our real-world computational case study results in the most populous county in Vermont quantify the total cost savings.

3 Service Region Design and Fleet Sizing for First and Last Mile On-Demand Services

Yineng Sun[1], Vikrant Vaze[2], [1]Dartmouth College, West Lebanon, NH, [2]Dartmouth College, Hanover, NH, Contact: phoebe.sun.th@dartmouth.edu

Over a million US households in primarily rural counties lack access to private cars and must rely on public transit. Yet, 87% of the 200 least productive bus networks are in rural counties. Effective first-last-mile connections via on-demand ridesharing can enhance access, but design of such a system must account for the sparsely distributed demand hotspots and geographically dispersed origins and destinations. To address these distinctive challenges, we propose a two-stage model with service region design and fleet sizing in the first stage and on-demand dynamic pickup and drop-off estimation in the second. We develop a spatial decomposition approach informed by an exact second-stage routing formulation and a vehicle dispatch simulation. On real-world case studies, our service region design approach shows strong practical insights and outperforms benchmarks.

4 A Hybrid Genetic Algorithm for the Minmax Multiple Traveling Salesman Problem with a Dynamic Programming-Based Solution Refinement

Sasan Mahmoudinazlou, Changhyun Kwon, University of South Florida, Tampa, FL, Contact: sasanm@usf.edu

This paper proposes a hybrid genetic algorithm for solving the Multiple Traveling Salesman Problem (mTSP), aiming to minimize the longest tour using a divide-and-conquer approach. The genetic algorithm utilizes a TSP sequence as the representation of each individual, and a dynamic programming algorithm, Split, is employed in order to evaluate the individual and find the optimal mTSP solution for the given sequence. A crossover operator has been designed that combines similar tours from two parents and offers great diversity for the population. The offspring are also improved by a self-adaptive random local search and a thorough neighborhood search. Our algorithms outperform all existing algorithms on average when tested against multiple benchmark sets found in the literature. Additionally, we improve the best solutions for several instances on each benchmark set.

5 Urban Design of an Automated Parcel Locker Network Using Simulation-Optimization Hybrid Models in Pamplona, Spain

Javier Faulin[1], Adrian Serrano[1], Luis Cadarso[2], [1]Public University of Navarre, Pamplona, Spain; [2]Rey Juan Carlos University, Fuenlabrada, Spain. Contact: javier.faulin@unavarra.es

Over the past few years, final delivery of goods in urban regions has encountered various issues including restricted delivery windows, a rise in demand for quick delivery services, and customers who fail to show up to receive their packages. To tackle these difficulties, the implementation of automated parcel locker (APL) systems has surfaced as a hopeful solution. Our study delves into the utilization trends of APLs in Pamplona (Spain) and suggests a simulation-optimization hybrid model to create an efficient APL network design in the same city. Agent-based modeling is utilized to project the future demand for APLs, factoring in socio-economic factors such as population size and e-commerce growth rates. Further, a dynamic optimization model is employed to determine the ideal APL locations, while minimizing operational and service expenses.

Integrated approaches in urban rail systems

Community Committee Choice Session

Session Chair: Jiateng Yin, 1</sup

1 Lagrangian Relaxation Based Speed Trajectory Optimization for Multiple Trains Under Virtual Coupling with Operational State Transition

Songwei Zhu, Beijing Jiaotong University, Beijing, China

The virtual coupling train operation is a promising way to increase the transport capacity of high speed railway systems. When the virtual coupling signaling is adopted, trains can be coupled and decoupled in the running process, making the train operation under virtual coupling different from that under the fixed block or moving block signaling system. Thus, the traditional speed trajectory optimization method for ordinary operation is unsuited for the train operation under virtual coupling. In this paper, a mixed integer nonlinear programming model is proposed to formulate the operation of trains under virtual coupling, where the states of virtual coupling, i.e., the moving block running state, the coupling state, the coupled running state and the decoupling state, are indicated explicitly by binary variables. By adopting a piecewise-linear method, the nonlinear model is transformed into a mixed integer linear programming model, which can then be solved by commercial solvers. To enhance the computational efficiency, a Lagrangian relaxation method is proposed to relax the constraints of safety distance. Based on the data of Beijing-Shanghai high-speed railway, numerical experiments are conducted to demonstrate the effectiveness of the proposed methodology in coupling and decoupling scenarios. The results indicate that the proposed model can be used to optimize the speed trajectory for multiple trains under virtual coupling, and the objective function value of Lagrangian relaxation method is reduced by 19.12% compared with solving by CPLEX directly in the coupling scenario of two trains. Moreover, the Lagrangian relaxation method obtains a solution better than that of the direct method after the first iteration, proving higher computational efficiency of the Lagrangian method.

2 Integrated Modeling for Optimal Travel Mode Choice and Train Schedule Design

Yiyao Zhang, Beijing Jiaotong University, beiJing, China. Contact: 21120274@bjtu.edu.cn

This paper introduces an innovative integrated modeling framework that addresses the simultaneous optimization of travel mode choice and train schedule design. To capture this dynamic behavior, we propose a multimodal route selection and assignment model that incorporates the choice between bus and subway modes. Concurrently, we integrate a rail transit train schedule optimization model to enhance service quality, utilizing an iterative learning framework that accounts for dynamic interactions between supply and demand. By considering the multimodal aspect, it captures the realistic decision-making process of travelers who choose between different modes based on their preferences and travel conditions. Additionally, the inclusion of the train schedule optimization model further improves service quality.

3 Rail Grinder Routing and Scheduling Problem

Zabih Ghelichi, Paul Kuhn, BNSF Railway, Fort Worth, TX

Freight railroad track components, such as curves and tangents, are subject to a range of load types that cause the development of different wear patterns. Railroads employ grinding method to restore the track profile and remove cracks and other irregularities from these worn track segments. Grinding frequency of a track segment is determined by the gross-ton-miles that segment accumulates, and it varies from component to component. Given the track component-wise thresholds, grinding could be an intermittent and costly while necessary operation. In this regard, this project introduces an optimization model to address the problem of routing and scheduling grinder machines in railroad operations. The main goal is to minimize the overall costs of grinding operations while maintaining the network health at a specific level.

AI Applications and the Digital Economy

Community Committee Choice Session

Session Chair: Xinxue Qu, University of Notre Dame, Granger, IN

1 An Economic Analysis of Apple’S Att Policy: Advertising Revenue and App Price

Zhen Yan, Jianqing Chen, Srinivasan Raghunathan, University of Texas at Dallas, Richardson, TX, Contact: zhen.yan@utdallas.edu

Apple’s App Tracking Transparency (ATT) policy mandates developers to obtain tracking permission from users. Given the trend of users opting out, it is predicted that advertising revenues may experience a downturn. This paper investigates the impact of the ATT policy on app pricing strategies. Our model reveals that when advertising revenue per user is comparatively low, developers are likely to reduce app prices, which encourages more users to purchase the app and decreases the developer’s reliance on advertising revenue.

2 Security Patch Management Based on Multi-Agent Reinforcement Learning

Qian Jia[1], Syam Menon[2], Zhengrui Jiang[3], [1]Nanjing University, Nanjing, China; [2]University of Texas at Dallas, Richardson, TX, [3]Nanjing University, Nanjing, China. Contact: qianjia@smail.nju.edu.cn

Security patch management is a critical process in ensuring the security of information systems, as it protects them from attacks that exploit vulnerabilities. However, it is a complex and challenging task that involves multiple stages, such as patch development, testing, release, and deployment, and requires decisions from both software vendors and enterprise system users. This study proposes a joint optimization framework for security patch management based on multi-agent reinforcement learning. Unlike previous research, which focused solely on either software vendors or enterprise system users, our framework provides an integrated solution that optimizes decision-making for both parties. Our study highlights the potential of multi-agent reinforcement learning for optimizing security patch management process in information systems.

3 Marketplace Or Logistics Provider: Extended Mfs Programs In Online Retailing

Geng Sun, University of Texas Rio Grande Valley, Edinburg, TX

We study the emerging phenomenon that online platforms expand their membership-based free shipping programs to merchants running their own e-commerce websites instead of listing on the marketplaces. We find that the external MFS revenue may compensate for the internal commission loss, making the platforms better off overall.

4 Lending in the Shadows: Shadow Bank Financial Fragility and Mortgage Credit

Yu Shan, Syracuse University, Syracuse, NY, Contact: yshan03@syr.edu

This paper examines the impact and dynamics of the financial fragility of shadow bank mortgage lenders. The overall financial fragility of the shadow bank sector has been consistently increasing in recent years, reaching its highest value of the past decade in 2021. Financially fragile shadow banks take advantage of favorable regulatory spillover shocks to build their market share in the riskier segment of the market and lower their underwriting standards more than other shadow banks. Meanwhile, fragile shadow banks' credit supply is less elastic in response to demand shocks. Our results underline the importance of more regulatory attention to the fragility and destabilizing effects of shadow bank lenders.

5 Inventory Control Involving Opaque Selling

Yuan Qu, Rutgers Business School, Newwark, NJ, Contact: ryanqu94@gmail.com

We proposed a stylized model to help a firm practice opaque selling optimally. Rather than set up a given replenishment policy in the background, we attempt to offer the best real-time decisions for both replenishment and rationing. As expected, themes like contraction mapping, submodularity, diagonal dominance, concavity, and mild monotonicity would all loom large in this study. Fitting the rationing aspect is a potentially new property of balance-inducing monotonicity. Key to the current joint rationing-replenishment control is the simultaneous preservation of all kinds of value-function properties, which has been verified. An immediate consequence is that rationing should still follow the balance-inducing principle even when the replenishment decision is jointly made.

Data, Learning, and Decision-Making

Community Committee Choice Session

Session Chair: Mohsen Bayati, Stanford University, Stanford, CA

1 Epidemic Prediction and Control, Learning from Network Data

Yeganeh Alimohammadi[1], Christian Borgs[2], Amin Saberi[1], [1]Stanford University, Stanford, CA, [2]UC Berkeley, Berkeley, CA, Contact: yeganeh@stanford.edu

People's interaction networks play a critical role in the dynamics of epidemics. However, acquiring comprehensive data regarding these interactions can be expensive and often impossible, limiting our ability to predict outbreak likelihood and size effectively. What information about people's social networks do we need to predict and prevent future outbreaks? In this talk, I will show how leveraging local information from a few samples of the population can estimate the time evolution of epidemics. I will give theoretical guarantees on the estimator's accuracy under general assumptions.

2 High-Dimensional Learning for Multi-Sourced Data

Wanning Chen[1], Chenglong Ye[2], [1]University of Washington, Bellevue, WA, [2]University of Kentucky, Lexington, KY

We propose a matrix transfer learning algorithm that facilitates the learning of a main dataset with the help from multiple auxiliary datasets, when the data can be cast as partial noisy observations of a main matrix and multiple auxiliary matrices that are low-rank. We provide theoretical guarantees on this algorithm and show superior empirical performance comparing with benchmark algorithms.

3 A Model for Experimentation Under Interference

Mohamad Sadegh Shirani Faradonbeh[1], Mohsen Bayati[2], [1]Stanford Graduate School of Business, Stanford, CA, [2]Stanford University, Stanford, CA, Contact: sshirani@stanford.edu

The estimation of causal effects in the presence of network interference is a fundamental challenge in scientific disciplines. Classical approaches are susceptible to bias due to the intricate interaction among individuals. This work introduces a new model to capture complex network interference effects and presents a novel toolbox that facilitates the analysis of network data. This research contributes to advancing our understanding of causal inference in networked settings and provides valuable tools for investigating the impacts of interventions in real-world scenarios.

4 Geometry-Aware Algorithms for Linear Bandits: Balancing Performance and Theoretical Guarantees

Yuwei Luo, Mohsen Bayati, Stanford University, Stanford, CA

This paper addresses the discrepancy between the promising empirical performance of algorithms such as Thompson sampling and Greedy, relative to their pessimistic theoretical regret bounds. We propose a new data-driven technique that tracks the uncertainty ellipsoid's geometry to establish an instance-dependent frequentist regret bound for a broad class of algorithms. This enables us to identify and ``course-correct" instances where the base algorithms perform poorly. The corrected algorithms achieve the minimax optimal regret while retaining the desirable properties of the base algorithms.

5 On Aligning Prediction Models with Clinical Experiential Learning: A Prostate Cancer Case Study

Jacqueline J. Vallon[1], William Overman[1], Wanqiao Xu[1], Neil Panjwani[2], Xi Ling[1], Sush Vij[1], Hilary P. Bagshaw[1], Sandy Srinivas[1], John Leppert[1,3], Erqi Pollom[1,3], Lei Xing[1], Mark K. Buyyounouski[1], Mohsen Bayati[1], [1]Stanford University, Stanford, CA, [2]University of Washington, Seattle, WA, [3]Palo Alto Veterans Affairs Hospital, Palo Alto, CA, Contact: jjvallon@stanford.edu

To increase estimation accuracy, advanced machine learning (ML) models trade off variance by injecting bias. However, in a healthcare setting, this artificial bias can lead to predictions that are inconsistent with the experiential learning of clinicians, limiting the models' use in clinical practice. In this project, we study this challenge by applying modern ML models to prostate cancer outcome predictions using the National Cancer Data Base. We hypothesize that integrating clinical expertise into the training of the ML models will reduce the inconsistencies without compromising model accuracy.

Analytics in Classrooms

Contributed Session

Session Chair: Kenneth E. Murphy, University of California Irvine, Irvine, CA

1 Case: Using Text Analysis to Investigate Fraud

Matthew D. Dean, Christine Petrovits, Jamie Diaz, William & Mary, Williamsburg, VA

We describe a case study that introduces business students to text analysis in the context of identifying fraud. After reviewing the fraud triangle, students use Python and/or Alteryx to analyze over 1,400 emails attempting to find the culprits. The case has been used in both MBA and MAcc classes. We collected student survey data over multiple offerings and provide some analysis and insights into the students' perceptions of the case and its ability to help them apply the tools of text analysis.

2 Using Generative AI to Build Realistic Classroom Case Studies

Cody Baldwin, University of Wisconsin-Madison, Madison, WI, Contact: cody.baldwin@wisc.edu

As educators, we strive to create learning opportunities that mimic challenges faced in industry. We want our students to be prepared. However, students sometimes feel that academia and industry are out of alignment. While being taught, they might say, "when will I ever use this in my career?" As an example, while performing data analysis on an assignment, students may feel the data is cleaner and more complete than data they would encounter in the "real world", which could be messy and poorly documented.

These experiences can be frustrating for students. To address these concerns, educators can use generative AI to create more realistic assignments. For instance, generative AI can be used to create synthetic datasets, which are modeled after real datasets, or to create video avatars that represent different business stakeholders who can provide business context for students.

3 Developing an Undergraduate Program in Navy Engineering Analytics

Cameron MacKenzie, Iowa State University, Ames, IA, Contact: camacken@iastate.edu

Thanks to funding from the Office of Naval Research, Iowa State University (ISU) is launching a Navy Engineering Analytics Program (NEAP) for undergraduate students. The objective of NEAP is to develop an innovative education and training program that teaches analytical skills to solve Navy and defense problems. The goal of NEAP is to provide undergraduate engineering students with the necessary analytical skills so that they can enter into exciting professions in the Navy and the broader defense community. NEAP is currently composed of four courses: (i) crisis decision making and risk management, (ii) design and evaluation of human-computer interaction, (iii) problem solving using R, and (iv) a project-based course in which students work on defense-sponsored projects. NEAP has awarded 20 students with scholarships for 2023.

4 Implementing an Analytics and Operations Research Project in a Second-Year Engineering Science Design Course

Kevin Jia, University of Auckland, Auckland, New Zealand. Contact: k.jia@auckland.ac.nz

The second-year Engineering Science design course at the University of Auckland includes a six-week analytics and operations research project, where students formulate and solve a moderately large vehicle routing problem. In groups, they are expected to apply their statistics and visualisation skills to estimate problem data; optimisation for problem formulation; and simulation to estimate the solution quality. Professional skills demanded by industry, such as report writing, teamwork, ethics and systems thinking, are further developed. The lessons learnt after five years of course development, including two years of online delivery, will be discussed, and potential ideas for further course and curriculum development explored.

5 Equity in an Online Management Science Course

Kenneth E. Murphy, University of California Irvine, Irvine, CA, Contact: murphyke@uci.edu

This talk hypothesizes that student outcomes in an online management science course are related to the quality of prerequisite coursework. We present empirical results with respect to student preparation and technology readiness and develop a model of the relationship between these variables and course performance. The results inform instructors with respect to actions that they may take to address student equity.

Modern Design and Analysis of Computer Experiments: Methodologies and Their Applications

Community Committee Choice Session

Session Chair: Cheoljoon Jeong, University of Michigan, Ann Arbor, MI

1 Robust Simulation Optimization with Stratified and Adaptive Sampling

Pranav Jain[1], Sara Shashaani[1], Eunshin Byon[2], [1]North Carolina State University, Raleigh, NC, [2]University of Michigan, Ann Arbor, MI, Contact: pjain23@ncsu.edu

Stratification has been widely used as a variance reduction technique when estimating a simulation output, whereby the input variates are generated following a stratified sampling rule from previously determined strata. This study shows that stratification could make an adaptive sampling class of simulation optimization solvers more robust. While stratified sampling improves the algorithm’s performance, its robustness is sensitive to the stratification structure.

2 Computer Model Parameter Calibration via Bayesian Optimization

Cheoljoon Jeong[1], Eunshin Byon[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: cjeong@umich.edu

Parameter calibration seeks to estimate unobservable parameters in a computer model by aligning field observations with computer model outputs. This study employs Bayesian Optimization (BO), which offers a sequential design technique for computer experiments that is sample-efficient. We note that in many applications, not all parameters have an impact on the model output and the relative importance of each parameter can vary. Existing calibration studies naively calibrate all parameters or choose a subset of parameters based on domain knowledge and/or through a pre-screening procedure. This study proposes a new sequential approach for identifying important parameters based on the most up-to-date information We demonstrate the effectiveness of our method through numerical studies and a real-life building energy simulation case study.

3 Confidence Intervals for Monitoring Simulated System Performance

David J. Eckman[1], Matthew Plumlee[2], Barry L. Nelson[2], [1]Texas A&M University, College Station, TX, [2]Northwestern University, Evanston, IL, Contact: eckman@tamu.edu

Many grey-box simulation models give rise to performance measures possessing known functional properties, such as monotonicity, Lipschitz continuity, or convexity. We introduce a framework that accommodates and exploits such forms of functional information to infer the performance of a simulated system when in an observed state. In particular, we use mathematical programming to construct upper and lower bounds on the unknown performance measure. Asymptotically, these lower and upper bounds achieve a desired level of confidence uniformly over system states and are consistent pointwise. These ideas are illustrated in numerical experiments.

4 Nonparametric Multivariate Importance Sampling in Stochastic Simulation

Chenfei Li[1], Eunshin Byon[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, MI, Contact: lchenfei@umich.edu

We propose a new multivariate importance sampling method in stochastic simulation. Importance sampling has the potential to significantly reduce the estimation variance when its instrumental density is well-designed. A nonparametric technique has been shown to provide benefits in the literature for capturing the significance of input variables and interaction effects between inputs. However, when the input dimension is higher than three, it easily faces the curse of dimensionality. This study presents an adaptive method to identify crucial input variables and devises a nonparametric instrumental density using those selected variables.

Sequential Learning & Optimization Under Uncertainty

Community Committee Choice Session

Session Chair: Imtiaz Ahmed, West Virginia University, Morgantown, WV

1 Targeted Variance Reduction: Robust Optimization of Expensive Black-box Simulators with Noise Parameters

John J. Miller[1], Simon Mak[2], [1]Duke University, Durham, NC, [2]Duke University, Durham, NC, Contact: john.joshua.miller@duke.edu

The problem of optimizing an expensive black-box function arises in many complex scientific and engineering problems. This function often has not only a set of controllable inputs that the user can optimize, but also a set of random inputs that are uncontrollable in practice. Random inputs may arise from uncontrollable noise factors or from unknown simulation parameters that must be inferred from data. We propose a new Bayesian optimization method that accounts for the presence of random input factors. Leveraging a carefully-constructed Gaussian process model, we derive a closed-form acquisition function that balances exploration, exploitation and solution precision over the random inputs for adaptive sampling of the black-box objective. We demonstrate the effectiveness of our approach for designing automobile braking materials.

2 Conformal Sequential Change-Point Detection Through Renewal Theory

Haoyun Wang, Yao Xie, Georgia Institute of Technology, Atlanta, GA, Contact: hwang800@gatech.edu

With the emergence of high-dimensional data where the generating mechanism is unclear, assuming a parametric form of the data distribution becomes sometimes unrealistic. We consider the problem of online monitoring of a process using conformity score, which allows more model robustness than the traditional parametric approach. Classic analysis through renewal theory can be generalized to such non-parametric case and we derive upper bounds on the expected detection delay while controlling average run length. We compare the proposed method with traditional change-point detection methods and show its effectiveness through numerical experiments.

3 Dynamic and Sequential Optimization for Systematic Decision-Making

Siqin Yang[1], Hao Yan[1], James Kong[2], [1]Arizona State University, Tempe, AZ, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA, Contact: syang240@asu.edu

In many applications, modeling the system uncertainty and optimizing the system performance in a sequential setting is a crucial task. For example, in additive manufacturing systems, finding the design process parameters for each layer is challenging. However, one distinct challenge is that many intermediate results in the sequential setting may not be fully observable. For example, it may not be feasible to measure the quality variables in each layer in additive manufacturing. This presentation will concentrate on sequential decision-making, employing Dynamic and Sequential Optimization with unknown intermediate variables online. By integrating optimal interventions into our graph models, we propose a method for making dynamic decisions applicable to various scenarios.

4 Collaborative Optimal Design: Showcasing the Power of Collaboration

Raed Al Kontar, University of Michigan, Ann Arbor, MI, Contact: alkontar@umich.edu

I present a framework for optimal collaborative design where multiple entities, such as scientists, digital twins, machines, or companies, collaborate to fast-track their optimal design process while preserving their intellectual property. I then showcase the power of collaboration for accelerated material discovery and design of process parameters in additive manufacturing.

Optimal Design of Experiments through Mathematical Programming Lens

Community Committee Choice Session

Session Chair: Alan Vazquez, University of Arkansas, Fayetteville, AR

1 Designing Optimal Experiments for Ordinal Responses

Rong Pan, Arizona State University, Tempe, AZ

In this talk, we argue that there is a necessity to propose practical methods for optimal design construction for mixtures when the response is ordinal. The primary reason is that ordinal responses are prevalent in industrial chemical applications. Aside from facilitating the mapping of psychological or sensory responses to numerical measurements, such as in sensory studies, ordinal scales could also serve as measurement surrogates for quantifying a dynamic system's progression through phases. We will discuss some search algorithms for finding optimal designs and some practicable approaches for dealing with common issues in design construction.

2 On the Asymptotics of Graph Cut Objectives for Network A/B Testing Design

Qiong Zhang, Clemson University, Clemson, SC, Contact: qiongz@clemson.edu

A/B testing is an effective approach to assess potential impacts of two treatments. For IT sectors, the test units of A/B testing are often connected in a social network. The responses of A/B testing can be related to the network connection of test units. In this talk, I will discuss the relationship between design criterion of network A/B testing and graph cut objectives. We develop asymptotic distributions of graph cut objectives to enable rerandomization algorithms for the design of network A/B testing.

3 An Integer Programming Algorithm for Constructing Maximin Distance Designs from Good Lattice Point Sets

Alan R. Vazquez, University of Arkansas, Fayetteville, AR, Contact: alanv@uark.edu

Computer experiments build computationally cheap statistical models to study complex computer models. These experiments are commonly conducted using maximin distance Latin hypercube designs (LHDs), generated using heuristic algorithms or algebraic methods. However, the performance of these algorithms deteriorates as the number of factors increases and the algebraic methods only work for specific numbers of tests. To overcome these limitations, we introduce an integer programming algorithm to construct flexible maximin distance LHDs. Our algorithm leverages the optimization techniques implemented in commercial solvers and the attractive algebraic structures given by good lattice point sets and the Williams' transformation. Using numerical experiments, we show that our algorithm outperforms benchmark algorithms and methods for constructing large LHDs.

Climate Resilience and Equity in Energy Systems

Community Committee Choice Session

Session Chair: Sofia Taylor, University of Wisconsin-Madison, Madison, WI
Session Chair: Line Roald, University of Wisconsin - Madison, Los Alamos, NM

1 Transmission Expansion Planning with Reliability Fairness Constraints

Rodrigo Moreno[1], Claudio Silva[1], Angela Flores[2,3], [1]University of Chile, Santiago, Chile; [2]TU Berlin, berlin, Germany; [3]Universidad de Chile, Santiago, Chile. Contact: rmorenovieyra@ing.uchile.cl

This presentation emphasizes the significance of reliability in electrical power systems and the need for fairness in its distribution. It proposes a methodology to address this issue by incorporating the distribution of reliability across the network in system operation and expansion planning optimization models. The models include linear constraints based on the Gini coefficient and a probabilistic/stochastic approach to model system failure scenarios. By modifying load-shedding plans and other operational and investment decisions, the models aim to improve reliability fairness. The results demonstrate that equitable reliability distributions can be achieved at marginal cost increases.

2 Climate Change Impacts on Future Residential Electricity Consumption and Energy Burden: A Case Study in Phoenix, Arizona

Andrew Jones[1], Destenie S. Nock[2], Constantine Samaras[1], Yueming Qiu[3], Bo Xing[4], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA, [3]University of Maryland College Park, College Park, MD, [4]Salt River Project, Phoenix, AZ, Contact: ajjones@andrew.cmu.edu

Air conditioning (AC) is vital for climate adaptation but can increase energy costs. We analyze temperature response functions across income, race/ethnicity, and age using smart-meter data and then project consumption from 2020 to 2070. Under RCP 8.5, we find the median household may see a 27.7% increase (16.7% to 38.0%) in summertime electricity consumption compared to 2017-2018. Additionally, we find (i) elderly and low-income households have higher percentage changes by nearly 5 points than their counterparts, (ii) AC efficiency upgrades can reduce cooling consumption for vulnerable groups by up to 70%, and (iii) upgrades can reduce energy burden by 1%-2% points still remaining unaffordable for low-income groups. This indicates that AC efficiency and cost structure changes are needed to allow households to adapt to a warming climate.

3 Community/Committee's Choice Submission

Jean-Paul Watson, 1</sup

4 Managing Wildfire Risk and Promoting Equity Through Optimal Configuration of Networked Microgrids

Sofia Taylor, University of Wisconsin-Madison, Madison, WI

As climate change increases the potential for wildfires, ignitions from electric power lines are a growing concern. To mitigate this risk, many electric utilities preemptively de-energize power lines to prevent electric faults, which could result in wide-scale power outages. Advanced technology, such as networked microgrids, can reduce the size of the resulting outages. However, even microgrids might not be sufficient to supply power to everyone, thus forcing questions about how to prioritize the provision of power among customers. We present an optimization problem that configures networked microgrids to manage wildfire risk while maximizing the power served to customers. Our formulation considers the ability of customers to cope with power outages and discourages the disconnection of particularly vulnerable customer groups.

5 Electric Vehicles Limit Equitable Access to Essential Services During Blackouts

Yamil Essus, Benjamin Rachunok, North Carolina State University, Raleigh, NC, Contact: yaessus@ncsu.edu

Mass adoption of electric vehicles will tie together mobility and electric power availability and exacerbate existing inequality in access to essential services. In this work we show that the intensity of this inequality is driven by geography, household electricity use and the types of vehicles accessible to each household. This happens because people living in areas with worse access to essential services are in turn depleting their EV batteries faster to access the same level of services. Our results provide insights for policymakers to help identify and mitigate the risk of losing access to essential services during prolonged power outages.

Vehicle Routing Optimization for Sustainable Intelligent Transportation Systems

Community Committee Choice Session

Session Chair: Tanveer Bhuiyan, UTSA

1 Locating and Allocating Chargers for Fixed-Route Freight Delivery

Amir Davatgari[1], Taner Cokyasar[2,3], Anirudh Subramanyam[4,2], Jeffrey Larson[5], Abolfazl K. Mohammadian[6], [1]University of Illinois Chicago, Chicago, IL, [2]Argonne National Laboratory, Lemont, IL, [3]TrOpt R&D, Adana, Turkey; [4]The Pennsylvania State University, University Park, PA, [5]Argonne National Laboratory, Argonne, IL, [6]University of Illinois Chicago, Chicago, IL, Contact: tcokyasar@anl.gov

As the target deadline for global net-zero economy is approaching, electrification is gaining more importance. In this study, we develop a mixed integer program, a clustering heuristic, and a genetic algorithm to solve the electric charger location and allocation problem of the e-commerce delivery industry. A thorough sensitivity analysis found charger costs to be the key parameter impacting the system cost including facility, charger, value of time, and energy. An 80% decrease in charger costs lead to 25% system cost reduction. While longer electric vehicle ranges decrease the system cost, the drop is up to a saturation point beyond which the system cost stabilizes.

2 Optimal Routing of a Mixed-Fleet of Aerial Drones for Medical Supplies: A Case Study of Blood Delivery Logistics

Tanveer Bhuiyan, The University of Texas at San Antonio, San Antonio, TX, Contact: tanveer.bhuiyan@utsa.edu

This research studies the cost and energy-efficient routing of a mixed fleet of aerial drones for medical supply logistics. The aim is to efficiently route the drone fleet while delivering time-sensitive packages within a specified time window. A novel mixed-integer programming model with several valid inequalities is presented to model the routing problem. A problem-specific heuristic algorithm is proposed for efficiently solving the problem for large problem instances. Numerical results based on actual drone flight test data and blood delivery data are presented to provide key insights into the cost and energy efficiency of aerial drone delivery under different operating conditions and business needs.

3 Community/Committee's Choice Submission

Feng Qiu, Argonne National Laboratory, Lemont, IL

4 Constrained One-to-Many K-Shortest Path with Replenishment

Amir Davatgari[1], Motahare Mohammadi[1], Taner Cokyasar[2], Abolfazl (Kouros) Mohammadian[1], [1]University of Illinois Chicago, Chicago, IL, [2]Argonne National Laboratory, Lemont, IL, Contact: adavat2@uic.edu

We have developed a method to solve the Constrained K-shortest Path (CKSP) problem with replenishment. This method determines K-shortest paths from a specified origin to all destinations while adhering to maximum travel distance constraints. Unlike existing literature, our method considers the replenishment aspect, allowing distance coverage along the paths to be renewed. In contrast to previous studies that solve the CKSP problem without constraints, sort paths by cost, and select the first K feasible paths, our method simultaneously considers constraints during shortest path computation, significantly accelerating the identification of K shortest paths. This method is applicable to the vehicle routing problem, where resource availability and replenishment are crucial factors in route planning and optimization.

5 Design of Drone-Based Last-Mile Delivery Network with Battery Swapping Stations

Wenquan Dong[1], Tanveer Bhuiyan[2], [1]Texas State University, San Marcos, TX, [2]The University of Texas at San Antonio, San Antonio, TX

This study proposes a drone delivery network design that employs Automated Battery Swapping Machines (ABSMs). The design aims to minimize long-term delivery costs, which include ABSM investment, drone ownership, battery expenses, and delivery time costs. It also determines the optimal location of ABSMs and the number of batteries required to serve a specific customer base. Each ABSM can be modeled as a semi-open queuing network and we have applied machine learning to create a closed-form formulation that represents the relationship between the waiting time of drones at an ABSM and the number of batteries, battery chargers, and charging time. The problem is modeled as a mixed-integer nonlinear program. We proposed an efficient algorithm to manage computational burdens. Numerical experiments have been conducted to provide valuable management insights.

Learning-Enabled Resilience for a Decarbonized Power Grid

Community Committee Choice Session

Session Chair: Yichen Zhang, ARGONNE NATIONAL LABORATORY, NAPERVILLE, IL

1 On Improving Resiliency of Networked Microgrids Using Federated Reinforcement Learning

Sayak Mukherjee, Pacific Northwest National Laboratory, WA

This talk will present a novel federated reinforcement learning (Fed-RL) methodology to enhance the cyber resiliency of networked microgrids. We formulate a resilient reinforcement learning (RL) training setup which (a) generates episodic trajectories injecting adversarial actions, and (b) trains the RL agents (or controllers) to alleviate the impact of the injected adversaries. To circumvent data-sharing issues and concerns for proprietary privacy we propose a novel Fed-RL algorithm to train the RL agents - a multi-agent vertically federated variation of actor-critic algorithms, namely federated soft actor-critic (FedSAC). We created a customized GridLAB-D/HELICS co-simulation platform compatible with the OpenAI Gym interface and validated using modified IEEE 123-bus benchmark test systems consisting of three coupled microgrids.

2 Physics-Informed Machine Learning for Enhancing Robustness and Verification of Neural Networks

Wenting Li, Deepjyoti Deka, Los Alamos National Laboratory, Los Alamos, NM, Contact: wenting@lanl.gov

Renewables are increasingly integrated into power grids to cater to the global energy demand. However, variable renewables, like solar and wind power, are random and intermittent, adversely perturbing the data with high uncertainty. Such perturbed data degrade the performance of machine learning for monitoring and controlling power grids. More challenges are the limited labeled data and measured nodes. We robustify neural networks against these challenges with physics-informed learning. We propose a physics-preserved graph neural network architecture for the fault location problem, and develop a robust training algorithm with physical constraints, and then provide a verification algorithm through physics-informed bound propagation. The numerical results demonstrate superior performance of our approaches over the baseline methods in various scenarios.

3 Enhancing Grid Resilience Using Policy-Based Optimal Control

Xiangyu Zhang, National Renewable Energy Laboratory, Golden, CO, Contact: xiangyu.zhang@nrel.gov

As extreme events become more frequent and larger in scale, it is increasingly important to enhance grid resilience to withstand their impact. Advanced control techniques can play a crucial role in achieving this goal. Policy-based optimal control is a promising approach that provides fast real-time response and end-to-end uncertainty management. In this presentation, we introduce two learning techniques, one model-free and one model-based, to obtain near-optimal control policies. Using a critical load restoration (CLR) problem in a distribution system as an example, we demonstrate the effectiveness of policy-based methods for grid resilience enhancement.

4 Distribution Service Restoration With Distributionally Robust Soft Actor-Critic Algorithm

Mohammad Esmaeil Khodayar[1], Seyed Saeed Fazlhashemi[1], Mahdi Khodayar[2], [1]Southern Methodist University, Dallas, TX, [2]University of Tulsa, Tulsa, OK

In this work, the service restoration of the distribution network is formulated as a multi-agent Markov decision process (MAMDP). In the proposed MAMDP, agents are repair crews in the distribution network which are responsible for repairing the faulted locations. The optimal policy for the formed MAMDP is determined using the distributionally robust multi-agent soft actor-critic (DR-MASAC) algorithm. The proposed MAMDP model and algorithm are tested on an IEEE 37-bus system. The performance of the DR-MASAC is compared with multi-agent soft actor-critic (MASAC), and multi-agent deep deterministic policy gradient (MADDPG) algorithms. It is shown that DR-MASAC is superior for improving the mean value and standard deviation of the expected reward and episode length in the training and testing phases.

5 Robust Power System Stability Assessment against Adversarial Machine Learning-based Cyberattacks via Online Purification

Tianqiao Zhao, Brookhaven National Laboratory, Upton, NY

Data-driven approaches for stability assessment (SA) have received significant research interest. However, machine learning models are recognized to be vulnerable to adversarial disturbances, where slight perturbations to power system measurements could lead to unacceptable errors. We have developed a lightweight mitigation strategy to enhance the ML-based assessment model against adversarial disturbances online. This strategy involves a supervised learning-based module for primary SA and a self-supervised learning-based module. These modules are trained jointly with different objective functions and implemented in sequence for SA applications, allowing them to adaptively tackle adversarial disturbances. The comparative results clearly illustrate the competitive and robust accuracy achieved against various online adversarial scenarios.

Optimization for Agricultural Operations and Sustainable Development

Community Committee Choice Session

Session Chair: Neng Fan, University of Arizona, Tucson, AZ

Session Chair: mahdi Mahdavimanshadi, 1</sup

1 Multistage Stochastic Optimization for Irrigation Scheduling and Planting Planning Under Drought Scenarios in Semiarid Areas

Mahdi Mahdavimanshadi, University of Arizona, Tucson, AZ, Contact: mahdimahdavi@arizona.edu

Extreme weather such as drought has posed a significant risk to the agricultural economy of the semi-arid region of the Southwestern US. To address the problem of drought in planting planning and water irrigation scheduling of guayule, a perennial woody shrub native to this region, we develop a multistage stochastic large-scale mixed-integer programming approach that considers various aspects, including deficit level for water irrigation, multi-method irrigation scheduling, shortage for unsatisfied demand, machinery cost for planting crops and crop rotation under drought scenarios in Arizona, aimed at maximizing expected farmers' NPV over a planning horizon. Due to Arizona's potential for drought scenarios, the amount of precipitation and water availability are stochastic parameters.

2 Multistage Stochastic Optimization for EV Charging Stations Considering Urban Design

Weiliang Deng, The University of Arizona, Tucson, AZ, Contact: wldeng@arizona.edu

This research proposed a comprehensive long-term planning framework for urban areas, taking the charging demand and user satisfaction into account, from the perspective of social planners. Several types of designs for charging stations, both for general and disabled individuals, are evaluated against potential charging stations. The projected number of electric vehicles (EVs) are transformed into number of charging ports. A multi-stage stochastic model for location and capacity optimization of electric vehicle charging station (EVCS) was proposed to minimize the total cost with the highest matching score. Then this model is applied to the urban area of Tucson, Arizona. An exact algorithm is designed to improve the calculation efficiency. The impacts of the distance between EVCSs and the EV charging demand rate on the planning results are also evaluated.

3 Design of a Supply Chain Network for Chemicals from Biomass Using Green Electrochemistry

Motahareh Kashanian[1], Sarah M. Ryan[2], [1]Iowa State University, Ames, IA, [2]Iowa State University, Ames, IA, Contact: motinaa@iastate.edu

Electrochemistry has emerged as a promising technology for converting biomass into specialty chemicals in distributed facilities that exploit renewable energy resources. We develop a mixed-integer linear programming model to investigate the tradeoff between cost and greenhouse gas emissions for alternative supply chain configurations. The optimal locations and capacities of manufacturing facilities balance transportation of raw materials and green energy availability against varying degrees of economies of scale for the processing steps. We explore the economic and environmental benefits of electrochemistry based on a techno-economic analysis and a U.S. case study.

4 Well-To-Tank Life Cycle Assessment of Various Energy Canes as Biomass Crops

Joaquin Haces Garcia[1], Hua Li[2], Jorge A. da Silva[3], Jamie Foster[4], Mahendra Bhandari[5], [1]Texas A&M University - Kingsville, Kingsville, TX, [2]Texas A&M University-Kingsville, Kingsville, TX, [3]Texas A&M AgriLife Research & Extension Center, Weslaco, TX, [4]Texas A&M AgriLife Research – Beeville Station, Beeville, TX, [5]Texas A&M University - Kingsville, Corpus Christi, TX, Contact: joaquin.haces-garcia@students.tamuk.edu

Energy cane is primarily harvested as a biomass crop for bioenergy. Although the growth of energy canes does not require high-input conditions, different genotypes of energy canes will produce different percentages of fibers and other chemicals in the crops, which will affect the production of biofuels. This study analyzes and compares the environmental impacts of different genotypes of energy canes using a well-to-tank Life Cycle Assessment approach, which compares the results from the end of production to utilization. Specific variables to measure environmental impacts are tested, such as global warming power, acidification, and ozone layer depletion, which will help to identify the best genotype to minimize environmental impacts.

5 A Study of Barriers and Challenges Associated with Agriculture E-Commerce in Afghanistan

Khwaja Bahman Qaderi[1], Noorullah Rafiqee[1], Milad Musadiq[2], [1]Central South University, Changsha, China; [2]Lovely Professional University, Punjab, India

This study examines the scope of e-commerce in Afghanistan's agriculture enterprises, how they harness the potential of internet users, and what obstacles they face in implementing e-commerce in their businesses. The study distributed a 39-question questionnaire to agribusinesses in five different zones of Afghanistan. After extracting the responses 280 were included in the analysis step to perform a non-parametric sign test. E-commerce in Afghanistan faces four major political, economic, Internet, and technological obstacles and no company in the country has implemented e-commerce. This study contributes to knowing the challenges and barriers that agriculture e-commerce faces in Afghanistan to find effective solutions to use the capacity of internet users in the country and increase the sales rate of agricultural products through the Internet.

Optimization Modeling Software II

Community Committee Choice Session

Session Chair: Susanne Heipcke, 1</sup

Session Chair: Robert Fourer, 1</sup

1 Advances in Model-Based Optimization with Ampl

Filipe Brandão, AMPL Optimization Inc., Mountain View, CA

The ideal of model-based optimization is to describe your problem the way you think about it, and then let the computer do the work of getting a solution. Recent enhancements aim to bring the AMPL modeling language and system closer to this ideal. Using a variety of modeling language extensions, common formulations are described more naturally, with the AMPL translator, the AMPL-solver interface, or the solver itself doing most of the needed transformations. Extensions described in this presentation include quadratic expressions, logical operators and constraints, simple near-linear and nonlinear functions, and combinations of these together with linear terms. All are supported by a new C++ AMPL-solver interface library that can be adapted to handle the multiple detection and transformation strategies required by large-scale solvers.

2 Jump: Recent Improvements to a Modeling Language for Mathematical Optimization

Oscar Dowson, JuMP

JuMP is an algebraic modeling language for mathematical optimization. JuMP makes it easy to formulate and solve a range of problem classes, including linear programs, mixed-integer programs, conic programs, semidefinite programs, and constrained nonlinear programs.

In this talk we briefly discuss recent changes to JuMP, including our 1.0 release, support for multi-objective optimization, improved documentation, and our on-going work to improve support for nonlinear programs.

3 Convenient Business Impact Demonstration of Operations Research Applications with Xpress Insight

Alexander Biele, FICO, Xpress Optimization, Germany

Many Operations Research (OR) applications suffer from not being able to quickly show the business impact. This reduces the number of deployed OR applications and their general acceptance in production environments. Most of the development time is spent on developing optimization models, tuning their parameters, and finessing textual output into slides for an appealing presentation. Demonstrating business impact of different scenarios displayed in attractive user interfaces in an automated way is out of reach. We will demonstrate how to reduce the development time, from model implementation, scenario analysis and closing the feedback loop with business users with FICO Xpress Insight with Python examples.

4 Optimization Modeling Software from Lindo Systems

Linus E. Schrage, LINDO Systems, Inc., Chicago, IL

We describe the latest enhancements to: 1) LINDO API, the solver engine, 2) What's*Best*!, the Excel add-in optimizer, and 3) LINGO, the algebraic modeling language. Some of the new features are: LINDO API: substantial improvements to the Global solver, especially linearization, and support for more external solvers. What's*Best*!: Smart support for more Excel functions, especially in large spreadsheets, plus, a new Black Box solver supporting all Excel functions. LINGO: Enhanced editor allowing split windows, auto-completion, and improved performance on large files/models.. We also discuss the extensive Models Library available to help users get started solving a variety of model types such as cutting stock, scheduling, financial models, and more.

Innovations in Sharing Economy

Contributed Session

Session Chair: Anuj Kapoor, Indian Institute of

Management Ahmedabad, Ahmedabad, India

1 Platform Leakage: Incentive Conflicts in Two-Sided Markets

Yingkang Xie[1], Huaiyu Zhu[2], [1]Washington University in St. Louis, St. Louis, MO, [2]Lalamove, Beijing, China. Contact: yingkang.xie@gmail.com

Leakage happens when buyers and sellers coordinate outside the platform to avoid paying fees. Using GPS data in cargo delivery, we identify offline transactions that are typically hard to track in on-demand service platform. We exploit a quasi-experiment that gradually introduced driver commissions, thereby generating variation in participants' incentives for leakage. A 15% commission increased leakage by nearly 4 percentage points, doubling the offline transactions we detected. We leverage this variation to estimate price sensitivities and transaction costs. The likelihood of leakage increases as the quoted price of the delivery increases, as the drivers' potential savings in the commission exceed the offline hassle costs. Customers typically receive half of the commission savings from drivers. We discuss ways to mitigate leakage by better aligning incentives.

2 Unraveling the Sanctions Regime: Exploring the Achilles Heel of Mnc'S Strategies

Mehdi Rasouli Ghahroudi[1], P.V. (Sundar) Balakrishnan[2], Yasuo Hoshino[3], [1]University of Washington, Bothell, WA, [2]University of Washington, Bothell, WA, [3]University of Tsukuba, Tsukuba, Japan

We investigate how sanctions impact strategic choices of MNCs in sanctioned markets. The study utilizes longitudinal data on Japanese MNCs operating in four sanctioned countries and employs various regression techniques. Integrating multiple theories, our findings suggest that market-seeking subsidiaries opt for divestment or shrinking, while resource-seeking subsidiaries prefer stability. It also considers the role of expatriate managers and employees in decision-making under sanctions. Moreover, the presence of subsidiary dynamic capabilities enhances their ability to withstand the turbulent environment until the lifting of sanctions. Our research enhances understanding of MNCs' strategic decision-making, providing valuable insights for practitioners.

3 Value of Notifications and Information Obfuscation Experimental Evidence from a Hyper Local News Platform

Anuj Kapoor, IIMA, Ahmedabad, India. Contact: anujk@iima.ac.in

Platforms deploy information notifications that influence consumer behavior. As an information design strategy, either the firm can be transparent and convey the true value of the notification to the user or can obfuscate the notifications (especially for low-value news items). We design and implement field experiments on a hyperlocal news platform that sends notifications for low-value as well as high-value (localized) news information to the users. Across two experiments, we randomize 8479 users in four Asian districts into the two types of notification cohorts for about 2458 unique news items. Within the obfuscated group, we vary the obfuscation of the type of notifications i.e. either low-value information or high-value information, or both. We find that obfuscation increases time spent on the app by 13.51 %, holding fixed all other attributes of the notification.

Solutions to Build Climate Resiliency

Contributed Session

Session Chair: Lamis Amer, University of Miami, MIAMI, FL

1 Optimal Energy Management of Networked Energy Hubs in Coastal Cities to Improve Power System Resiliency During Natural Disasters

Md. Monirul Islam, Delia Rosales, Texas A&M University-Kingsville, Kingsville, TX, Contact: md.monirul.islam@tamuk.edu

Smart power system is a crucial building block of a smart city. The key challenges faced by smart power systems are to achieve cost-effectiveness, zero carbon emission, and resiliency. The challenges become further intensified for the coastal cities due to the requirement of achieving additional capabilities to combat extreme natural events while meeting the higher energy demand for the industrial belt around the cities and managing different energy-intensive processes unlike from the islands. Optimally designing and controlling the energy hub network can be a promising solution to address the challenges and enhance the robustness of the power system during natural disasters. A mathematical model is developed for optimal energy management strategies of the network to improve the preparedness and resiliency of the system before approaching disasters.

2 Driving the Residential Heating Transition - Policy Assessment Considering Parametric Uncertainty and Near-Optimal Solutions

Linda Brodnicke, Paolo Gabrielli, Albane Sérès, Giovanni Sansavini, ETH Zurich, Zurich, Switzerland. Contact: lbrodnicke@ethz.ch

Residential heating electrification via heat pumps will be key to achieving climate targets and moving away from fossil-based heating supply. Our study assesses the impact of policies, namely a carbon tax and a heat pump rebate, on residential heating electrification. To do so, we determine the cost-optimal design and operation of residential multi-energy systems for different policy levels and emissions targets. The analysis accounts for i) parametric uncertainty and ii) uncertainty related to human decision-making by i) performing sensitivity analysis and ii) assessing the near-optimal feasible solution space. Results suggest that introducing policies increases the robustness of the transition to highly electrified low-carbon heating.

3 Future-Proofing Septic Systems to Sea-Level Rise: An Optimization Approach for Adaptation Planning

Lamis Amer[1], Murat Erkoc[2], [1]University of Miami, MIAMI, FL, [2]University of Miami, Coral Gables, FL, Contact: lxa659@miami.edu

This study examines the adaptation of septic systems to sea-level rise risks. A mixed-integer linear programming model is developed with the objectives of minimizing total adaptation costs and maximizing the resilience of wastewater disposal and treatment systems. The proposed adaptation strategies include connecting to existing sewer network, constructing new clusters of micro sewer networks, and building mound systems. The proposed model is applied to actual data obtained from Miami-Dade County to provide optimal decisions regarding the adaptation of septic systems and the expansion of pump station capacity in a real-life setting. The results demonstrate the relevance of the model in comparison to the county's adaptation plans.

Best Paper Award

Award Session

Session Chair: Alessandro Hill, California Polytechnic State University, San Luis Obispo, CA

1 Network Migration Problem: A Hybrid Logic-Based Benders Decomposition Approach

Maryam Daryalal[1], Hamed Pouya[2], Marc-Antoine De Santis[3], [1]HEC Montreal, Montreal, QC, Canada; [2]Ciena Canada, Inc., Ottawa, ON, Canada; [3]Ciena Canada, Inc., Montreal, QC, Canada

Telecommunication networks frequently face technological advancements and need to upgrade their infrastructure. Adapting legacy networks to the latest technology requires synchronized technicians responsible for migrating the equipment. The goal of the network migration problem is to find an optimal plan for this process. This is a defining step in the customer acquisition of telecommunications service suppliers, and its outcome directly impacts the network owners' purchasing behaviour. We propose the first exact method for the network migration problem, a logic-based Benders decomposition approach that benefits from a hybrid constraint programming-based column generation in its master problem and a constraint programming model in its subproblem. This integrated solution technique is applicable to any integer programming problem with similar structure, most notably the vehicle routing problem with node synchronization constraints. Comprehensive evaluation of our method over instances based on six real networks demonstrates the computational efficiency of the algorithm in obtaining quality solutions. We also show the merit of each incorporated optimization paradigm in achieving this performance.

2 Rapid Influence Maximization on Social Networks: The Positive Influence Dominating Set Problem

Rui Zhang[1], S. Raghavan[2], [1]University of Colorado Boulder, Boulder, CO, [2]University of Maryland-College Park, College Park, MD

Motivated by applications arising on social networks, we study a generalization of the celebrated dominating set problem called the Positive Influence Dominating Set (PIDS). First, we propose a strong and compact extended formulation for the PIDS problem. We then project the extended formulation onto the space of the natural node-selection variables to obtain an equivalent formulation with an exponential number of valid inequalities. Restricting our attention to trees, we show that the extended formulation is the strongest possible one. We derive the necessary and sufficient facet-defining conditions for the valid inequalities and discuss a polynomial time separation. We embed this (exponential size) formulation in a branch-and-

cut framework and conduct experiments using real-world graph instances, with up to approximately 2.5 million nodes and 8 million edges.

3 Fixed Set Search Applied to the Clique Partitioning Problem

Stefan Voß[1], Raka Jovanovic[2], Antonio P. Sanfilippo[3], [1]University of Hamburg, Hamburg, Germany; [2]Hamad bin Khalifa University, Doha, Qatar; [3]Hamad bin Khalifa University, Doha, Qatar

The Clique Partitioning Problem (CPP) seeks to decompose a set of vertices into disjoint subsets (cliques) maximizing the sum of edge weights over all cliques. The interest for the CPP comes from the fact that it represents well many practical problems from areas like data mining, engineering, etc. To address this NP-hard problem, the novel fixed set search (FSS) metaheuristic is applied. For this, firstly, we develop a GRASP using a new type of neighborhood in the local search. The GRASP is further extended to the FSS by adding a learning mechanism. The FSS application to the CPP provides a new approach for generating fixed sets for problems with solution symmetries. This opens the application of the FSS to new families of combinatorial optimization problems. The conducted computational experiments show that the FSS significantly outperforms state-of-the-art metaheuristics for the CPP.

4 Design of 5G MEC-based Networks with 1:N:K Protection Scheme

Hernani Chantre, State University of Campinas, Campinas, Brazil

With the advent of 5G networks, telecommunications InP have faced numerous challenges as they attempt to meet the stringent quality of service requirements. The placement of applications at the edgeof the mobile network in MEC and slicing techniques have provided powerful tools to enable networks to support these requirements. This paper studies the problem of locating MECs and slices in a 5G infrastructure protected by a 1:N:K protection scheme. The aim is to supporthigh reliability and low latency requirements at a minimum cost. A bi-objective non-linear formulation is proposed, and a solution is derived by employing the non-dominated sorting genetic algorithm (NSGA-II). Results show that the enhanced 1:N:K scheme is cost-effective. The proposal is evaluated on the basis of various levels of reliability, latency requirements, and probabilityof failure.

Analytics and AI for Agriculture and Food Security

Contributed Session

Session Chair: Shanjukta Nath, University of Georgia, Athens, GA

1 Decision Support Tool for EONR Combing Crop Simulation and Ml Model

Saiara Samira Sajid[1], Baum Mitchell[2], Sotirios Archontoulis[2], Guiping Hu[1], [1]Iowa State University, Ames, IA, [2]Iowa State University, Ames, IA, Contact: sajids@iastate.edu

Knowledge of the economic optimum nitrogen rate (EONR) in farm management is crucial and can help improve nitrogen efficiency while reducing environmental impact. It is challenging to determine EONR since it varies based on site location, management practice, weather, and soil properties. Furthermore, the data availability is limited to building a machine-learning (ML) model to determine EONR. We propose a decision support tool to determine EONR, where the ML models are trained on crop models (APSIM) simulation outputs and historical weather data. The simulation outputs were generated with varying management, weather, and genotype properties to have robust data. We build a random forest multi-target regression (RFMTR) model to predict yield and EONR for a specific location. The model was evaluated for 2020 with an RRMSE of 11.88% and 22.55%, respectively.

2 Crop Detection Using Deep Learning with Satellite Images

Daisy Zhuo[1], Jack Dunn[2], Luca Mingardi[3], [1]Interpretable AI, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, [3]Interpretable AI LLC, Cambridge, MA

Remote sensing technologies have enabled large-scale monitoring of land use. Classification of crop types is one of the most important applications, as it can inform the agricultural and economic planning at a country level. We have launched an initiative in Africa to collect in-ground labels with GPS locations, and have used this data to build machine learning models that predict crop types from satellite images. We have used a suite of deep learning models including 3D CNNs, GRU-CNNs, and transformers to extract features from both temporal and spatial aspects of the images. We show how we handled the unique challenges in Africa where the fields are smaller and most days are cloudy. The model achieves high accuracy in Senegal, Kenya, Nigeria, and other regions.

3 Field Delineation and AI for Food Security in Africa

Luca Mingardi, Interpretable AI LLC, Cambridge, MA, Contact: luca@interpretable.ai

One of the key challenges in agriculture is to accurately identify arable land, to enable farmers to optimize their resources and maximize their yields. This is especially important in less developed countries like Africa, where a growing population and climate change threaten food security. In our work, we created a framework to leverage satellite images to accurately identify cropland. The characteristics of African fields vary significantly from those of more developed countries like France, which provide publicly available field data. For example, varying field size, crop type and clouds are among the biggest challenges to achieve a strong model performance. To address these issues, we developed custom image segmentation models to identify field boundaries using deep learning and achieved competitive performance.

4 Optimization of National Grain Imports to Balance Risk and Return: A Portfolio Theory Approach

Deniz Berfin Karakoc, Megan Konar, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: denizberfinkarakoc@gmail.com

Global grain trade plays a key role in food security, as many nations rely on imported grain to meet their dietary requirements. Grain imports may be at risk due to economic crises or international conflicts, and countries aim to balance the import risk with the expected return of their grain supplies. Here, we use Markowitz mean-variance optimization model for identifying opportunities to reduce risk in existing national grain import accounts without increasing cost under supply mass constraint of trade partners. Several major grain importers may reduce risk in their grain imports without increasing cost, such as wheat imports in Egypt, maize imports in Vietnam, and rice imports in Saudi Arabia. However, some countries may have to pay more for more stable grain supplies, such as wheat imports in Turkey. This study can inform future policy and decision-making in grain-trade.

5 Convenience, Personalization, and Engagement in an Agricultural Advisory Service

Shanjukta Nath[1], Susan Athey[2], Shawn Cole[3], Jessica Zhu[4], [1]University of Georgia, Athens, GA, [2]Stanford University, Stanford, CA, [3]Harvard University, Boston, MA, [4]Precision development, Newton, MA

Automated systems have been used to deliver information in areas such as public health, education, and agriculture. Automated delivery enables users to consume information at a convenient time and place. We examine whether personalizing timing of information delivery in an agricultural advisory service can lead to higher user engagement. We develop, implement, and evaluate a personalized recommendation system that customizes contact times to user characteristics. We find scope for significant gains from personalized recommendation in terms of farmers' propensity to pick-up calls, estimating an 8% increase over the baseline pick-up. We address several challenges to implementing customized policies in developing country settings, such as bandwidth constraints, equity-efficiency concerns and how technology or preference shocks affect performance of policies.

Community Committee Choice Session

Session Chair: Birsen Karpak, Youngstown State University, Canfield, OH

Session Chair: Ilker Topcu, Istanbul Technical University, Istanbul, Turkey

1 Application of the Analytic Hierarchy Process to Evaluate the Impact and Effectiveness of School Safety Approaches

Luis G. Vargas[1], Marcel C. Minutolo[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]Robert Morris University, Moon Township, PA, Contact: minutolo@rmu.edu

We put forth a model to evaluate the effectiveness of school safety approaches. The model uses the Analytic Hierarchy Process (AHP) to measure the risk associated with school safety hazards. Risk measurement uses three components, probability, severity, and manageability. The risk measurement model requires the involvement of experts and the community at large. Once developed, a web-based application specific to school districts can evaluate the programs developed to address the hazards to ameliorate the risks identified. The results are: a model to measure the risk of school safety hazards; a web-based application to collect information about how schools deal with safety hazards, that will create a knowledge base of effective policies; and, a systematic process for evaluating exiting programs used to deal with school safety hazards.

2 Determination of Forest Risk Maps and Planning of Preventive Measures

Zuhal Ozcan Yavuz[1], Özgür Kabak[2], Inci Yaylaci Caglayan[3], [1]Istanbul Technical University, Sariyer, Turkey; [2]Istanbul Technical University, Istanbul, Turkey; [3]Istanbul University, Sariyer, Turkey. Contact: zuhalozcan.09@gmail.com

This project endeavors to pioneer a novel approach to wildfire risk mapping and introduce a probabilistic optimization model for resource allocation, integrating risk maps and various situational conditions. We will initiate our work by conducting comprehensive literature reviews, followed by critical analysis of specific criteria. Based on these insights, we'll integrate climate, topography, and land cover data to generate risk maps via Analytic Hierarchy Process (AHP) and Ordered Weighted Averaging (OWA). Utilizing multi-criteria decision-making strategies, we'll optimize the distribution of first responder resources, including fire brigade, artificial pools, and aerial vehicles, through the cluster coverage method.

3 Impact of Digital Technologies on Supply Chain Resilience

Birsen Karpak[1], Gurkan I. Akalin[2], Ilker Topcu[3], [1]Youngstown State University, Canfield, OH, [2]Eastern Illinoius University, Charleston, IL, [3]Istanbul Technical University, Istanbul, Turkey. Contact: bkarpak@ysu.edu

The study explores the link between supply chain resilience and supply chain digitalization. Supply chain digitalization provides several benefits that directly contribute to the development of supply chain resilience capabilities. Digital technologies enhance visibility, support better anticipation of potential disruptions, facilitate collaboration, and enable agility and flexibility within supply chains. Considering the interactions among digital technologies as well as supply chain resilience capabilities, Analytic Network Process is used as a methodology and digital technologies influencing supply chain capabilities are prioritized. Supply chain managers should consider adopting digital technologies and leveraging their capabilities to develop resilient supply chains.

Disaster Management & Humanitarian Logistics

Community Committee Choice Session

Session Chair: Luke Muggy, 1</sup

Session Chair: Mahyar Eftekhar, New York, NY

1 Facilitating Coordination in Multi-Objective, Multi-Stakeholder Humanitarian Operations

Ayesha Farooq, Jessica Heier Stamm, Kansas State University, Manhattan, KS, Contact: ayeshafarooq@k-state.edu

Humanitarian contexts are characterized by many independent decision makers who each act based on multiple criteria. Coordination among such entities can lead to more efficient and effective operations, yet existing models do not fully capture these features. Most optimization frameworks assume a single decision maker, while game theory approaches assume each decision maker has a single objective. We integrate cooperative game theory and optimization to identify ways to facilitate coordination in multi-objective, multi-stakeholder settings. We analyze player behavior and system outcomes under several policies for allocating system-wide costs and benefits, providing insight to support improved humanitarian operations.

2 Enhancing Transportation Network Resiliency: Pre-Event Disaster Mitigation Interventions

Ahmad Ghasemkhani, University of Oklahoma, Norman, OK, Contact: a.ghasemkhani@ou.edu

Transportation network resiliency means a system's ability to recover from disruptive events like natural disasters. It's crucial to maintain mobility and access to critical services. Pre-event disaster mitigation interventions, structural retrofits, and data-driven approaches can enhance network resiliency. Ranking infrastructure components by criticality help prioritize interventions. Overall, transportation network resiliency is vital for community safety during times of crisis.

3 Developing Decision Support System in Disaster Management

Baba Nasiru Lawal[1], Joon-Yeoul Oh[2], David Hicks[3], [1]Texas A&M University-Kingsville, Kingsville, TX, [2]Texas A&M University-Kingsville, Kingsville, TX, [3]Texas A&M University-Kingsville, Kingsville, TX, Contact: kfjo000@tamuk.edu

The challenges for the resilience of the social infrastructure damages after a disaster are often associated with the effective coordination of resources with real time information. The decision support system in disaster management requires the resources coordination for emergency preparedness, responses, and resilience. The objective of this research is to propose an effective yet efficient decision support system to improve allocation of the necessary resources for recovering the damaged infrastructure in a timely manner. The proposed system integrates the damage assessment and geological data to enable real time analysis.

Supply Chain Scheduling and Optimization

Community Committee Choice Session

Session Chair: Zhi-Long Chen, University of Maryland, MD

1 Service Costs in Assortment Projects

George Vairaktarakis, Case Western Reserve University, Cleveland, OH

When nursing home patients visit a hospital for routine or post-acute care, they experience wait in service that strain both the hospital and these vulnerable patients. Given a set R of distinct resources (e.g., medical specialties) serving an assortment of tasks in a project (i.e., all the patients of a nursing home) the problem is to minimize the total service cost over all projects. In this article we present an exhaustive list of optimality conditions that govern optimal solutions for any given number |R| of resources, develop two different - but related - fully polynomial-time approximation schemes (FPTAS) for |R| = 2, and amplify their use to generate near-optimal solutions for any fixed |R|. In particular, for up to four resources our FPTAS yields a less than 3/2-approximation.

2 Usage-Based Lease Contract for Service-Oriented Supply Chain Under Stochastic Demand: A Stackelberg Game Model

Ting Zhao[1], Zhi-Long Chen[2], Xinbao Liu[1], [1]Hefei University of Technology, Hefei, China; [2]University of Maryland, College Park, MD, Contact: tingzhao@umd.edu

We propose a Stackelberg game model for optimizing usage-based lease contracts in a service-oriented supply chain subject to stochastic demand. In such contracts, the operator pays a fixed rental plus a charge per unit of output to the manufacturer, while the manufacturer provides maintenance services during the lease period. The demand uncertainty poses challenges for both the manufacturer and operator to optimize their net profits. In our proposed model, the manufacturer acts as the leader and determines maintenance policy under uncertain demand, then the operator acts as the follower and decides the optimal production rate after knowing the actual demand. By solving this game model, we obtain new insights into the design of optimal production and maintenance policy in the lease contract.

3 Survey of Online Integrated Production and Distribution Scheduling

Zhi-Long Chen, University of Maryland, College Park, MD

We give several real-world applications of online integrated production and distribution scheduling problems. We then review the existing literature on online IPDS problems with a focus on existing online algorithms for these problems and their theoretical performance. We also derive some new results to fill several gaps left in the literature, and discuss possible topics for future research.

Innovations in Service Operations

Community Committee Choice Session

Session Chair: Yueyang Zhong, The University of Chicago Booth School of Business, Chicago, IL

Session Chair: Neha Sharma, Kellogg School of Management, Evanston, IL

1 Algorithmic Interventions to Prevent Burnout in Icu Workforces

Ken Moon, The Wharton School, Philadelphia, PA, Contact: kenmoon@wharton.upenn.edu

In recent decades, hospitals have pursued operational efficiency at the expense of increasing on-the-job stress for their intensive care nursing staff. The resultingly “quicker and sicker” workflows lead to elevated rates of provider turnover and burnout. In collaboration with the University of Pennsylvania hospital system, we equipped the nurses staffing three highly sophisticated ICUs with biometric sensors during their shifts. We design and train learning algorithms to identify exceptionally stressful workflows and intervene based on data in near real-time.

2 Consumer Responses to Time Limits in Discretionary Services

Michelle A. Shell[1], Pnina Feldman[2], Ella Segev[3], [1]Dartmouth Tuck School of Business, Hanover, NH, [2]Boston University, Boston, MA, [3]Ben-Gurion University of the Negev, Beer Sheva, Israel

Service providers often request that customers limit their consumption of experiential goods - particularly during periods of congestion. This research seeks to shed light on trade-offs between customer satisfaction, desired operational efficiencies, and general welfare by improving our understanding of how customers respond to voluntary time limits in discretionary service environments.

3 Heterogeneous Treatment Effects Under Marketplace Interference

Arthur J. Delarue[1], Kleanthis Karakolios[2], [1]H. Milton Stewart School of Industrial and Systems Engineering at Georgia Tech, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: kleanthis@gatech.edu

Treatment effect estimators in two-sided marketplace experimentation are typically biased due to interference. We build a simple general model of a two-sided matching marketplace and propose an improved treatment effect estimator by leveraging linear programming duality, as well as scaling techniques, to develop upper and lower bounds for the treatment effect. We discuss also the estimation of heterogeneous treatment effects in marketplaces. We show that in the presence of interference, such heterogeneous treatment effects are not unique, and it is not clear which to estimate. This estimation failure suggests an optimization approach, in which the outcome of the experiment is used not to estimate treatment effects but to decide which types should be offered treatment.

4 Group-Sparse Matrix Factorization for Transfer Learning of Word Embeddings

Kan Xu[1], Xuanyi Zhao[1], Hamsa Sridhar Bastani[2], Osbert Bastani[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Wharton School, Philadelphia, PA, [3]University of Pennsylvania, Shenzhen, China. Contact: kanxu@sas.upenn.edu

Unstructured text provides decision-makers with rich data source in many domains. To leverage this information, words are typically translated into word embeddings through unsupervised learning algorithms such as matrix factorization. However, learning embeddings from new domains with limited training data can be challenging, because the meaning may be different in the new domain, e.g., the word "positive" in medical notes. Intuitively, we expect that only a small number of domain-specific words have new meanings. We propose a two-stage estimator that exploits this structure via a group-sparse penalty to transfer learn domain-specific embeddings by combining large-scale text corpora (such as Wikipedia) with limited domain text data. We prove that it can achieve the same accuracy (compared to not transfer learning) with substantially less domain data.

Analytics in social networks

Contributed Session

Session Chair: Marcel Goic, University of Chile / Instituo de Sistemas Complejos de Ingeniería, Santiago, Chile

1 The Bidirectional Relationship Between Social Networking Site use and Depression - Exploring the Impact of Usage Patterns and Active vs. Passive Engagement

Chinju Paul[1], Minsek Ko[2], [1]Mississippi State University, Mississippi State, MS, [2]Iowa State University, Ames, IA, Contact: cp2041@msstate.edu

This study examines the complex relationship between the use of social networking sites (SNS) and depression. Drawing on the reflective-impulsive model and the cognitive theory of depression, we explain the circular cause-and-effect relationship. We also explore the impact of SNS use patterns and user engagement on the relationship. Based on three cross-sectional and one longitudinal national survey datasets, we found a positive bidirectional relationship between the frequency of SNS use and depression. This relationship follows a U-shaped pattern, suggesting that individuals who are heavy users or abstain from SNS may experience greater levels of depression than moderate users. Moreover, we found that passive SNS use (e.g., watch videos via SNS) may exacerbate depression, while active use (e.g., participate in current events via SNS) does not have the same effect.

2 The Web's Great Conversation: Unveiling the Secrets of Chat-Based Search Engines

Lijia Ma, Xingchen Xu, Yong Tan, University of Washington,

Seattle, WA, Contact: lijiam@uw.edu
This study examines the selection criteria differences between chat-based search engines and their traditional counterparts, using a unique dataset compiled from queries on New Bing. The analysis focuses on the responses generated by Bing Chat and reveals a tendency to select mainstream websites for nucleus sentences and niche websites for elaboration parts, suggesting an inclination towards diverse content. However, further analyses show that Bing Chat favors specific linguistic styles, such as greater objectivity, and that the selected niche websites exhibit considerable similarity, limiting the diversity of information available to users. The findings have implications for both users and website owners and highlight the need for further research on chat-based search engines to ensure the provision of accurate and varied content.

3 Managing Influencer-Brand Collaboration: A Multitask Learning Model for Influencer Selection
Magie Cheng, Harvard Business School, Boston, MA, Contact: macheng@hbs.edu

4 Estimating Policy Effects In A Social Network With Independent Set Sampling
Eugene Ang[1], Prasanta Bhattacharya[2], Andrew E.B. Lim[3], [1]National University of Singapore, Singapore, Singapore; [2]Agency for Science, Technology and Research (A*STAR), Singapore, Singapore; [3]National University of Singapore, Singapore, Singapore. Contact: eugene.ang@u.nus.edu
Evaluating the impact of policy interventions on respondents in a social network is challenging due to the presence of network interference. We propose a strategy that combines existing work on stochastic actor-oriented models with a novel network sampling method based on the identification of independent sets. Through this sampling method, we can block any direct spillover of the treatment, thereby allowing us to isolate the direct treatment effect from the indirect network-induced effects. Thus, our method allows for the estimation of both the direct and net effect of the policy intervention, in the presence of network interference. We show that our proposed technique leads to smaller and distinct estimates for both direct and net effects of the policy, and larger and significant estimates for the relevant network effects, such as homophily.

5 Assessing the Complementary Role of Firm and Friend Recommendations in Mobile Environments
Marcel Goic[1], Jose A. Guajardo[2], Liye Ma[3], [1]University of Chile / Instituto de Sistemas Complejos de Ingeniería, Santiago, Chile; [2]University of California-Berkeley, Berkeley, CA, [3]University of Maryland, College Park, MD, Contact: mgoic@dii.uchile.cl
We investigate the effectiveness of recommendations from friends and firms, and we analyze how they interact in affecting the conversion of mobile promotions. For friend recommendations, we propose an identification approach to separate the underlying *selection* and direct *influence* effects, while controlling for *homophily*. Using a unique dataset from a mobile platform that sends geo-targeted coupons to customers and allows them to recommend to friends, we show that geo-targeting makes a consumer more likely to consider an offer, and friends' recommendations increase conversions. When disentangling the mechanisms driving the effects of friend recommendations, we found that they are mostly attributed to the selection effect and that the effect is enhanced when recommenders are more selective and have stronger ties with the recipients.

1 Early Patent Disclosure and Radical Innovation
Xiaojie Wang[1], Huijun Chen[2], Ying-Ju Chen[3], [1]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]HKUST, Hong Kong, Hong Kong; [3]The Hong Kong University of Science and Technology, Kowloon, Hong Kong. Contact: xwangdx@connect.ust.hk
How does the early publication of patents affect radical innovation? We investigate the question by exploiting a large-scale national experiment, the passage of the American Inventor's Protection Act (AIPA), which accelerates the publication by two years. We develop a novel measurement of radical innovation and focus on the heterogeneous impacts of firm size. We look into the questions using both traditional fixed effects regressions and debiased /double machine learning method where we can tease out selection bias in a more flexible way.

2 The First-Mile Problem in the Reverse Supply Chain of E-Waste
Yunke Mai, Haoying Sun, University of Kentucky, Lexington, KY, Contact: yunke.mai@uky.edu

In this paper, we study the first-mile problem in the reverse supply chain of e-waste recycling using an evolutionary game theory framework. Our analysis establishes that utilizing existing retail channels could be generally effective, but such an approach could also have ambiguous effects that regulators need to be aware of.

3 Platform Transformation Risk and the Role of Hosting Rivals

Shiva Shekhar[1], Sarvesh Bandhu[2], Marshall Van Alstyne[3], [1]Tilburg University, Tilburg, Netherlands; [2]Indian Institute of Management Bangalore, Bangalore, India; [3]Boston University, Boston, MA, Contact: S.Shekhar_1@tilburguniversity.edu

We study the decision of traditional firms to transform into digital platforms. While digital transformation enhances value through externalizing value creation, it also entails investment risk. When transformation risks are low or network effects due to transformation are very valuable, platform transformation is profitable. Interestingly, when firms choose to transform, we show that inviting rivals onto the platform can raise profits in certain cases. Apart from the benefits associated with aggregation, inviting rivals onto a proprietary platform also lowers the rival's competitive aggressiveness. This is a novel strategic rationale for inviting rivals on to the platform elicited in this paper. We provide clear managerial and policy implications from these results and use real world examples to illustrate our theory.

4 The Impact of Dual Conceptualizations of Brand Equity on Radical Product Launch Strategy

Junghee Lee[1], Mallapragada Girish[2], Mitchell Olsen[1], Daewon Sun[1], Dennis Z. Yu[3], [1]University of Notre Dame, Notre Dame, IN, [2]Indiana University, Bloomington, IN, [3]Clarkson University, Potsdam, NY, Contact: jlee93@nd.edu

We consider the follower's new product launching strategy with incorporating two different types of consumers' perception of the firm's brand equity: 1) Absolute and 2) proportional brand equity. We develop the follower's decisions about whether and when to launch a radical innovation given the dual conceptualizations of brand equity and relative product quality. The results show that the follower should more strongly consider launching the radical product and risking failure if consumers perceive brand equity absolutely, rather than proportionally. The paper provides nuanced insights into the way consumers' brand equity perceptions interact with product and market conditions to affect the firm's optimal product launch strategies.

Robust Artificial Intelligence and Applications

Community Committee Choice Session

Session Chair: Seoung Bum Bum Kim, Korea University, Seoul, Korea, Republic of

1 Unsupervised Multi-Modal and Multi-Domain Learning for Structural Robust Stain Normalization

Minjung Kang[1], Jiyeon Kang[1], Jeeyoung Park[2], Heounjeong Go[3], Sangmin Lee[1], [1]Kwangwoon University, Seoul, Korea, Republic of; [2]Kyungpook National University School of Medicine, Seoul, Korea, Republic of; [3]Asan Medical Center, University of Ulsan College of Medicine, Seoul, Korea, Republic of. Contact: smlee5679@gmail.com

We propose an unsupervised multi-modal and multi-domain learning with structure preserving adversarial networks for histopathology. Recently, histopathology has been recognized as the gold standard for identifying cancerous tissues. Stain normalization is a processing task for fast and accurate pathology diagnosis. However, structure preserving stain normalization remains a challenge. We propose a L1-norm regularized multimodal learning with two grayscaled images of Hematoxylin and eosin-stained tissues. This study aims to obtain structural consistency to prevent inter- and intra-sacnner variations. The proposed technique was demonstrated to have superior performance quantitatively and qualitatively compared to competing algorithms through comparative experiments.

2 Noisy Label Filtering for Class Imbalanced Datasets

Sanghoon Kim, Seoung Bum Kim, Korea University, Seoul, Korea, Republic of. Contact: dawonksh@korea.ac.kr

Label noise learning is crucial for maintaining the robust performance of deep neural networks. Recent research has primarily relied on training loss-based filtering methods to separate clean and noisy samples. However, these methods face difficulties in effectively filtering noisy label in class-imbalanced data due to the use of uniform filtering rules across all classes. To overcome this limitation, we propose a methodology specifically designed for noisy label filtering in class-imbalanced scenarios. Our approach leverages class-specific training loss values to accurately identify clean

samples. Extensive experiments conducted on benchmark datasets demonstrate the effectiveness of our methodology in addressing class imbalance.

3 Improving Calibration of Deep Learning Models Through Efficient Confidence Alignment and Temperature Scaling

Jinsoo Bae, Seoung Bum Kim, Korea University, Seoul, Korea, Republic of. Contact: wlstn215@korea.ac.kr

Addressing overconfidence issues in deep neural networks is crucial for reliable confidence scores, especially in real-world applications. Various calibration methods have been developed to address overconfidence issues. However, these calibration methods fail to consider the model's accuracy, which makes it challenging to determine the appropriate degree of calibration. To overcome these limitations, we propose an efficient confidence alignment and temperature scaling method that regulates the network output distribution to an accuracy-aware confidence distribution. We demonstrate the effectiveness of our proposed method through experimental results on the CIFAR-10, CIFAR-100, and SVHN datasets, showing improved calibration.

4 Noise-Robust Graph-Based Semi-Supervised Learning with Dynamic Shaving Label Propagation

Jiyoon Lee[1], Younghoon Kim[2], Seoung Bum Kim[1], [1]Korea University, Seoul, Korea, Republic of; [2]Kyung Hee University, Yongin, Korea, Republic of. Contact: y.kim@khu.ac.kr

Graph-based semi-supervised classification is popular due to its effective use of unlabeled data. Current methods, however, overlook inherent data noise, compromising overall performance. To address this, we introduce a noise-robust model, the Dynamic Shaving Label Propagation Algorithm, with three components: graph construction, noise identification and removal, and label propagation. The graph construction phase determines *k* at the point where reverse nearest neighbors are identified for the most isolated nodes. Noise identification then classifies nodes as noise based on their reverse nearest neighbors' number and distance. Label propagation dynamically adjusts the noise removal intensity in an iterative manner. We compare our method's accuracy and noise robustness against existing methods, demonstrating its superior performance and applicability.

CC-West 104A

Applied Online Learning and Decision-making

Community Committee Choice Session

Session Chair: Rafid Mahmood, Telfer School of Management, Mississauga, ON, Canada

1 Data-pooling Reinforcement Learning For Personalized Healthcare Intervention

Xinyun Chen[1], Pengyi Shi[2], Shanwen Pu[3], [1]Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]Purdue University, West Lafayette, IN, [3]Shanghai University of Finance and Economics, Shanghai, China. Contact: chenxinyun@cuhk.edu.cn

Motivated by the emerging needs of personalized intervention, we consider a multi-stage, dynamic decision-making problem in the online setting with unknown model parameters. To deal with the pervasive issue of small sample size in personalized planning, we develop a novel data-pooling reinforcement learning (RL) algorithm. Our algorithm adaptively pools historical data, with three main innovations: (i) the weight of pooling ties directly to the performance of decision (measured by regret); (ii) no parametric assumptions are needed between historical and current data; and (iii) requiring data-sharing only via aggregate statistics. We establish a theoretical guarantee for performance improvement of the data-pooling algorithm over benchmark methods. We also record empirically better performance of our algorithm in a case study of post-discharge intervention.

2 Dynamic Pricing And Learning With Bayesian Persuasion

Wei Tang[1], Shipra Agrawal[1], Yiding Feng[2], [1]Columbia University, New York, NY, [2]University of Chicago, Chicago, IL, Contact: wt2359@columbia.edu

We consider a novel dynamic pricing and learning setting where in addition to setting prices of products in sequential rounds, the seller also ex-ante commits to `advertising schemes'. Using the popular Bayesian persuasion framework to model the effect of these signals on the buyers' valuation and purchase responses, we formulate the problem of finding an optimal design of the advertising scheme along with a pricing scheme that maximizes the seller's expected revenue. Without knowing the buyers' demand function, our goal is to design an online algorithm that can adaptively learn the optimal pricing and advertising strategy.
Our main result is a computationally efficient online algorithm that achieves O(T^{2/3}(N\log T)^{1/3}) regret when the valuation function is linear in the product quality. Here N is the # of the discrete product quality domain and T is the time horizon.

3 Contracting, Pricing, and Data Collection Under the Ai Flywheel Effect

Huseyin Gurkan[1], Francis de Véricourt[2], [1]ESMT GmbH, Berlin, Germany; [2]ESMT GmbH (VAT-ID: DE814050117), Berlin, Germany. Contact: huseyin.gurkan@esmt.org

This paper explores how firms that lack expertise in machine learning (ML) can leverage the so-called AI Flywheel effect. This effect designates a virtuous cycle by which, as an ML product is adopted and new user data are fed back to the algorithm, the product improves, enabling further adoptions. However, managing this feedback loop is difficult, especially when the algorithm is contracted out. Indeed, the additional data that the AI Flywheel effect generates may change the provider's incentives to improve the algorithm over time.

4 Optimizing Data Collection for Machine Learning

Rafid Mahmood[1,2], James Lucas[2], Jose Alvarez[3], Sanja Fidler[2], Marc Law[2], [1]Telfer School of Management, Ottawa, ON, Canada; [2]NVIDIA, Toronto, ON, Canada; [3]NVIDIA, San Jose, CA, Contact: mahmood@telfer.uottawa.ca

Training modern deep learning systems requires massive data sets, but there is little guidance on how to best collect this data. Over-collecting data incurs unnecessary present costs, while under-collecting may incur future costs and delay workflows. We introduce an optimal data collection problem, enabling designers to define performance targets, costs, time horizons, and penalties for unmet targets. This framework further permits custom analyses, such as collecting new data to upgrade an existing AI model or choosing between different collection strategies. To solve the problem, we propose Learn-Optimize-Collect (LOC), which minimizes expected future costs. Evaluating on six computer vision applications, our method outperforms conventional approaches consistently by achieving performance targets while maintaining low collection costs.

Time Series Methods and Applications

Community Committee Choice Session

Session Chair: Xaimarie Hernandez Cruz, [1</sup]

1 Self-Supervised Representation Learning and Anomaly Detection in Time-Structured Datasets: Case Studies and Applications in Health

Francisca Quijada Dibarrart, Klim Drobnyh, George Runger, Arizona State University, Tempe, AZ

The time series representation and anomaly detection problems have been traditionally addressed via supervised learning. However, in practice, labeled data required for model training may sometimes be limited or nonexistent. This research learns representations of multivariate time-structured datasets. Furthermore, the methodology can be directly extended to address the anomaly detection problem by exploiting the information captured that distinguishes among instances originating from different sources. Case studies are presented for detecting abnormalities in the health domain, with a particular focus on overall human activities.

2 Improved Crop Price Predictions Using Social Media

Grace Neal, Xaimarie Hernandez Cruz, George Runger, J. Rene Villalobos, Arizona State University, Tempe, AZ, Contact: gneal2@asu.edu

There are times when disruptive events can affect fresh fruit and vegetable (FFV) produce prices, hindering the forecasting of prices solely based on the historical price time series. To address this challenge, this work evaluates the use of social media data in price prediction, applying the general public's interest in products at different times to improve the forecasting of FFV prices. Twitter data, such as the frequency of tweets and the overall sentiment values of the tweets are used to monitor the public impression of products. In addition, Google Trends data, such as the search relative frequency of the product is also explored as an exogenous variable. Through a case study, this work will compare the combined use of social media to generate a more accurate FFV market price prediction than when used individually or not at all.

3 Predicting Without Data

Xaimarie Hernandez Cruz, Grace Neal, George Runger, J. Rene Villalobos, Arizona State University, Tempe, AZ

Spatio-Temporal forecasting, as other supervised tasks, requires an ample amount of historical data to train forecasting models. Nonetheless, there are certain applications in which forecasts for a particular spatial location with little to no data availability is desired. This work addresses this challenge by developing a two-phased approach in which forecasts of locations that have data available are used to obtain predictions for a location that does not have data. An application case study is provided to illustrate the proposed approach in which crop market prices in the United States are predicted for a market for which data is not available.

4 Low-Rank Approximation of Attention in Transformer for Time Series Forecasting

Fahim T. Azad, Arizona State University, Tempe, AZ, Contact: fazad@asu.edu

Transformers have performed well in domains like natural language processing and computer vision. The use of transformers is also gaining popularity in the field of time series. A few current state-of-the-art works use the low-rank approximation of Transformer attention for long-sequence forecasting. The intuition behind that is that the attention weights are sparse, and approximate values can replace them without drastically affecting efficiency. In this presentation, we will describe their approaches and introduce our approach for low-rank approximation of the attention weights. The presentation will also include a comparison of the different techniques mentioned earlier.

Data Mining and Machine Learning for Sustainable Transportation

Community Committee Choice Session

Session Chair: Jimi Oke, University of Massachusetts Amherst, Amherst

1 Shared Parking and Charging Management in Multi-Unit Dwellings

Ruolin Zhang, Eleftheria Kontou, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: ruolin3@illinois.edu

In urban areas, the search for parking and charging results in vehicle cruising and congestion. However, private parking spaces and charging infrastructure in multi-unit dwellings (MUDs) could be available during daytime, when MUD residents drive their vehicles to work. We design a shared parking and charging reservation and allocation system for MUD charging hubs and public users to provide accessible parking and charging services to the general public. This system accounts for diverse stakeholders and models their objectives. To accommodate both electric and gasoline vehicles' requests, a binary integer linear programming (BILP) model incorporating a set of matching rules is formulated. Counterfactual analysis is conducted to model users' charging behavior. Results from a numerical experiment in Chicago, Illinois using real-world data will be presented.

2 An Innovative Method of Using Social Media Data to Develop Policy Sensitive Model

Rifa Tasnia[1], Daud Nabi Hridoy[2], Khondhaker Al Momin[3], Arif Mohaimin Sadri[4], Md Sami Hasnine[2], [1]North Carolina Agricultural and Technical State University, Greensboro, NC, [2]Howard University, Washington, DC, [3]University of Oklahoma, Norman, OK, [4]The University of Oklahoma, Norman, OK, Contact: hasnine@mit.edu

The objective of this study is to use social media data and develop policy sensitive model. First, this project analyzes two case studies where tweets are retrieved during Hurricane IAN and IDA. Then, tweets are transformed into various activity types and disruption types using text mining, classification, and natural language processing. Next, various data sources are used to add sociodemographic information, such as US Census, American Community Survey, Climate and Economic Justice Screening Tool, and Social Security Administration (SSA) database. Based on the final datasets, a series of econometric models are estimated. The econometric models reveal a series of policies that will help us take various disaster preparedness steps.

3 Electrifying Public Transit Benefits Public Finances in Small Island Developing States

Zakia Soomauroo[1,2], [1]Technical University of Berlin, Berlin, Germany; [2]Reiner Lemoine Institut, Berlin, Germany. Contact: zakia.soomauroo@rl-institut.de

Decarbonizing transport in small island states addresses issues of energy security, high fuel import prices, and climate change mitigation measures while ensuring higher levels of wellbeing for citizens. Electrification plays a vital role in the decarbonization process. Here, we explore transition pathways using Mauritius' public transit system as an example. We simulate a variety of public bus turnover scenarios, considering initial costs of investments, energy and fuel requirements, and reductions in emissions. We demonstrate that optimized investment into electrifying public transit pays off, with annualized investments of about $5 million superseded by annual savings on fossil fuel imports of about $15 million. We suggest that international donors can accelerate this transition by providing loan guarantees and, by this, reducing the cost of capital.

4 Metropolitan Area Road Network Typologies and Their Implications for Sustainable Mobility

Jimi Oke, University of Massachusetts Amherst, Amherst

Over 80% of commuters across America's metropolitan statistical areas (MSAs) use single or shared car rides on increasingly congested roads. The growth of ridehailing and e-commerce is further driving demand for roadway use. Understanding and managing our road networks is therefore important to current and future climate change mitigation planning. Using network data from about 300 MSAs, we employ manifold learning approaches to derive a novel latent low-dimensional description of key network features. From the latent space, we learn network typologies without supervision. Finally, we investigate the significance of the latent features and the typologies themselves in explaining longitudinal congestion patterns, car usage and other sustainability indicators.

1 The Merton Model Re-Visited: Design of Optimal Incentives for Traders in Copy Trading

Kai Sun[1], Mingwen Yang[2], Vijay S. Mookerjee[3], [1]University of Texas at Dallas, Richardson, TX, [2]University of Washington, Seattle, WA, [3]University of Texas- Dallas, Richardson, TX

Copy trading allows retail investors (followers) to automatically copy the trades of experts (traders) in real time after paying the following fees to the platform. To help mitigate the potential principle-agency problem, we propose a model that compensates the trader in a way that his trading behavior will not be altered.

2 How Much Personalization Do You Want? An Analytical Model of Online Retailer Product Displays

Jordan He, James Dearden, David Zhang, Oliver Yao, Lehigh University, Bethlehem, PA, Contact: qih320@lehigh.edu

We develop a game-theoretic model to analyze the impact of web content personalization on consumer behavior, taking into account two dimensions of personalized product recommendations (depth vs. width) and consumer types (focused vs. browsing). By allowing consumers to choose their preferred content, retailers can identify their types and personalize shopping pages accordingly. The proposed model provides evidence of the efficacy of customization strategies and addresses the challenge of balancing web content personalization in theory and practice.

3 Designing Randomness in Digital Games

Xianghua Wu[1], Hong Guo[2], Kay-Yut Chen[3], Jie Zhang[4], [1]University of Houston, Houston, TX, [2]Arizona State University, Tempe, AZ, [3]University of Texas at Arlington, Mansfield, TX, [4]University of Texas, Arlington, TX, Contact: hguo@asu.edu

This paper investigates the design of randomness in digital games. Two forms of randomness are analyzed - luck and matching. Managerial implications are discussed.

Managing Crowd Platforms

Community Committee Choice Session

Session Chair: Jinyang Zheng, Purdue University, West Lafayette, IN

1 When Reward Meets Donation: A Paradoxical Dilemma

Yipu Deng[1], Jinyang Zheng[2], Guo Xin Li[3], Karthik Kannan[4], [1]University of Hong Kong, Hong Kong, China; [2]Purdue University, West Lafayette, IN, [3]Harbin Institute of Technology, Harbin Heilongjiang, China; [4]University of Arizona, Tucson, AZ, Contact: yipudeng@hku.hk

Reward-based crowdfunding platforms are increasingly incorporating a donation option, which enables backers to contribute money without redeeming any rewards. While this option has been touted as a novel fundraising channel, our study highlights the negative externalities it can generate, which ultimately leads to a decline in total raised funds. We identify two mechanisms that contribute to the adverse effect. Firstly, the bystander effect, wherein prior donations diminish prospective backers' willingness to support the campaign, leading them to either opt out of reward purchases or decrease their contribution amounts. Secondly, the social conformity effect, whereby prior donations shape backers' perceptions of social norms and consequently decrease their support levels. Our study makes substantial contributions to both the literature and practice.

2 Breaking the Glass Ceiling or Breaking Trust: How a Female Fraudster Affects Crowdfunding for Female Entrepreneurs?

Stan Shi, Chen Liang, University of Connecticut, Storrs, CT

Our study examines the impact of a high-profile female entrepreneur's fraud conviction on female entrepreneurship in the context of crowdfunding. Using a matched set of projects launched by male and female creators on a prominent crowdfunding platform, we employ a difference-in-differences model to estimate the gender-differential impact of this scandal. Our findings reveal that projects launched by female creators received 21.7% less funding, 12.5% fewer backers, and 9.2% less average amount contributed per backer than projects launched by male creators. The negative effect of the scandal on female creators is more pronounced in the technology section. These results shed light on the adverse consequences of a scandal on female entrepreneurship in the crowdfunding space and underscore the need to address gender disparities in the entrepreneurial landscape.

3 A Tale of Two Channels: Monetizing Free and Paid Channels on a Video-Sharing Platform

Ian Ho[1], Dongsheng Li[2], Xiangjing Chen[3], [1]Pennsylvania State University, State College, PA, [2]Penn State University, University Park, PA, [3]University of Nebraska-Lincoln, Lincoln, NE, Contact: xchen76@unl.edu

Video-sharing platforms (e.g., YouTube) enable content creators to monetize their videos via not only the advertising commission from free channels but the subscription fees from paid channels. While such a monetization model prevails, the strategic interactions among creators, consumers, and a platform remain unclear. Thus, we develop a game-theoretical model to study how a creator optimally chooses its efforts (i.e., qualities) and subscription fee to operate the two channels. We further extend the model by incorporating the creator competition in a duopoly setting. Our analytics provide clear guidance for creators and implications for consumers.

4 Game for Brainstorm: The Impact of a Badge System on Knowledge Sharing

Lei Wang[1], Yifan Zhang[2], Ian Ho[1], [1]Pennsylvania State University, State College, PA, [2]Kennesaw State University, Kennesaw, GA, Contact: lei.wang@psu.edu

Knowledge-sharing platforms have widely adopted gamification to encourage users to contribute high-quality content. This research thus carefully evaluates the impact of a badge system regarding the volume (the number of badges), variety (the number of badge categories), and valence (the level of badges), along with the moderating effect of user membership tenure. To characterize the dynamics of user-system interactions on Stack Overflow, we specify a structural hidden Markov model (HMM) to quantify users' corresponding knowledge contributions and engagement-state transitions. This study provides new aspects to contribute to the gamification and knowledge-sharing literature and generates actionable implications for platforms and gamification-system designers.

Privacy and Behavioral Economics

Community Committee Choice Session

Session Chair: Laura Brandimarte, University of Arizona, Tucson, AZ

1 What Do Parents' Comments Tell Us? Privacy and Review Quality in Children's Mobile Apps Market

Vincent Lefrere, Grazia Cecere, Institut Mines-Telecom Business School, Paris, France

This study examined a panel data of more than 27,000 mobile apps targeting children to explore the relationship between privacy intrusion and the quality of associated user reviews. Using related keywords and a specialized app category for children, we collected app reviews and evaluated their quality in terms of grammatical mistakes and readability index. Our findings indicate that apps with higher levels of privacy intrusion tend to receive lower quality comments. These results highlight the importance of addressing privacy concerns to maintain positive user experiences and promote quality in children's mobile apps.

2 Examining the Effect of Personalized PII Exposure Alerts on Individuals' Privacy Protection Motivation

Fang yu Lin, University of Arizona, Tucson, AZ

Personally Identifiable Information (PII) leakage can lead to identity theft, financial loss, reputation damage, and anxiety. However, individuals remain largely unaware of their PII exposure on the Internet, and whether providing individuals with information about the extent of their PII exposure can trigger privacy protection actions requires further investigation. In this study, grounded by Protection Motivation Theory (PMT), we examine whether receiving privacy alerts in the form of threat and countermeasure information will trigger senior citizens to engage in protective behaviors. We also examine whether providing personalized information moderates the relationship between information and individuals' perception. We contribute to the literature by shedding light on the determinants and barriers to the adoption of privacy protection behaviors.

3 Gpt or Not to Be? Measuring the Trade-Off Between Functionality and Privacy Concerns

Laura Brandimarte[1], Jerg Gutmann[2], Gerd Muehlheusser[3], Franziska Weber[4], [1]University of Arizona, Tucson, AZ, [2]University of Hamburg, Hamburg, Germany; [3]University of Hamburg, Hamburg, Georgia; [4]Rotterdam University, Rotterdam, Netherlands

The use of modern AI technologies promises efficiency and productivity gains, but it also implies privacy costs that may or may not be present in users' mind when deciding to adopt. In this ongoing work, we present the results of an experiment run in two countries (Germany and the US) in which we manipulate between subjects the salience (low or high) of the privacy loss associated with the use of an AI, as well as the stringency of the active privacy regulatory environment (low or high). We also manipulate whether the AI is preset or needs to be activated, and measure the difference between these defaults. Similar to large language models like GPT, the AI we consider is capable of writing sophisticated and authentic text after being trained with the user's email exchanges. We use incentive-compatible mechanisms to measure willingness to use the technology and discuss implications.

Contemporary Studies in Finance

Community Committee Choice Session

Session Chair: Umit Gurun, University of Texas-Dallas, Richardson, TX

1 Real Estate Investors and Property Taxation

Serena Xiao, 1</sup

We study the inequality in property taxation in the U.S. single-family home market based on a property's assessed value. Comparing the assessment ratio of properties owned by investors with those of owner-occupiers, we find a 3.0%-4.7% assessment discount nationwide for properties owned by large investors relative to owner-occupied homes in the same area. This difference translates into an estimated total annual property tax savings of $66-$104 million for large investors. Further evidence based on micro-level appeals data suggests that the assessment discount results from a higher likelihood of appeal and more favorable outcomes upon a successful appeal for large investors. States with a fairer property taxation administration, a higher market share by large investors, and a higher property tax burden show a greater assessment discount for large investors.

2 Performance Attribution for Portfolio Constraints

Andrew W. Lo[1], Ruixun Zhang[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Peking University, Beijing, China. Contact: zhangruixun@pku.edu.cn

We propose a new performance attribution framework that decomposes a constrained portfolio's holdings, expected utility, expected returns, variance, and realized returns into components attributable to: (1) the unconstrained mean-variance optimal portfolio; (2) individual static constraints; and (3) information, if any, arising from those constraints. A key contribution of our framework is the recognition that constraints may contain information that is correlated with returns, in which case imposing such constraints can affect performance. We derive conditions for when the excess return and variance from information is positive or negative. We provide simulated and empirical examples involving constraints on ESG portfolios. Contrary to conventional wisdom, constraints may improve portfolio performance under certain scenarios.

3 Prenatal Stress and Portfolio Decisions During Adulthood

Alok Kumar, 1</sup

Using earthquake exposure during pregnancy as a proxy for *in utero* insult, we examine the impact of prenatal stress on investment decisions during adulthood. We find that, compared with investors born immediately before an earthquake, investors exposed to a major earthquake *in utero* participate less in the stock market, hold less diversified portfolios, trade excessively, and earn lower returns. Earthquake exposure in the third trimester of pregnancy has stronger impact, and female investors exhibit greater sensitivity to *in utero* insults. In contrast, the adverse impact of earthquake exposure is weaker among individuals who are exposed to extreme *in utero* insults, as surviving babies are likely to have superior characteristics.

4 Who Benefits from Anti-Corruption Enforcement?

Jim Goldman[1], Stefan Zeume[2], [1]University of Warwick, Coventry, United Kingdom; [2]UIUC, Champaign, IL, Contact: zeume@illinois.edu

We exploit enforcement actions for violations of the U.S. Foreign Corrupt Practices Act in non-OECD countries to study the effect of anti-bribery enforcement on unpunished firms. Firms in the same country-industry as the violator experience significant increases in revenue (+6.4%) and asset productivity (+4.2%). This result is driven by foreign-owned business group affiliates and amplified when affiliates are active in government-dependent industries, members of groups with limited corruption experience, and owned by productive parents. Overall, anti-bribery enforcement actions, which also reduce local corruption levels, result in reallocation of economic activity and level a playing field disrupted by corruption.

Algorithmic Learning in Games

Community Committee Choice Session

Session Chair: Clemens Possnig, Vancouver School of Economics, University of British Columbia, Vancouver, BC, Canada

1 Reinforcement Learning and Collusion

Clemens Possnig, Vancouver School of Economics, University of British Columbia, Vancouver, BC, Canada

This paper presents an analytical characterization of the long run policies learned by algorithms that interact repeatedly. These algorithms update policies which are maps from observed states to actions. I show that the long run policies correspond to equilibria that are stable points of a tractable differential equation. As a running example, I consider a repeated Cournot game of quantity competition, for which learning the stage game Nash equilibrium serves as non-collusive benchmark. When algorithms determine actions based only on the past period’s price, the Nash equilibrium can be learned. However, conditioning actions on a richer type of information can preclude the Nash equilibrium from being reached. This type of information allows for the existence of a collusive equilibrium that will be learned with positive probability.

2 Efficient-Q Learning for Stochastic Games

Muhammed O. Sayin, Onur Unlu, Bilkent University, Ankara, Turkey. Contact: sayin@ee.bilkent.edu.tr

We present the new efficient-Q learning dynamics for stochastic games beyond the recent concentration of progress on provable convergence to possibly inefficient equilibrium. Agents follow log-linear learning in stage games whose payoffs are the Q-functions and estimate the Q-functions iteratively with a vanishing stepsize. This (implicitly) two-timescale dynamic makes stage games relatively stationary so that the agents can track the efficient equilibrium. We show the provable convergence of the Q-function estimates to the ones associated with (near) efficient equilibrium in identical-interest stochastic games. The key idea is to approximate the dynamics with a fictional scenario where Q-function estimates are stationary over finite-length epochs and then couple these scenarios such that the approximation error decays to zero due to the vanishing stepsize.

3 Kernelized Multiplicative Weights for 0/1-Polyhedral Games: Bridging the Gap Between Learning in Extensive-Form and Normal-Form Games

Gabriele Farina, MIT, Cambridge, MA, Contact: gfarina@mit.edu

While extensive-form games (EFGs) can be converted into normal-form games (NFGs), doing so comes at the cost of an exponential blowup of the strategy space. So, progress on NFGs and EFGs has historically followed separate tracks, with the EFG community often having to catch up with advances from the larger NFG community. I will show that the Optimistic Multiplicative Weights Update (OMWU) algorithm—the premier learning algorithm for NFGs—can be simulated on the normal-form equivalent of an EFG in linear time per iteration in the game tree size using a kernel trick. The resulting algorithm, Kernelized OMWU, applies also to convex games whose strategy space is a polytope with 0/1 integral vertices, and closes several standing gaps between NFG and EFG learning, by enabling transfer of desirable properties of learning dynamics so far known to be achievable only in NFGs.

Optimization of Pick-up and Delivery Operations

Contributed Session

Session Chair: Elson Cibaku, New Jersey Institute of Technology, Rutherford, NJ

1 Field Experiments to Assess the Environmental, Social, and Economic Benefits of Creating Dedicated Loading-Unloading Areas for Freight Vehicles in Emerging Markets

Camilo Mora[1], Jan C. Fransoo[2], Leopoldo Cardenas Barron[1], Josue Velazquez Martinez[3], [1]Tecnologico de Monterrey, Monterrey, Mexico; [2]Tilburg University, Tilburg, Netherlands; [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: camilomora@tec.mx

The lack of parking for freight vehicles in urban areas negatively impacts the distribution of goods, resulting in increased costs, and carbon emissions. As the world's urban population rises and urban freight transportation increases, this problem is expected to grow. One potential solution is the creation of dedicated loading-unloading zones. We conducted two field experiments in Mexico to assess the effects on carbon emissions, noise pollution, and traffic congestion. The results show a 4% reduction in the carbon intensity factor, over 10% savings in logistics costs, a reduction of 2.73% in CO2 in the air, a 7.94% reduction in noise pollution, and an increase in the average speed of vehicles by 1.55%. These findings suggest that creating these spaces is an effective solution for improving the efficiency and sustainability of urban freight transport in developing cities.

2 Pickup and Delivery Facilities for Small Shipments

Anton J. Kleywegt, Xinyu Liu, ISyE Georgia Tech, Atlanta, GA, Contact: xinyu.liu@gatech.edu

Large numbers of shipments are picked up and delivered at urban locations every day. Most of these shipments are relatively small, not needing loading docks for their pickups and deliveries. These pickups and deliveries often take place at curbsides, aggravating traffic congestion. Thus there is a great need for designated spaces designed for pickups and deliveries, with minimal effects on traffic. This work proposes policies for the operation of such facilities, and methods to evaluate these policies in terms of throughput capacity. We formulate the problem as an MDP, provide bounds on throughput capacities, and present numerical results.

3 Multi-Pickup and Delivery of Restaurant Orders - A Graph-Aware Reinforcement Learning Approach

Elson Cibaku[1], Sanchoy Das[2], [1]New Jersey Institute of Technology, Rutherford, NJ, [2]New Jersey Institute of Technology, Newark, NJ

This research delves into the intricate process of multiple pickup and delivery mechanisms for restaurant orders, employing a unique approach that draws upon the capabilities of graph-aware reinforcement learning (RL). Advanced graph representation learning techniques are applied to handle the food service industry's complex logistics, aiming to improve service, reduce delays, and cut costs. A promising RL model is proposed to learn from environmental interactions, refining decision-making over time. This study provides a promising perspective on the role of artificial intelligence in revolutionizing food service logistics, making a significant contribution to the growing domain of intelligent and automated delivery systems.

Supply Chain Risk and Resilience

Contributed Session

Session Chair: Guilherme Tortorella, University of Melbourne, Docklands, Australia

1 Assessing the Resilience of Supply Chains to Climate Change:Building a Climate-Resilient Supply Chain and Enhancing Competitiveness

Laharish Guntuka, Rochester Institute of Technology, Rochester, NY, Contact: lguntuka@saunders.rit.edu

This study investigates the relationship between climate hazards, business risk exposure, supply chain susceptibility, disruption impact, resilience, and response capacity. The study aims to provide a better understanding of how firms can improve their supply chain resilience in the face of increasing climate hazards and business risk exposure. Data from a supply chain visibility firm, Resilinc, from various industries will be used to test the hypotheses. The study's findings will be relevant for managers and policymakers seeking to strengthen supply chain resilience in the face of disruptive events.

2 Research on the Impact of Supply Chain Network Structure on Firm Innovation Performance

Ying Teng[1], Jiao Liu[1], Fuying Jing[2], [1]Yangtze Delta Region Institute (Huzhou), University of Electronic Science and Technology of China, Chengdu, China; [2]Chongqing Technology and business University, Chongqing, China

With the increasing demand from consumers and rapidly shortening product cycles, supply chain partnerships between enterprises have become highly intertwined. As a result, complex network characteristics have emerged within the supply chain. To analyze the impact of these characteristics on innovation performance, this paper adopts a social network perspective and utilizes data from publicly listed companies in China's manufacturing industry as the basis of research. The findings suggest that within supply chain networks, the centrality of enterprises has a significant negative effect on their innovation performance, while the structural hole has a positive influence. Moreover, the absorptive capacity of enterprises plays a partial mediating role between the supply chain network's structure and innovation performance.

3 Forecasting Estimated Arrival Time (ETA) with Confidence for Supply Shipments in a Globalized Supply Chain

Dan Hu[1], Zuochun Tang[2], [1]IBM, San Jose, CA, [2]IBM, san francisco, CA, Contact: dan.hu@ibm.com

In today's global business landscape, companies operate supply chains spanning multiple countries, encompassing suppliers, manufacturing facilities, and shipments that navigate shared routes and ports. However, the exact shipment travel time remains uncertain, posing challenges for supply assurance managers. To address this, we propose a forecasting model that estimates the arrival time (ETA) of supply shipments along with a measure of confidence. Our model leverages features derived from suppliers' information, route information, as well as information from orders and shipments. By incorporating these factors, we offer valuable insights into understanding and anticipating ETA variations for supply assurance managers.

4 Resilience and Digital Transformation of the Food Supply Chains

Guilherme Tortorella[1], Marianne Gloet[1], Daniel Samson[1], Sherah Kurnia[1], Flavio Fogliatto[2], Michel Anzanello[2], [1]University of Melbourne, Docklands, Australia; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil. Contact: gtortorella@bol.com.br

This study investigates the relationship between resilience development and digital transformation and its effect on food supply chain performance. A survey of 208 practitioners in Australia was conducted. Findings suggest a positive impact on performance, particularly in terms of on-time, in-full delivery and inventory turnover. Organizations with low resilience can significantly improve their performance through the adoption of technologies, while those with well-established resilience display a lesser impact.

Reinforcement Learning and Bandit Problems

Contributed Session

Session Chair: Audrey Bazerghi, Northwestern University, Evanston, IL

1 Multi-Agent and Multi-Objective Multi-Armed Bandit

Mengfan Xu[1], Diego Klabjan[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: mengfanxu2023@u.northwestern.edu

EXP-based algorithms are often used for exploration in non-stochastic bandit problems assuming rewards are bounded. Motivated by the recent advancements in reinforcement learning (RL) with rewards of any scale, we propose a new algorithm, namely EXP4.P, and extend EXP4.P from bandit to RL to incentivize exploration. Furthermore, we study Pareto optimality in multi-objective multi-armed bandit by providing a formulation of adversarial settings and defining its Pareto regrets that can be applied to both stochastic and adversarial settings. We also present new (nearly) optimal algorithms. Lastly, we study a decentralized multi-agent multi-armed bandit problem in which multiple clients are connected by graphs. We introduce a novel algorithmic framework and derive (nearly) optimal instance-dependent and instance-free regret upper bounds.

2 Transfer Reinforcement Learning for Momdps with Time-Varying Interval-Valued Parameters and Its Application in Pandemic Control

Mu Du[1], Hongtao Yu[1], Nan Kong[2], [1]Dalian University of Technology, Dalian, China; [2]Purdue University, West Lafayette, IN, Contact: dumu@dlut.edu.cn

We investigate a novel type of online sequential decision problem, namely, *mixed observability Markov decision process with time-varying interval-valued parameters*. We propose a novel transfer reinforcement learning (TRL) based algorithmic approach that ingrates transfer learning into deep reinforcement learning in an offline-online scheme. To accelerate the online re-optimization, we pre-train a collection of promising networks and fine-tune them with new observation dynamically. Our approach is the first-ever endeavor of employing intensive neural network training in solving MDPs requiring online system identification and re-optimization. TRL outperforms existing methods in solution optimality, robustness, efficiency, and scalability. A retrospective study on a pandemic control shows it improves decision making on several public health metrics.

3 Flexible Relative Value Iteration for Reinforcement Learning in Ridesharing

Audrey Bazerghi[1], Sebastien Martin[1], Garrett J. van Ryzin[2], [1]Kellogg School of Management, Northwestern University, Evanston, IL, [2]Amazon, New York, NY

We introduce a flexible relative value iteration algorithm (FlexRVI) for dynamic programming, which allows the computation of value differences between any pair of states. We prove that the Bellman operator of FlexRVI is a contraction, and that its convergence rate is equivalent to the classical relative value iteration algorithm. Applied to a large-scale reinforcement learning problem in ridesharing, the FlexRVI idea leads to simpler state approximations and better performing policies than conventional methods, two results which could extend to many important classes of problems.

Deep Learning and Scheduling Problems

Contributed Session

Session Chair: Tianyu Wang, Fudan University, Shanghai, China

1 Minimizing Makespan for Job Shop Scheduling Problem Using Deep Learning Model Employing Critical Paths of Schedules for Large Neighborhood Search

Gwanhee Lee, Kyungduk Moon, Myungho Lee, Dongyun Kim, Yeonjun Choi, Insoo Park, Kangbok Lee, POSTECH (Pohang University of Science and Technology), Pohang, Korea, Republic of. Contact: ghlee22@postech.ac.kr

We propose a heuristic for job shop scheduling problems (JSSP) minimizing makespan by developing deep learning models to identify parts of the schedule to reconstruct in large neighborhood search. Recent studies have demonstrated that deep learning can perform well to build initial solutions of JSSP or other combinatorial optimization problems step by step. However, there have been few discussions on improving solutions after taking relationship with makespan and critical paths of the incumbent schedule into account. In this presentation, we discuss the effectiveness of developing deep learning modules trained with critical paths for makespan minimization in JSSP which carefully select the parts of the schedule which need to be rescheduled.

2 A Search Algorithm Based on Makespan Ranking for Solving Job-Shop Scheduling Problems

Yi-Wen Yang, Sheng-I Chen, National Yang Ming Chiao Tung University, Hsinchu, Taiwan. Contact: tiffan888928.mg11@nycu.edu.tw

This study considered job-shop scheduling problems with the objective of minimizing the makespan. We aim to provide a fast and quality solution to enhance manufacturer agility when making decisions. We develop a local search algorithm to explore neighbors that have the same medium completion-time jobs as the current solution. When the objective is not improved, a k-combination search is used to prevent the algorithm from stocking at the local optimum. The computational experiment compares our algorithm performances with prior works using public testing-bed instances. The result is promising where our method can obtain solutions in 4~8% gaps to the best-known solution in a restively short run time.

3 Lipschitz Bandits with Batched Feedback

Tianyu Wang, Yasong Feng, Zengfeng Huang, Fudan University, Shanghai, China. Contact: wangtianyu@fudan.edu.cn

We study Lipschitz bandit problems with batched feedback, where the expected reward is Lipschitz and the reward observations are communicated to the player in batches. We introduce a novel landscape-aware algorithm, called Batched Lipschitz Narrowing (BLiN), that optimally solves this problem. Specifically, we show that for a T-step problem with Lipschitz reward of zooming dimension d_z, our algorithm achieves theoretically optimal (up to logarithmic factors) regret rate $\widetilde{\mathcal{O}}\left(T^{\frac{d_z+1}{d_z+2}}\right)$ using only $ \mathcal{O} \left(\log\log T\right) $ batches. We also provide complexity analysis for this problem. Our theoretical lower bound implies that $\Omega(\log\log T)$ batches are necessary for any algorithm to achieve the optimal regret. Thus, BLiN achieves optimal regret rate using minimal communication.W

Optimization Approaches for Machine Learning

Contributed Session

Session Chair: Rick Willemsen, Erasmus University Rotterdam, Rotterdam, Netherlands

1 Estimation of Optimal Treatment Regime in High Dimensional Single-Index Quantile Regression

Suneel Babu Chatla[1], Indrabati Bhattacharya[2], [1]University of Texas at El Paso, El Paso, TX, [2]Florida State University, Tallahassee, FL, Contact: sbchatla@utep.edu

Estimation of the optimal treatment regime is an important problem and has useful applications in various fields. The mean-optimal treatment regime is not reliable when the outcome distribution is not symmetric. The quantile-optimal treatment regime, which optimizes some desired quantile of the potential outcome instead of the mean, may occasionally be of interest. We propose a flexible penalized single-index model which can select the important variables from high-dimensional baseline covariates. We discuss the asymptotic properties of the proposed estimators. Our results help to quantify the variability related to the estimated quantile optimal treatment regime by constructing simultaneous confidence bands. The usefulness of the proposed methodology is illustrated using simulations and data analysis.

2 Graph Neural Networks with Dynamic Programming for Workflow Scheduling

Vivek Anand Rajopanth[1], Rakesh Nagi[2], [1]University of Illinois at Urbana Champaign, Urbana, IL, [2]University of Illinois at Urbana Champaign, Urbana, IL, Contact: var4@illinois.edu

Workflow scheduling is a well-known combinatorial optimization problem for which researchers have tried designing numerous heuristics over the years. Recent advances use machine learning methods that either replace traditional algorithms with fast function approximations learned through neural networks or reinforcement learning. Our approach uses Graph Neural Networks (GNN) to create a "heatmap" of edges that describes the probability of every task-executor pairing in the optimal solution. This heatmap is learned by formulating the corresponding Mixed Integer Linear Program and training the GNN on its optimal solutions. The heatmap generated by the GNN is then leveraged to find the best solution using Dynamic Programming.

3 Exact Methods for Hierarchical Clustering

Rick Willemsen, Carlo cavicchia, Wilco van den Heuvel, Michel van de Velden, Erasmus University Rotterdam, Rotterdam, Netherlands. Contact: willemsen@ese.eur.nl

The aim of hierarchical clustering is to obtain a hierarchy of nested partitions. Researchers have proposed several objective functions and approximation algorithms. Commonly applied heuristics are not guaranteed to find an optimal solution. However, exact methods that can optimize these objective functions have received less attention. We propose several exact methods for hierarchical clustering, based on the partitional clustering literature and an objective based on a sum of partitional clustering objectives. We introduce compact linear programming formulations, as well as a set-covering formulation that can handle various objective functions. In addition, we provide a branch-and-price framework to solve the set-covering formulation. We validate our approach on labeled instances and evaluate the scalability of our method on real-world data.

Analysis of Online Reviews and Frontiers in Conversational AI

Contributed Session

Session Chair: Ivan Belik, Norwegian School of Economics, Bergen, Norway

1 The Effect of Identity Multiplicity Signaling on Interpersonal Trust

Yi Su, Yiqi Yu, Yunlu Yin, Fudan University, Shanghai, China. Contact: suy20@fudan.edu.cn

This research investigates how and why signaling multiple identities (vs. a single identity) influences interpersonal trust. Six studies—including a field experiment, analysis of social media data, and lab and online experiments—demonstrate that identity multiplicity signaling fosters interpersonal trust by promoting perceived authenticity. We replicate this finding across studies with various measures and designs. We also show that the effect of identity multiplicity is attenuated when the identity signaling message is presented together with monetary exchange mentions as a cue that suggests lack of authenticity. Taken together, the results advance the understanding of the multifaceted nature of identity and its social cognitive consequences in contexts such as (online) communication, collaboration, and persuasion.

2 Chatbot Persuasion: An Elaboration Likelihood Model Perspective

Tianling Xie[1], Iryna Pentina[2], Benjamin T. George[3], [1]University of Toledo, Toledo, OH, [2]University of Toledo, Toledo, OH, [3]University of Toledo, Toledo, OH, Contact: tianling.xie@rockets.utoledo.edu

Conversational agents (CAs) are AI-enabled programs engaging in conversations and interactions with humans. While simple rule-based CAs primarily assist users with predefined queries and information retrieval, more advanced CAs can understand user intentions, and exhibit emotions, personality traits, and empathy. Recently, there has been a growing interest in utilizing CAs to influence users' attitudes, beliefs, and behaviours, such as AI counselors and AI coaches. Recognizing this trend, we propose a laboratory experiment design under the Elaboration Likelihood Model and the Social Response Theory, to compare the persuasion effectiveness of a chatbot and a website without the interactive conversational capability.

3 The Impact of Privacy Data Utilization and Protection on Enterprises Performance: A Structural Equation Modeling Approach

Chen Menting, Park Kwangtae, KUBS, Seoul, Korea, Republic of. Contact: douzi-zaoer@naver.com

The development of big data and AI technologies has driven enterprises to benefit from accurate analysis of user data. However, it has also raised concerns about privacy data security. Thus, this research aims to explore the impact of enterprise usage and protection of user privacy data on business performance. Hypotheses and measurement scales of this research will be designed from the perspectives of both enterprises and users, by using the privacy risk perception process. Furthermore, a structural equation model will be used for empirical testing, in order to optimize enterprises utilization and protection strategies of private data in the data revolution.

4 Analysis of Online Consumer Discussions on Reddit Based on a Machine Learning Approach

Ivan Belik, Denis Utochkin, Norwegian School of Economics, Bergen, Norway

We employ state-of-the-art data analysis techniques such as natural language processing, opinion analysis, and complex network analysis to understand customer preferences on the Reddit media platform. In particular, we collect a large-scale dataset about online discussions, extract customer opinions, and predict the distribution of information on customer networks. Specifically, we collect the dataset that encompasses all activity from nearly two million anonymized users in a twelve-month period and employ the developed approach for extracting customer opinions and forecasting dissemination of electronic word-of-mouth in real-world customer networks.

Tuesday, October 17, 12:45 PM - 2:00 PM

Resource Management in Healthcare Settings

Contributed Session

Session Chair: Jaeyoung Kim, Clemson University, Clemson, SC

1 Revisiting the Operating Room Utilization Problem in Surgical Services

Saharnaz Mehrani, Ravi S. Behara, Florida Atlantic University, Boca Raton, FL, Contact: smehrani@fau.edu

Operating room (OR) scheduling significantly impacts patient and healthcare-provider satisfaction and has clinical and financial effects on hospitals. This study investigates the application of data analytics and optimization to improving OR utilization while considering patients and providers criteria. We perform numerical experiments on real data from a large urban hospital.

2 A Study on Policy Decisions to Embed Flexibility in the Planning and Scheduling in Operating Roomsconsidering Multiple Resource Stages in the Operating Room

Babak Akbarzadeh[1], Broos Maenhout[2], [1]University of Gent, Ghent, Belgium; [2]Ghent University, Ghent, Belgium. Contact: babak.akbarzadeh@ugent.be

The endeavor for operational excellence in the operating room (OR) department is hampered by uncertainty underlying patient demand for healthcare resources. Incorporating this uncertainty is complicated since planning and scheduling decisions are organized according to a hierarchical decision structure in different phases. In this study, we link the strategic, tactical, and operational decision-making in the OR department and study the impact of policy decisions embedding flexibility in the OR planning and scheduling processes to improve the operational outcome, making the trade-off between efficiency and consistency. We consider a sequential but interrelated proactive-reactive decision framework that is guided by both generic assumptions from literature and real life. Analysis is performed via computational experimentation on a real-life dataset.

3 Integer Programming for Surgery Scheduling Under Uncertainty

Nicklas Klein, Robin Hauenstein, Nicola Travaglini, Norbert Trautmann, University of Bern, Bern, Switzerland. Contact: nicklas.klein@unibe.ch

Flexible operating rooms can be used for scheduled elective surgeries and randomly arriving emergency surgeries, both with uncertain durations. The scheduling problem we deal with consists of assigning given elective surgeries to operating rooms and determining their start times to minimize the sum of the room-assignment cost and the expected cost associated with delays or cancellations of surgeries and with idle- or overtime. We formulate this problem as a two-stage mixed-integer linear program; to tackle instances of realistic size and complexity, we propose a corresponding matheuristic.

4 Optimaloperation Room Scheduling in the Large-Scale Hospital

Shao-Jen Weng, Tunghai University, Taichung City, Taiwan. Contact: sjweng@thu.edu.tw

The operating room in the hospital has high-tech, expensive medical equipment and various professional medical personnel, making the operating room to be a high cost place and one of the main incomes for the hospital. Thus, the better use of the operating room plays an important role in the operation of the hospital. If a more effective and appropriate surgical scheduling plan and effective resource allocation in the operating room can be realized, limited medical resources can be fully utilized, effective utilization rate can be improved, and medical costs can be relatively reduced. This research used simulation and optimization method to find the optimal resource allocation decision to reduce hospital operating costs and increase revenue.

5 Do New Partner and Procedure Exposure Influence Operating Room Nurse Turnover?

Jaeyoung Kim[1], Ahmet Colak[2], Lawrence Fredendall[2], [1]University of Dayton, Dayton, OH, [2]Clemson University, Clemson, SC, Contact: jkim02@udayton.edu

High operating room (OR) nurse turnover presents significant financial and operational challenges for hospitals. However, there are limited empirical insights for OR nurse turnover despite a growing stream of empirical studies on nurse turnover outside of the OR. Motivated by these recent insights, we conduct an exploratory empirical study to investigate the impact of OR nurse scheduling data on predicting nurse departure. Using granular data for 547 OR nurses across 77,046 surgeries, we show substantial connections between nurse scheduling and departure: we find new procedure and partner exposures---as well as diversity and familiarity of partners and procedures---to significantly influence nurse departure conditional on nurse tenure and role. Hence, our study documents the importance of nurse scheduling for hospital managers while reducing costly OR turnover.

Agriculutural Applications

Contributed Session

Session Chair: Lei Xu, Georgia Tech Shenzhen Institute, Shenzhen, China

1 The Impact of Blockchain on Profit and Waste in Food Supply Chains

Fan Si, Lucy Gongtao Chen, National University of Singapore, Singapore, Singapore. Contact: e0546111@u.nus.edu

Food supply chains can incur significant waste due to different quality standards adopted by supply chain members. In this paper, we investigate the impact of blockchain technology on food waste and profitability in a supply chain with one supplier and one retailer. We find that adopting blockchain technology always improves the supplier's profit but can hurt the retailer's and the supply chain's profitability. We also find that when the supplier's quality standard is very high, the implementation of blockchain is more likely to reduce the waste in the supply chain.

2 Crop Production in Emerging Economies: The Value of Pricing Mechanisms

Jian Li[1], Guang Xiao[2], Panos Kouvelis[3], [1]Northeastern Illinois University, Chicago, IL, [2]Hong Kong Polytechnic University, Hung Hom, Hong Kong; [3]Washington University in St. Louis, ST. LOUIS, MO, Contact: j-li3@neiu.edu

This paper examines an agricultural supply chain for a particular crop, where farmers can choose to sell their product in a side market or to a processing plant. In addition, the government offers a minimum price guarantee for the crop. We explore various pricing strategies that the processing plant can use to engage with farmers regarding land and harvest allocation decisions. We develop two-stage stochastic program models to analyze these allocation and pricing decisions at an aggregate farming level.

3 Embracing the Growth of Responsibly-Driven Procurement Through an Innovative Two-Bin Strategy for Selling Short-Shelf Life Produce

Li-Ming Chen, National Chengchi University, Taipei, Taiwan. Contact: lmchen@nccu.edu.tw

We explore a supply chain problem—the application of a two-bin selling strategy by an upstream vendor to sell produce to responsible buyers (RBs) and mainstream buyers (MBs). The primary bin with the fresh goods is prepared for an RB, which is willing to provide higher-than-market procurement prices and guarantee stable procurement quantities of goods. Unsold fresh goods are then moved to the secondary bin, which is prepared for price-sensitive

RBs; in this bin, goods have new and old ages and the good consumption follows the first-in, fist-out issuing policy. We consider a periodic review model for a perishable product with fixed lifetime equal to two review periods, and analyze the optimal replenishment quantity and secondary bin price. We further investigate the benefits came from primary bin by comparing with the scenario where the vendor sells goods only to the MBs.

4 Allocation of Humanitarian Relief Budget with In-Kind and Cash Assistance

Yingling Zhao, Lei Xu, Georgia Tech Shenzhen Institute, Shenzhen, China. Contact: xulei@gtsi.edu.cn

In this paper, we consider a humanitarian relief budget allocation problem. The humanitarian organization (HO) can spend the budget on relief item purchase, on media coverage to attract in-kind and cash assistance, and on warehouse capacity operation and expansion. A two-period dynamic model is proposed to find the optimal spending decisions for the HO to maximize the total expected utility. We first analyze the optimal allocation in the second period. We observe that the warehouse's capacity influences the optimal decisions in the first period. To further explore this relationship, we establish different thresholds for the warehouse's capacity and analyze the constraints of the model to obtain different optimal allocations under various capacity values. The HO can thus better understand the key factors in budget allocation and satisfy the needs of beneficiaries.

3 Capacity Management and Modelling in the Agri-Food Supply Chain: A Systematic Literature Review

Chenqiang Yue, Dong Li, Dongping Song, University of Liverpool, Liverpool, United Kingdom. Contact: yuecq@liverpool.ac.uk

This paper conducts a systematic literature review of capacity management and modelling in the context of agri-food supply chains. Descriptive and theme-based analysis are presented to reveal how capacity management is modelled under uncertainty and risk preferences from perspectives of optimal decisions, influencing factors, and methodology. We highlight current research status and identify future research opportunities.

Session.Location:CC-West 213B

Advacing Inventory and Supply Chain Management

Contributed Session

Session Chair: Austin Saragih, Massachusetts Institute of Technology, Cambridge, MA

1 Deep Inventory Management

Dhruv Madeka[1], Carson Eisenach[2], Kari Torkkola[2], Anna Luo[3], Dean P. Foster[2], Sham Kakade[4], [1]Amazon, Seattle, WA, [2]Amazon, Seattle, WA, [3]Pinterest, Seattle, WA, [4]Harvard University/Amazon, Seattle, WA

This work provides a Deep Reinforcement Learning approach to solving a periodic review inventory control system with stochastic vendor lead times, lost sales, correlated demand, and price matching. In order to train these algorithms, we develop novel techniques to convert historical data into a simulator. On the theoretical side, we present learnability results on a subclass of inventory control problems, where we provide a provable reduction of the reinforcement learning problem to that of supervised learning. On the algorithmic side, we present a model-based reinforcement learning procedure (Direct Backprop) to solve the periodic review inventory control problem by constructing a differentiable simulator. Under a variety of metrics Direct Backprop outperforms model-free RL and newsvendor baselines, in both simulations and real-world deployments.

2 The Inventory Routing Problem with Split Deliveries

Luca Bertazzi[1], Claudia Archetti[2], Nho Minh Dinh[1], [1]University of Brescia, Brescia, Italy; [2]University of Brescia, Brescia, Italy. Contact: luca.bertazzi@unibs.it

We study the benefit of introducing split deliveries in the Inventory Routing Problem, both when the Order-up-to level and the MaximumLevel replenishment policies are applied. We first propose a mathematical formulation and solve it by implementing a branch-and-cut algorithm. Then, we carry out a worst-case analysis to show the cost increase we have in the worst case by using unsplit deliveries instead of split deliveries, both for the Order-up-to level and the Maximum-Level replenishmentpolicies. Finally, we design a matheuristic algorithm. Extensive computational results on benchmark instances allow us to understand the benefit of introducing split deliveries and to show that the matheuristic algorithm is effective.

3 Tipdat: Ml Based Optimization Explainer

Brijesh Singhal, Manan Chopra, Saurabh Unercat, Amazon, Bellevue, WA, Contact: brijesh.singhal@outlook.com

Amazon's Retail Inventory is outcome of systems optimizing stochastic variables to met demand and maximize profit. Historically, we've relied on long manual subjective deep-dives to inspect defects, and improve outcomes, which have proved to be unscalable and disconnected from actual supply-chain behavior. We developed a 2 staged algorithm that can connect these inputs to inventory. Stage 1 of the algorithm trains a large-scale ML model over a billion observations to approximate a complex stochastic programming algorithm used to make buying decisions. We developed an attribution algorithm that leverages the concept from Shapley values where attribution follows efficiency, symmetry, linearity, and null player properties, it also jointly attributes to the variables in the case when variables are highly dependent and independent attribution is not desirable.

4 Plastic Waste Reverse Logistics Network Design Under Decision-Dependent Uncertainty

Austin I. Saragih[1], Milena Janjevic[1], Matthias Winkenbach[2], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: saragih@mit.edu

This paper proposes a holistic approach to large-scale plastic waste Reverse Logistics Network Design (RLND) considering strategic logistics network design and tactical collection design. It integrates flexibility, uncertainty, and decision-dependency through a two-stage stochastic program with sample average approximation and quantile regression. The case study from MIT Climate Sustainability Consortium highlights the benefits of distribution flexibility under uncertainty.

SAS/AMPL

Technology Tutorial

1 Building and Solving Optimization Models with SAS

Rob Pratt, SAS Institute, Inc., Cary, NC, Contact: rob.pratt@sas.com

SAS offers extensive analytic capabilities, including machine learning, deep learning, natural language processing, statistical analysis, optimization, and simulation. SAS analytic functionality is also available through the open, cloud-enabled design of SAS® Viya®. You can program in SAS, Python, Lua, Java, and R. SAS Analytics is also equipped with AI-enabled automations and modern low-code or no-code user interfaces that democratize data science usage in your organization and offer unparalleled speed to value. OPTMODEL from SAS provides a powerful and intuitive algebraic optimization modeling language and unified support for building and solving LP, MILP, QP, conic, NLP, constraint programming, network-oriented, and black-box models. This tutorial will include an overview of the optimization capabilities and demonstrate recently added features.

2 Python and AMPL: Build Prescriptive Analytics Applications Quicklywith Pandas, Colab, Streamlit, and amplpy

Filipe Brandão, Robert Fourer, AMPL Optimization, Inc., Mountain View, CA, Contact: fdabrandao@ampl.com

Python and its vast ecosystem are great for data pre-processing, solution analysis, and visualization, but Python's design as a general-purpose programming language makes it less than ideal for expressing the complex optimization problems typical of OR and prescriptive analytics. AMPL is a declarative language that is designed for describing optimization problems, and that integrates naturally with Python.In this presentation, you'll learn how the combination of AMPL modeling with Python environments and tools has made optimization software more natural to use, faster to run, and easier to integrate with enterprise systems. Following a quick introduction to model-based optimization, we will show how AMPL and Python work together in a range of contexts:•Installing AMPL and solvers as Python packages•Importing and exporting data naturally from/to Python data structures such as Pandas dataframes•Developing AMPL model formulations directly in Jupyter notebooks•Using AMPL and full-featured solvers on Google Colab,with no installation overhead and free access for courses•Turning Python scripts into prescriptive analytics applications in minutes with amplpy, Pandas, and Streamlit

Pricing and Other Considerations in Business Operations

Contributed Session

Session Chair: Rajeev Tyagi, University of California, Irvine, Irvine, CA

1 Fair Skill Brier Score: Evaluating Probabilistic Forecasts of One-Off Events with Different Numbers of Categorical Outcomes

Junnan Wang[1], Barbara Mellers[2], Lyle Ungar[2], Ville Satopaa[3], [1]INSEAD, Singapore, Singapore; [2]University of Pennsylvania, Philadelphia, PA, [3]INSEAD, Paris, France. Contact: junnan.wang@insead.edu

Experts' abilities to make accurate probabilistic forecasts are often evaluated with proper scoring rules. The Brier score is one of the most commonly used scoring rules when the target outcomes are categorical. The score, however, is not only influenced by the expert's forecasting skill but also by the inherent uncertainty of the events. For instance, an event with more outcomes is typically more difficult to forecast. It is then unfair to compare the Brier scores of experts who forecast events with different numbers of outcomes. In this paper, we introduce a simple fair skill adjustment to the Brier score to refine such comparisons. We introduce a behavioral model of experts' forecasts and show that the fair skill Brier score is a more reliable measure of experts' forecasting skills in general. We then find empirical support for our theoretical results from experimental data.

2 A Dynamic Choice Model-based Stated Preference Analysis Study for Tradable Goods

Myoungjn Oh, Jungwoo Shin, Kyung Hee University, Yongin, Korea, Republic of

Choice models are widely used to assess the monetary value of goods and services based on consumer preference analysis. This study, among them, presents a dynamic choice model that depicts the strategic multi- and future-ownership behavior of individuals. The model can evaluate the impact of purchase and sale decisions independently. In addition, the model can derive the phenomena of waiting demand, which moves current consumption into the future, and demand self-cannibalism, which draws future demand into the present, as a reflection of consumers' forward-looking behavior. In this study, the model is applied to the vehicle market, but it can also be used to analyze real estate, mobile phones, and subscription services.

3 Survive And Thrive: Strategic Firm Expansion Under Partially Observed Business Cycles

Zhide Wang[1], Lu Sun[2], Yanling Chang[2], Alfredo A. Garcia[2], [1]Texas A&M University, College Station, TX, [2]Texas A&M University, College Station, TX, Contact: liang93429@tamu.edu

Business cycles are a primary driver behind a firm's expansion or contraction decisions. However, there is inherent uncertainty about the state of the business cycle because observed economic fundamentals are imperfect indicators. In this paper, we develop an equilibrium model with an estimation methodology of strategic expansions. In the model, firms make entry/exit decisions based upon a *belief* distribution about the underlying *hidden* state of business cycle. The modeling and estimation methodology is tested on a dataset of Canada's fast food industry. Our estimation results show that the Canadian fast-food industry is recession-proof as its marginal profitability is largely immune to economic downturns. Moreover, a firm with high expansion base profit is not guaranteed to maintain a steadily growing market share if its not sufficiently recession-proof.

4 Approximate Linear Programs for Network Revenue Management: Reduction via Constraint Decomposition and Adaptation for Locally Separable Basis Functions

Chung-seung Lee[1], Metin Cakanyildirim[2], Xiao Zhang[3], [1]SUNY Korea, Incheon, Korea, Republic of; [2]The University of Texas at Dallas, Richardson, TX, [3]Saint Louis University, Saint Louis, MO, Contact: chungseung.lee@sunykorea.ac.kr

We develop compact approximate linear programs (ALPs) that can accommodate any type of basis function for the value function approximation. Our approach leverages an intuitive constraint decomposition method, enabling us to derive the compact ALPs in a versatile and primal form. We also propose a *local multivariate* approximation that allows for sophisticated control over the trade-off between approximation accuracy and tractability, enabling us to achieve a more favorable trade-off between the two. The employed basis functions are multivariate functions that are additively separable in specific regions of their domains.

To validate the advantage of the proposed method, we conduct an extensive numerical study, demonstrating that the larger the non-separable regions, the tighter the upper bound and the larger the expected revenue, but the longer the solution time.

5 A Model of Shrinkflation

Sreya Kolay[1], Rajeev Tyagi[2], [1]University at Albany, SUNY, Albany, NY, [2]University of California, Irvine, Irvine, CA, Contact: rktyagi@uci.edu

The practice of firms responding to their cost increases with a reduction in package size, while not decreasing the package price, has attracted considerable attention recently. Commonly called "downsizing," or "shrinkflation," this practice has often been explained as a sneaky backdoor way to increase the per-unit price, thus hurting consumers. We build formal models in which a monopolist or two competing firms sell to consumers who are aware of any change in package size. We find conditions on consumer tastes, degree of competition, and magnitude of cost increase under which seller(s) prefer to use shrinkflation in spite of consumer awareness of shrinkflation. We analyze if/when shrinkflation can be beneficial to consumers and society.

Pricing and Information in Modern Marketplaces

Community Committee Choice Session

Session Chair: Yiding Feng, Microsoft Research, Cambridge, MA

Session Chair: Wei Tang, Columbia University, New York, NY

1 Information Design of a Delegated Search

Yangge Xiao[1], Zhenyu Hu[1], Shouqiang Wang[2], [1]National University of Singapore, Singapore, Singapore; [2]University of Dallas, Texas, Dallas, TX, Contact: yangge_xiao@u.nus.edu

A principal delegates a sequential search to an agent, who bears the search cost and controls when to terminate searching. Upon termination, the search payoff is split between the principal and agent. However, only the principal can evaluate each search outcome. The principal designs an information policy to strategically disclose private outcomes over time to the agent. We show the optimal policy is fully prescribed by a sequence of deterministic acceptance standards. The agent is recommended and voluntarily willing to continue the search if and only if the current termination payoff fails to meet that period's standard. When the search results are not recallable, the acceptance standards are informative and determined recursively across different periods. When the search results are recallable, the optimal policy provides no information till a cutoff period, after which the acceptance standard is determined independently of other periods.

2 Online Resource Allocation: Bandits Feedback and Advice on Time-Varying Demands

Lixing Lyu[1], Wang Chi Cheung[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: lyulixing@u.nus.edu

We consider a non-stationary bandits with knapsack problem, which serves as a fundamental model for online resource allocation. The outcome distribution at each time is scaled by a non-stationary quantity that signifies changing demand volumes. Instead of studying settings with limited non-stationarity, we investigate how online predictions on the total demand volume Q allows us to improve our performance guarantees. We show that, without any prediction, any online algorithm incurs a linear-in-T regret. In contrast, with online predictions on Q, we propose an online algorithm that judiciously incorporates the predictions, and achieve regret bounds that depends on the accuracy of the predictions. These bounds are shown to be tight in settings when prediction accuracy improves across time. Our theoretical results are corroborated by our numerical findings.

3 Optimization of Scoring Rules

Yifan Wu, Northwestern University, Evanston, IL

This paper introduces an objective for optimizing proper scoring rules. The objective is to maximize the increase in payoff of a forecaster who exerts a binary level of effort to refine a posterior belief from a prior belief. In this framework we characterize optimal scoring rules in simple settings, give efficient algorithms for computing optimal scoring rules in complex settings, and identify simple scoring rules that are approximately optimal. In comparison, standard scoring rules in theory and practice - for example the quadratic rule, scoring rules for the expectation, and scoring rules for multiple tasks that are averages of single-task scoring rules - can be very far from optimal.

Sequential Markets and Mechanism Design

Community Committee Choice Session

Session Chair: Sean Sinclair, Cornell University, Ithaca, NY

1 Statistical Inference and A/B Testing for First-Price Pacing Equilibria

Luofeng Liao[1], Christian Kroer[2], [1]Columbia University, NYC, NY, [2]Columbia University, New York, NY, Contact: ll3530@columbia.edu

We initiate the study of statistical inference and A/B testing for first-price pacing equilibria (FPPE). The FPPE model captures the dynamics resulting from large-scale first-price auction markets where buyers use pacing-based budget management. Such markets arise in the context of internet advertising, where budgets are prevalent.
We propose a statistical framework for the FPPE model, in which a limit FPPE with a continuum of items models the long-run steady-state behavior of the auction platform, and an observable FPPE consisting of a finite number of items. We develop central limit theorems and asymptotically valid confidence intervals. Furthermore, we establish the asymptotic local minimax optimality of our estimators.
We then show that the theory can be used for conducting statistically valid A/B testing on auction platforms.

2 Representation with Incomplete Votes

Daniel Halpern, Harvard University

Platforms for online civic participation rely heavily on methods for condensing thousands of comments into a relevant handful based on whether participants agree or disagree with them. We argue that these methods should guarantee fair representation of the participants, as their outcomes may affect the health of the conversation and inform impactful downstream decisions. To that end, we draw on the literature on approval-based committee elections. Our setting is novel in that the approval votes are incomplete since participants will typically not vote on all comments. We prove that this complication renders non-adaptive algorithms impractical in terms of the amount of information they must gather, and complement this with an adaptive algorithm that provably satisfies commonly used notions of fair representation.

3 Enabling Long-Term Fairness in Dynamic Resource Allocation

Tareq Si Salem[1], George Iosifidis[2], Giovanni Neglia[3], [1]Northeastern University, Boston, MA, [2]TU Delft, Delft, Netherlands; [3]Inria, Sophia-Antipolis, France. Contact: t.sisalem@northeastern.edu

We study the fairness of dynamic resource allocation problem under the ⍰-fairness criterion. We recognize two different fairness objectives that naturally arise in this problem: the well-understood slot-fairness objective that aims to ensure fairness at every timeslot, and the less explored horizon-fairness objective that aims to ensure fairness across utilities accumulated over a time horizon. We argue that horizon-fairness comes at a lower price in terms of social welfare.
We study horizon-fairness with the regret as a performance metric and show that vanishing regret cannot be achieved in presence of an unrestricted adversary. We propose restrictions on the adversary's capabilities corresponding to realistic scenarios and an online policy that indeed guarantees vanishing regret under these restrictions.

4 Robust Pseudo-Markets for Reusable Public Resources

Giannis Fikioris[1], Siddhartha Banerjee[2], Eva Tardos[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, Contact: gfikioris@cs.cornell.edu

We study mechanisms for the fair and efficient allocation of *reusable public resources*, where a limited resource is shared among some agents, each of whom requests to use the resource over multiple consecutive rounds. We design a *pseudo-market mechanism* where each agent is endowed with some budget of artificial credits. Each agent has an *ideal utility* which is her maximum utility with no competition, subject to getting at most her fair share. Our mechanism runs a first-price auction with a selective reserve. We consider this problem in a Bayesian setting and show that under a certain reserve price, irrespective of how others bid, each agent can guarantee half her ideal utility in expectation. We also show this result is tight.

Learning and Decision-Making in Operations Management

Community Committee Choice Session

Session Chair: Zuo-Jun Max Shen, University of California Berkeley, Berkeley, CA

Session Chair: Mo Liu, UC Berkeley, Berkeley, CA

1 Data Privacy in Pricing: Estimation Bias and Implications

Ningyuan Chen[1], Ming Hu[2], Jialin Li[3], Sheng Liu[1], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Minneapolis, MN, [3]University of Toronto, Toronto, ON, Canada. Contact: jln.li@rotman.utoronto.ca

We study two privacy protection mechanisms motivated by emerging privacy regulations - limited retention and self-protection, in the context of data-driven (personalized) pricing. Privacy protection affects the estimation of the demand model and, thus, the offered price. Assuming a linear demand curve, we find that which customer groups benefit from the protection depends on the product/service type. For inferior goods (as opposed to normal goods), offered prices would decrease for all customers due to limited retention, and counter-intuitively, under self-protection, only privacy-protecting customers would see a price increase. On the other hand, the magnitude of the resulting price change is greater for industries with stronger historical price personalization. We validate our theoretical findings with a real dataset of online auto loans.

2 Active Label Acquisition with Personalized Incentives in Assortment Optimization

Mo Liu[1], Junyu Cao[2], Zuo-Jun Max Shen[3], [1]University of California Berkeley, Berkeley, CA, [2]The University of Texas at Austin, Austin, TX, [3]University of California Berkeley, Berkeley, CA, Contact: mo_liu@berkeley.edu

We study how to tailor incentives to motivate customers to reveal their preferences during the survey process in the capacitated assortment optimization problem. Based on the survey responses collected, the retailer develops a model that predicts each customer's preference and customizes the assortment accordingly. To assign incentives to customers efficiently, the primary challenge lies in evaluating each customer's potential revenue contribution to the prediction model. Notably, a smaller prediction error in the customers' preference model does not necessarily guarantee better assortment decisions or higher revenue. We design efficient personalized incentive algorithms with non-asymptotic guarantees and demonstrate both theoretically and empirically that our personalized incentive policy can achieve a much smaller cost than the fixed incentive policy.

3 Estimate-then-optimize Versus Integrated-estimation-optimization Versus Sample Average Approximation: A Stochastic Dominance Perspective

Adam Elmachtoub, Henry Lam, Haofeng Zhang, Yunfan Zhao, Columbia University, New York, NY, Contact: hz2553@columbia.edu

Recent literature in data-driven stochastic optimization considers integrating the estimation and optimization processes. This integrated approach which we call integrated-estimation-optimization (IEO) can be readily shown to outperform simple estimate-then-optimize (ETO) when the model is misspecified. In this paper we show that a reverse behavior appears when the model class is well-specified and there is sufficient data: ETO outperforms IEO asymptotically when the model class covers the ground truth in the strong sense of stochastic dominance of the regret. Our results also apply to constrained, contextual optimization problems where the decision depends on observed features. Whenever applicable, we also demonstrate how standard sample average approximation (SAA) performs the worst when the model class is well-specified, and best when it is misspecified.

4 Pasta: Pessimistic Assortment Optimization

Juncheng Dong[1], Weibo Mo[2], Zhengling Qi[3], Cong Shi[4], Ethan Xingyuan Fang[1], Vahid Tarokh[1], [1]Duke University, Durham, NC, [2]Purdue University, West Lafayette, IN, [3]The George Washington University, D.C., [4]University of Michigan, Ann Arbor, MI

We consider a fundamental class of assortment optimization problems in an offline data-driven setting. Due to the combinatorial nature of assortment optimization, the problem of insufficient data coverage is likely to occur in the offline dataset. To this end, we propose a novel algorithm called Pessimistic ASsortment opTimizAtion (PASTA for short), which can correctly identify the optimal assortment by only requiring the offline data to cover the optimal assortment. In particular, we establish the first regret bound for the offline assortment optimization problem under the celebrated multinomial logit model (MNL). We also propose an efficient computational procedure to solve our pessimistic assortment optimization problem. Our numerical studies demonstrate the superiority of the proposed method over the existing baseline method.

5 Best Arm Identification in Batched Multi-Armed Bandit Problems

Shengyu Cao[1], Simai He[2], Ming Hu[1], Jin Xu[2], Hongsong Yuan[2], [1]Rotman School of Management, University of Toronto, Toronto, ON, Canada; [2]Shanghai University of Finance and Economics, Shanghai, China

Recently multi-armed bandit problem arises inmany real-life scenarios where arms must be sampled in batches and the numberof arms is large, e.g., biological experimentation and online marketing. Weconsider pure exploration in a batched multi-armed bandit problem where the armsize tends to infinity, and the number of batches is small. We introduce

alinear programming framework and propose a two-step algorithm which achievesgood theoretical properties and has good simulation performance.

Digital Platforms: New Challenges and Directions

Community Committee Choice Session

Session Chair: Yuri Fonseca, Columbia University, New York, NY

Session Chair: Ilan Lobel, New York University, New York, NY

Session Chair: Fanyin Zheng, Columbia University, New York, NY

1 The Role of Driver Behavior in Moving the Electric Grid to Zero Emissions

Leann Thayaparan, Georgia Perakis, Massachusetts Institute of Technology, Cambridge, MA, Contact: lpgt@mit.edu

As renewable energy production increases, energy storage becomes a significant challenge. Electric Vehicles (EVs) could act as distributed storage, however complex driver behavior must be accounted for first. In this work, we model driver behavior using probability models and machine learning and show how these forecasts can be incorporated into optimizations for EV charging and discharging. We prove analytically the regimes for which the recommendations from the optimization do not negatively affect driver usage and propose a method to solve the optimization efficiently. We collaborate with an American EV manufacturer to size the capacity EVs can offer the grid as a source of distributed energy storage.

2 Design of Resale Platforms

Ilan Morgenstern[1], Daniela Saban[1], Divya Singhvi[2], Somya Singhvi[3], [1]Stanford University, Palo Alto, CA, [2]New York University, New York, NY, [3]USC Marshall School of Business, Los Angeles, CA, Contact: ilanmor@stanford.edu

We study resale platforms, an emerging type of online marketplaces in developing countries. These platforms are designed for users (resellers) to sell products to others, enabling them to supplement their income as they earn a margin on the transactions they generate. Using data from a major platform in India, we find that resellers reduce their margins and exert less effort when searching for products to sell as more of them join the platform. Motivated by these observations, we develop a model of resale platforms to understand how competition among resellers influences their product selection and margin decisions in equilibrium. Finally, we explore two potential interventions through which the platform can benefit resellers: centralizing margin decisions and optimizing its product ranking algorithm.

3 The Impact of AI Technology on the Productivity of Gig Economy Workers

Benjamin Knight[1], Dmitry Mitrofanov[2], Serguei Netessine[3], [1]Instacart, San Francisco, CA, [2]Boston College, Chestnut Hill, MA, [3]The Wharton School, Philadelphia, PA

We conducted field experiments on a grocery shopping platform that uses an AI-enabled guidance system to help shoppers find products on store shelves. We find that, as one would expect, such technology helps by reducing the number of refunds (due to the item being hard-to-find, e.g. located at a pop-up display, etc.) and that less experienced shoppers tend to use this guidance the most. However, counter-intuitively, we also find that the usage of more complex routing algorithms is not free: it takes a longer time to consult AI guidance and picking times increase as a result. Overall, we find that AI improves the effectiveness of gig workers by helping less experienced workers achieve order outcomes that are more comparable to those of more experienced workers, thus increasing both customer satisfaction and revenue per order.

4 Signaling Competition in Two-Sided Markets

Omar Besbes[1], Yuri Fonseca[1], Ilan Lobel[2], Fanyin Zheng[1], [1]Columbia University, New York, NY, [2]New York University, New York, NY, Contact: yfonseca23@gsb.columbia.edu

Consider a platform facilitating decentralized many-to-many matches between two sides. A key attribute of supply is how competitive it will be for demand to obtain the supply after the match. Should the platform reveal competition levels to potential demand? We answer this question empirically in the context of a labor platform. We partnered with a services marketplace which sells non-exclusively labor market leads to service workers. We propose and estimate a structural model in which workers internalize expected competition levels. Our counterfactual analysis finds that signaling competition significantly improves outcomes for market participants and may lead to a win-win situation for both the platform and agents depending on certain market characteristics.

Combating Illicit Networks

Community Committee Choice Session

Session Chair: Maria Esther Mayorga, North Carolina State University, Raleigh, NC

1 Detecting Human Trafficking: Automated Classification of Online Customer Reviews of Massage Businesses

Ruoting Li, North Carolina State University, Raleigh, NC

The problem of human trafficking through illicit massage businesses (IMBs) in the United States is significant. While IMB review boards provide information for the investigation, they are likely to be shut down by law enforcement. Open websites like Yelp provides accessible information on a larger set of businesses that can be screened for risk factors of trafficking. We develop a natural language processing approach to detect online customer reviews indicating a business is engaged in trafficking. We train and evaluate different classification models, including lexicon-based and embedding-based models, and use ensemble learning to combine their strengths. The proposed models can save law enforcement countless hours by automatically flagging potential illicit activity in Yelp reviews, eliminating the need for manual screening.

2 Using Spatiotemporal Analysis to Identify Potential Sex Trafficking Victims in Commercial Sex Advertisements

Shailesh J. Divey, Nickolas K. Freeman, Gregory Bott, Burcu B. Keskin, The University of Alabama, Tuscaloosa, AL, Contact: sdivey@cba.ua.edu

In this paper, using text and image data associated with sex ads collected from websites that host advertisements for commercial sex services, we create a curated dataset that is used to construct a graphical representation for all the individuals identified in the data. By leveraging techniques from the field of machine learning and graph theory, we analyze spatiotemporal patterns of these individuals in order to isolate and cluster those that exhibit highly correlated movement patterns across space and time. The information obtained from these clusters provide insights regarding geographical circuits that are likely to be employed by sex traffickers. These insights, in turn, are important for policymakers, law-enforcement, and non-profit organizations for devising strategies to conduct effective counter-trafficking operations.

3 Labor Trafficking Disruption with Collaborating Actors

Priscila de A. Drummond[1], Kayse Lee Lee Maass[2], Arezoo Jafari[2], [1]Northeastern University, Boston, MA, [2]Northeastern University, Boston, MA, Contact: deazevedodrummond.p@northeastern.edu

Catastrophically disrupting illicit supply chains requires many hands. In anti-labor trafficking efforts, collaboration is the only way to protect the victims and disrupt the operation. Unlike nuclear material trafficking, in which we can build physical sensors to help its detection, labor trafficking can happen in many forms, usually in a spectrum of exploitation traversing different jurisdictions. Task forces and multiple interventions are necessary to address this challenge. Thus, to properly model the success of interventions in disrupting labor trafficking, we must account for collaboration. We present a stochastic network interdiction problem with multiple interventions and actors.

4 An Active Learning Approach for Training Review Classification Models to Detect Human Trafficking

Osman Ozaltin[1], Margaret Tobey[2], Maria Esther Mayorga[1], Sherrie Caltagirone[3], [1]North Carolina State University, Raleigh, NC, [2]NC State University, Raleigh, NC, [3]Global Emancipation Network, Orlando, FL

Active learning is a machine learning approach that aims to optimize the learning process by selecting and labeling the most informative data points. We formulate active learning as a decision process and learn a policy to query the most informative data points through deep reinforcement learning. We assess the effectiveness of the proposed approach for an imbalanced natural language processing classification task. Specifically, our classification task is to detect Yelp reviews that contain risk factors of human trafficking. The classifier trained on the reviews selected by the proposed query policy can achieve a similar or higher F1 score compared to uncertainty sampling. Additionally, the proposed policy is more effective than uncertainty sampling in large batch query settings.

Frontiers in Online Decision-Making: Applications to e-Commerce Fulfillment

Community Committee Choice Session

Session Chair: Chamsi Hssaine, Cornell University, Ithaca, NY

1 Approximation Schemes for Dynamic Pricing with Opaque Products

Jacob Feldman[1], Yukai Huang[2], Xingxing Chen[3], [1]Olin Business School, Saint Louis, MO, [2]WashU, St. Louis, MO, [3]University of Richmond, Richmond, VA, Contact: yukaihuang@wustl.edu

In this paper, we consider a multi-period, multi-product dynamic pricing problem in which each product is endowed with an exogenous starting inventory level, and there is the added complexity of an opaque selling option. That is, alongside traditional (transparent) products, the retailer or platform also has the option to create and price an opaque product, which corresponds to a dummy product comprised potentially of any subset of the displayed transparent products. In the event that a customer selects the opaque product, the platform has the freedom to choose any of the opaque product's constituents to satisfy this demand. All-in-all, we are left with a classical dynamic pricing problem with a twist, since the addition of the opaque selling option gives the platform an extra lever of flexibility to balance supply and demand.

2 No-Regret Learning in Two-Echelon Supply Chain with Unknown Demand Distribution

Mengxiao Zhang[1], Shi Chen[2], Haipeng Luo[1], Yingfei Wang[3], [1]University of Southern California, Los Angeles, CA, [2]University of Washington, Foster School of Business, Seattle, WA, [3]University of Washington, Seattle, WA, Contact: mengxiao.zhang@usc.edu

Supply chain management has been recognized as an important discipline with applications to many industries, where the *two-echelon* stochastic inventory model plays a fundamental role. In this work, we aim at designing online algorithms for this problem with an *unknown* demand distribution, which brings distinct challenges as compared to classic online problems. Specifically, we consider the model in [CZ99] under both *centralized* and *decentralized* settings. We design algorithms achieving favorable guarantees for both regret and convergence to the best policy in both settings, and additionally for individual regret in the decentralized setting. Our algorithms are based on Online Gradient Descent and Online Newton Step, together with several new ingredients specifically designed for our problem. We also implement our algorithms and show the empirical effectiveness.

3 Joint vs. Separate Optimization in Large-Scale E-Commerce Fulfillment Systems

Boris Epstein, Will Ma, Columbia University, New York, NY

E-commerce fulfillment systems involve a wide spectrum of decisions. In practice, each of these decisions is assigned to a specific team within the organization. We take a step towards understanding the effects of this separate optimization as opposed to a joint optimization by developing a model involving inventory allocation and fulfillment decisions. The optimal allocation depends on the fulfillment policy implemented, but it is challenging to take this policy exactly into account. An approach in the literature is for the allocation team to make an assumption about how fulfillments will be made, e.g. by a Myopic policy or a clairvoyant Offline policy. We derive the structural result that assuming Offline causes the allocation team to put more inventory in flexible locations. Moreover, we show that assuming Offline provides a more robust solution than assuming Myopic.

1 Double Pessimism is Provably Efficient for Distributionally Robust Offline Reinforcement Learning: Generic Algorithm and Robust Partial Coverage

Jose Blanchet[1], Miao Lu[1], Tong Zhang[2], Han Zhong[3], [1]Stanford University, Stanford, CA, [2]The Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]Peking University, Beijing, China. Contact: miaolu@stanford.edu

Distributionally robust offline reinforcement learning seeks to find an optimal robust policy purely from offline data that performs well in perturbed environments. In this work, we propose a generic algorithm framework, Doubly Pessimistic Model-based Policy Optimization, for sample-efficient distributionally robust offline RL with function approximations. In algorithmic design, the *double pessimism* principle is crucial to overcome the distributional shift incurred by i) the mismatch between behavior policy and the family of target

policies; and ii) the perturbation of the nominal model. Our work first showed that the principle of double pessimism achieves sample-efficient learning for distributionally robust offline RL with general function approximations.

2 Exact Description of Limiting SIR and SEIR Dynamics on Locally Tree-like Graphs

Juniper Cocomello, Kavita Ramanan, Brown University, Providence, RI

We study the Susceptible-Infected-Recovered (SIR) and the Susceptible-Exposed-Infected-Recovered (SEIR) models of epidemics with time-varying rates on a class of locally tree-like networks, which includes sparse Erdős-Rényi graphs, regular graphs, and other configuration models. We identify tractable systems of ODEs that exactly describe the dynamics of the SIR and SEIR processes in a suitable asymptotic regime where the population size goes to infinity. Furthermore, we use this ODE characterization to study the outbreak size under both constant and time-varying recovery rates. We demonstrate via simulations the efficacy of the dynamics and outbreak size approximations for populations of moderate size.

3 Rare-Event Simulation for Machine Learning Models: Challenges and Remedies

Henry Lam, Columbia University, New York, NY

In estimating rare-event probabilities, naive Monte Carlo is inefficient due to its infrequent hits on the target rare events, which motivates variance reduction techniques such as importance sampling (IS) to speed up simulation. However, these techniques are often "double-edged swords", i.e., while they can substantially increase the estimation efficiency when properly configured, they could also significantly hurt the estimation if poorly designed. We discuss some challenges in applying IS to safe-AI applications, which arise from the interplay of model sophistication and the subtlety in IS design. We also present some (partial) remedies including IS search algorithms via mathematical programming, the revisit of statistical criteria to evaluate algorithms, and adaptivity that allows the incorporation of rare-event estimation into safe model training.

4 Distributionally Robust Optimization of Boosting for Efficient Ensemble Learning

Mark S. Squillante[1], Soumyadip Ghosh[2], [1]IBM Research, Mathematical Sciences Department, Yorktown Heights, NY, [2]IBM TJ Watson Research Center, Yorktown Heights, NY, Contact: mss@us.ibm.com

Boosting is an approach in learning theory that combines weak learners into an ensemble, adaptively picking learners by training on data re-weighted to emphasize those points on which the current ensemble performs poorly, and ensembling a weighted combination of the outputs of the individual learners. Various algorithms have been proposed to determine the data and weak learner weights, most notably the AdaBoost multiplicative weights scheme. We propose and analyze a sequence of distributionally robust formulations for both re-weighting problems seeking to pick a compact ensemble that optimizes generalization performance. We devise computationally efficient estimation algorithms for these formulations that provably balance a fundamental tradeoff between computation and variance. Numerical experiments demonstrate the significant benefits of our approach.

Bayesian Optimization

Community Committee Choice Session

Session Chair: Peter Frazier, Cornell / Uber, Ithaca, NY
Session Chair: David Eriksson, Meta, Boulder, CO
Session Chair: Jana Doppa, Washington State University, Pullman, WA

1 Bayesian Optimization over Combinatorial Spaces: Progress and Outstanding Challenges

Jana Doppa, Aryan Deshwal, Washington State University, Pullman, WA

The problem of optimizing combinatorial spaces (e.g., sequences, graphs, sets, and permutations) using expensive black-box function evaluations arises in many science and engineering applications. For example, optimizing hardware architecture using computational simulations. There are two key challenges in solving this problem within the framework of Bayesian Optimization (BO). First, effective surrogate modeling in the small-data setting. Second, solving a hard combinatorial optimization problem as part of the acquisition strategy. This talk will present a holistic view of current progress in this problem space with a focus on principles. We will end the talk with lessons learned and some outstanding challenges.

2 Sparse Bayesian Optimization

David Eriksson, Meta, Boulder, CO

Bayesian optimization (BO) is a powerful approach to sample-efficient optimization of black-box objective functions. However, the application of BO to areas such as recommendation systems often requires taking the interpretability and simplicity into consideration, a setting that has not been previously studied in the BO literature. To make BO applicable in this setting, we present several regularization-based approaches that allow us to discover sparse and more interpretable configurations. We propose a novel differentiable relaxation based on homotopy continuation that makes it possible to target sparsity by working directly with L0 regularization. We identify failure modes for regularized BO and develop a hyperparameter-free method, sparsity exploring Bayesian optimization (SEBO) that seeks to simultaneously maximize a target objective and sparsity.

3 Bayesian Optimization of Function Networks with Partial Evaluations

Poompol Buathong[1], Jiayue Wan[1], Samuel Daulton[2], Raul Astudillo[3], Maximilian Balandat[2], Eytan Bakshy[2], Peter Frazier[4], [1]Cornell University, Ithaca, NY, [2]Meta, Menlo Park, CA, [3]California Institute of Technology, Pasadena, CA, [4]Cornell / Uber, Ithaca, NY, Contact: pb482@cornell.edu

Bayesian optimization of function networks (BOFN) aims to optimize the final output of a network of functions. It leverages intermediate outputs of the network to achieve better experimental design than standard Bayesian optimization algorithms. However, existing BOFN algorithms either require evaluating every function node at every iteration or are applicable to a limited class of networks. To address these issues, we propose a knowledge gradient (KG) acquisition function that chooses which nodes to evaluate and the inputs for that node in a cost-aware fashion. We provide an efficient approach to optimizing our acquisition function, and show that it outperforms existing BOFN methods across several synthetic and real-world applications.

4 Conjunctive Bayesian Optimization for Min/max of Multiple Functions

Surdeep Chotaliya, Arizona State University, Tempe, AZ, Contact: surdeepchotaliya541997@gmail.com

This work proposes a novel approach called conjunctive Bayesian optimization (conBO) for optimizing functions comprising multiple nonlinear components. Unlike previous methods, conBO explicitly considers dependencies between components, enhancing optimization accuracy. It introduces a paired sampling algorithm (conBO-PS) that leverages mutual contributions from function pairs. To handle large-scale problems, the conBO-LS framework employs conBO-PS on adaptively chosen component subsets, allowing control over computational resources. Experimental results demonstrate conBO's superiority in solution quality and computational efficiency across various scenarios, including complex analytical functions and industrial challenges.

Empirical Analysis for Agri-Food Supply Chain Decision-Making

Community Committee Choice Session

Session Chair: Deniz Berfin Karakoc, University of Illinois at Urbana-Champaign, Urbana, IL

1 Dynamic Irrigation Management Under Temporal and Spatial Variability

Erkut Sonmez[1], Baris Ata[2], Derek Heeren[3], [1]University of Nebraska Lincoln, Lincoln, NE, [2]University of Chicago, Chicago, IL, [3]University of Nebraska Lincoln, Lincoln, NE

Agricultural productivity must improve significantly soon following increasing food demand. One way to improve productivity is irrigation. However, freshwater scarcity, increasing costs, and climate change necessitate sustainable and efficient methods for irrigation. We study dynamic irrigation management under uncertainty considering temporal variability and spatial soil heterogeneity of the field.

2 Enhancing Effectiveness of USAID's Humanitarian Supply Chain Operations for Both On-Going and Sudden-Onset Food Aid Needs

Lluvia (Weijia) Jing[1], Ozlem Ergun[2], [1]Northeastern University, Boston, MA, [2]Northeastern University, Newton, MA, Contact: jing.we@northeastern.edu

Millions of tons of food aid are distributed each year by the U.S. Agency for International Development's Bureau for Humanitarian Assistance and the legacy Office of Food for Peace (BHA/FFP). However, the need always exceeds available food aid resources. Efficiency gains in existing supply chains offer potential for closing this gap. Through analytics and optimization, we build data-driven models to help the organization achieve more effective decision making for food aid procurement, preposition and distribution. We generate scenarios to develop insights on strategic planning - warehouse location selection and prepositioning decision for a merged supply chain serving both long-tern operations and emergency response.

3 Equitable Distribution of Perishable Items in a Food Bank Supply Chain

Irem Sengul Orgut[1], Emmett J. Lodree[2], [1]University of Alabama, Tuscaloosa, AL, [2]University of Alabama, Tuscaloosa, AL, Contact: isorgut@cba.ua.edu

In the United States, food banks help reduce food insecurity by distributing donated food among the population in need. They aim to equitably distribute food donations among their clients while minimizing waste that occurs due to spoilage and capacity limitations. Perishable food items present specific challenges since they are susceptible to spoilage and need to be distributed before their expiry dates. Based on our partnership with a large food bank, we present a capacitated, multi-period, multi-product network flow model to help them equitably and effectively distribute perishable food donations. The model is applied within the context of a case study and reveals managerial insights that would be useful to practitioners. Given the inevitability of inequitable food allocations in practice, we provide guidance on how to strategically control inequities.

Information Disclosure and Behavior on Networks

Community Committee Choice Session

Session Chair: Guangwen Kong, 1</sup

Session Chair: Ankur Mani, University of Minnesota - Twin Cities, Minneapolis, MN

1 Information Disclosure and Consumer Search on the Experience Goods: Theory and Empirical Evidence of Online Platforms

Yushu Zeng[1], Hu Huang[2], Ying-Ju Chen[3], Xin Wang[4], [1]Hong Kong University of Science and Technology, Hong Kong, China; [2]HKUST, Hong Kong, China; [3]The Hong Kong University of Science and Technology, Kowloon, Hong Kong; [4]The Hong Kong University of Science and Technology, Hong Kong, China. Contact: yzengao@connect.ust.hk

In this paper, we develop a stylized game-theoretical model to study the information disclosure strategies of a firm that sells experience goods through an online platform. The platform can offer vertical quality information and the firm may disclose the horizontal quality attributes. We find that the firm is more likely to reveal its horizontal attribute information when its vertical quality level is lower, the search cost is lower, or the vertical quality information is public. We also find that the platform should not provide consumers with the vertical quality information of the product when the search cost is low. Moreover, we also conduct an empirical study on an online web novel platform and find that the lower-level authors (with lower vertical quality) of web novels tend to choose longer book names (more attribute information), which confirms the theoretical results.

2 Advice Provision in the Pandemic: The Impact of Information Granularity on Social Protection

Guangwen (Crystal) Kong[1], Yang Zhang[2], Jingjing Weng[1], [1]Temple University, Philadelphia, PA, [2]University of Kent, Uxbridge, United Kingdom. Contact: jingjing.weng@temple.edu

This paper explores advice provision against a pandemic outbreak (COVID-19, or similar future diseases). We investigate how the granularity of information provided by the social planner impacts people's pandemic protection efforts. The planner can either provide decomposed statistics for each social group---e.g. death rate at each age (referred as targeted strategy), or provide a simple aggregate over all social groups---e.g. average death rate for all ages (referred as uniform strategy). Surprisingly, our findings challenge the conventional wisdom that granular data is always superior. Instead, we reveal instances where the uniform strategy outperforms the targeted strategy in pandemic response.

3 The Value of Community Information for Pricing Under Network Externalities

Calvin Roth[1], Jiali Huang[2], Ankur Mani[1], [1]University of Minnesota, Minneapolis, MN, [2]Meta Platforms, Inc., Cambridge, MA

We study the value of network information for pricing decisions when selling divisible goods with positive network externalities to consumers in a social network. We consider consumers whose utility functions are homogeneous except for their position in the network and examine the value of network information for dense stochastic block models which give information on how communities on average interact with the rest of the network instead of consumers. We find that for this class of networks there will be significant losses when pricing with no information about the network. We also find that for asymptotically large networks making pricing decisions using only the information about community structure and community memberships of the consumers does not introduce any significant change in expected profits over optimal pricing under full network information.

4 Solving Present Bias Inefficiency with Deadlines

Nicholas Hall[1], Zhixin Liu[2], [1]The Ohio State University,

Columbus, OH, [2]University of Michigan-Dearborn, Dearborn, MI, Contact: hall.33@osu.edu
Present bias without self-awareness causes a significant loss of utility in operational decisions through poor task choice and procrastination. We study the use of a deadline to mitigate the loss. We use a backward recursion procedure to identify critical times at which task choice and timing tradeoffs are evaluated, leading to a closed-form characterization of a schedule under imperfect self-awareness. The task completion times increase monotonically or change cyclically with the deadline under different self-awareness levels. Times at which the decision-maker fails to follow an anticipated decision are learning opportunities, which suggest a scheme for developing self-awareness. This leads to specific recommendations for deadline setting.

On Security and Rescue Operations

Contributed Session

Session Chair: Michael Morin, Université Laval, Québec, QC, Canada

2 A Stochastic Game Framework for Patrolling a Border

Matthew Darlington[1], Kevin Glazebrook[1], David Leslie[1], Rob Shone[1], Roberto Szechtman[2], [1]Lancaster University, Lancaster, United Kingdom; [2]Naval Postgraduate School, Monterey, CA, Contact: m.darlington@lancaster.ac.uk
We consider a stochastic game for modelling the interactions between smugglers and a patroller along a border. The problem we examine is a group of cooperating smugglers making regular attempts at bringing small amounts of illicit goods across a border. A single patroller has the goal of preventing the smugglers from doing so, but must pay a cost to travel from location to location. We have proven a number of properties of the Nash equilibria in the game that lead towards new methods of calculating them. The methods we have developed are then significantly more computationally efficient than existing general ways to find Nash equilibria in our model. We explore how parameters such as the penalties applied to the smugglers by the patroller and topology of the border can affect the patroller's strategy.

3 Maximal Coverage Information Collection Problem Using Kriging

Esther Jose, Moises Sudit, Rajan Batta, University at Buffalo (SUNY), Buffalo, NY, Contact: estherjo@buffalo.edu
The goal of this project is to identify which image sensors in an ISR mission should collect data from which cells at which resolutions to maximize information gain. However, information is not only gained from cells where data is directly collected from; data fusion techniques such as Kriging can be used to collect information from other cells as well. Using Kriging, the estimated error of the prediction in each cell can be calculated. We can say a cell is "confidently covered" if this estimated error is below a certain acceptable level.
While Kriging is non-linear, we develop an approximate MIP to solve this problem called Simplified Kriging (SK). SK obtains solutions within 1% of optimality. We also show that SK is equivalent to the Maximal Coverage location problem (MCLP) and we test different heuristics and solution methods to solve the information collection problem.

4 Metamodels of a Search Simulator for Maritime Search Operations Efficiency Evaluation

Michael Morin, Thomas Laperrière-Robillard, Irene Abi-Zeid, Université Laval, Québec, QC, Canada
Planning an efficient maritime search and rescue operation (MSAR) requires estimating the quality of search plans. Nowadays, decision support systems (DSS) for MSAR planning use Monte Carlo drift simulation and search simulators. Carrying multiple simulations is computationally intensive. We present supervised learning-based metamodels to reduce the time required to find high-quality search plans and answer the following questions: Can the probability of success be closely approximated? To what extent does our approach improve the current system?

Frontiers of Algorithmic Fairness

Community Committee Choice Session

Session Chair: Vahideh Manshadi, Yale University, New Haven, CT

Session Chair: Rad Niazadeh, Chicago Booth School of Business, CHICAGO, IL

1 Algorithmic Precision and Human Decision: A Study of Interactive Optimization for School Schedules

Arthur J. Delarue[1], Zhen Lian[2], Sebastien Martin[3], [1]H. Milton Stewart School of Industrial and Systems Engineering at Georgia Tech, Atlanta, GA, [2]Yale, New haven, NY, [3]Kellogg School of Management, Northwestern University, Evanston, IL, Contact: sebastien.martin@kellogg.northwestern.edu

Motivated by a collaboration with the San Francisco Unified School District (SFUSD), this paper presents an interactive optimization framework for addressing complex public policy problems. Our framework addresses this challenge by combining three key elements: (1) an efficient optimization algorithm that can solve the problem given certain known objectives, (2) a method for generating a large set of diverse, near-optimal solutions, and (3) an interface that facilitates exploration of the solution space. We illustrate the effectiveness of this framework by applying it to the problem of improving school schedules at SFUSD. The resulting schedule, implemented in August 2021, saved the district over $5 million and, to our knowledge, represents the first successful optimization-driven school start time change in the United States.

2 A Theory of Dynamic Benchmarks

Ali Shirali[1], Rediet Abebe[2], Moritz Hardt[3], [1]University of California, Berkeley, Berkeley, CA, [2]Harvard University, Cambridge, MA, [3]Max-Planck Institute for Intelligent Systems, Tübingen, Tübingen, Germany

Dynamic benchmarks interweave model fitting and data collection in an attempt to mitigate the limitations of static benchmarks. In contrast to an extensive theoretical and empirical study of the static setting, the dynamic counterpart lags behind due to limited empirical studies and no apparent theoretical foundation to date. Responding to this deficit, we initiate a theoretical study of dynamic benchmarking. Our results illuminate the benefits and practical limitations of dynamic benchmarking, providing both a theoretical foundation and an explanation for observed bottlenecks. Although our study centers around lowering risk or improving the accuracy of the induced models, our framework opens up a new way for future works to address other concerns surrounding dynamic benchmarks including robustness and fairness.

3 Auditing for Human Expertise

Rohan Alur, Massachusetts Institute of Technology, Cambridge, MA, Contact: ralur@mit.edu

High-stakes prediction tasks (e.g., patient diagnosis) are often handled by human experts. One source of concern about automation in these settings is that experts may exercise intuition that is difficult to model and/or have access to information (e.g., conversations with a patient) that is unavailable to a would-be algorithm. This raises a natural question whether human experts add value which could not be captured by an algorithmic predictor.
We develop a statistical framework under which this becomes a natural hypothesis test. Indeed, as our framework highlights, answering this question is more subtle than simply comparing expert performance to that of an algorithm. Instead our procedure takes the form of a conditional independence test, and can be viewed as assessing whether human experts may value to *any* algorithm trained on the available data.

4 Multi-Objective Learning: A Unifying Perspective on Fairness

Eric Zhao, University of California, Berkeley, Berkeley, CA, Contact: eric.zh@berkeley.edu

Addressing fairness in machine learning has far-reaching implications for the robustness, equity, and collaborative aspects of real-world systems*. Various formalizations of fair data-driven decision-making have been proposed, among which multicalibration and multidistribution learning have emerged as especially foundational and versatile frameworks. In this talk, we will explore how an algorithmic toolbox of no-regret learning and dynamic decision-making enables the design of efficient algorithms for these frameworks. Specifically, we will highlight the significance of game dynamics as a unifying perspective, allowing us to obtain optimal guarantees for these problems through multi-objective learning.

Understanding Customer Attitudes Towards Waiting

Community Committee Choice Session

Session Chair: Kyle Hyndman, University of Texas at Dallas, Richardson, TX

1 Experienced and Prospective Wait in Queues: A Behavioral Investigation

Jing Luo[1], Leon Valdes[2], Sera Linardi[2], [1]University of

Science and Technology Beijing, Beijing, China; [2]University of Pittsburgh, Pittsburgh, PA, Contact: lvaldes@katz.pitt.edu

Contrary to rational predictions, empirical evidence suggests that queuing disutility does not depend solely on waiting time. However, how the speed, length, and waiting time of a queue jointly affect disutility is not well understood. Similarly, it remains unclear whether and how the *experience* of wait—controlling for the *remaining* wait—impacts people's responses. In this paper, we conduct a series of controlled incentivized experiments to study these questions in observable queues. Our results show that, in contrast to rational models, the length and service speed of the residual queue affect individuals' costs additively, not multiplicatively. We also find that the experience of wait does not typically affect completion costs, except when both the service time and amount of progress are large.

2 AI Chatbots in Customer Service: Adoption Hurdles and Simple Remedies

Evgeny Kagan[1], Maqbool Dada[2], Brett Hathaway[3], [1]Johns Hopkins Carey Business School, Baltimore, MD, [2]Johns Hopkins University, Baltimore, MD, [3]Brigham Young University, Provo, UT, Contact: ekagan@jhu.edu

We conduct experiments in which participants choose, and then experience, the chatbot or the live agent channel as we vary operational (i.e., times spent and chatbot success rates) and qualitative features of the chatbot. We find that users respond positively to improvements in chatbot operational performance; however, the chatbot channel remains underutilized relative to what expected time minimization would predict. Additional experiments show that this is caused by two mechanisms: algorithm aversion (aversion to an algorithmic service provider), and gatekeeper aversion (aversion to any service format that may involve multiple stages). Examining potential remedies, we find that algorithm aversion can be mitigated by making salient the expected time savings offered by the chatbot. However, gatekeeper aversion is more persistent and harder to overcome

3 Understanding How Individuals Perceive Waiting

Kyle Hyndman[1], Andrew M. Davis[2], Evgeny Kagan[3], [1]University of Texas at Dallas, Richardson, TX, [2]Cornell University, Ithaca, NY, [3]Johns Hopkins Carey Business School, Baltimore, MD

We conduct a series of experiments where we elicit valuations for waiting in order to receive a high prize. We consider known, risky and uncertain (i.e., ambiguous) wait times. We also attempt to identify the role of expectations and information on valuations for waiting.

Data-Driven Decision-Making in Healthcare

Community Committee Choice Session

Session Chair: Yingchao Lan, University of Nebraska-Lincoln, Lincoln, NE

Session Chair: Vishal Ahuja, Southern Methodist University, Dallas, TX

1 Crowdsourced Drug Discovery

Brian Lee, Hui Zhao, Pennsylvania State University, University Park, PA

This paper presents a novel setting to explore crowdsourcing as a new approach to the lengthy and risky drug discovery process. We leverage a quasi-experimental setup to examine how collaborative crowdsourcing can help drug discovery. In particular, we study how availability of the prior design's effectiveness information affects the effectiveness the crowdsourced drug designs. In light of the rising cost and many challenges in drug discovery, our paper has significant theoretical and practical meaning. It represents the first study to explore the mechanisms driving successful crowdsourced drug discovery.

2 Colocation of Family Medicine with Rural and Urban Hospitals

Benjamin Grant[1], Peter Tilkemeier[2], [1]Clemson University, Greenville, SC, [2]Prisma Health, Greenville, SC, Contact: bngrant@clemson.edu

We examine the impact of colocation of Family Medicine practices on both hospital operations and patient outcomes for urban and rural locations.

3 Causal Effects of Telehealth Follow-Up Visits on Postdischarge Adverse Events

Jaeyoung Park, Julia Ran, Shah Sachin, Daniel Adelman, University of Chicago, Chicago, IL

Following COVID-19, the use of telehealth surged due to pandemic-related restrictions but declined as pandemic mitigation. Physicians and patients were found to prefer in-person care to telehealth in the recent literature, suggesting the current telehealth care setting is not optimal. In this study, we examined the role of telehealth in improving post-discharge health outcomes, especially 90-day unplanned readmission, for heart failure patients. We hypothesized 1) telehealth can complement the in-person modality for follow-up visits, and 2) for a specific type of patients, it can substitute the in-person modality for follow-up visits. We identified the causal effects and tested the hypotheses, using the Medicare claims data and controlling for observed and unobserved confounders. Finally, we proposed improved telehealth care delivery based on our findings.

Community Committee Choice Session

Session Chair: Naoru Koizumi, George Mason University, Arlington, VA

Session Chair: Hadi El-Amine, George Mason University, Fairfax, VA

1 Analyzing the Formation of Transnational Kidney Trafficking Networks

Zifu Wang, Meng-Hao Li, Patrick Baxter, Jiaxin Wei, Naoru Koizumi, George Mason University, Fairfax, VA

Transnational kidney trafficking networks involve multiple actors, including buyers, sellers, brokers, and surgeons, operating across international borders. However, the lack of systematic kidney trafficking data collection and network analysis hinders our understanding of the formation and dynamics of these networks. In this study, we utilized OpenAI's GPT-3.5 model to identify the role of countries involved in kidney trafficking, using a large dataset of 50,228 newspaper articles extracted from LexisNexis between 2000 and 2022. We then applied Temporal Exponential Random Graph Models to analyze how country characteristics (i.e., GDP, rule of law quality, human rights scores, cultural distance, and healthcare resources) influence the formation of transnational kidney trafficking networks.

2 The Role of Kidney Broker Countries in Global Buyer-Seller Networks

Meng-Hao Li, Zifu Wang, Anna Matthei, Gabriel Yossick, Yu Yang, Naoru Koizumi, George Mason University, Arlington, VA

Kidney buyers, sellers, and brokers play vital roles in transnational kidney trafficking networks. However, the precise ways in which kidney broker countries mediate relationships between buyer and seller countries remain unclear. In this study, we collected 975 kidney trafficking-related newspaper articles from LexisNexis spanning 2000 to 2019 to identify the countries involved in kidney sellers, buyers, or brokers. We then used exponential random graph models to analyze how country characteristics - such as GDP, rule of law quality, human rights scores, religions, migration networks, and international trade - affect the formation of transnational kidney buyer-broker-seller networks.

Workforce and Capacity Management for Healthcare

Community Committee Choice Session

Session Chair: Sandeep Rath, University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC

1 The Impact of Historical Workload on Nurses Perceived Workload

Carri Chan[1], Yi Chen[2], Jing Dong[3], Sarah Rossetti[4], [1]Columbia Business School, New York, NY, [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]Columbia University, New York, NY, [4]Columbia University Medical Center, New York City, NY, Contact: yichen@ust.hk

Recent and ongoing nursing shortages have highlighted the work that nurses provide round the clock in hospital inpatient care. Intense and sustained high nursing workload has been linked to nurse burnout and patient safety concerns, necessitating targeted approaches to better managing nursing workload. In this work, we take an empirical approach to understanding the effect of historical workload on nurses' perceived workload. Our estimation results show that one level of increase in historical order-based workload can lead to a 0.629 increase in the discrepancy between the clinically perceived workload and the order-based workload. Based on the temporal effect of nursing workload, we design an integer program-based patient-to-nurse assignment policy that achieves a more balanced workload over time while maintaining a high level of continuity of care.

2 Delta Coverage: The Analytics Journey to Implement a Novel Nurse Deployment Solution

Jonathan Eugene Helm[1], Pengyi Shi[2], Mary Drewes[3], [1]Indiana University, Bloomington, IN, [2]Purdue University, West Lafayette, IN, [3]IU Health, Indianapolis, IN, Contact: helmj@indiana.edu

This talk describes an academia industry collaboration to design and execute a new *internal travel nursing program* at IU Health that moves flexible nurses between the 16 system hospitals to respond short term geographic fluctuations in demand. For adoptability, we developed decision support to create an on-call list of how many nurses will move and where 2 weeks in advance and deployment decisions 24-48 hours in advance. This required developing a machine-learning-based occupancy forecasting model that accounts for different levels of patient acuity and outputs distributional information that can be used to characterize stochastic nurse demand across the network that feed a stochastic optimization. Implemented in Oct 202, subsequent 5 months indicates reductions of 5% understaffing, 3% misallocation of nurses, and 1% overstaffing. Annual savings >$400K.

3 The Impact of Introducing Release Times for Operating Rooms on Surgery Waiting Times

Guang Cheng[1], Mitchell H. Tsai[2], Joel Goh[3], [1]National University of Singapore, Singapore, Singapore; [2]University of Vermont Medical Center, South Burlington, VT, [3]NUS Business School, Singapore, Singapore. Contact: gcheng@u.nus.edu

The relationship between the implementation of a block release policy and surgery waiting times has not been studied. To evaluate the relationship of implementing a 7-day release policy on surgery waiting times at an academic medical center. At this center, a 7-day release policy was implemented on May 1, 2019, although not all specialties adopted this policy. A difference-in-differences regression was used to assess how the policy impacted surgery waiting times differentially between adopters and non-adopters. Our results show that waiting times in the follow-up period increased by 3.59 (95% CI: 1.84 - 5.35) days relative to baseline on average. Specialties that adopted the 7-day waiting time policy, however, saw a reduction of 6.89 (95% CI: 4.64 - 9.14) days of waiting relative to specialties that did not.

4 Nurse Workload Balancing Using Real-Time Location Data

Beste Kucukyazici[1], Pouya Hoseinpour[2], Vedat Verter[3], [1]Queen's University, Kingston, ON, Canada; [2]Amirkabir University of Technology, Tehran, Iran, Islamic Republic of; [3]Queen's University, Kingston, ON, Canada. Contact: beste.kucukyazici@queensu.ca

In this research, we develop a data-driven analytical framework to achieve balanced nurse workloads by optimizing the nurse-patient assignment decisions. To this end, we utilize an extensive data set collected by a real-time location system installed in the surgical services department of a large tertiary hospital. This enabled us to track the care providers as well as the surgical patients through their journey from the emergency department to the operating room, and the surgical ward. The nurse workload is modeled as a multi-attribute, multilinear function, where the significance of each attribute is elicited using an inverse optimization procedure integrated into a clustering method. The nurse workload balancing problem is then formulated for the upcoming shift, whereby the nurse-patient assignment decisions constitute the primary lever.

Health Care Models

Community Committee Choice Session

Session Chair: Martin L. Puterman, University of British Columbia, Vancouver, BC, Canada

Session Chair: Seyed Amirhossein Moosavi, University of Ottawa, Ottawa, ON, Canada

1 Dynamic Policies for Inter-Hospital Patient Transfers

Timothy Chan, Jangwon Park, Vahid Sarhangian, University of Toronto, Toronto, ON, Canada. Contact: jangwon.park@mail.utoronto.ca

During the COVID-19 pandemic, inter-hospital patient transfers have emerged as a key strategy to rectify imbalanced congestion in many countries including the U.S. and Canada. To gain insights into the structure of "good" transfer policies, we propose a class of transient queueing control problems. We consider multiple parallel queues, starting with a large imbalanced initial state, and seek discrete-time dynamic transfer policies that minimize the expected total cost over a finite horizon or until the system reaches a desirable state. We characterize the structure of the optimal policy for an associated fluid control problem and investigate the robustness of the structure for the original stochastic problem. Using simulation experiments, we illustrate the performance of fluid-based policies and examine the value of optimal transfers.

2 A Hybridized Approximate Dynamic Programming and Neural Network for Distributed Ambulatory Care Scheduling

Amirhossein Moosavi[1], Onur Ozturk[1], Jonathan Patrick[2], [1]University of Ottawa, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada

This work studies an ambulatory care scheduling problem that offers multi-appointment, multi-class, multi-priority treatments in geographically distributed campuses with multiple resources. A dynamic setting is considered with uncertain patient arrival and use of the emergency department. The problem is formulated as an infinite-horizon Markov decision process model and is accelerated using a neural network. An affine approximation architecture is used to approximate the value function. Then, an equivalent linear programming model is solved through column generation to compute approximate optimal policies. Simulation results demonstrate that the approximate optimal policy outperforms alternative scheduling policies and can equip a booking clerk with intelligent scheduling rules that are difficult to predict in real-time.

3 Inverse Learning of Radiotherapy Treatment Planning Criteria

Houra Mahmoudzadeh[1], Kimia Ghobadi[2], Sara Ebrahimkhani[1], Bradley Hallett[1], Ernest Osei[3], Johnson Darko[3], [1]University of Waterloo, Waterloo, ON, Canada; [2]Johns Hopkins University, Baltimore, MD, [3]Grand River Regional Cancer Centre, Waterloo, ON, Canada. Contact: houra.mahmoudzadeh@uwaterloo.ca

In radiotherapy treatment planning, the goal is to find an acceptable treatment plan that best meets a set of clinical guidelines. These guidelines, however, are not universally agreed upon and are often violated in approved plans or made looser/stricter based on the opinion of an oncologist. Using a large number of historically approved plans, we use inverse optimization to learn these implicit clinical acceptability criteria for different patient cohorts. The proposed inverse models learn the feasible region of a mathematical optimization problem based on a set of past observations that are either approved or rejected. We discuss several recent approaches in inverse optimization for feasible region inference and compare their performance in practice.

4 Dynamic Assignment of Capacity and Fair Balancing of Covid-19 Patients over Hospitals

Richard J. Boucherie, University of Twente, Enschede, Netherlands. Contact: r.j.boucherie@utwente.nl

We introduce models that support dynamic fair balancing of COVID-19 patients over hospitals in a region and across regions. Patient flow is captured in an infinite server queueing network. Input for the model is an accurate real-time forecast of the number of COVID-19 patients hospitalised in the ward and the Intensive Care Unit of the hospitals based on the predicted inflow of patients, their Length of Stay and patient transfer probabilities among ward and ICU. For a given number of available beds, we introduce a dynamic load balancing model for assignment of patients to hospitals within a region, and a stochastic program for allocation of patients across regions. Subsequently, we consider optimal up- and downscaling of capacity for COVID-19 patients, leaving maximum capacity for regular (non-COVID) patients.

Tackling Challenges in Healthcare Using Operations Research

Community Committee Choice Session

Session Chair: Lauren Lindley Czerniak, 1</sup

1 Sequential Hypothesis Testing to Detect Arrhythmia in Electrocardiogram Data

Yousef Oleyaeimotlagh[1], Taposh Banerjee[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: taposh.banerjee@pitt.edu

The problem of sequential hypothesis testing in statistically periodic data is studied. Statistically periodic data is observed in neuroscience, medicine, and cyber-physical systems, and has the property that the statistical behavior of data repeats after a fixed amount of time. Using a novel optimal control theory, it is shown that the optimal test is a likelihood ratio-based test with a periodic sequence of thresholds. It is further shown that a single threshold test is asymptotically optimal. The effectiveness of the algorithm is shown by applying it to electrocardiogram data.

2 Decision Making for Type Ii Fetal Heart Rate Tracing Using Deep Learning

Jaber Qezelbash-Chamak[1], Karen T. Hicklin[2], [1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, Contact: qezelbashc.jaber@ufl.edu

Fetal heart rate monitoring during labor helps healthcare providers to identify fetal hypoxia in an effort to reduce the risk of permanent neurologic damage. However, rates of fetal brain injury and cerebral palsy have remained unchanged, and there has been an increase in operative interventions. To address this, we developed a computer-aided system using deep learning convolutional neural networks to predict and classify neonatal intensive care unit admissions with cooling versus no cooling, which may be needed to allow the body to heal faster at lower body temperatures. The system provides sufficient prediction accuracy that helps physicians intervene more effectively.

3 Privacy-preserving Health Monitoring Via Federated Online Collaborative Learning

Tanapol Kosolwattana[1], Huazheng Wang[2], Ying Lin[3], [1]University of Houston, Houston, TX, [2]Oregon State University, Corvallis, OR, [3]University of Houston, Houston, TX, Contact: tkosolwa@cougarnet.uh.edu

Personalized health modeling and monitoring is critical for cost-effective disease prevention. Due to limited information and dependencies of disease progression between patients, it requires data sharing across patients to obtain an accurate monitoring strategy. However, it leads to a risk of privacy leakage in real-world healthcare systems. To solve this issue, this study proposed a federated online collaborative learning algorithm that allows decentralized online modeling and monitoring of patients without sharing raw data. It real-time integrates monitoring data into local statistics to infer patients' health conditions and allocates monitoring resources based on a patient's availability and risk. The efficiency of the proposed method is demonstrated through theoretical analysis, simulation studies, and cognitive monitoring in Alzheimer's disease.

4 When is It Worth It for Two Hospital Network Pharmacies to Operate as an Integrated Inventory System?

Lauren L. Czerniak, Mariel S. Lavieri, Mark S. Daskin, Burgunda V. Sweet, Jennifer Leja, Matthew A. Tupps, Karl Renius, University of Michigan, Ann Arbor, MI, Contact: czernl@umich.edu

Hospital network pharmacies provide drugs that are critical to patient care. However, it is unclear if lateral transshipments between two hospital network pharmacies benefit the inventory systems in the presence of supply chain disruptions. We create a modeling framework to solve for continuous review inventory policies in a two-hospital network pharmacy perishable inventory system with supply chain disruptions and lateral transshipments. We find that (i) the cost of a lateral transshipment must be sufficiently less than the cost of shortage for it to be beneficial to operate as an integrated inventory system. We also find that (ii) hospital network pharmacies need to consider the supply chain disruption characteristics (i.e., disruption and recovery rate) of the partner hospital network pharmacy and (iii) hoarding inventory can cause significantly more shortages.

5 Forecasting Organ Transplant Allocation Scores Using Machine Learning Models

Hyunwoo Shin, Xi Chen, Sait Tunc, Virginia Tech, Blacksburg, VA

Allocation scores significantly influence patient prioritization for organ transplants across the United States. The forecasting accuracy of these scores (e.g. Lung Allocation Score (LAS), Model for End-stage Liver Disease (MELD)) is a key determinant in the enhancement of patient care and in the critical analysis of the existing transplant infrastructure. In our study, we devised machine learning models for time series estimation and forecasting to accurately predict allocation scores across varying time horizons. We further undertook an in-depth examination of an intricate tree-based model embedded within the prediction model to elucidate its interpretability. Our research outcomes hold substantial potential to advance patient care, to improve decision-making, and to provide critical assessment metrics for the organ transplant systems.

Social Responsibility in Operations

Contributed Session

Session Chair: Robert Eberhart, Stanford University, Palo Alto, CA

1 Buyer-Imposed and Supplier-Initiated Social Responsibility Codes of Conduct

Han Zhang, Mevan Jayasinghe, Sriram Narayanan, Michigan State University, East Lansing, MI, Contact: hzhang@broad.msu.edu

A buyer procuring from a socially irresponsible supplier will impose the buyer's code of conduct on the supplier. The supplier may voluntarily adopt a code of conduct to signal social responsibility. We show in equilibrium the buyer always waives the buyer's code when the supplier has adopted a voluntary code.

2 CSR Violations & Media Reactions - Domestic vs. Foreign Firms Operating in the U.S.

Stewart R. Miller[1], Kefeng Xu[2], Sarfraz Khan[3], Lorraine Eden[4], [1]University of Texas-San Antonio, San Antonio, TX, [2]University of North Carolina at Greensboro, Greensboro, NC, [3]University of Louisiana at Lafayette, Lafayette, LA, [4]Texas A&M University, College Station, TX, Contact: kefeng.xu@uncg.edu

We develop a conceptual framework to examine major media reactions to CSR violations by domestic and foreign firms. Based on EPA's environmental violation data, we draw upon expectancy violation theory and ingroup-outgroup literature to empirically examine how foreignness influences the likelihood of media coverage following environmental misconduct and moderates the effect of CSR reputation on media coverage.

4 Unlocking Blockchain Technology for Sustaining Plastic Recycling

Nesreen El-Rayes, Aichih (Jasmine) Chang, Jim Shi, NJIT (New Jersey Institute of Technology), Newark, NJ, Contact: nde4@njit.edu

To study the growing challenge of the plastic crisis, we devise a mathematical model that investigates the potential of Blockchain Technology in enhancing recycling. The model envisions a comprehensive and systematic coordination of the plastic value chain, from production to disposal, emphasizing optimal interoperability. We aim to foster effective and efficient recycling processes, which can profoundly improve plastic waste management.

5 Entrepreneurialism and the Acceptance of Inequality: What Causedit, What Keeps It Going, and What to Do About It

Robert Eberhart[1], Andrew J. Nelson[2], [1]UCLA, Los Angeles, CA, [2]University of Oregon, Eugene, OR, Contact: robert.eberhart@anderson.ucla.edu

We take up Thomas Piketty's challenge to uncover the ideology the underpins and facilitates acceptance of the inequality we observe. We capture an emergent entrepreneurial ideology that is a new ideology the stabilizes the social order by making it acceptable as to who garners the benefits of an entrepreneurial society and hold out hope that we all might someday be an entrepreneurial success. This new entrepreneurial ideology explains and creates a justification for social inequality. Attributing wealth to individual actions rather than personal attributes establishes a narrative that makes it more challenging to address the systemic factors contributing to inequality. Moreover, suggesting that the disadvantaged are responsible for their fate, but ought to try again to succeed, justifies the growing divide between the rich and the poor and stabilizes our social order.

Improving Health Decision-Making: Screening, Diagnosis, and Policy

Community Committee Choice Session

Session Chair: Jacob Jameson, Allston, MA

Session Chair: SIDIAN Lin, Harvard University, Cambridge, MA

1 The Impact of Batch vs Sequential Ordering of Diagnostic Tests in the Emergency Department

Jacob Jameson[1], Arshya Feizi[2], Soroush Saghafian[1], [1]Harvard University, Cambridge, MA, [2]Boston University, Boston, MA, Contact: jacobjameson@g.harvard.edu

The accurate and expeditious diagnosis of patients in the emergency department (ED) is crucial for initiating appropriate treatment in a timely manner. Nevertheless, the optimal number of tests required to minimize diagnostic uncertainty remains unknown a priori. In situations where more than one diagnostic test is needed, it is more effecient for physicians to order theses tests in a batch. This study examines the comparative effects of sequential and batched test ordering strategies in the ED, specifically analyzing their implications for patient length of stay, hospital readmission, and resource utilization. We conduct a retrospective analysis of ED operational data to assess the causal impact of batching given various levels of patient complexity.

2 Should Race and Ethnicity be Used in Predictive Risk Models? Evidence from Diabetes Screening

Madison Coots[1], Soroush Saghafian[2], David Kent[3], Sharad Goel[4], [1]Harvard University, Cambridge, MA, [2]Harvard University, Cambridge, MA, [3]Tufts University, Boston, MA, [4]Harvard University, Harvard, MA, Contact: mcoots@g.harvard.edu

Predictive algorithms are used to inform patient screening decisions for many diseases, including diabetes. Some recent work recommends using race and ethnicity in risk assessments to improve accuracy, but other work argues that doing so risks stigmatizing marginalized communities. We introduce a utility framework and show that there is, perhaps surprisingly, minimal benefit from improved accuracy—both across the entire patient population and within patient subgroups—from including race and ethnicity in diabetes risk models. This is because few patients receive different screening decisions under different models, and, for those who do, the decision to screen is a close call, making them largely ambivalent. These findings suggest that past recommendations in diabetes screening likely overestimated the statistical benefits of using race and ethnicity.

3 Health Policy Modeling of Breast Cancer in Mexico

Melissa Franco[1], Karla Unger Saldaña[2], Jeremy Goldhaber-Fiebert[1], Joshua Salomon[1], Fernando Alarid Escudero[1], [1]Stanford University, Stanford, CA, [2]National Cancer Institute, Mexico, Mexico City, Mexico. Contact: mifranco@stanford.edu

Policymakers in resourced-constrained-low-to-middle-income-countries face a unique barrier in implementing breast cancer control policies that reduce the time from symptom presentation to diagnosis and treatment. We developed an age-structured ordinary differential equation (ODE) population-level model to simulate the dynamics of the natural history of breast cancer for women in Mexico, including both detection through screening and breast cancer symptom presentation. Using this population-level decision-analytical model, we critically consider a realistic capacity constraint in Mexico that has not been previously evaluated on breast cancer outcomes.

4 A Novel Evaluation of the Dose Constraints of an Adaptive Intervention Algorithm

Xiang Meng[1], Walter Dempsey[2], Nick Reid[3], Pedja Klasnja[2], Susan Murphy[1], [1]Harvard University, Cambridge, MA, [2]University of Michigan, Ann Arbor, MI, [3]University of Washington, Seattle, WA, Contact: xmeng@g.harvard.edu

Online adaptive algorithms in mobile health have transformed interventions, yielding promising health outcomes. Optimizing dose constraints is crucial for effective treatment delivery and maximizing user benefits. Two key constraints are the avg. treatment and uniformity constraints. The former limits treatment frequency to balance intervention effectiveness and user engagement, while the latter ensures even treatment randomization across potential risk times. To meet these constraints, the Sequential Risk Time Sampling (SeqRTS) algorithm was developed and used in a trial to evaluate anti-sedentary messages' effectiveness during sedentary behavior. We present an analytical framework assessing whether SeqRTS satisfies these constraints and evaluates its efficacy, offering insights for algorithm improvement.

Analytics in Complex Supply Chains

Community Committee Choice Session

Session Chair: Dan Andrei Iancu, Stanford University, Stanford, CA

1 Clustering and Reinforcement Learning Approaches in Digital Supply Chains Analytics

Kevin Hu, Benjamin Siegel, Retsef Levi, Raphael (Rafi) Yahalom, MIT, Cambridge, MA, Contact: kevinkhu@mit.edu

The increasing frequency and severity of cyberattacks has made reliable cyber risk assessment a critical concern for organizations worldwide. Traditional cyber risk methodologies focus on the enterprise's level of cyber maturity. Moreover, several commercial companies provide cyber ratings using information about the organization accessible by outside parties, often called outside-in ratings. However, merely focusing on the enterprise's own cyber maturity may be insufficient given the increasing number of cyberattacks that exploit vulnerabilities in the organization's supply chain. This presentation introduces innovative approaches to cyber risk assessment that incorporate attributes of the digital supply chain.

2 Optimal Resource Allocation for Remediating Networked Contagions

Marios Papachristou[1], Siddhartha Banerjee[2], Jon M. Kleinberg[2], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY

We study the problem of designing intervention policies for minimizing failures in dynamic networked contagion settings. Formally, we consider an extension of the Eisenberg-Noe model of financial network liabilities and use this to study the design of external intervention policies subject to budget constraints. We show how we can leverage the problem structure to efficiently compute optimal intervention policies with continuous interventions and provide approximation algorithms for discrete interventions. Going beyond financial networks, we argue that our model captures network intervention in a much broader class of demand/supply settings with networked inter-dependencies.

3 Platform Design for the First Mile of Commodity Supply Chains

Sergio Camelo[1], Dan Andrei Iancu[1], Joann de Zegher[2], [1]Stanford University, Stanford, CA, [2]MIT Sloan, Cambridge, MA, Contact: camelo@stanford.edu

We propose a data-driven platform that provides traceability to the first mile of agricultural supply chains by coordinating the transactions of farmers and intermediaries. We model unique aspects of the supply chain, including pre-existing informal relationships between farmers and intermediaries, and we develop algorithms to solve real-world instances. We test the results on data from the palm oil supply chain and show the platform's potential to reduce costs and increase farmers' welfare.

4 The Operational Origins of Child Labor in Cocoa Production

Andreas K. Gernert[1], Andre Du Pin Calmon[2], Dan Andrei Iancu[3], Luk N. Van Wassenhove[4], [1]KLU, Hamburg, Germany; [2]Scheller College of Business, Georgia Institute of Technology, Atlanta, GA, [3]Stanford University, Stanford, CA, [4]INSEAD, Fontainebleau Cedex, France

In the cocoa supply chains of Ghana and Ivory Coast, many smallholder farmers still rely on child labor for cocoa production. Our work examines, both analytically and empirically, how aspects of farmers' operations and financing can exacerbate or mitigate child labor use. Based on an analytical model capturing a farming household's key decisions, we characterize several relevant comparative statics and derive insights concerning the impact of distinct interventions aimed at mitigating child labor. We find, for instance, that the availability of loans increases the use of child labor for higher-income farmers but that it either increases or decreases the use of child labor for very low-income farmers, depending on uncertainties in yield, prices, or costs. We then leverage two distinct datasets to empirically validate some of our findings.

Service Design and Pricing under Customers' Choice Behavior

Community Committee Choice Session

Session Chair: Ruxian Wang, Johns Hopkins University, Carey Business School, Kensington, MD

Session Chair: Chenxu Ke, 1</sup

1 Discrete Choice Models with Piecewise Linear Utility: Modeling, Estimation and Pricing

Zifeng Zhao, University of Notre Dame, Notre Dame, IN

This paper incorporates a piecewise linear structure into the utility-price relationship of the classic multinomial logit (MNL) model, and studies the associated operations problems such as estimation and pricing. The derived model provides greater modeling flexibility by allowing consumers to exhibit asymmetric price sensitivities around unknown inflection points. We study the model identification for the piecewise MNL and further propose an MLE for its calibration. Due to the presence of inflection points, the likelihood is non-differentiable, which poses major challenges to both numerical and statistical analyses. We propose a novel profile-based numerical optimization procedure which locates the MLE efficiently and further establish statistical guarantees for the MLE based on the empirical process theory.

2 Search And Choice: Modeling, Optimization And Estimation

Ruxian Wang, Johns Hopkins University, Carey Business School, Kensington, MD, Contact: ruxian.wang@jhu.edu

In this paper, we present a new model that captures new features in customer choice behavior. The analytical results and estimation validation show that the new model can describe customers' purchase behavior more accurately and model misspecification can lead to substantial losses for firms.

3 A Simple Way to Fair Assortment Planning: Market Exposure and Welfare Implications

Wentao Lu[1], Ruxian Wang[2], Ozge Sahin[3], [1]Johns Hopkins Carey Business School, Baltimore, MD, [2]Johns Hopkins University, Carey Business School, Kensington, MD, [3]Johns Hopkins Carey Business School, Brooklyn, NY, Contact: wlu25@jhu.edu

We consider the fair assortment planning problem where we propose new fairness constraints for the platform. We show that the optimal solution admits nice structure and can be found in polynomial time. We then consider cases where there are additional constraints and develop efficient heuristics. We investigate the welfare implications of imposing the fairness constraints and find that overall welfare for consumers, sellers, and the platform could increase .

Recent Empirical and Theoretical Work in Operations

Community Committee Choice Session

Session Chair: Damian Beil, University of Michigan, Ann Arbor, MI

Session Chair: Andrew Wu, Ross School of Business, University of Michigan, Ann Arbor, MI

1 Behavioral Externalities of Process Automation

Ruth Beer[1], Anyan Qi[2], Ignacio Rios[2], [1]Baruch College, CUNY, New York, NY, [2]The University of Texas at Dallas, Richardson, TX, Contact: axq140430@utdallas.edu

We study the behavioral effects of process automation on human workers interacting with automated tasks. A stylized model with two workers completing their tasks sequentially predicts that workers do not delay their tasks if the early completion bonus is high enough. Our behavioral experiment shows that workers actually tend to delay their tasks. Process automation improves the project completion rate and time but reduces the productivity of the worker who collaborates with the robot.

2 Does Business Leaders' Operational Experience Generate Firm Operational Performance?

Hyungchan Cho[1], Damian Beil[2], Andrew Wu[3], [1]Ross School of Business, University of Michigan, Ann arbor, MI, [2]University of Michigan, Ann Arbor, MI, [3]Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: chohc@umich.edu

Firms hire business leaders (executives, board members, etc.) for their experience and expertise. In this paper, we examine whether business leaders' operational excellence translates into firm operational performance. Using historical panel data on public firms' operational performance and senior leadership, we first formulate a measure of business leaders' operational excellence based on their employment history. Then, using this measure, we find that good operational excellence scores of business leaders are associated with better operational outcomes for firms. We find evidence of causality in this relationship by leveraging exogenous changes in firms' senior leadership, and perform a variety of checks to establish the robustness of our findings.

3 Exploit or Explore? an Empirical Study of Resource Allocation in Scientific Labs

Ran Zhuo, University of Michigan

Allocating innovation resources to their most productive uses is a challenge because innovators have incomplete information about which projects are productive. I empirically study how a group of large scientific labs traded off the exploitation of safe projects to maximize short-term productivity versus the exploration of high-variance projects to acquire information and improve long-term productivity. To recover how these labs made the tradeoff, I estimate a dynamic decision model, assuming the labs approximated the value of exploration with an Upper Confidence Bound (UCB) index. The model captures the labs' decisions well. Estimates of its free parameters suggest that the labs explored extensively. Counterfactual simulations show that, had the labs not explored, their output quantity would have decreased by 51%, and their citations would have decreased by 57%.

4 The Whiplash Effect: Congestion Dissipation and Mitigation in a Circulatory Transportation System

Ming Hu[1], Chaoyu Zhang[2], [1]University of Toronto, Minneapolis, MN, [2]University of Toronto, Toronto, ON, Canada. Contact: cyu.zhang@rotman.utoronto.ca

We build an analytical fluid model to investigate how disruptions at one port can affect the disrupted port and its counterpart in another country. Our analysis reveals two main effects of port disruption: the inbound backlog and the outbound backlog. We provide an analytical expression for the recovery time of two ports and track the evolution of backlogs of goods and ships. In addition, we identify a whiplash effect that occurs in the outbound backlog level at two ports, resembling the commonly known "bullwhip effect". Furthermore, we extend our analysis to a network of ports and show that the key findings still hold in the multi-port system. Finally, we apply machine learning techniques to predict the time vessels spend in the Shanghai port and show that our proposed model reduces prediction errors compared to the benchmark, indicating the application potential of our model.

Emerging Research within Social Sustainability

Community Committee Choice Session

Session Chair: Priyank Arora, University of South Carolina, Columbia, SC

Session Chair: Wei Wei, University of New Hampshire, Durham, NH

1 Subsidizing Social Welfare Programs: Contracted Slots or Vouchers?

Wei Wei[1], Priyank Arora[2], Senay Solak[3], [1]University of New Hampshire, Durham, NH, [2]University of South Carolina, Columbia, SC, [3]University of Massachusetts Amherst, Amherst, MA

We study the interplay of decisions by multiple players within two popular service-focused subsidy welfare programs--subsidy vouchers and contracted slots. Through game-theoretic models, we analyze how program-related factors influence the quantity and quality of services provided by local providers. We also compare the societal outcomes generated by these two programs.

2 Competing with Cause Marketing: Transactional vs. Non-Transactional Campaigns

Mike M. Gordon[1], Arian Aflaki[2], Esther Gal-Or[2], Jennifer Shang[2], [1]Virginia Tech, Blacksburg, VA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: mmgordon@vt.edu

Firms increasingly invest in corporate social responsibility (CSR) as a competitive strategy. Cause Marketing is a type of CSR where a firm donates to a cause to attract prosocial customers. Donations broadly belong to two categories: *Transactional CM (T-CM)*, based on units sold; and *Non-Transactional CM (N-CM)*, independent of customer purchases. We study various CM types and the choice of CM type under competition for different stakeholders, including firms, consumers, nonprofits, and society.

3 Matching Volunteers with Clients in a Non-Profit Organization

Shikha Safaya[1], Basak Kalkanci[2], Ravi Subramanian[3], [1]Scheller College of Business Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, [3]Georgia Tech, Atlanta, GA, Contact: ssafaya3@gatech.edu

Non-profit organizations are often challenged with volunteer participation and retention in the absence of monetary incentives. We explore the tradeoff between incorporating volunteer preferences in task assignments versus pooling volunteers to alleviate mismatch between supply and demand. In doing so, we endogenize volunteers' decisions to participate based on their expected utilities from serving clients and from their outside options. We analytically derive the conditions under which a particular policy may be preferred by all the stakeholders (the non-profit, volunteers, and clients). Consequently, we suggest levers that can be utilized by non-profits to better align the incentives of all the stakeholders.

4 Approaches for Identifying Hotspots of Low or Variable Crop Yields

Sanchita Das[1], Leonard Boussioux[2], Shweta Manjunath[3], [1]University of Washington, Seattle, WA, [2]MIT, Operations Research Center, Cambridge, MA, [3]University of Washington, Seattle, WA, Contact: sanchd20@uw.edu

We use a multimodal deep learning approach to combine survey data and satellite imagery to assess hotspots where agriculture yield for major crops in India is significantly lower or more variable compared to the country average. Farmers are resource constrained but have found significant efficiencies in agriculture operations for certain crops by using precision agriculture technology like sensors. Despite their proven efficiency, sensors are very expensive for implementation at scale. Hence there is value in exploring hotspots which should be prioritized for deploying sensors. Combining multimodal deep learning on satellite imagery and NLP on tab text data we provide a step in this direction, which can be an important decision making tool for farmers.

Data-Driven Demand Modeling and Fulfillment Optimization in E-commerce

Community Committee Choice Session

Session Chair: Sheng Liu, University of Toronto, ON, Canada

Session Chair: Stefanus Jasin, University of Michigan, Ann Arbor, MI

1 Online Demand Fulfillment Problem with Initial Inventory Placement: A Regret Analysis

Alessandro Arlotto, Irem Nur Keskin, Yehua Wei, Duke University, Durham, NC, Contact: iremnur.keskin@duke.edu

We investigate a joint inventory placement and online fulfillment problem. We consider two state-of-the-art resolving policies: probabilistic fulfillment and score-based fulfillment. We study the minimum inventory regret of these policies, a measure that considers both the performance of the policies and initial inventory selection. We provide a regret bound for the score-based fulfillment policy that is independent of the time horizon and polynomial with respect to the number of warehouses and demand regions. In contrast, the minimum inventory regret for probabilistic fulfillment scales with the square root of the time horizon. Our findings suggest that score-based fulfillment is preferable to probabilistic fulfillment for this problem.

2 Data-Driven Nonparametric Deep Newsvendor

Jinhui Han[1], Ming Hu[2], Guohao Shen[3], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Minneapolis, MN, [3]The Hong Kong Polytechnic University, Hong Kong, Hong Kong

We propose utilizing a nonparametric deep neural network (DNN) method to address the data-driven Newsvendor problem. The remarkable representational power of DNN enables our framework to incorporate or approximate various extant data-driven models. We provide analytical theoretical guarantees that bound the excess risk of DNN solution in terms of the network structure and sample size in a non-asymptotic manner, justifying the applicability of DNN in relevant contexts. Furthermore, our theoretical framework can be extended to cover the data-dependent scenario, where the historical data follows any stochastic process and the future demand is not necessarily an independent sample, which is highly relevant for practical prediction problems based on time series data. We apply the DNN method to a dataset from a deli company to illustrate its practical performance.

3 Does Locker Alliance Network Improve Last Mile Delivery Efficiency?

Quanmeng Wang[1], Guodong Lyu[2], Long He[3], Chung Piaw Teo[4], [1]National University of Singapore, Singapore, Singapore; [2]The Hong Kong University of Science and Technology, Hong Kong, China; [3]George Washington University, Washington, [4]National University of Singapore Business School, Singapore, Singapore. Contact: e0210515@u.nus.edu

We study the locker network design problem in last-mile delivery. The challenge lies in the characterization of home delivery cost reduction for a Logistic Service Provider (LSP) when some customers are attracted to use locker instead of requesting home delivery. We propose a generalization of BHH theorem to capture this effect, and subsequently formulate a Prize-collecting Travelling Salesman Problem. The model allows us to derive insights for the following two important issues: (1) does locker network improves delivery efficiency for a single LSP, and (2) how should the government build one common network facility for all LSPs in the region. We illustrate the insights on the case study of Locker Alliance Network project in Singapore.

4 Pooling and Boosting for Demand Prediction in Retail: A Transfer Learning Approach

Dazhou Lei[1], Hao Hu[2], Dongyang Geng[3], Jianshen Zhang[3], Yongzhi Qi[3], Sheng Liu[4], Zuo-Jun Max Shen[5], [1]Tsinghua university, Beijing, China; [2]JD, Beijing, China; [3]JD.com, Beijing, China; [4]University of Toronto, Toronto, ON, Canada; [5]University of California Berkeley, Berkeley, CA, Contact: ldz19@mails.tsinghua.edu.cn

How should retailers leverage aggregate (category) sales information for individual product demand prediction? Motivated by inventory risk pooling, we develop a new prediction framework that integrates category-product sales information to exploit the benefit of pooling. We propose to combine data from different aggregation levels in a transfer learning framework. We characterize the error performance of our model in linear cases and demonstrate the benefit of pooling. Moreover, our approach exploits a natural connection to regularized gradient boosting trees that enable a scalable implementation for large-scale applications. Based real data, we show the better out-of-sample forecasting performance of our approach than state-of-the-art benchmarks. We further validate its generalizability through alternative pooling and prediction methods.

5 E-Fulfillment Strategies Under Stochastic Orders and Cancellations

Tirui Cao[1], Lei Zhao[1], Yang Wang[2], Yiqiang Su[2], [1]Department of Industrial Engineering, Tsinghua University, Beijing, China; [2]Alibaba Group, Beijing, China. Contact: ctr20@mails.tsinghua.edu.cn

In the order fulfillment process of an online retailer, holding the received order for a while before dispatching it to a warehouse can help hedge the risk of future order cancellations and reduce the order fulfillment cost. In this paper, we consider customers' stochastic order cancellation behavior and study how to design order-holding strategies to reduce the fulfillment cost while not significantly disturbing the existing order fulfillment process (e.g., work schedules of the warehouses). We formulate the problem as a Markov Decision Process, design a cost function approximation (CFA) policy, and apply the optimal computing budget allocation method to search for the optimal policy parameters. Preliminary numerical results demonstrate that the CFA policy can better capture the uncertainty in order arrivals and cancellations and outperform the benchmark policies.

Outbound Transportation Network Optimization

Community Committee Choice Session

Session Chair: Meltem Ozmadenci, Amazon, Bothell, WA

1 Better Delivery Promises at Lower Cost: Concurrent Optimization of Truck and Labor Schedules in Amazon's Middle Mile

Nicholas D. Kullman, Amazon, Bellevue, WA

We introduce a mixed-integer program that optimizes the schedule of Critical Pull Times (CPTs) that define connections in Amazon's Middle Mile network. The model recommends modifications to the existing CPT schedule, navigating tradeoffs between conflicting objectives: maximizing Volume Availability (alignment between inbound volume and scheduled labor) at Sort Centers (SCs) and Delivery Stations (DSs); maximizing the delivery speeds Amazon offers customers; and minimizing violations of operational constraints at Fulfillment Centers (FCs), SCs, and DSs. Moreover, the model recommends changes to labor plans at SCs and DSs, allowing objective improvement with fewer or no modifications to the CPT schedule. We showcase the effectiveness of the model under various scenarios, emphasizing the benefits of concurrently optimizing CPT schedules and labor plans.

2 Volume Accumulation Prediction and Optimization in near Real Time

Martin Bagaram[1], Shauna Robertson[2], Sam Hansen[1], Bryan Maybee[1], Theodoros Pantelidis[3], Meltem Ozmadenci[4], [1]Amazon.com, Bellevue, WA, [2]Amazon.com, Denver, CO, [3]Amazon.com, Dallas, TX, [4]Amazon.com, Bellevue, WA, Contact: mbagaram@amazon.com

Amazon Middle-Mile schedules truck departure times via volume accumulation curves (VAC). VAC represent future package accrual at an Amazon facility when they are ready to depart for a destination. We introduce our model that i) predicts the end-to-end package flow through the network and ii) builds VAC that are optimal for Linehaul and Amazon Logistics metrics. In the first step, package paths from start to finish are simulated via upstream constraints with varying levels of uncertainty to produce probable accumulation scenarios. In the second step, a two-stage stochastic MIP model schedules trucks on each lane without the full knowledge of the forecasted volume; then, we take two recourse actions: a) schedule cancellations if the actual volume does not warrant trucks, and b) schedule additional trucks if the materialized volume requires less equipment than first stage.

3 Modeling Promise in Fulfillment Execution

Daniel Chen[1,2], Tolga Cezik[3], Zsolt Csizmadia[4], [1]Amazon, Singapore, Singapore; [2]Institute of High Performance Computing, Singapore, Singapore; [3]Amazon.com, Seattle, WA, [4]Amazon, London, United Kingdom. Contact: danielchen1987@gmail.com

Every customer shipment ordered at Amazon has to be assigned a fulfillment path that is feasible for the promised delivery date. In order to account for future usage of resources on these fulfillment paths, future demand is modeled as shipments with similar promise feasibility requirements. However, when demand is high, this model may be unable to meet the promise of forecasted shipments, incurring large penalties. This distorts the implied costs of resource utilization and potentially results in under-utilized capacity. Therefore, we propose modeling the ability to offer slower promises on forecasted demand so as to more accurately reflect promises on future shipments and utilize resources better. We discuss preliminary simulation results.

4 Amazon Last Mile Sort Center Functionality Optimization

Shanshan Zhang, Amazon, Bellevue, WA

Last Mile Sort centers (LMSCs) are a critical component of Amazon's logistic network, sorting packages for downstream last mile nodes operated by different carriers, such as Amazon owned carrier AMZL delivery station (DSs) and United States Postal Service (USPS) destination delivery units. The functionality of a LMSC determines the sorting resources for packages, directly impacting the efficiency of the entire LMSC network. This talk presents a scientific methodology that quantifies the material trade-offs related to LMSC functionality, guiding Amazon's LMSC network design. The methodology uses machine learning and optimization models to estimate various cost components in the network. These cost components are then fed into a centralized mixed-integer optimization model, incorporating piece-wise linear approximations, to determine LMSC functionality.

Amazon Last Mile Geospatial Optimization

Community Committee Choice Session

Session Chair: Yaniv Mordecai, [1</sup]
Session Chair: Liron Yedidsion, Amazon, Redmond, WA

1 Contiguous Spatial Unit Allocation Through Resource Constrained Shortest Path

Julie Poullet[1], Andre Snoeck[2], [1]Amazon - Last Mile, Seattle, WA, [2]Amazon, Austin, TX

At Amazon, 95% of the deliveries are made by our 3000+ Delivery Service Partners (DSPs) which are independent local business. DSPs operate out of a given station and are assigned to areas of the station's jurisdiction to produce consistent routes for their drivers. We present PAAT, a spatial unit allocation model that assigns areas to each DSP, maximizing consistency while balancing labor and workload. While this problem can be formulated as a MIP, solving it using commercial solvers quickly becomes intractable for real-world instances. Therefore, we develop a graph model that reduces the problem to a classical set covering problem, which we solved through a column-generation. Its key point is a novel application of resource based bounds in the pricing sub-problem algorithm, modeled as a Resource Constrained Shortest Path problem. It is 10 times faster than the MIP approach.

2 Revolutionizing Last Mile Delivery Through Multiple Modes of Transport

Dipal Gupta[1], Jin Ye[2], Vasanth Ramasamy[1], Rohit Malshe[1], Marc Anderson[3], Ehsan Jafari[3], [1]Amazon, Seattle, WA, [2]Amazon, Kirkland, WA, [3]Amazon, Austin, TX

The expansion of Amazon Logistics (AMZL) is one of the key enablers for the continued growth of Amazon's consumer business. Sustaining this growth rate is dependent on our ability to leverage alternative delivery methods, such as Hub Delivery Partners, walkers, and cargo electric bikes, to supplement traditional delivery modes. The Multiple Modes of Transportation (MMOT) program aims to combine these modes of delivery in flexible, cost-efficient, and sustainable ways to support last-mile delivery. Amazon Logistics (AMZL) needs to determine the most suitable combination of delivery methods for a given geography to ensure optimal efficiency and lower cost.

3 Reducing Geo-Temporal Anti-Coincidence of Multiple Shipping Methods

Yaniv Mordecai[1], Rohit Malshe[2], Liron Yedidsion[3], [1]Amazon, Redmond, WA, [2]Amazon, Bellevue, WA, [3]Amazon, Redmond, WA, Contact: yvm@amazon.com

We introduce an optimization model for last-mile multi-channel anti-coincidence reduction. Anti-coincidence occurs when two or more different delivery agents visit the same place on the same day. This can happen due to Amazon's offering of speed options next to traditional Prime service. We defined a new Geo-Temporal Anti-Coincidence (GTAC) metric, which relies on entropy across shipping channels' share distribution. We identified ZIP codes suffering from consistently high GTAC. We adapted the multi-commodity flow optimization (MCFO) problem formulation. Our model accounts for resource pool differences across channels, e.g., professional vs. gig economy drivers. We applied the model to a representative scenario in the Austin, TX metro to pick volume consolidation strategies that lead to significant savings in cost, mileage, service time, and GTAC.

4 Overlapping Jurisdictions to Increase Speed and Capacity Utilization

Rohit Malshe, Vasanth Ramasamy, Dipal Gupta, Chinmoy Mohapatra, Amazon, Seattle, WA

We discuss the benefits of implementing an Overlapping Jurisdiction (OJ) strategy in Amazon's delivery network. By allowing multiple delivery stations to service a single customer address, we can enhance connectivity, minimize volume loss, and increase fulfillment speeds. This technique has already resulted in over $50 million in savings and improved customer satisfaction. We will also explore the use of OJ selection algorithms and their impact on savings. Additionally, we will present research on the Variability Reduction use case, which is projected to drive $70 million in annual savings.

Community Committee Choice Session

Session Chair: Hugh Medal, University of Tennessee, Knoxville, TN

1 Joint UAV and Truck Routing Under Uncertainty: Measuring the Value of Information

Leonardo Lozano[1], Juan Sebastian Borrero[2], [1]University of Cincinnati, Cincinnati, OH, [2]Oklahoma State University, Stillwater, OK, Contact: leolozano@uc.edu

We consider a joint truck and UAV routing problem subject to uncertain disruptions. The planner can refine her knowledge about the disruptions by spending resources to probe, removing the uncertainty for the probed nodes. To determine the best route, the planner requires measuring the value of information, which is computed by a two-stage stochastic optimization problem. In the first stage, the planner selects the locations to probe, and in the second stage, the planner selects the route based on the results of the probes. We reformulate the problem as a bilevel problem with multiple followers, propose two formulations for the joint UAV and truck routing problem, and develop two exact approaches to solve the bilevel problem. Our results show that probing, even if it is only on a small subset of locations, can yield significant gains in solution quality.

2 A Two�Stage Network Interdiction� Monitoring Game
Di Nguyen[1], Yongjia Song[2], Cole Smith[3], [1]University College Dublin, Dublin, Ireland; [2]Clemson University, Clemson, SC, [3]Syracuse University, Syracuse, NY
We study a network interdiction problem involving two agents: a defender and an evader. The evader seeks to traverse a path from a source node to a sink node in a directed network without being detected. The game takes place in two stages. In the first stage, the defender removes a set of arcs in the network. In the second stage, the defender and evader play a simultaneous game. The defender monitors a set of arcs, thus increasing the probability that the evader will be detected on that arc. The evader selects a source-sink path. Because the second stage is played simultaneously, both agents use mixed-strategy solutions. The second-stage problem is solved using a constraint-and-column generation algorithm. Then, to link the first- and second-stage problems, we model the original problem using an epigraph reformulation, which we solve using Benders decomposition.

3 Maximum Flow Network Problem with Imperfect Protection and Imperfect Interdiction
Hugh Medal, University of Tennessee, Knoxville, TN, Contact: hmedal@utk.edu
We investigate a network protection-interdiction problem in which a defender allocates resources to arcs in order to protect them from attack. Subsequently, an attacker allocates resources in order to destroy the arcs. Arcs fail with a probability determined by the amount of defense and attack resources allocated to it. The defender's objective is to maximize the expected flow through the network after arcs have failed. We formulate the problem as a stochastic program with decision-dependent uncertainty due to the fact that the uncertainty in the problem depend on defense and attack decisions. To solve this non-convex problem, we employ a column-and-constraint-generation approach.

4 An Optimization Approach for Network Biosurveillance
Ankan Mitra[1], Jorge A. Sefair[2], Tony H. Grubesic[3], Edward Helderop[3], [1]Arizona State University, Tempe, AZ, [2]University of Florida, Gainesville, FL, [3]University of California at Riverside, Riverside, CA
Network biosurveillance efforts focus on disease activity and threats to human, animal, or plant health to improve situational awareness and provide early warnings of disease emergence or activity. The goal is to monitor the consumption of, or exposure to, chemicals and pathogens at the community/population level. This talk presents a network optimization model for sensor placement in a wastewater network. The overarching goal is to maximize the amount of information captured from the network while narrowing down the potential geographical source of chemical or biological markers (i.e., signals) in the system.

2 Reliable Adaptive Stochastic Optimization with High Probability Guarantees
Miaolan Xie, Billy Jin, Katya Scheinberg, Cornell University, Ithaca, NY, Contact: mx229@cornell.edu
To handle real-world data that is noisy, biased and even corrupted, we consider a simple adaptive framework for stochastic optimization where the step size is adaptively adjusted according to the algorithm's progress instead of manual tuning or using a pre-specified sequence. Function value, gradient and possibly Hessian estimates are provided by probabilistic oracles and can be biased and arbitrarily corrupted, capturing multiple settings including expected loss minimization in machine learning, zeroth-order and low-precision optimization. This framework is very general and encompasses stochastic variants of line search, quasi-Newton, cubic regularized Newton and SQP methods for unconstrained and constrained problems. Under reasonable conditions on the oracles, we show high probability bounds on the sample (and iteration) complexity of the algorithms.

3 Retrospective Approximation for Stochastic Equality Constrained Problems Using Sequential Quadratic Programming

Shagun Gupta[1], Raghu Bollapragada[2], Albert Solomon Berahas[3], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]University of Michigan, Ann Arbor, MI, Contact: shagungupta@utexas.edu

Sequential Quadratic Programming (SQP) is one of the state of the art algorithms to solve deterministic equality constrained problems. In recent years the framework has been extended to solve equality constrained problems with stochastic objective functions. To adapt the step size in stochastic settings, new schemes like stochastic line search, Lipschitz constant estimation, hessian averaging have been introduced in SQP. We use SQP algorithms in a Retrospective approximation framework that allows us to solve a series of subsampled deterministic subproblems to solve the the stochastic constrained problem. This framework decouples the stochasticity from the SQP algorithm allowing us to use legacy deterministic solvers (other than SQP as well) to solve constrained stochastic programs.

4 On the Convergence of a Decomposition Algorithm for Nonlinear Two-Stage Optimization

Yuchen Lou[1], Andreas Waechter[1], Xinyi Luo[1], Ermin Wei[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL

We consider the theoretical convergence properties of an algorithm for nonlinear continuous two-stage optimization problems that is based on a novel log-barrier-based smoothing technique. In particular, we explore how fast local convergence can be obtained with extrapolation steps and what global convergence guarantees can be obtained for nonconvex instances.

Large-Scale Structured Optimization

Community Committee Choice Session

Session Chair: David Huckleberry Gutman, Texas Tech University, Lubbock, TX

1 Tangent Subspace Descent on Reductive Homogeneous Spaces

David Huckleberry Gutman[1], Nam Ho-Nguyen[2], Daniel Grady[3], Bruno Mello[4], Guilherme Menezes[5], [1]Texas A&M University, College Station, TX, [2]The University of Sydney, The University of Sydney, Australia; [3]Wichita State University, Wichita, KS, [4]Aetos Tech, Rio de Janeiro, Brazil; [5]INOA, Rio de Janeiro, Brazil. Contact: david.gutman@ttu.edu

The tangent subspace descent method (TSD) extends the coordinate descent algorithm to manifold domains. The key insight underlying TSD is to draw an analogy between coordinate blocks in Euclidean space and tangent subspaces of a manifold. The core principle behind ensuring convergence of TSD for smooth functions is the appropriate choice of subspace at each iteration. In this talk, we will show that it is always possible to appropriately pick such subspaces on the broad class of manifolds known as reductive homogeneous spaces. This class includes Grassmannians, flag manifolds, and the positive definite manifold when endowed with an appropriate geometry. As a result of our developments we derive new and efficient methods for large-scale optimization on these domains.

2 The Inexact Block Proximal Gradient Method

Leandro Maia[1], David Huckleberry Gutman[1], Ryan C. Hughes[2], [1]Texas Tech University, Lubbock, TX, [2]Addx Corporation, Alexandria, VA, Contact: leandro.maia@ttu.edu

In this talk, we expand the Cyclic Block Proximal Gradient method for block separable, composite minimization to allow for inexactly computed gradients and proximal maps. The resultant algorithm, the Inexact Cyclic Block Proximal Gradient (I-CBPG) method, shares the same convergence rate as its exactly computed analogue, provided how the allowable errors decrease. The foundation of our convergence analysis is our proposed ⍰-Second Prox Theorem, which contains a tight relationship between inexact proximal map evaluations and ⍰-subgradients. Further, we highlight numerical experiments that showcase the practical computational advantage of I-CBPG for certain fixed tolerances of approximation error and for a dynamically decreasing error tolerance regime in particular.

3 Distributed Nonconvex Functional Constrained Optimization via Ghost Penalty

Ying Sun, 1</sup

This talk considers distributed optimization problems with nonconvex functional constraints. Such problems have received increasing importance due to their flexibility in capturing real-world demands, including resource limitations, safety guarantees, fairness, and system dynamics. Leveraging the technique of successive convexification and average consensus, we develop an SQP-type algorithm that can handle common/shared/private types of constraints in a unified fashion. We prove the convergence of the algorithm based on a Lyapunov function consisting of a non-smooth exact penalty function and consensus violation measures. Sublinear convergence rate is established with a diminishing step size; whereas for the shared common constraint setting, we prove the algorithm attains faster convergence with a constant step size.

Global Guarantees in Nonconvex Optimization

Community Committee Choice Session

Session Chair: Salar Fattahi, University of Michigan, Ann Arbor, MI

1 Implicit Regularization Leads to Benign Overfitting for Sparse Linear Regression

Mo Zhou, Duke University, Durham, NC, Contact: mo.zhou7@duke.edu

In deep learning, often the training process finds an interpolator (a solution with 0 training loss), but test loss is still low. This is known as benign overfitting and is a major mystery in deep learning. One common mechanism is implicit regularization, where training process leads to additional properties for the interpolator, often characterized by minimizing certain norms. However, even for simple sparse linear regression, neither minimum L_1 or L_2 norm interpolator gives the optimal test loss. In this work, we give a new parametrization of the model that combines the benefit of L_1 and L_2 interpolators. We show that training new model via gradient descent leads to an interpolator with near-optimal test loss. Our result is based on careful analysis of training dynamics and provides another example of implicit regularization effect that goes beyond norm minimization.

2 The Power of Preconditioning in Overparameterized Low-Rank Matrix Sensing

Xingyu Xu[1], Yandi Shen[2], Yuejie Chi[1], Cong Ma[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Chicago, Chicago, IL, Contact: xingyuxu@andrew.cmu.edu

We propose ScaledGD(?), a preconditioned gradient method to tackle the low-rank matrix sensing problem when the true rank is unknown and when the matrix is possibly ill-conditioned. Using overparameterized factor representations, ScaledGD(?) starts from a small random initialization and proceeds by gradient descent with a certain form of *damped* preconditioning to combat bad curvatures induced by overparameterization and ill-conditioning. We prove that at the expense of light overhead incurred by preconditioners, ScaledGD(?) is remarkably robust to ill-conditioning even with overparameterization, converging to the ground truth in a number of iterations almost independent of the condition number. Our work provides evidence on the power of preconditioning in accelerating the convergence without hurting generalization in overparameterized learning.

3 Nonconvex Optimization: When Can Gradient Descent Escape Saddle Points in Linear Time?

Rishabh Dixit, Rutgers University, Piscataway, NJ

The large-scale nature of many of the data driven problems also necessitates the use of first-order optimization methods for computational purposes. But the first-order methods, which include the gradient descent algorithm, face a major hurdle in nonconvex optimization: first-order methods can potentially get stuck at the saddle points of the objective function. And while recent works have established that gradient descent almost surely escapes the saddle points, there remains a concern that first-order methods can spend an inordinate amount of time in the saddle neighborhoods. It is in this regard that we revisit the behavior of the gradient descent trajectories within the saddle neighborhoods and ask whether it is possible to provide conditions under which these trajectories escape the saddle neighborhoods in linear time.

4 Invariant Low-dimensional Subspaces In Gradient Descent For Learning Deep Linear Networks

Can Yaras, University of Michigan

In this presentation, we reveal a surprising simplicity in the learning dynamics of deep linear networks, showing that gradient descent only affects a minimal portion of singular vector spaces across all weight matrices when there is low-dimensional structure in the data. In other words, the learning process occurs only within a minimal subspace of each weight matrix, despite the fact that all weight parameters are updated throughout training. This result enables us to considerably improve training efficiency by taking advantage of the low-dimensional structure in learning dynamics by constructing smaller, equivalent deep linear networks. Second, it allows us to better understand deep representation learning by elucidating the linear progressive separation and concentration of representations from shallow to deep layers.

Towards Understanding Offline Reinforcement Learning: Theory and Applications

Community Committee Choice Session

Session Chair: Jiawei Zhang, MIT, Cambridge, MA
Session Chair: Kaiqing Zhang, MIT, Cambridge, MA
Session Chair: Asuman Ozdaglar, Massachusetts Institute of Technology, Cambridge, MA

1 A Finite-Sample Analysis of Multi-Step Temporal Difference Estimates

Yaqi Duan, [1]</sup

We consider the problem of estimating the value function of an infinite-horizon ⍰-discounted Markov reward process (MRP). We establish non-asymptotic guarantees for a general family of multi-step temporal difference (TD) estimates, including canonical *K*-step look-ahead TD for *K* = 1, 2, ... and the TD(⍰) family for ⍰ [0,1) as special cases. Our bounds capture the dependence of these estimates on both the variance as defined by Bellman fluctuations, and the bias arising from possible model mis-specification. Our results reveal that the variance component shows limited sensitivity to the choice of look-ahead defining the estimator itself, while increasing the look-ahead can reduce the bias term. This highlights the benefit of using a larger look-ahead: it reduces bias but need not increase the variance.

2 Optimal Conservative Offline Reinforcement Learning with General Function Approximation via Augmented Lagrangian

Jiantao Jiao, University of California, Berkeley, Berkeley, CA

Offline reinforcement learning (RL), which aims at learning good policies from historical data, has received significant attention over the past years. We leverage the marginalized importance sampling (MIS) formulation of RL and present the first set of offline RL algorithms that are statistically optimal and practical under general function approximation and single-policy concentrability, bypassing the need for uncertainty quantification. We identify that the key to successfully solving the sample-based approximation of the MIS problem is ensuring that certain occupancy validity constraints are nearly satisfied. We enforce these constraints by a novel application of the augmented Lagrangian method and prove the following result: with the MIS formulation, augmented Lagrangian is enough for statistically optimal offline RL.

3 Provable Statistical Benefits of Hybrid Reinforcement Learning

Yuxin Chen, [1]</sup

In this paper, we study tabular reinforcement learning (RL) in the hybrid setting, where we have access to both an offline dataset and online interactions with the unknown environment. A key question boils down to how to efficiently utilize online data collection to strengthen and complement the offline dataset and improve policy fine-tuning. Leveraging recent advances in reward-agnostic exploration and model-based offline RL, we design a three-stage hybrid RL algorithm that beats the best of both worlds --- pure offline RL and pure online RL --- in terms of sample complexities. Our theory is developed based on a new notion called single-policy partial concentrability, which captures the trade-off between distribution mismatch and lack of coverage, and guides the interplay between offline data and online exploration.

4 Offline Reinforcement Learning with Differentiable Function Approximation is Provably Efficient

Ming Yin[1], Mengdi Wang[2], Yu-Xiang Wang[1], [1]UC Santa Barbara, Santa Barbara, CA, [2]Princeton University, Princeton, NJ, Contact: ming_yin@ucsb.edu

Offline reinforcement learning has been extensively applied in real-life applications. State-Of-The-Art algorithms usually leverage powerful function approximators to alleviate the sample complexity hurdle for better empirical performances. Despite the successes, a more systematic understanding of the statistical complexity for function approximation remains lacking. Towards bridging the gap, we take a step by considering offline reinforcement learning with differentiable function class approximation (DFA). This function class naturally incorporates a wide range of models with nonlinear structures. We show offline RL with differentiable function approximation is provably efficient by analyzing the pessimistic fitted Q-learning (PFQL) algorithm. In addition, we further improve our guarantee with a tighter instance-dependent characterization.

1 First-Order Methods for Stochastic Variational Inequality Problems with Function Constraints

Digvijay Boob[1], Qi Deng[2], [1]Southern Methodist University, Dallas, TX, [2]Shanghai University of Finance and Economics, Shanghai, WY, China. Contact: dboob@smu.edu

This talk introduces novel single-loop first-order methods for function-constrained VI (FCVI) problems which can be smooth or nonsmooth with a stochastic operator and/or constraints. We present the (stochastic) OpConEx method, which employs extrapolation of the operator and constraint functions. This method achieves optimal operator or sample complexities when the FCVI problem is either (i) deterministic nonsmooth, or (ii) stochastic, including smooth or nonsmooth stochastic constraints without requiring the knowledge of Lagrange multipliers. We also present the AdLagEx that achieves optimal operator complexity for smooth deterministic problems without knowledge of Lagrange multipliers. Our methods also apply to saddle point problems with coupled function constraints. To our best knowledge, many of these complexities are new in the literature.

2 Accelerated Primal-Dual Methods for Convex-Strongly-Concave Saddle Point Problems

Mohammad Khalafi[1], Digvijay Boob[2], [1]Southern Methodist University, Dallas, TX, [2]Southern Methodist University, Dallas, TX, Contact: mohamadk@smu.edu

We investigate a primal-dual (PD) method for the saddle point problem (SPP) that uses a linear approximation of the primal function instead of the standard proximal step, resulting in a linearized PD (LPD) method. For convex-strongly concave SPP, we observe that the LPD method has a suboptimal dependence on the Lipschitz constant of the primal function. To fix this, we combine features of Accelerated Gradient Descent with the LPD method resulting in a single-loop Accelerated Linearized Primal-Dual(ALPD) method. ALPD method achieves the optimal gradient complexity when the SPP has a semi-linear coupling function. We also present an inexact ALPD method for SPPs with a general nonlinear coupling function that maintains the optimal gradient evaluations of the primal parts and significantly improves the gradient evaluations of the coupling term compared to the ALPD method.

3 Exact Matrix-Vector Multiplication Complexity for Kernel Projection and Its Application on Distributed Consensus Optimization

Yibo Xu[1], Yuyuan Ouyang[1], Yunheng Jiang[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Central, SC, Contact: yibox@clemson.edu

We study the problem of computing a matrix kernel projection of a vector, when the matrix is not known, but its matrix-vector oracle is accessible. We first explore three perspectives: in control, the best-known method is not optimal; in optimization, we can device a novel accelerated gradient method, yet it is only optimal in the order of linear convergence; in linear algebra, there is known study of exact oracle complexity for solving a linear equation provided with the same matrix-vector oracle, yet this result is not readily applicable to our problem. Based on our observations, under a linear-span assumption, we propose a novel iterative method which attains the exact oracle complexity. In the realm of general methods, we provide an exact lower complexity bound under the assumption that the dimension of our problem is sufficiently large.

4 Nonconvex Stochastic Bregman Proximal Gradient Method with Application to Deep Learning

Kuangyu Ding, National University of Singapore, Singapore, Singapore. Contact: e0444161@u.nus.edu

Classical gradient methods to solve nonconvex composite optimization problems assume Lipschitz smoothness of the differentiable part, which does not hold true for problem classes such as training neural networks. To address this issue, we investigate stochastic Bregman proximal gradient (SBPG) methods, which only require smooth adaptivity of the differentiable part, which captures the non-Lipschitz gradients of the nonconvex objective. We establish the vanilla SBPG's convergence properties and propose a momentum-based SBPG and prove its improved convergence properties. We apply this momentum-based SBPG to train deep neural networks with a polynomial-type kernel, which ensures the smooth adaptivity of the loss function. Experimental results on representative benchmarks demonstrate the effectiveness and robustness of SBPG in training neural networks.

Food and Agricultural Distribution and Transportation

Community Committee Choice Session

Session Chair: Christine Vi Nguyen, Northern Illinois University, Dekalb, IL

1 Modeling the Impact of Decentralization in Food Supply Chain Systems on Food Loss

Tejas Bhatt, Shahram Sarkani, Thomas A. Mazzuchi, George Washington University, Washington, DC, Contact: tejasbhatt@gwu.edu

It is unknown what impact new trends in food supply chain systems, such as e-Commerce and Industry 4.0, will have on food loss and waste which costs up to $400 billion annually and is getting worse. In response to recent global crises, another new trend emerging in food supply chains is decentralization to become less vertically integrated. This research study aims to quantify the impact of decentralization of food supply chain systems on food loss using an agent-based simulation model. Such a model could be used by food companies designing their sourcing, procurement, and logistics strategies as well as by policymakers designing incentives to fight food insecurity. The research is broadly applicable to any industry where waste occurs due to perishability, such as food and agriculture.

2 Assessing Food Supply Chain Risk

Isabella T. Sanders, United States Military Academy at West Point, West Point, NY, Contact: isabella.sanders@westpoint.edu

Though COVID may be waning, food supply chains continue to be vulnerable to unintentional and intentional attacks. This presentation provides a new model to assess food supply chain risk starting at the farm and finishing with the consumer. We present a study of Meals Ready to Eat or MRE's (and similar) a staple in Military Foods as well as disaster relief.

3 Forecasting Egg Price Rise Using Machine Learning

Luyana Franco[1], Wen-Chyuan Chiang[1], Weiping Pei[2], [1]University of Tulsa, Tulsa, OK, [2]University of Tulsa, Tulsa, OK, Contact: lpf4772@utulsa.edu

This study investigates the feasibility of using machine learning models for egg price prediction. We train machine learning models based on historical pricing data and economic indicators and evaluate the performance of models. The prediction results enable stakeholders to make informed decisions regarding production, distribution, and purchasing strategies, while policymakers can address challenges related to the affordability and accessibility of eggs.

4 Enhancing Food Bank Supply Chain Efficiency an Optimal Model Considering Perishable & Non-Perishable Items with Uncertain Supply and Demand

Christine Vi Nguyen[1], Michael Hewitt[2], Mahsa Mahdavisharif[3], [1]Northern Illinois University, Dekalb, IL, [2]LOYOLA UNIVERSITY, Chicago, IL, [3]Northern illinois university, Dekalb, IL

The study proposes a model of a food bank's supply chain operations. Our motivating application is a 3PL that connects food donors to food banks and pantries (e.g. Feeding America). We consider a 3PL that seeks to match uncertain product supply levels (i.e. donations) with uncertain product demand levels from a set of demand points. Demand points can also purchase items to meet their needs. The 3PL seeks to maintain a service level, driven by the organizational mission, to meet demand point needs, and a service level of accepting donations. The 3PL operates distribution centers that serve as inventory and consolidation points for goods. The proposed model aims to minimize the transportation and inventory costs.

Planning Multi-tier City Logistics Systems

Community Committee Choice Session

Session Chair: Julia Lange, RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

1 Two-Echelon Vehicle Routing Problems: A Review, Some Models and Direction for Future Research

Tom Van Woensel, Eindhoven University of Technology, Eindhoven, Netherlands

The distribution network is split into two echelons in the two-echelon vehicle routing problem (2E-VRP). Different vehicles are operated on the first and second echelons to maintain economies of scale and adhere to any vehicle restrictions that may be present in either echelon. Intermediate facilities are located at the borders of the echelons to facilitate the consolidation and transshipment of goods between echelons. The literature on the 2E-VRP has expanded significantly in recent years. In this presentation, mathematical formulations and benchmark datasets used to test and evaluate new algorithms are reviewed and discussed.

2 A Location-Network Design Problem with Vehicle Selection in City Logistics

Francesco Contu[1], Teodor Gabriel Crainic[2], Massimo Di Francesco[1], Enrico Gorgone[1], [1]University of Cagliari, Cagliari, Italy; [2]Université du Québec à

Montréal, Montréal, QC, Canada. Contact: francesco.contu97@unica.it

We study a location-network design problem arising in the field of city logistics [1], [2]. A set of containers must be moved from a port to satellites, where pallets are unpacked from the containers, loaded on vehicles and sent to final destinations. We must select satellites and vehicles, assign containers to satellites, determine paths for selected vehicles, and the flows of pallets. A mixed integer programming formulation and an iterative solution method are proposed; in this method the overall problem can be split at each step into two subproblems: (i) we select satellites, assign containers to satellites, select and assign vehicles to satellites; (ii) we solve a network design problem with routing constraints to determine the paths of vehicles and pallets from satellites to customers. We propose an adaptive large neighbourhood search (ALNS) algorithm for problem(ii).

3 Uncertainty in City Logistics Location-Routing

Teodor Gabriel Crainic[1], David Escobar-Vargas[2], Walter Rei[3], [1]Université du Québec à Montréal, Montréal, QC, Canada; [2]Université de Montréal, Montréal, QC, Canada; [3]University of Quebec-Montreal, Saint-Lambert, QC, Canada. Contact: teodorgabriel.crainic@cirrelt.net

We address the Multi-attribute Two-Echelon Location-Routing Problem with Stochastic Travel Times, where location and routing decisions are to be taken on both tiers of City Logistics systems under uncertainty regarding travel times and demand availability. The problem setting includes time-dependent origin-destination demand, time windows at customers, limited storage capacity at intermediate facilities, and tight synchronization requirements at these facilities of the fleets operating on different tiers. We briefly present the problem, our modelling and algorithmic developments, and the results of an extensive experimentation campaign.

4 Efficient Move Selection in Classical Non-Overlapping Neighborhoods for Routing Optimization

Cesar Rego, University of Mississippi, University, MS

Emerging logistics, transportation, and distribution applications require routing methods exhibiting fast response time, high accuracy, stability, and conciseness. At their core, modern approaches harness classical local search operators prized for their ease of implementation, replicability, and adaptability to diverse routing constraints. However, a significant limitation arises from the sequential examination of non-overlapping neighborhoods during local search, which escalates complexity and limits exploration to one neighborhood type at each step. Our research offers a remedy by revealing properties that identify the best solution within the composite set of neighborhoods in the time required to examine just one of them.

5 Planning Scheduled Services in Multimodal Synchronized City Logistics Systems

Julia Lange[1], Teodor Gabriel Crainic[2], Timo Gschwind[1], Walter Rei[3], [1]RPTU Kaiserslautern-Landau, Kaiserslautern, Germany; [2]Université du Québec à Montréal, Montréal, QC, Canada; [3]University of Quebec-Montreal, Saint-Lambert, QC, Canada. Contact: julia.lange@rptu.de

Future city logistics systems focus on multi-tier and multimodal transportation, an integration of freight movements into mobility and minimal spatial requirements. The presented planning approach is based on two-tier service network design, where transportation services with routes, departure time windows and capacities are given, and waiting time policies exist for customer and handover locations. Demands involve inbound, outbound and inner-city commodity flows. The goal is to find a selection of operated services, an assignment of all demands and a precise schedule for each service so that operating costs and waiting times are minimal. Exact synchronization of services to avoid storage space necessity is a major challenge. Promising results are obtained by general mixed-integer programming methods with enhancements through fixing and bounding techniques.

Data-driven Transit Optimization

Community Committee Choice Session

Session Chair: Ayan Mukhopadhyay, Vanderbilt University, Nashville, TN

1 Designing Equitable Transit Network

Sophie Pavia, Vanderbilt University, Nashville, TN, Contact: sophie.r.pavia@vanderbilt.edu

Public transit is an essential infrastructure enabling access to employment, healthcare, education, and recreational facilities. While accessibility to transit is important in general, some sections of the population depend critically on transit. However, existing design paradigms for public transit do not explicitly consider equity, which is often added as an additional objective post hoc. We present a mathematical formulation for transit network design that explicitly considers different notions of equity and welfare. Our formulation is an integer linear program based on a piece-wise linear utility function that quantifies the utility of a passenger from the installed transit network compared to the use of personal vehicles. We study the interaction between network design and different concepts of equity and present trade-offs and results.

2 I-24 Motion: An Instrument for Freeway Traffic Science

Gergely Zachar, Vanderbilt University, Nashville, TN

The Interstate-24 MObility Technology Interstate Observation Network (I-24 MOTION) is a new instrument for traffic science located near Nashville, Tennessee. I-24 MOTION consists of 276 pole-mounted high-resolution traffic cameras that provide seamless coverage of approximately 4.2 miles on I-24, a 4-5 lane (each direction) freeway with frequently observed congestion. Vehicle trajectories are extracted from the video using computer vision techniques. Approximately 230 million vehicle miles of travel occur within I-24 MOTION annually. The main output of the instrument are vehicle trajectory datasets that contain the position of each vehicle, as well as other supplementary information, like vehicle dimensions, and class. This presentation introduces the design and creation of the instrument, and provides insight into the first publicly available datasets.

3 Request-Vehicle Matching with Consumer Choice Modeling in High-Capacity Ride-Pooling

Youngseo Kim[1], Vindula Jayawardana[2], Samitha Samaranayake[1], [1]Cornell University, Ithaca, NY, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: yk796@cornell.edu

Demand-responsive transit services have received attention due to their flexibility and sustainability. However, developing request-vehicle matching algorithms for pooling services proves more challenging than for ride-hailing services due to the additional complexity of shared rides. One such complexity is the maximum detour time that a service induces on a shared rider. This research proposes a novel matching algorithm that optimizes the system performance while considering user preferences on maximum detours. Our approach estimates the expected future value of matchings for non-myopic solutions to the online optimization. To achieve this, we utilize discrete choice modeling and a reinforcement learning framework to estimate the values of matchings, then solve an integer linear programming to find the best matching pairs and maximum detours.

UAS Traffic Management (UTM) Risk Assessment

Community Committee Choice Session

Session Chair: Valentin Polishchuk, 1</sup

1 Understanding Different Connector Buses' Effect on People's Choices in Selecting Itinerary

Junzhe Cao[1], Xuan Jiang[1], Yuhan Tang[1], Qiyang Mo[2], Hao Yang[3], [1]University of California, Berkeley, Berkeley, CA, [2]Shanghai University, Shanghai, China; [3]University of Washington, Seattle, WA, Contact: j.cao@berkeley.edu

Airline Connector Buses can transform air travel with their potential to address the 'last hundred miles' challenge. This study investigates their impact on airline itinerary choices, considering direct or re-entry security options. The convenience and reduced security hassle may result in higher utility for travelers, as assessed in an extended airline itinerary choice survey. By employing a nested logit model, we capture passenger behavior shifts and trade-offs among itinerary attributes. The study utilizes survey data to understand passenger preferences in different scenarios. Findings guide airlines, policymakers, and transport researchers in comprehending the Airline Connector Buses' potential to reshape air travel. A proposed framework outlines the implementation of this model, fostering a more efficient and passenger-centric air travel ecosystem.

2 Remote Identification Trajectory Coverage and Plausible Deniability Trajectory Planning

Max Z. Li, University of Michigan, Ann Arbor, Ann Arbor, MI, Contact: maxzli@umich.edu

As Urban and Advanced Air Mobility (UAM/AAM) continue to mature, a safety-critical system that will need to be implemented in tandem is Remote Identification (Remote ID) for uncrewed aircraft systems (UAS). To ensure successful and efficient deployment, as well as to better understand secondary impacts (e.g., consumer privacy risks in collecting real-time UAS trajectory information), the *coverage* of broadcast-receive Remote ID architectures needs to be characterized. Motivated by this need, we examine theoretical and empirical trajectory coverage of several common Remote ID technologies (e.g., Bluetooth, Wi-Fi) deployed for urban package delivery missions, a commonly-cited use case for UAM and AAM.

3 Drone Routing Problems Under Stochastic Urban Wind Conditions

Minghao Chen[1], Max Zhaoyu Li[2], Marco Giometto[3], Andrew Smyth[3], [1]Columbia University, New York, NY, [2]University of Michigan, Ann Arbor, Ann Arbor, MI, [3]Columbia University, New York, NY, Contact: mc5276@columbia.edu

This paper addresses the challenges of drone routing in windy urban areas by proposing a novel method that incorporates the stochastic and spatial diversity of urban wind fields. We develop stochastic mixed integer programs (S-MILPs) that integrate the realistic wind scenarios generated by the large eddy simulation (LES) into the stochastic drone routing problem (SDRP). We employ the simulated annealing (SA) algorithm, which effectively explores the solution space and handles visits for hundreds of locations in a short time. Through extensive numerical experiments, we demonstrate the effectiveness of our approach under different wind conditions. We also conduct sensitivity analysis of key factors such as operational altitude on performance. Our results provide valuable insights for optimizing drone routing decisions in windy urban environments.

4 Towards Sustainable UAV Operations: Balancing Economic Optimization with Environmental and Social Considerations in Path Planning

Zhangchen Hu[1], Heng Chen[2], Senay Solak[3], Eric Lyons[3], Michael Zink[3], [1]California State University, Fullerton, Fullerton, CA, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]University of Massachusetts Amherst, Amherst, MA, Contact: zhhu@fullertton.edu

Unmanned aerial vehicles (UAVs) are expected to be widely used in the near future as an alternative transportation mode to mitigate congestion and pollution in a variety of applications. We design a dynamic and data-driven decision support system for UAV path planning through stochastic programming based implementation, where both weather uncertainty and environmental impacts are directly considered.

Human-AI Interaction

Community Committee Choice Session

Session Chair: Nasim Mousavi, Emory University, Atlanta, GA

1 When the Internet of Things Meets Algorithms and the Impacts on the Multi-Stakeholder Service-Profit Chain

Liwei Chen[1], J.j. Po-An Hsieh[2], Kimmy Wa Chan[3], [1]University of Cincinatti, Cincinnatti, OH, [2]Georgia State University, Atlanta, GA, [3]Hong Kong Baptist University, Ithaca, Hong Kong

We propose a techno-service-profit chain to understand how agentic technologies (e.g., IoT-enabled algorithmic customer service systems [IACSs]) impact customer service. We test our model using a sequential mixed-method design with longitudinal data from employees, supervisors, and customers before and after IACS implementation. We theorize the interactions between human and technology agents and scrutinize how technology agents affect the linkages between internal employee management and external customer service. Our findings further reveal the emerging issues of competing bosses, competing employees, and the unintended dehumanization effects of IACSs on supervisors and employees.

2 Overcoming the Stigma Barrier: Information-Seeking from AI Chatbots vs. Human Experts

Bojd Behnaz[1], Aravinda Garimella[2], Haonan Yin[1], [1]University of California - Irvine, Irvine, CA, [2]University Of Illinois - Urbana-Champaign, Champaign, IL

Timely access to information plays a key role in mitigating the impact of challenging circumstances and crises. However, stigma presents a significant barrier to seeking information. Our research examines attitudes towards AI chatbots for information-seeking in stigmatized situations. We conduct online randomized controlled experiments to analyze the effect of stigma on individuals' likelihood of seeking information from AI chatbots compared to human experts, while considering the roles of fear of judgment and the need

for empathy. Our results display that people are unlikely to seek information from both AI chatbots and human experts, but they show less unwilling to talk to AI chatbots. Our study provides insights for practitioners on how to help people overcome the barriers of stigma and seek the information they need in an efficient and cost-effective way manner.

3 Do We Trust AI Agents as Much as We Trust Their Creators? Investigating the Crucial Role of AI Alignment

Kambiz Saffarizadeh[1], Mark Keil[2], Likoebe Maruping[2], [1]Marquette University, Milwaukee, WI, [2]Georgia State University, Atlanta, GA

The technology companies that create AI agents (i.e., AI creators) have been the subject of negative news coverage and are not trusted among the general public. This raises an important question for managers about the extent to which users' trust (or lack thereof) in the AI creator might extend to their trust in the creator's AI agent. In this paper, we leverage the agentic IS framework to explain why AI alignment plays a major role in trust transference in the context of AI agents. We conduct four randomized experiments with 1,140 participants and find that users' assessment of creator-based steerability, user-based steerability, and autonomy—three important alignment-related attributes of AI agents—influence trust transference. We discuss the implications of our findings for research and practice.

4 Counterfactual Explanations for Incorrect Predictions Made by Machine Learning Models

Amir Asrzad, Xiaobai Li, University of Massachusetts Lowell, Lowell, MA

The lack of interpretability in black-box machine learning models poses significant challenges in high-stakes applications such as finance and healthcare. Interpretable machine learning (IML) aims to address this challenge. However, existing IML approaches are limited to generate explanations for correct predictions. To address this issue, our study aims to rectify and explain incorrect predictions made by machine learning models. We propose a novel decision tree-based counterfactual explanation method that provides explanations for both correctly and incorrectly classified cases. The proposed method is validated in an empirical evaluation study using real-world data.

Finding and Adjusting for Data Bias (in ML)

Community Committee Choice Session

Session Chair: Andrew Ilyas, MIT EECS, Cambridge, MA

Session Chair: Manolis Zampetakis, 1</sup

1 Quantifying Distributional Uncertainty

Dominik Rothenhaeusler, Stanford University, Palo Alto, CA

How can we draw trustworthy scientific conclusions? It has been argued that trustworthy scientific conclusions require disparate sources of evidence. For example, in causal inference from observational data, it is common to compute regression-adjusted estimators for different choices of adjustment sets. Then stability investigations can be done by studying the estimator-to-estimator variability between sensible choices of adjustment sets. However, different methods might have shared biases, making it difficult to judge the theoretical guarantees of this practice. We introduce a "distributional uncertainty model", which captures biases in the data collection process. We show that a stability analysis on a single data set allows to construct confidence intervals that account for both sampling uncertainty and distributional uncertainty.

2 Diagnosing Model Performance Under Distribution Shift

Tiffany Cai, Columbia University

Prediction models can perform poorly when deployed to target distributions different from training. In response, we develop a method to attribute a drop in performance to different types of distribution shifts, as different shifts require different interventions. Our method decomposes the performance drop into terms for 1) an increase in harder but frequently seen examples from training, 2) changes in the relationship between features and outcomes, and 3) poor performance on examples infrequent or unseen during training. Empirically, we show how our method can 1) guide model improvements across distribution shifts for employment prediction on tabular census data, and 2) help to explain why certain domain adaptation methods fail to improve model performance for satellite image classification.

3 What Makes a Good Fisherman? Linear Regression Under Self-Selection Bias

Andrew Ilyas[1], Yeshwanth Cherapanamjeri[2], Constantinos Daskalakis[1], Manolis Zampetakis[2], [1]MIT EECS, Cambridge, MA, [2]UC Berkeley, Berkeley, CA

What makes a good fisherman? A reasonable approach to figure this out is to collect data comprising features of fishermen and their daily catch, and then learn a model mapping the former to the latter. Reasonable as this approach may sound, it will likely result in a biased model. The reason for this bias is that the data will miss the individuals who were not good enough at fishing and decided to become hunters instead. Such self-selection bias is pervasive. From understanding what it takes to be a good student to to studying strategic behavior in markets, data available for learning statistical models are the results of strategic decisions that have filtered out some of the relevant data. We discuss recent progress on estimating linear models under self-selection bias and identification of non-parametric auction models, and present some open directions for future investigation.

4 More Data, More Problems: How Sampling Bias Compromises Data Scaling Properties in Machine Learning

Irene Chen[1], Judy Shen[2], Inioluwa Deborah Raji[1], [1]UC Berkeley, Berkeley, CA, [2]Stanford, Palo Alto, CA, Contact: iychen@berkeley.edu

The accumulation of data in the machine learning setting is often presented as a panacea to address its many modeling problems---including issues with correctness, robustness, and bias. But when does adding more data help, and when does it hinder progress on desired model outcomes? We model data accumulation from multiple sources and present analysis of two practical strategies that result the addition of more data degrading overall model performance. We then demonstrate empirically on three real-world datasets that adding training data can result in reduced overall accuracy and reduced worst-subgroup performance while introducing further accuracy disparities between subgroups. We conclude with a discussion on considerations for data collection and the importance of data composition in the age of increasingly large models.

Scheduling Problems in Varied Settings

Contributed Session

Session Chair: Eman Almehdawe, University of Regina, Regina, SK, Canada

1 Analysis of Combining LPT and Multifit Algorithms for Identical Parallel Machine Scheduling to Minimize the Makespan

Insoo Park, Kyungduk Moon, Kangbok Lee, POSTECH, Pohang, Korea, Republic of. Contact: factorpark@postech.ac.kr

The parallel machine scheduling problem to minimize the makespan is one of the most studied problems in scheduling theory. Two famous algorithms are LPT(Longest Processing Time first) and MULTIFIT. Interestingly, several worst-case instances of LPT can be optimally solved by MULTIFIT and vice versa. Taking advantage of this fact, Lee and Massey (1988) proposed the COMBINE algorithm, which combines LPT and MULTIFIT algorithms. Despite the importance of LPT and Multifit, theoretical analysis of the COMBINE algorithm has been limited. We provide its theoretical analysis by proving the approximation ratio. We introduce a MIP-based approach to prove this ratio, which is extensible to any other algorithms that can be described as a mathematical programming model.

2 Minimizing the Maximum Flow Loss in the Network Maintenance Scheduling Problem with Flexible Arc Outages

SHUANG JIN, YING LIU, JING ZHOU, QIAN HU, Nanjing University, Nanjing, China. Contact: shuangjin@smail.nju.edu.cn

We investigate a network maintenance scheduling problem where maintenance tasks are carried out on the arcs within flexible time windows. During the maintenance, the arc is interrupted and no flow can pass through. The problem is to find a feasible schedule so that the maximum flow loss during the horizon is minimized. We study the min-max formulation and introduce a Benders reformulation. A Benders decomposition algorithm is designed, in which effective cutting planes, strengthened initial cuts and an efficient separation procedure are proposed. There are two extensions to minimize the total flow loss and the duration of maximum flow loss, respectively, via hierarchical optimization to select more desirable schedules. Computational experiments show the outstanding performance of the proposed algorithm. The schedules of these problems are analyzed in a number of ways.

3 The Technician Routing and Scheduling Problem: A Genetic Algorithm Approach Versus a Simulated Annealing Approach

Eman Almehdawe, University of Regina, Regina, SK, Canada. Contact: eman.almehdawe@uregina.ca

We develop a Technician Routing and Scheduling Problem (TRSP) model that is motivated by a telecom provider in Saskatchewan, Canada. The problem becomes more complex when a group of technicians must be assigned to a set of tasks with different service times and time windows.

The technicians are expected to serve customers that are distributed across a vast working area. To treat the large-scale instances of the model, we develop a Simulated Annealing (SA) algorithm and a Genetic Algorithm (GA), which generate high-quality solutions. The obtained results demonstrate that our designed metaheuristics outperform the commercial exact solver in terms of the CPU-time. Moreover, findings show that the proposed GA generates better solutions than the SA with respect to the obtained optimality gaps.

QSR: A Gallery of Research Activities

Flash Session

Session Chair: Andi Wang, Arizona State University, Mesa, AZ

1 From Reliability to Resilience

Elsayed A. Elsayed, Rutgers University, East Brunswick, NJ

This is a short flash presentation that focuses on quantifying systems' resilience and relating it to the systems' availability. Approaches for resilience quantifications for both repairable and nonrepairable systems will be addressed. A case study of assessing the reliability of a supply chain will be presented.

2 Overview of IoT Enabled System Monitoring, Prognosis, and Decision Making

Shiyu Zhou, 1</sup

In this talk, I will provide an overview of the research topics of my group on Internet of Things enabled system monitoring, prognosis, and maintenance decision making.

3 Tensor Analysis for Systems Modeling and Improvement

Mostafa Reisi, 1</sup

This talk discusses different aspects of tensor data analysis, including distributed and robust tensor modeling, applied to various applications such as healthcare and agriculture.

4 Characterizations of Mechanical Nanomachining Using Advanced Machine Learning Method

Zimo Wang[1], Qiyang Ma[2], [1]SUNY Binghamton, Binghamton, NY, [2]State University of New York at Binghamton, Vestal, NY

We present a framework of sensor-based modeling that enables real-time characterizations for mechanical-based nanomachining. The extensive experimental case study suggests that the presented autonomous ensemble classification and prediction models allow in-process characterization and quality inspection, with an accuracy of over 90% for real-time remapping on the surface profile, for complicated machining structures under nanoscale precision.

5 A Prototype of Digital Twin for Multi-stage Distributed Manufacturing Systems

Hongyue Sun, University at Buffalo, Buffalo, NY

Smart manufacturing and Industry 4.0 are bringing disruptive changes to the manufacturing sector. Smart manufacturing increases productivity, creates safer conditions for workers, and simplifies product customization, all while decreasing business expenses. In this talk, I will introduce an architecture for remote machine management, using it to build a digital twin prototype of a multi-stage smart manufacturing system. This twin provides users with the ability to monitor and control the machine from anywhere in the world through a web interface. The framework is flexible, capable of supporting many different machines.

6 Modeling, Monitoring, and Diagnosis of Complex Systems with High-dimensional Streaming Data

Ana Maria Estrada Gomez, Purdue University, West Lafayette, IN

Nowadays, most complex systems are continuously monitored by a large number of sensors. The low implementation cost, high acquisition rate, and variety of sensing systems allow for the collection of a large volume of data. Modeling and analyzing such rich datasets provide unique opportunities for real-time process monitoring and control, and for accurate fault diagnosis, in a wide range of applications. However, the intricate characteristics of the high-dimensional streaming data pose significant analytical and computational challenges yet to be addressed. The data might be decentralized, high-dimensional, incomplete, correlated, and/or heterogeneous. This talk focuses on my group's recent efforts to tackle some of these challenges.

7 Data Science in Biointelligent Manufacturing

Bianca Maria Colosimo, Politecnico di Milano, Milan, Italy. Contact: biancamaria.colosimo@polimi.it

Biointelligent manufacturing is a cutting-edge field that fuses biology, artificial intelligence, and advanced manufacturing techniques to revolutionize the production of tissues, organs, and even bio-inspired materials, holding immense potential for regenerative medicine and personalized healthcare.

Together, the synergy of bioprinting and data modeling and monitoring in biointelligent manufacturing opens up unprecedented possibilities for advancements in healthcare, sustainable materials, and numerous other industries, shaping a brighter and more sustainable future.

Computer Experiments: Methods, Theory & Applications

Community Committee Choice Session

Session Chair: Simon Mak, Duke University, Durham, NC

1 In Situ Uncertainty Quantification

Earl Lawrence, Los Alamos National Laboratory, Los Alamos, NM

The Department of Energy's investment in exascale computing will enable simulations with unprecedented resolution. This will let scientists investigate fine-scale behavior in areas of interest to DOE such as climate and space physics. However, the computational power of exascale machines has outstripped their I/O and storage capacity which will make some forms of post hoc analysis impossible. To address this, we are working on methods for in situ uncertainty quantification, that is analysis done inside the simulations as they are running. I will provide an overview of the problem and describe some of the work that we are doing at LANL to fit Bayesian hierarchical models to data inside of simulations of climate and space weather.

2 Sequential Designs for Causal Inference

Difan Song[1], Simon Mak[2], C F Jeff Wu[1], [1]Georgia Institute of Technology, Atlanta, GA, [2]Duke University, Durham, NC, Contact: dfsong@gatech.edu

Experiments are the gold standard for causal inference. In many applications, experimental units are recruited or chosen sequentially; therefore, short-term outcomes can provide valuable information for the design of experiments for later units. This work studies the role of sequential designs in causal inference problems in which we can either design the user included in the study or the treatment applied. We employ Gaussian process (GP) models to allow for flexible modeling of the potential outcomes. More importantly, the GP model allows for uncertainty quantification of a variety of causal estimands. We develop acquisition functions for sequential designs based on minimizing the prediction variance of these estimands. We demonstrate the broad applicability of our approach through several semi-synthetic examples in behavioral and marketing experiments.

3 A Scalable Gaussian Process for Large Scale Periodic Data

Yongxiang Li[1], Yuting Pu[1], Changming Cheng[1], QIAN XIAO[2], [1]Shanghai Jiaotong University, Shanghai, China; [2]THE UNIVERSITY OF GEORGIA, Athens, GA, Contact: qian.xiao@uga.edu

The periodic Gaussian process (PGP) has been increasingly used to model periodic data due to its high accuracy. Yet, computing the likelihood of PGP has a high computational complexity of $\mathcal{O}\left(n^{3}\right)$ (n is the data size), which hinders its wide application. To address this issue, we propose a novel circulant PGP (CPGP) model for large-scale periodic data collected at grids that are commonly seen in signal processing applications. The proposed CPGP decomposes the log-likelihood of PGP into the sum of two computationally scalable composite log-likelihoods, which do not involve any approximations. Computing the likelihood of CPGP requires only $O(p^{2})$ (or $Op\log(p))$ in some special cases) time for grid observations, where the segment length p is independent of and much smaller than n.

4 Energetic Variational Gaussian Process Regression for Computer Experiments

Lulu Kang, University of Massachusetts Amherst, Chicago, IL, Contact: lulukang@umass.edu

The Gaussian process (GP) regression model is a popular surrogate modeling approach for computer experiments. Both frequentist and In this talk, we build the GP model via variational inference, specifically, the newly proposed energetic variational inference by Wang et al. (2021). Following the GP model assumption, we first derive the posterior distributions of the parameters for the GP model with non-zero mean functions. The energetic variational inference method is used to generate samples of the posterior distributions. It can bridge the Bayesian sampling and optimization and provides a much more computationally efficient solution. With a normal prior on the mean component of the GP model, shrinkage estimation is also applied to the parameters to achieve model sparsity of the mean function.

Surrogates for Digital Twin

Community Committee Choice Session

Session Chair: Chiwoo Park, Florida State University, Tallahassee, FL

1 Spatiotemporal Predictions of Toxic Urban Plumes Using Deep Learning

Yinan Wang[1], M. Giselle Fernández-Godino[2], Nipun Gunawardena[2], Donald Lucas[2], Xiaowei Yue[3], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Lawrence Livermore National Lab, Livermore, CA, [3]Virginia Tech, Blacksburg, VA, Contact: wangy88@rpi.edu

Industrial accidents, chemical spills, and similar events can release large amounts of harmful materials that disperse into urban atmospheres and can impact populated areas. Computer models are typically used to predict the transport of toxic plumes by solving fluid dynamical equations. However, these models can be computationally expensive. In emergency response situations, alternative methods are needed that can run quickly and adequately resolve important spatial features. Here, we present a novel deep learning model called ST-GasNet was inspired by the mathematical equations that govern the behavior of plumes as they disperse through the atmosphere. ST-GasNet predicts the spatiotemporal evolution of a toxic plume in a complex city, using a limited set of temporal sequences of ground-level toxic urban plumes.

2 Surrogate Model-Based Simulation Optimization of Vehicle Positioning Strategy in a Semiconductor Fab

Bonggwon Kang[1], Chiwoo Park[2], Haejoong Kim[3], Soondo Hong[1], [1]Pusan National University, Busan, Korea, Republic of; [2]Florida State University, Tallahassee, FL, [3]Kyonggi University, Suwon, Korea, Republic of

Semiconductor fabs often rely on simulation-based optimization to position vehicles considering complex, large-scale operations and demand uncertainty. Simulation-based optimization is challenging due to the high computational cost of simulation runs and the vast search space with numerous control variables. We propose Bayesian optimization with a Gaussian process (GP) to obtain efficient vehicle positioning for upcoming transportation demands. The proposed method expedites the simulation optimization by replacing a computationally expensive simulation with a GP surrogate model. Experiments demonstrate that the proposed method significantly decreases vehicle utilization and delivery time within limited simulation runs.

3 Community/Committee'S Choice Submission

Syed Bahauddin Alam, MO

4 Adaptive Reduced-Order Models Using Wrapped Gaussian Processes

Xiao Liu, University of Arkansas, Fayetteville, AR

A ROM can be obtained, using the well-known Proper Orthogonal Decomposition (POD), by projecting the full-order model to a subspace spanned by modal basis modes which are learned from experimental, simulated or observational data, i.e., training data. However, the optimal basis can change with the parameter settings. When a ROM, constructed using the POD basis obtained from training data, is applied to new parameter settings, the model often lacks robustness against the change of parameters in design, control, and other real-time operation problems. This talk proposes an approach that learns the mapping between parameters and POD bases using Wrapped Gaussian Processes (WGP).

5 Jump Gaussian Process Surrogates for Digital Twin

Chiwoo Park, Florida State University, Tallahassee, FL

Active learning of Gaussian process (GP) surrogates has been useful for optimizing experimental designs for physical/computer simulation experiments and constructing digital twins. In this talk, we present a method for active learning of piecewise, Jump GP surrogates. Jump GPs are continuous within, but discontinuous across, regions of a design space, as required for applications spanning autonomous materials design, configuration of smart factory systems, and many others. We demonstrate that additionally accounting for model bias, as opposed to the usual model uncertainty, is essential for effective learning of the Jump GP.

Integrating Weather and Climate Uncertainty into Energy Systems Planning and Management

Community Committee Choice Session

Session Chair: Jordan Kern, North Carolina State University, Raleigh, NC

1 Balancing Accuracy and Computing Costs: Are Decomposition Methods Still Needed in the Era of Optimization Packages?

Phumthep Bunnak, Stefano Galelli, Singapore University of Technology and Design, Singapore, Singapore. Contact: stefano_galelli@sutd.edu.sg

A big challenge with the integration of weather uncertainty into power system models is the increase in computational requirements. Energy system modelers have typically traded-off model accuracy with tractability by simplifying temporal, spatial, or technological dimensions. Few production cost models have instead relied on decomposition methods that preserve the 'original' problem formulation. Here, we explore this direction and contribute a novel computational framework that implements the Dantzig-Wolfe decomposition while supporting popular algebraic modeling languages in Python. Extensive experiments on country-scale grids reveal speed-up reaching two orders of magnitude.

2 Exploring How Changing Hydropower Operations Can Facilitate Renewable Energy Transitions and Sustainable Climate Change Adaptation

Julianne Quinn[1], Samarth Singh[1], Jacob Wessel[2], Jordan Kern[3], Jonathan Herman[4], [1]University of Virginia, Charlottesville, VA, [2]Tufts University, Medford, MA, [3]North Carolina State University, Durham, NC, [4]University of California, Davis, Davis, CA, Contact: jdq6nn@virginia.edu

Meeting global carbon mitigation targets will require a rapid transition to more renewable energy sources, but doing so will make energy supply more variable and out of phase with demand. Hydropower operations can be adapted to balance these loads, but at the expense of sustaining environmental flows for wildlife and ensuring sufficient flood protection. This project investigates how alternative reservoir operations influence water-energy systems under different grid decarbonization and climate change scenarios in the Columbia River Basin. Our analysis reveals that systems exhibiting these changing dynamics could benefit from re-designing operations to prioritize hydropower production and load balancing at high-capacity dams while meeting flood protection and environmental spills objectives through coordination across multiple smaller reservoirs.

3 Identifying Robust Energy Decarbonization Pathways in the Presence of Deep Climate Uncertainty

Srihari Sundar[1], Flavio Lehner[2], Nathalie Voisin[3], Michael Craig[1], [1]University of Michigan, Ann Arbor, MI, [2]Cornell University, Ithaca, NY, [3]Pacific Northwest National Lab., Seattle, WA

Uncertainty in policy and technology adoption has led to a suite of plausible energy system decarbonization pathways. In all pathways though, system operations will be increasingly driven by meteorology, and climate projections used to model operations have large uncertainties. In the near term, internal variability is a significant source of this uncertainty and is quantified using large ensemble (LE) climate data. Here, we apply the robust decision making (RDM) framework to identify decarbonization pathways for the Western United States that are robust against many climate realizations from the CESM2 LE. Using metrics such as regret and satisficing from the RDM framework, we find climate realizations and extremes that cause significant failures across pathways. Our research will help utilities make decarbonization decisions that are robust to climate change.

4 Synchronous Stochastic Simulation of U.S. Bulk Electric Power and Natural Gas Markets

Jordan Kern, Cameron Lisy, North Carolina State University, Raleigh, NC

The Eastern and Western parts of the U.S. electric power grid are not electrically connected, but winter extremes in the East put pressure on natural gas prices nationwide. In 2014 and 2021, severe winter weather in the East was then compounded by summers marked by historical droughts and heatwaves in the West, forcing Western power producers to rely more on expensive natural gas in short supply. Key challenges exist in exploring this phenomenon. This talk will discuss progress in linking open-source models of the U.S. bulk power system with a network model of the natural gas market.

5 Power System Expansion Planning for California Under Variable Climate Projections

Amelia Musselman[1], Tomas Valencia Zuluaga[2,1], Jean-Paul Watson[1], [1]Lawrence Livermore National Laboratory, Livermore, CA, [2]University of California, Berkeley, Livermore, CA

Climate change impacts power system operations through factors such as increased temperatures, droughts, changing wind patterns, and solar irradiance shifts. In this work, we develop a novel climate-resilient capacity expansion planning model, which seeks to minimize costs while ensuring power system resilience. We model the problem as a stochastic mixed-integer program, which we implement in Pyomo and solve using mpi-sppy and Gurobi. We extend an existing synthetic but realistic test case for California. Leveraging climate data from the CMIP6 model repository, we map future climate projections onto power system parameters, focusing initially on changes in temperature, wind speed, and solar irradiance. We compare investment decision based on present-day climate with future-climate resilient solutions. Prepared by LLNL under Contract DE-AC52-07NA27344.

Optimizing Energy Systems

Community Committee Choice Session

Session Chair: Alexandra M. Newman, Colorado School of Mines, Golden, CO

1 Grid-Aware Tradeoff Analysis for Outage Mitigation Microgrids at Emerging Resilience Hubs

Arnav Gautam[1], Destenie S. Nock[1], Amritanshu Pandey[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]University of Vermont, Burlington, VT, Contact: ajgautam@andrew.cmu.edu

Sustained power outages are growing primarily due to i) disasters and ii) decarbonization and electrification-driven changes on the grid. Outage mitigation technologies can provide vital electricity access during disasters, but their adoption is inequitable due to individual- or community-level barriers. We postulate that community-based Resilience Hubs (RHs) can be expanded to address this inequity by supplying backup power to marginalized communities during disasters. We present a Grid-Aware Tradeoff Analysis framework to identify the best backup power systems for expanded RHs. We use three-phase power flow to enforce the electrical feasibility of RH microgrid options, and multi-criteria decision analysis to quantify the economic, environmental, and equity-weighted outage mitigation performance. We evaluate a case study based on the city of Richmond, CA.

2 Policy Recommendations for a Microgrid with Mixed Energy

Karoline Hood, US Army, Lakewood, CO

The frequency of power outages has significantly increased over the past twenty years due to climate change and a rise in natural disasters. These outages put at risk the operation of critical infrastructure. The integration of microgrids, using mixed-energy technology to include solid oxide fuel cells, provides relief during outages. We use an existing mixed-integer nonlinear model that provides a cost minimizing design and dispatch strategy. Our extension of the model includes case studies of different communities which have unique demands due to the size and design of the community. We provide analysis and policy recommendations on the deployment of microgrids to the communities to include the use of solid oxide fuel cells.

3 Transitioning from Diesel Backup Generators to PV-Plus-Storage Microgrids in California Public Buildings

Sunjoo Hwang, University of North Carolina, Chapel Hill, NC, Contact: shwang2@unc.edu

Frequent power outages including Public Safety Power Shutoffs have increased demands for backup generators in California, whereas the state aims to achieve 100% clean electricity by 2045. This research quantifies the value of replacing diesel backup generators with PV-plus-storage microgrids in California public buildings. The results show that replacing diesel generators in one building would save ~$3M of public expenditures and reduce ~10,000 tons of CO_2 emissions over 20 years. It implies that the same application in the state's 22 air districts could save $31-385M annually. Also, this research develops a marginal resilience curve for the cost and environmental impact of extended outages, which demonstrates that increasing energy storage capacity greatly outweighs increasing PV or generator capacity to enhance resilience, while reducing costs and emissions.

4 Wasserstein Metric-Based Clustering for Large-Scale Power Distribution System Modeling

Alfredo Oneto, Blazhe Gjorgiev, Giovanni Sansavini, ETH Zurich, Zurich, Switzerland

The electric power system comprises many distribution grids supplying various customers. These grids are complex infrastructures due to the interconnections between their components. Therefore, it is computationally challenging to assess a large number of such systems. To address this challenge, we propose a method that finds representative grids. The method performs spatial pattern aggregation by combining clustering and differential geometry concepts. We extend classic clustering ideas in Euclidean spaces to the Wasserstein metric space, leveraging techniques of Riemannian geometry. When applied to a large set of distribution grids, this method can produce a small representative subset. Moreover, we provide a case study of the clustering of distribution networks in Switzerland to demonstrate a real-world application.

Decarbonizing China's Energy Systems: Pathways and Challenges

Community Committee Choice Session

Session Chair: Qingyu Xu, Tsinghua University, Beijing, China
Session Chair: Qingyu Xu, Princeton University, Princeton, NJ
Session Chair: Jing Dai, Tsinghua University, Beijing, China

1 A Fully Open-Source Power Dataset for Policy Applications in China

Michael R. Davidson, Ming Wei, Boyu Yao, University of California, San Diego, La Jolla, CA, Contact: mrdavidson@ucsd.edu

China's power system is the largest in the world. Analysis on it is crucial to addressing climate change and other environmental challenges, yet this is complicated by a lack of easily accessible open datasets. In this presentation, we introduce a new open dataset containing transmission network (500kV and select 220kV and above), generators, and demand s(provincial and sub-provincial) collected and simulated from a vast range of publicly available data. A unit commitment model is developed with this dataset for the case of assessing resource adequacy in northeast China in light of recent power shortages. Findings show that key institutional and policy drivers are primary contributors to shortages, and that new coal capacity development is not needed to maintain energy security.

2 Spatially Resolved Land and Grid Model of Carbon Neutrality in China

Da Zhang, Tsinghua University, Beijing, China. Contact: zhangda@tsinghua.edu.cn

China has committed to achieve net carbon neutrality by 2060 to combat global climate change, which will require unprecedented deployment of negative emissions technologies, renewable energies (RE) and complementary infrastructure. At terawatt-scale deployment, land use limitations interact with operational and economic features of power systems. To address this, we developed a spatially resolved resource assessment and power systems planning optimization that models a full year of power system operations, sub-provincial RE siting criteria, and transmission connections. Our modeling results show that wind and solar must be expanded to 2,000-3,900 GW each, with one plausible pathway leading to 300 GW/yr combined annual additions in 2045--2060, a four-fold increase from today.

3 Short-Term Interval-Valued Load Forecasting with a Combined Strategy of Ihw and Multioutput Machine Learning

Feng Gao[1], Jie Song[1], Xueyan Shao[2], [1]Peking University, Beijing, China; [2]Chinese Academy of Sciences, Beijing, China

Interval-valued load forecasting can provide more comprehensive and richer information for decision-making. However, the existing literature mainly focused on point-valued load forecasting and neglect the significance of interval-valued load forecasting. In this paper, we propose a combined framework based on interval Holt-Winters and multioutput machine leaning method to predict daily interval-valued load. We improve traditional Holt-Winters and proposed interval Holt-Winters taking account of the seasonal characteristics of daily load. Multiple multioutput machine learning models are employed to predict residual series of interval Holt-Winters. Empirical results show that the proposed combined interval model outperforms the corresponding single interval model and has excellent robustness.

4 Where to Go? Transition of China's Coal-Fired Generation in a Power Sector Under Decarbonization and Deregulation

Qingyu Xu, Jing Dai, Peixin Qin, Yao Meng, Geye Lu, Tsinghua University, Beijing, China. Contact: xuqingyu@tsinghua.edu.cn

China's power sector is facing unprecedented pressure: establishing organized wholesale markets and steadily decarbonizing its generation fleets. A rapidly increasing penetration of wind and solar generation would lead to an unstable system, while the overprotection over coal power could mean China missing its decarbonization goal. With a capacity expansion planning model, we evaluate strategies for coal power transition in China, including retiring, mothballing, and retrofitting for post-combustion CCS or renewables. Then we discuss each coal-power transition option's monetary and environmental benefits under uncertainties.

Circular Economy and Sustainable Manufacturing

Community Committee Choice Session

Session Chair: Sidi Deng, Purdue University, West Lafayette, IN

1 Optimizing Reverse Logistics Supply Chain Network for Sustainable Value Recovery from Li-Ion Batteries in the United States

Apurba Kumar Saha[1], Hongyue Jin[2], [1]The University of Arizona, Tucson, AZ, [2]University of Arizona, Tucson, AZ
Value recovery from spent LIBs could facilitate sustainable EOL management and recover valuable materials to create a resilient supply of the critical raw materials such as lithium and cobalt. This study focuses on the design of an optimal reverse logistic supply chain network for sustainable collection and recycling of spent LIBs. Optimization models have been developed to (1) evaluate the impact of governmental policies on the adoption of LIB recycling technologies and (2) maximize the economic and environmental benefits from LIB recycling in the next ten years. The model was applied to the case of United States and suggested the optimal facility locations, processing capacities, recycling technology, and material flows for LIB recyclers.

2 Development of Manufacturing-Relevant Indicators for Measuring Progress Towards Circular Economy
Yong Han Kim, Sidi Deng, Thomas Maani, John W. Sutherland, Purdue University, West Lafayette, IN, Contact: kim3822@purdue.edu
The manufacturing sector plays a key role in the U.S. economy while at the same time being responsible for a large portion of energy/material consumption and environmental burdens. However, there is a lack of standardized manufacturing-relevant indicators for measuring progress toward a circular economy. Without standardized indicators in the manufacturing sector, it is difficult for decision-makers to create appropriate decisions, and will make them challenging to assess the effectiveness of their efforts to adopt circular practices. Therefore, the objective of this research is to develop indicators that will allow decision-makers to understand the consequences of their strategies in terms of end-of-life product management (and more broadly in terms of closing loops within product life cycles).

3 A Two-Stage Distributed Learning-Based Framework for Dynamic Electric Vehicle Sharing
Wentao Zhao[1], Maged M. Dessouky[2], [1]University of Southern California, Los Angeles, CA, [2]University of Southern California, Los Angeles, CA, Contact: wzhao009@usc.edu
We study the dynamic relocation of an electric vehicle-sharing system providing on-demand service. We propose a two-stage framework. First, we develop a multi-agent reinforcement learning model that treats stations as agents and trains them to determine their relocation requests independently. Then, the obtained requests are transformed into an executable relocation strategy that satisfies all systematic constraints, like fleet conservation, by solving an auxiliary optimization problem.

4 Observed and Optimal EV Charging Behavior and Their Impact on the Grid
Hannah Davalos[1], Shmuel S. Oren[2], Candace Arai Yano[3], [1]University of California, Berkeley, Berkeley, CA, [2]UC Berkeley, Berkeley, CA, [3]University of California-Berkeley, Berkeley, CA
How electric vehicle drivers charge their vehicles has a major impact on the pattern of loads on the electrical grid. In addition to range anxiety, the capacity of the grid to support EV charging is a concern for prospective EV purchasers and thus also for auto manufacturers. Using results of a survey of EV drivers who work at a large university, we analyze self-reported EV charging patterns and develop a model to optimize charging for prototypical classes of drivers in view of time-of-use rates for residential and public charging. We then compare observed and "optimal" charging patterns and discuss differences in their impact on the electrical grid. We also explore the fraction of charging likely to be from renewable resources.

5 Planning a Remanufacturing System for Electric Vehicles Using Network Analysis
Sidi Deng[1], Yuehwern Yih[2], John W. Sutherland[3], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, [3]Purdue University, West Lafayette, IN, Contact: deng100@purdue.edu
This study discusses a potential EV Renewal System (EVRS) that aims to directly rebuild used EVs and recover maximum value from EoL components and materials. The designed process chain coordinates and synergizes concomitant procedures such as disassembly, processing, and reassembly. The EVRS was modeled as an activity-on-arc (AoA) network, and a simulation approach based on a stochastic activity network (SAN) is employed. Moreover, based on network topology analysis, proxy variables are defined to characterize system complexity under different operating scenarios. To enable mass-scale processing of used EVs, the EVRS is further compartmentalized into serially located workstations. The proposed network analysis framework is adaptable to a diverse range of industries and can galvanize more remanufacturing practices.

Optimization Modeling Software and Software Engineering

Community Committee Choice Session

Session Chair: Ryan O'Neil, Nextmv
Session Chair: Susanne Heipcke, FICO, Birmingham, United Kingdom

1 The Sushi is Ready, How Do I Deliver It? Developing, Deploying and Managing Real-Time Optimization Systems

Sebastian Quintero, Nextmv, Bogota, Colombia. Contact: sebas@nextmv.io

We propose a holistic approach towards real-time optimization systems (such as food & groceries delivery, ride sharing) that transcends traditional OR boundaries. We assert that real-time planning is not an isolated analytical problem, but an integral part of a decision "supply chain", deeply interconnected with other decision models.We treat these systems as engineered software components in a production stack. We emphasize the necessity of rigorous testing and seamless integration with other software systems. This leads to a more resilient, adaptive, and real-time planning process.

2 Adapting to Change in On-Demand Delivery: Unpacking a Suite of Testing Methodologies

Nicole Misek, Ryan O'Neil, Nextmv, Philadelphia, PA, Contact: nicole@nextmv.io

The volatile world of on-demand, gig-economy delivery employs a diverse suite of testing methodologies to master change and operational risk. We explore common testing techniques, in the context of a multi-sided marketplace. We discuss historical testing, batch experimentation, acceptance testing, shadow testing, switchback testing, and digital twin simulation. We present these not as isolated tools, but as a cohesive toolbox deployed against real-world examples.

3 Pyddopt: Solving Dynamic Programming Models with Decision Diagram-Based Optimization

Timothy Curry[1], Laurent Michel[1], Willem-Jan van Hoeve[2], [1]University of Connecticut, Storrs, CT, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: vanhoeve@andrew.cmu.edu

We present PyDDOpt, a Python modeling interface for solving combinatorial optimization problems using decision diagram-based optimization solvers. Currently this optimization technology is accessible via lower-level programming languages which limits easy modeling experimentation and wider adoption. PyDDOpt allows to represent state-based (dynamic programming) models in an intuitive manner. These models are converted into specifications which are used to automatically compile relaxed and restricted decision diagrams, as well as the search process. We demonstrate the functionality of PyDDOpt on applications such as the traveling salesperson problem, the maximum independent set problem, and the Golomb ruler problem.

4 The Best of Both Worlds: Integrating Python and Gams

Steven P. Dirkse, GAMS Development Corporation, Fairfax, VA

Optimization applications combine technology and expertise from many different areas, including model-building, algorithms, and data-handling. Often, the gathering, pre/post-processing, and visualization of the data is done by a diverse organization-spanning group that shares a common bond: their skill in and appreciation for Python and the vast array of available packages it provides. For this reason, GAMS offers multiple ways to integrate with Python on the data-handling side, as well as offering some packages of our own (e.g. GAMS Transfer, GAMS Connect). In this talk, we will explore the benefits of this integration and demonstrate them using a real-world example complete with results on performance.

Improving Efficiency and Resilience of Power System Infrastructure

Contributed Session

Session Chair: Heraldo Rozas, Georgia Institute of Technology, Atlanta, GA

1 Bio-Inspired Self-Healing for Enhancing Resilience in Power Systems

Tianye Wang, George Washington University, Washington, DC, Contact: twang87@gwu.edu

Inspired by self-healing in biological systems, this study proposes a novel framework to enhance the resilience of integrated energy systems. The self-healing operation borrows from morphogenesis, i.e., cell recombination and tissue formation, implemented through sectioning of faulted zones in the event of a disruption. The objective is to determine restoration pathways with the least cost of optimally configured capacities. Specifically, how much should be invested in building such redundant capacities? What electricity generating technologies should make up the portfolio? An IEEE reference network model is used to validate the restorative intervention.

2 Integrated Modeling of Thermal Power Plants and Regasification Terminal for Lng Load Allocation Under Operational Uncertainties

Lucas Guerreiro[1], Guilherme Bodin[1], Joaquim Masset Lacombe Dias Garcia[1], Tiago Coutinho Carneiro de Andrade[2], [1]PSR, Rio de Janeiro, Brazil; [2]PSR-inc, Rio de Janeiro, Brazil. Contact: lucasaguerreiro@psr-inc.com

This study presents an integrated modeling approach for the allocation of liquefied natural gas (LNG) loads, considering both thermal power plants and a regasification terminal. The model addresses operational uncertainties and aims to optimize the allocation decisions. By combining mathematical programming and decision tree techniques, the model provides insights into the optimal operation under different conditions. It considers factors such as fuel allocation, storage, gas supply, and marketing. The model's implementation is available as an open-source package and demonstrates its potential to enhance efficiency and decision-making in the thermal power generation sector.

3 Assessing the Effects of Various Assumptions on Equilibrium Models in Power System Expansion Planning

Jonghwan Kwon[1], Todd Levin[2], Audun Botterud[3], Zhi Zhou[4], [1]Argonne National Laboratory, LEMONT, IL, [2]Argonne National Laboratory, Lemont, IL, [3]Argonne National Laboratory, Lemon, IL, [4]Argonne National Laboratory, Argonne, IL, Contact: kwonj@anl.gov

The modeling of strategic interactions between competing profit-seeking entities in the context of power system expansion planning has been investigated in the literature. Game-theory based equilibrium modeling approaches have been commonly employed for this purpose. However, due to computational complexities associated with these equilibrium models, many simulation models tend to make simplifications and assumptions. This presentation aims to explore the impact of different assumptions on the solutions derived from equilibrium models.

4 Computing Optimal Replacement Policies for Offshore Wind Farms via Approximate Dynamic Programming

Morteza Soltani[1], Amin Khademi[2], Jeffrey P. Kharoufeh[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC

We study the problem of replacing degrading turbines in an offshore wind farm affected by normal usage and random environmental factors. Considering the economic and stochastic dependence arising from shared setup costs and the common environment, our aim is to determine the optimal replacement policy that minimizes total discounted costs, including setup, replacement, and lost power production. To address the curse of dimensionality resulting from the increase in the number of turbines, we utilize Approximate Dynamic Programming (ADP) to approximate the value function. Bounds are also established to evaluate the accuracy of our approximation method.

5 Condition-Based Maintenance for Wind Farms Using a Distributionally Robust Chance Constrained Program

Heraldo Rozas, Weijun Xie, Nagi Gebraeel, Georgia Institute of Technology, Atlanta, GA, Contact: heraldo.rozas@gatech.edu

Existing Condition-based maintenance (CBM) strategies for wind farms rely on the assumption that prognostic algorithms can accurately predict wind turbines' remaining lifetime distribution (RLD), allowing for the implementation of stochastic programming or simulation-based optimization methods. However, this assumption might not hold in practice. This talk addresses this issue by presenting a new CBM strategy for wind farms that uses a Distributionally Robust Chance Constrained (DRCC) optimization model. This formulation acknowledges that estimated distributions may be incorrect and seeks robust solutions against distribution fluctuations. We show that the DRCC optimization problem can be reformulated as an integer linear program. The strategy is validated through computational studies using synthetic and real-world degradation data.

6 Solar And Storage Hybrid Operational Optimization Model For Energy And Ancillary Services Markets

Gaurav S. Mahamuni, Eina Ooka, The Energy Authority, Bellevue, WA, Contact: gmahamuni@teainc.org

Storage + renewable hybrid resources can now operate as a single generation and load resource in California Independent System Operator (CAISO) market. However, given the uncertainties around prices, renewable generation, and ancillary services (AS) dispatch, optimizing a hybrid resource's market offering to maximize revenue without curtailing energy or missing dispatch is challenging.
We present a mixed integer linear programming (MILP) model that has been operational to bid a 2.3 MW solar + 2.3 MW 4-hour storage hybrid resource in CAISO's day-ahead and real-time markets for energy and ancillary

services. We introduce constraints to capture dispatch uncertainty and solar curtailment due to AS. The model helps reduce curtailment and follows dispatch while simultaneously generating twice the revenue compared to the solar component alone.

Transitioning to Sustainable Systems

Contributed Session

Session Chair: Robin Mutschler, Swiss Federal Laboratories for Materials Science and Technology, Empa, Dübendorf, Switzerland

1 Optimizing Lignin Valorization in Biorefinery Systems with Biological Upgrading: Assessing Economic Viability and Uncertainty Analysis

Yajie Wu[1], Juan Manuel Restrepo Florez[2], Juliana Vasco-Correa[1], [1]The Pennsylvania State University, State College, PA, [2]University of Florida, Gainesville, FL, Contact: yzw301@psu.edu

We study the economic optimization of lignin valorization with biological upgrading in biorefinery system. Using a superstructure-based process optimization method, we identify the optimal pathway and assess the impact of parameters such as feedstock and production costs, bioproduct price, and process yield through uncertainty analysis. The deterministic case reveals the optimal process involves using herbaceous plants as feedstock, undergoing base catalyzed depolymerization, resulting a maximum net present value of $1,627.39 million and internal rate of return 25.20%. Uncertainty analysis via stochastic programming demonstrates that the optimal strategy depends significantly on economic scenarios. Our findings lay the groundwork for developing lignin valorization biorefineries, furthering climate change mitigation and circular economy efforts.

2 Assessing and Enabling the Feasibility of the European Energy Transition Under Myopic and Constrained Technology Deployment

Jacob Mannhardt[1], Paolo Gabrielli[2], Giovanni Sansavini[2], [1]ETH Zurich, Zurich, Switzerland; [2]ETH Zurich, Zurich, Switzerland

Current evidence casts doubt on the feasibility of performing an energy transition that complies with the 1.5°C climate goal. Yet, an abundant body of energy system optimization models (ESOMs) proposes guidelines to achieve the transition. However, ESOMs often simplify the capacity expansion process by assuming perfect foresight and instantaneous technology deployment, resulting in potentially unrealistic and ineffective transition recommendations. Focusing on Europe, we investigate two barriers to the optimal decision-making: i) myopic foresight, and ii) real-world constraints on technology deployment. We find that the combination of the two barriers might delay the energy transition and make Europe miss its climate targets. Based on these insights, we explore and propose measures to enable a successful transition.

3 Do Homeowners Care About Sustainability?

Milind Goel, London Business School, London, United Kingdom. Contact: mgoel@london.edu

We compile a comprehensive dataset containing 55% of all residential property transactions in the UK from 2010 to 2020, and provide large-scale evidence that homeowners derive both pecuniary and non-pecuniary benefits from the energy efficiency of their dwellings. Homeowners price energy efficiency based on the expected utility savings and on their ability to recoup their investments. The market uses a social discount rate (SDR) of 4.83% to value investments in sustainability. Homeowners who purchase greener dwellings pay a premium in excess of the present value of future energy savings. We observe a commensurate increase in proportion of energy upgrades across market segments impacted and not impacted by regulation, but absence of a price-impact. This suggests that government interventions facilitated sustainable development through an indirect channel.

4 Learning from Stress: Decision Making in Dynamic Events

Louise K. Comfort, University of California, Berkeley, Oakland, CA, Contact: comfort@gspia.pitt.edu

Dynamic conditions create unique tensions for decision processes. As conditions change, decision makers need to remain open to incoming information and update their understanding of the operational context in real time. Yet, mobilizing response to changing conditions requires sufficient control over information to maintain a coherent operational framework and logic of action. This tension between openness and control varies with intensity, severity of threat and capacity of decision makers to comprehend the rate of change and adapt their actions accordingly. Balancing openness with control goes beyond resilience to achieve a stronger antifragile state. Data drawn from CalFire 209 field reports of wildfire operations document the rate of change in key operational functions entered as parameters in a system dynamics model to explore learning from stress in practice.

5 The Energy Carbon Nexus of Sustainable Energy Systems

Robin Mutschler, Swiss Federal Laboratories for Materials Science and Technology, Dübendorf, Switzerland. Contact: robin.mutschler@empa.ch

To achieve carbon neutrality by 2050, Switzerland needs a comprehensive understanding of its energy system and the potential for using carbon as a recyclable commodity in Energy-X paths. Our study uses a MILP method to investigate the Energy-Carbon nexus and demonstrates the critical role of Energy-X in supplying sustainable fuels and achieving net-zero CO2 emissions. Leveraging OR/MS techniques and data-driven approaches, our work optimizes energy system design and provides a scientific basis for decision-makers. Integration of Energy-X results in cost-effective storage solutions during times of limited import capacities or high prices. Our insights are applicable to other national energy systems.

Session Chair: Giyoon Kwag, Clemson University, Clemson, SC

1 Verification and Validation: Building Trust in Digital Twins

Julia Bitencourt, Gregory Harris, Auburn University, Auburn, AL

Digital Twin (DT) involves the integration of Internet-of-Things (IoT), Machine Learning (ML), Artificial Intelligence (AI), cloud computing, and other innovative technologies to predict the outcomes of its physical counterpart, as well as to generate what-if scenarios and to support decision-making. Although the definition of DT varies among experts, DTs are models, and as with any model, a DT needs to be verified and validated in order to be trusted and used in real-world environments. Our research investigated the status of DT verification and validation (V&V). We found that very few studies reported V&V procedures and that there is disagreement over what verification and validation in the context of DTs represent. To address this gap, we developed a methodology and demonstrated it in a case study.

2 User-Generated Content Shapes Judicial Reasoning: Evidence from a Randomized Control Trial on Wikipedia

Neil Thompson[1], XUEYUN LUO[2], Brian McKenzie[3], Edana Richardson[4], Brian Flanagan[4], [1]MIT, Cambridge, MA, [2]Cornell University, Ithaca, NY, [3]Maynooth University, maynooth, Ireland; [4]Maynooth University, Maynooth, Ireland

While Wikipedia articles are easily accessible, they have unknown provenance and reliability and is problematic to be used in professional settings. Using an RCT, we find that the presence of a Wikipedia article about Irish Supreme Court decisions makes it more likely that the corresponding case will be cited in subsequent judgments. These effects are only present for citations by the High Court, not for the higher levels of the judiciary. Since the High Court faces higher caseloads, this may indicate that settings with greater time pressures encourage greater reliance on Wikipedia. Our results add to the growing recognition that Wikipedia and other frequently-accessed sources of user-generated content have profound effects on important social outcomes. Greater attention should therefore be paid to ensuring that they contain the highest quality of information.

3 What is Missing: A Meta-Analysis of User Participation Behavior in Online Communities

Giyoon Kwag[1], Russell L. Purvis[2], Jennifer E. Pullin[3], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, [3]Virginia Military Institute, Lexington, VA, Contact: gkwag@clemson.edu

Active user participation is essential for sustainable and successful online communities. However, research on the key drivers of user participation and their performance under different conditions remains inconsistent. To address this, we conducted a meta-analysis of over 200 empirical papers, classifying their antecedents into 20+ categories based on established theoretical frameworks of technology acceptance model and social capital theory. We analyze each category's relationship with user participation and multiple moderators that affect these relationships to address variations in online community research thoroughly. Practitioners can use our results to enhance user engagement and sustainability through informed design and management of online communities.

Stochastic Models on Cancer Treatment and Learning

Contributed Session

Session Chair: Clyde Fare, 1</sup

1 Using Birth-death Processes to Infer Tumor Subpopulation Structure from Live-cell Imaging Drug Screening Data

Chenyu Wu[1], Einar Bjarki Gunnarsson[2], Even Moa Myklebust[3], Alvaro Köhn-Luque[3], Arnoldo Frigessi[3], Kevin Leder[4], Jasmine Foo[5], [1]University of Minnesota - Industrial and Systems Engineering, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, [3]University of Oslo, Oslo, Norway; [4]University of Minnesota - Industrial and Systems Engineering, MINNEAPOLIS, MN, [5]University of Minnesota-Twin Cities, Minneapolis, MN, Contact: wu000766@umn.edu

Tumor heterogeneity is a complex trait that poses significant challenges in the development of effective cancer therapies. Accurately characterizing the subpopulation structure within a tumor is crucial. One possible strategy is to analyze the differential responses of subpopulations to various drugs using live-cell imaging high throughput drug screen techniques. However, such data exhibits dynamic variance and positive correlation in time, making analysis difficult.To address this challenge, we propose a stochastic model based on the linear birth-death process. Our newly developed model can provide more precise and robust estimations than the existing methods. We conclude our study by testing our model on both simulated data (in silico) and experimental data (in vitro), which supports our argument about its advantages.

2 Single Sample Estimation For Cancer Recurrence

Kevin Leder[1], Zicheng Wang[2], Xuanming Zhang[3], [1]University of Minnesota - Industrial and Systems Engineering, MINNEAPOLIS, MN, [2]University of Minnesota, Minneapolis, MN, [3]University of Minnesota - Industrial and Systems Engineering, Minneapolis, MN, Contact: zhan8093@umn.edu

In this work, we derive consistent estimators for key parameters that govern the evolution of a tumor cell population in response to therapy. The therapy decreases the population of sensitive cells, but eventually, a population of drug-resistant cells takes over, and the tumor burden increases again. We study this phenomenon using a collection of mathematical models of increasing complexity. Based on our theoretical results, we derive estimators for our model parameters based on a single observation of the tumor at the recurrence time.

3 Enhancing Breast Cancer Survival Prediction with a Graph Neural Network

Roya Aghaeifar[1,2], Mohammad Khasawneh[2], [1]Binghamton University, Binghamton, NY, [2]Binghamton University, Binghamton, NY, Contact: raghaei1@binghamton.edu

Cancer results from genetic mutations disrupting cell growth and can lead to the formation of tumors. Breast cancer is the most common cancer in women. Microarray technology enables scientists to measure the activity of thousands genes simultaneously, but analyzing the data can be challenging, especially when there is many genetic information but limited observation data. In this study, a novel Graph Neural Network is developed to predict the survival time of patients with breast cancer. The model incorporates the patient's age at diagnosis and whether they have a mutation in a gene associated with breast cancer. The proposed approach may provide insights into breast cancer survival prediction and could be useful in developing personalized treatment plans.

4 Driving Data Generation in Molecular Discovery Through Development of Benchmark Reinforcement Learning Environments

Clyde Fare[1], Lamogha Chiazor[1], Lan Hoang[2], [1]IBM, Daresbury, United Kingdom; [2]IBM, Warrington, United Kingdom. Contact: clyde.fare@ibm.com

Molecular and materials discovery is an area of great technological significance that continues to greatly benefit from the data revolution. Here we present a series of benchmark reinforcement learning environments that allow mixing and matching different design goals, different representations, and different molecular spaces with different reinforcement learning agents. These provide both a set of standards to evaluate different reinforcement learning algorithms applied to molecular design but also a standardised way of generating molecular datasets capturing the molecular design process.

Methodological Advancements in Multiobjective Optimization II

Community Committee Choice Session

Session Chair: Margaret M. Wiecek, Clemson University, Clemson, SC

1 Re-Visiting the Parametric Simplex Algorithm in the Context of Equitable Optimization

Özlem Karsu[1], **Firdevs Ulus[2], [1]Bilkent University - Industrial Engineering Department, Ankara, Turkey; [2]Bilkent University, Ankara, Turkey**

We consider equitable linear optimization problems (ELOP), which are multiobjective optimization problems, with each objective representing the benefit that one entity receives. In such problems, the concept of dominance is replaced by equitable dominance. The aim is finding the set of equitably nondominated points, which lie within a spectrum between the utilitarian and Rawlsian solutions. Between these two extremes, each solution corresponds to a different degree of inequity-aversion. We discuss a novel use of the parametric simplex algorithm to address ELOP. The algorithm not only provides the set of equitably nondominated solutions, but also informs the decision maker on the degree of inequity-aversion each solution corresponds to. This analysis would be of great value as it facilitates making informed decisions in various resource allocation settings.

2 Solving Bi-Objective Knapsack Problem Using Deep Reinforcement Learning

Hanieh Rastegar Moghaddam[1], Hadi Charkhgard[1], Ali Eshragh[2], [1]University of South Florida, Tampa, FL, [2]Johns Hopkins University, Baltimore, MD

This study introduces the first Deep Reinforcement Learning (DRL) approach to solve the Bi-Objective Knapsack Problem (BOKP). An exact Q-learning method is developed for smaller problems, while a deep reinforcement learning model is designed to handle larger instances. Challenging BOKPs beyond the solvability of exact solvers are generated to evaluate the DRL approach. Results demonstrate that the proposed DRL method outperforms state-of-the-art heuristics in solving these difficult problems. This research contributes to combinatorial optimization by offering a novel paradigm for solving the BOKP through DRL, showcasing the potential of DRL as a promising technique for addressing complex and computationally demanding BOKPs.

3 Solution Approaches to Two-Stage Robust Biobjective Linear Programs

Rakhi Goswami[1], Margaret M. Wiecek[2], Herve Louis-Marie Kerivin[3], [1]VIPR-GS, ICAR, Clemson, SC, Clemson, SC, [2]Clemson University, Clemson, SC, [3]University Clermont Auvergne, Aubiere, France. Contact: rgoswam@g.clemson.edu

Two-stage biobjective linear programs (TSBOLPs) model decision situations under uncertainty having conflicting objectives at every stage. The assumptions about discrete or continuous uncertainty, and the number of objectives in the second stage, and the application of weighted-sum scalarization lead to four parametric single objective optimization problems (SOPs) resulting from the robust counterpart to TSBOLP. These SOPs have bilinear terms composed of parameters and variables in different configurations. Solution approaches using MATLAB Multiparametric Toolbox, Benders' decomposition and the Biconvex Approximation Simplex Method are proposed and illustrated with numerical examples.

4 Computing Set-Based Regret in Online Multiobjective Optimization

Kristen Savary, Margaret M. Wiecek, Clemson University, Clemson, SC, Contact: ksavary@g.clemson.edu

In online multiobjective optimization (OMO), solutions are computed before the objective functions are revealed and set-based regret measures the cost of not achieving the Pareto solutions of the associated offline multiobjective problem. To compute this regret, auxiliary single-objective optimization problems (SOPs) are solved in OMO settings. The SOPs involve minimization of a performance indicator such as the generational distance or hypervolume. It is shown that the computed set-based regret achieves similar upper bounds to those obtained in online single-objective optimization. Numerical examples are included.

Community-engaged OR and Diversity, Equity, and Inclusion in OR/analytics.

Community Committee Choice Session

Session Chair: Michael P. P. Johnson, University of Massachusetts Boston, Boston, MA

Session Chair: Christopher W. Zobel, Virginia Tech, Blacksburg, VA

Session Chair: Mahyar Eftekhar, 1</sup

1 Home-Matching Preferences Among Disadvantaged Residents: A Value-Focused Thinking Approach

Mubarak Idrissu, University of Massachusetts Boston, Boston, MA, Contact: mubarak.iddrisu001@umb.edu

The housing crisis in urban areas arises from a shortage of affordable housing, unaffordable housing stock and underutilized housing units. While government policies have failed to address the challenges faced by low-income renters, home-matching programs have emerged as potential solutions. Using a community-engaged operations research approach, we study the housing challenges faced by marginalized groups such as the elderly, disabled, and low-income earners. By applying value-focused thinking and collaborating with Front Porch, a community-based organization, we construct objective hierarchies for home-matching the elderly and disabled with other low-income renters. Our findings will contribute to the literature by learning the complexities of the housing crisis and recommend effective strategies for promoting policies aimed at sustainable solutions.

2 Diversity, Equity, and Inclusion in Operations Research and Analytics Fields: National Survey of Program Directors

Elham Hesari[1], Michael Johnson[1], Tayo Fabusuyi[2], [1]University of Massachusetts Boston, Boston, MA, [2]University of Michigan, Ann Arbor, MI

Despite the fact that the US population is becoming more diverse, women and minorities remain underrepresented in OR/Analytics fields. As a result, many different disciplines have shifted their program emphasis to include strategies that help them represent society more accurately. This study project's main goal is to better comprehend DEI among OR/ Analytics university programs at undergrad and graduate academic levels. The study's participants were the program directors of academic OR/Analytic programs in the US. 376 program directors were surveyed by Qualtrics with 49 institutionally reviewed and validated items. Analyses were conducted using quantitative and descriptive statistics. The results reveals that, despite some improvement, women and minority students and faculties representation continue to be underrepresented in OR/Analytics programs.

3 How Does OR/Analytics Scholarship Engage with Diversity, Equity and Inclusion? An Analysis of Published Journal Articles

Michael P. P. Johnson[1], Tayo Fabusuyi[2], Elham Hesari[1], Samanthi Dijkstra-Silva[3], Sebastian Oelrich[4], [1]University of Massachusetts Boston, Boston, MA, [2]University of Michigan, Ann Arbor, MI, [3]TU Dresden, Dresden, Germany; [4]TU Dresden, Dresden, Germany. Contact: michael.johnson@umb.edu

We seek to better understand how operations research and operations management scholars engage with concepts of diversity, equity and inclusion in their research. We evaluate peer-reviewed articles in four different volumes to understand how authors exploit opportunities to address DEI across a range of application areas and analytic methods - even if a paper's topic does not specifically address DEI. We also perform a systematic review of articles whose titles or abstracts contain evidence of DEI-related content to understand the types of diversity dimensions that appear in these works. Through a critical approach and a focus on intersectionality, we identify unmet opportunities to incorporate DEI�related themes into research where such perspectives can amplify the theoretical, empirical and application�oriented impact of this work.

4 We'Re Here: Lgbtq+ Stories of Identity, Mentorship, and Community from Informs Members

Tyler Perini[1,2], [1]US Naval Academy, Anapolis, MD, [2]Rice University, Houston, TX, Contact: tyler.perini@rice.edu

This presentation shares samples from an interview study initiated as a 2021 INFORMS DEI Ambassador project. The experiences of 11 LGBTQ+ INFORMS members, whose identities are protected using pseudonyms, are summarized. Unmet needs of these community members are identified, including: (i) an absence of mentorship from senior LGBTQ+ professionals, (ii) broader inclusion of gender identities and ("professional") gender presentations, and (iii) representation or guidance for starting a family as an LGBTQ+ academic. The participants display a variety of preferences for coming out in professional relationships, i.e., with respect to advisors, students, and colleagues. Some advice is shared on strategies for the academic job market, finding a "fulfilling" LGBTQ+ community, and how to become a (better) ally.

5 Racial and Ethnic Health Disparities in Patient Experience of Care Between Children Enrolled in Medicaid Managed Care Organizations

Sara Abu-Aridah[1], Paul Griffin[1], Areen Alsaid[2], [1]The Pennsylvania State University, University Park, PA, [2]University of Michigan, Dearborn, MI

Medicaid children enrollees who are members of racial and ethnic minority groups have historically reported worse healthcare experiences. Consumer assessments of healthcare are used as an indicator of the care quality provided by health plans and providers. Health disparities among adults and the elderly received significant attention in the literature within the last two decades, while disparities in younger populations remain understudied. To understand the reasons behind disparities in Medicaid plans for children; using The Consumer Assessment of Healthcare Providers and Systems (CAHPS®) health plan survey, this study examines parents' responses to the experience-of-care assessments to investigate the current situation of racial and ethnic disparities within children's healthcare plans in the United States.

Operations and Resource Management in Nonprofit Organizations

Community Committee Choice Session

Session Chair: Milan Preet Kaur, RPI

1 A Dynamic Model for Managing Volunteer Engagement

Mustafa Hayri Tongarlak[1], Deishin Lee[2], Baris Ata[3], Joy Field[4], [1]Ivey Business School - Western University, London, ON, Canada; [2]Ivey Business School, London, ON, Canada; [3]University of Chicago, Chicago, IL, [4]Boston College, Boston, MA, Contact: mtongarlak@ivey.ca

Non-profit organizations that provide food, shelter, and other services to people in need, rely on volunteers to deliver their services. Unlike paid labor, non-profit organizations have less control over unpaid volunteers' schedules, efforts, and reliability. However, these organizations can invest in volunteer engagement activities to ensure a steady and adequate supply of volunteer labor. We study a key operational question of how a non-profit organization can manage its volunteer workforce capacity to ensure consistent provision of services. In particular, we formulate a multiclass queueing network model to characterize the optimal engagement activities for the non-profit organization to minimize the costs of enhancing volunteer engagement, while maximizing productive work done by volunteers.

2 A Recommender System for Crowdsourcing Food Rescue Platforms

Ryan Shi, Fei Fang, Carnegie Mellon University, Pittsburgh, PA, Contact: ryanshi@cmu.edu

Food rescue organizations match food donations to the non-profits that serve low-resource communities. However, they rely on external volunteers to pick up and deliver the food, which bring significant uncertainty. Working with 412 Food Rescue, we develop a recommender system to send push notifications to the most likely volunteers for each given rescue. We leverage a mathematical programming based approach to diversify our recommendations, and propose an online algorithm to dynamically select the volunteers to notify without the knowledge of future rescues. Our recommendation system improves the hit ratio from 44% achieved by the previous method to 73% on historical data. We designed and ran a randomized trial for the recommender system. The trial showed that the algorithm significantly improved the claim rate and hit rate.

3 How Should Volunteers be Dispatched to Out-Of-Hospital Medical Emergencies?

Pieter van den Berg[1], Shane Henderson[2], Caroline Jagtenberg[3], Hemeng Li[2], [1]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [2]Cornell University, Ithaca, NY, [3]Vrije Universiteit Amsterdam, Amsterdam, Netherlands. Contact: hl2359@cornell.edu

When out-of-hospital medical emergencies occur, in addition to the traditional ambulance response, smartphone-enabled volunteer schemes can help alert volunteers near patients through an app on their phone. While alerting all volunteers increases patient survival probability, it could also lead to volunteers receiving too many alerts and reduce their acceptance probabilities in the future. Hence, the problem is to choose which volunteers should receive an alert and when to maximize the survival probability while considering volunteer fatigue. In this talk, we present a model of this problem through dynamic programming and discuss important characteristics of an optimal dispatch policy.

4 Creation of Personalized Task Recommendation Menus to Form and Assign Volunteer Groups

Milan Preet Kaur, Jennifer A. Pazour, Rensselaer Polytechnic Institute, Troy, NY, Contact: milankaur22@gmail.com

We introduce an integer programming-based framework for nonprofit organizations to form groups of volunteers and assign them to nonprofit tasks. Creating volunteer groups requires balancing the nonprofit's need to successfully complete tasks, with the volunteers' motivations to get the opportunity for successful engagement, skill learning, and skill utilization during their experience. Further, nonprofits make group formation decisions in the face of uncertain volunteer preference information. To address these challenges, our framework creates personalized recommendation menus to be presented to volunteers to select tasks they are available and willing to work on, and then feeds this willingness information into a group formation optimization model to form ideal groups. Performance is tested based on an online volunteer crowdsourcing platform case study.

Tuesday, October 17, 2:15 PM - 3:30 PM

Methodology and Applications in Scheduling

Community Committee Choice Session

Session Chair: Wenhui Zhao, China

1 Present Bias in Scheduling Decisions

Zhixin Liu[1], Nicholas Hall[2], [1]University of Michigan-Dearborn, Dearborn, MI, [2]Ohio State University, Columbus, OH, Contact: zhixin@umich.edu

This talk discusses the effect of present bias in a simple scheduling system that requires decisions about project timing and sequencing. We design algorithms that enable optimization of value less cost under present bias for both naive and sophisticated (i.e., self-aware) decision-makers. We describe managerial insights about the relative performance of time-consistent, naive, and sophisticated decision-makers and how to mitigate the effects of present bias.

2 Outpatients Appointment Scheduling with Patient Preferences on Time-Windows and Walk-In Patients

Shenghai Zhou[1], Guohua Wan[2], [1]Central South University, Changsha, China; [2]Shanghai Jiao Tong University, Shanghai, China. Contact: ghwan@sjtu.edu.cn

We consider an appointment scheduling problem with both walk-in patients and scheduled patients. Each scheduled patient has preference on the service time windows captured by MNL Model. The objective is to make appointments for scheduled patients, in anticipation of walk-in patients, so as maximize the total reward from the services less the total waiting costs. We consider both preemptive and nonpreemptive cases. For the preemptive case, we study the structural properties of the optimal policy and formulate the problem as a second order cone program. For the nonpreemptive case, we model the problem as a dynamic program with knapsack-type of constraints. The computational experiments, together with sensitivity analyses, show that the models and algorithms may significantly improve the schedules generated by two typical scheduling policies widely used in practices.

3 A Decomposition Method for the Group-Based Quay Crane Scheduling Problem

Defeng Sun[1], Lixin Tang[2], Roberto Baldacci[3,4], Zihan Chen[5], [1]Northeastern University, China, Shenyang, China; [2]Northeastern University, Shenyang, China; [3]University of Bologna, Cesena, Italy; [4]Hamad Bin Khalifa University, Doha, Qatar; [5]Huawei Cloud Computing Technologies Co., Ltd, Beijing, China. Contact: sundefeng@ise.neu.edu.cn

This study considers the Quay Crane Scheduling Problem (QCSP), wherein a fixed number of quay cranes must be scheduled to load and unload containers into and from a ship to minimize the completion time subject to precedence, safety margin and non-crossing constraints. For solving the QCSP, we consider alternative schedule directions for the quay cranes, namely, unidirectional, bidirectional, and multi-directional, and we describe a new compact mathematical formulation for the bidirectional QCSP. To compute valid lower bounds on the optimal completion time, we derive different relaxations of the new formulation under the different schedule directions. The new formulation is used in an exact solution framework based on the logic-based Benders decomposition, where the problem is decomposed into an assignment master problem and operation-sequence slave sub-problems.

Social Commerce and Platforms

Community Committee Choice Session

Session Chair: Kejia Hu, Vanderbilt University

Session Chair: Jiding Zhang, New York University Shanghai, Shanghai, China

1 Deal Now or Later? Transaction Mechanisms for Home Sales

Chenhao Zhang[1], Yixin Lu[2], Luyi Gui[3], [1]Northwestern University, Evanston, IL, [2]George Washington University, Washington, [3]The Paul Merage School of Business, UC Irvine, Irvine, CA

Instant buyers (iBuyers) are online platforms that leverage technology to make instant cash offers to homeowners in real estate transactions. iBuyers' profitability hinges on their ability to effectively manage the risks of instant home transactions.To strike timely deals, iBuyers typically skip inspections and rely on seller-reported home attributes, which makes it difficult for them to obtain accurate information about the quality of a property. In this paper, we adopt a signaling game framework to examine the tradeoff between the iBuyer's appeal to home sellers and its susceptibility to adverse selection. We propose a hybrid mechanism combining an instant, guaranteed upfront payment and an ex-post payment contingent on the resale price. We show that adopting such a mechanism can improve the platform's profit when the platform has limited market power.

2 Information-Enhanced Position Auction

shaoyu wang[1], Pin Gao[2], Yang Li[3], Ying-Ju Chen[4], [1]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]The Chinese University of Hong Kong, Shen Zhen, Shenzhen, China; [3]Ivey Business School, Western University, London, ON, Canada; [4]The Hong Kong University of Science and Technology, Kowloon, Hong Kong

Live-streaming and video advertising commerce have gained popularity as effective means of showcasing products. Both Amazon and Alibaba have successfully implemented this marketing strategy to attract consumers. In this paper, we examine a live-streaming platform's revenue-maximizing problem in which sellers with private information bid for a limited number of Ad spots. Unlike traditional position auction literature that aims solely to maximize platform revenue from Ad spot allocation, we allow the platform to customize information provision at each Ad spot. The analysis highlights the crucial role of information provision in enhancing the matching efficiency between products and heterogeneous consumers. Furthermore, we establish that information provision can deter competition among sellers, thereby reaping the payoffs of both the platform and sellers.

3 Does Kol Matter in Live Ecommerce: An Empirical Study on Tiktok

Kai Tian[1], Rui Jie Zhang[2], Yun Fong Lim[2], Ke Jia Hu[3], [1]Singapore Management University, Singapore, Singapore; [2]Singapore Management University, Singapore, Singapore; [3]Vanderbilt University, Nashville, TN, Contact: kai.tian.2020@pbs.smu.edu.sg

We utilized PSM (Propensity Score Matching) and auto-regressive linear models to investigate the impact of targeting audiences of KOL (Key Opinion Leaders) followers on advertising outcomes. Based on marketing theories and PSM criteria, we gradually incorporated matching variables into the PSM and identified four categories of marketing outcomes that reflect customers' willingness to buy the advertised products, in increasing order of customer valuation and willingness-to-buy: traffic, purchase intention, engagement, and loyalty. Our results indicate that targeting audiences of KOL followers enhances traffic volume, but has no effect on other types of marketing outcomes. Therefore, our findings suggest that practitioners can benefit from targeting audiences of KOL followers when their advertising objective is to increase traffic.

4 The Role of Within-day Learning on Gig Workers' Performance and Task Allocation: Evidence from an On-Demand Platform

Reeju Guha, Daniel S. Corsten, IE Business School, Madrid, Spain. Contact: reejuguha@student.ie.edu

Most platforms allocate tasks without considering gig worker behaviors. Experience-based allocations are not useful when workers are new. We investigate whether same-day learning (SDL) impacts worker performance and be utilized for ranking. Using data from an on-demand platform, we analyze worker performance based on SDL while accounting for sample selection & endogeneity. Our findings reveal that as SDL increases performance improves. Furthermore, when workers batch orders, SDL reduces delays, but also reduces substitutions. Similarly, for complex tasks, a moderate level of SDL is most beneficial. We rank workers based on prior & same-day experience and develop an algorithm to allocate tasks based on rank & complexity. We predict improvements in performance & demonstrate that allocating higher-ranked workers to complex tasks leads to performance improvements.

Session Chair: Zlatana Dobrilova Nenova, University of Denver, Denver, CO

1 Enhancing Energy Forecasts in Public Transit Using Advanced Machine Learning Techniques and High-Level Planning Metrics

Zhuo Han, Eleni Christofa, Eric Gonzales, Jimi Oke, University of Massachusetts Amherst, Amherst, MA, Contact: zhuohan@umass.edu

This research represents a groundbreaking approach to forecasting energy usage in public transit systems, specifically the Massachusetts Bay Transportation Authority (MBTA) urban rail network in Boston. Building on previous work that achieved a 3.95% test error in energy estimation, this study utilizes high-level planning metrics to model low-level variables, contributing significantly to energy efficiency. We then estimated vector autoregressive models and long-short term memory networks to develop a robust energy forecasting model. This study offers a generative model trained to map high-level metrics to movement variables, proving its effectiveness in driving energy efficiency.

2 Multiobjective Algorithm for the Political Redistricting Problem

Blake Splitter[1], Matthew J. Saltzman[2], [1]Clemson University, Clemson, SC, [2]Clemson University, Clemson, SC, Contact: bsplitt@clemson.edu

This presentation continues on previous work by the authors towards creating a multicriteria model for solving the political districting problem in South Carolina. We consider four key objectives: population equality, county divisions, district compactness, and political fairness. By utilizing a non-dominated sorting genetic algorithm (NSGA-II), we can find a set of high-quality solutions approximating a Pareto Front for the state of South Carolina.

3 Analytically Focused Business Intelligence Solution for Bus Operation Safety Improvement

Xiaotong Ding[1], John Maleyeff[2], [1]MBTA, Boston, MA, [2]Boston University, Boston, MA, Contact: XDing@mbta.com

A business intelligent system was designed for users to customize analyses concerning bus operation safety at the MBTA in Boston. It integrates data sources to form a data eco-system. Its application includes: KPI management, targeted actions used to flag issues and alert operation personnel, and issue investigation designed for routine or ad-hoc analyses. Various analytical methods were used to rank feature relevancy and importance. The presentation will demonstrate the system and discuss the development and implementation challenges.

4 Tolerance of Ambiguity Among People with Different Political Affiliations

Zlatana Dobrilova Nenova[1], Dennis F. Galletta[2], Valerie Bartelt[3], [1]University of Denver, Denver, CO, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of Denver, Highlands Ranch, CO, Contact: zlatana.nenova@du.edu

We surveyed individuals on Mechanical Turk and Prolific. We collected data from 2,180 individuals, and disqualified all but 1,244 of the participants because 936 did not pass various attention checks. We examined participants' tolerance of ambiguity (TA). Additionally, we collected data on their willingness to read news articles on two different in terms of polarization topics originating from left-leaning, independent and right-leaning news sources. Through our analysis we identified that liberals and independents had significantly higher TA and propensity to select articles with balanced and diverse political affiliations than conservatives. This analysis provides some preliminary evidence that one innate trait, TA, leads consumers of news to avoid seeing arguments counter to their opinions, thus preventing more balanced reading choices.

Blockchain and New Technologies

Community Committee Choice Session

Session Chair: Jingxing (Rowena) Gan, Cox School of Business, Southern Methodist University, Dallas, TX

1 Exploring Multihoming Behavior of dApps and Their Users Across Layer 2 Blockchains

Daniel Obermeier, NYU Stern School of Business, New York, NY

With the proliferation of Ethereum as a leading blockchain platform for dApp development, the network's scalability and congestion issues have prompted developers and users to explore alternative solutions. One solution is to evade congestion on Ethereum by moving to more scalable and less congested Layer 2Blockchain platforms. This study analyzes the migration patterns of dApps across multiple platforms and investigates how network effects and congestion drive multihoming decisions. Based on a sample of 3450 dApps and their users, we find that most dApps stay on Ethereum even in periods of severe congestion, but multihoming increases with an increase of the installed based on layer 2platforms. Interestingly, users of multihoming dApps use layer 2 platforms only temporarily to evade high gas fees.

2 The Economics of Federated Learning in Online Advertising

Luoying Chen, Jianqing Chen, Amit Mehra, The University of Texas at Dallas, Richardson, TX, Contact: luoying.chen@utdallas.edu

Federated learning (FL) techniques allow firms to train machine learning models without collecting user data. Instead of transferring raw data to a central server, models are trained collaboratively on users' devices and only model updates are shared to the server, ensuring sensitive user information being protected. Due to the growing restrictions pertaining to privacy protection that diminishes ads targeting, FL has garnered amplified recognition in the realm of online advertising. In this paper, we study the economic implications when a platform adopts FL in online advertising and examine the platform's strategy in setting up monetary rewards to attract users' enrollment in FL.

3 Contract Tokenization in the Renewable Energy Market

Rowena J. Gan[1], Rong Li[2], [1]Cox School of Business, Southern Methodist University, Dallas, TX, [2]Syracuse University, Syracuse, NY, Contact: jingxingg@smu.edu
Endorsed by the blockchain technology, contracts can be digitally recorded and stored in crypto tokens, which is referred to as being tokenized. Using the renewable energy market as a backdrop, we study the impact of contract tokenization on different parties in the industry based on their respective incentives.

Knowledge Graph and Graph Analytics Applications

Community Committee Choice Session

Session Chair: Lili Zhang, Hewlett Packard Enterprise

1 A Random Graph Algorithm for Modeling Social Networks

Ryan A. Parker, Kennesaw State University, Kennesaw, GA
A common goal in network analysis is the modeling of social network graphs, which tend to exhibit low average path length, high clustering, and a power law degree distribution. However, most existing attempts to do so fall short on one or more of these properties. Here, a novel approach is utilized, which uses an older algorithm over many iterations to generate the bulk of the nodes, as well as a modified version the highly connected 'influencer' nodes. Several expectations of the model were derived and compared to values calculated from scaled-down simulations. The model, when tuned correctly, reasonably mimics the properties displayed by social network graphs. This algorithm not only provides a quick-performing method to model social network graphs, but also a possible alternative for modeling other types of graphs, given proper appropriate hyperparameter tuning.

2 AI Biases in Graph Neural Networks

Henry Han, Baylor University, Waco, TX
GNN have revolutionized the field of graph representation learning by enabling effective modeling and analysis of complex relational data. They have been successfully applied in various AI and data science domains. However, they may introduce potential biases, particularly when dealing with imbalanced data. This study aims to investigate different mechanisms behind AI bias generation in graph neural networks and explore their impacts on credit risk prediction applications. By examining the biases inherent in GNN and their variants, we develop effective strategies to mitigate bias and improve the fairness and accuracy of credit risk prediction models. We have found that those AI biases generated under those imbalanced learning-hard problems may demonstrate different characteristics than other datasets in credit risk applications.

3 A B2B Persona Knowledge Graph Framework

Lili Zhang[1], Zainab Jamal[2], Swarup Chandra[1], [1]Hewlett Packard Enterprise, San Jose, CA, [2]HPE, Saratoga, CA
Identification of core buyer personas in B2B is critical for marketing and sales to streamline the efforts of influencing a purchase decision making process. In B2B, a persona represents the customers' job function and job seniority. In this work, we showcase how we have built a knowledge graph to classify the millions of job titles and identify core buyer personas. The outcome has been strategically improving the contact data quality and creating more relevant audience for marketing campaigns.

DEI Research: How Can Your Research Promote DEI in Public Policy and Health?

Community Committee Choice Session

Session Chair: Bing Si, State University of New York at Binghamton, Binghamton, NY

Session Chair: Ying Lin, University of Houston, Houston, TX

1 Optimal Design of Diabetic Retinopathy Telescreening Program for Patients at Risk

Taewoo Lee, University of Pittsburgh, Pittsburgh, PA
Diabetic retinopathy (DR) is the leading cause of blindness among working-age Americans. Teleretinal imaging (TRI) has emerged as an affordable tool that has the potential to increase screening rates among patients with limited access to care. However, little is known how TRI-based screening should be recommended in conjunction with traditional screening exams for patients with different levels of financial or geographic access to care. We develop a POMDP model that determines personalized screening policies that take into account patient-specific characteristics.

2 Optimal Vaccine Promotion Campaigns Considering Disease Transmission and Opinion Propagation with Fairness

Serin Lee, Shan Liu, Zelda B. Zabinsky, University of Washington, Seattle, WA, Contact: serinlee@uw.edu

Efforts are underway to promote vaccination and increase vaccine willingness, which can alleviate disease burden. Our study identifies near-optimal solutions for vaccine promotion campaigns across different age and geographic groups with the goal of of minimizing disease burden. We take fairness into consideration and ensure equitable budget allocation. The model is a coupled dynamics on disease transmission and opinion propagation within a networked compartmental model. We use representative calibration parameters for disease and opinion parameters to address model uncertainties that is calibrated to the COVID-19 pandemic data in Clark County, WA between January and February 2023. We use an optimization algorithm to determine a range of optimal solutions and explore different scenarios such as changes in vaccine effectiveness or transmissibility.

3 Addressing Disparities in College Mental Health: A Quantitative Framework for Improved Access and Personalized Care

Sohom Chatterjee, Youssef Hebaish, Hrayer Aprahamian, Lewis Ntaimo, Texas A&M University, College Station, TX

We consider the timely issue of rising mental health problems among college students. Studies highlight the alarming disparity in unmet mental health needs among minority students, as they have unique requirements that are not always adequately addressed by conventional treatments. Moreover, resource limitations hinder access to critical services, exacerbating the situation. In this project, we consider a quantitative framework to optimize the operations of college counseling centers, addressing disparities in access to care among diverse groups. Additionally, we seek to enhance service quality by analyzing student outcome data to construct more effective personalized treatments based on students' specific needs. A case study on Texas A&M's counseling center reveals the substantial benefits of the approach in improving both service quality and availability.

4 Fairness Constrained Adaptive Boosting Algorithm

Ying Lin, Muyun Lu, University of Houston, Houston, TX, Contact: ylin58@uh.edu

Adaptive boosting (AdaBoost) is an efficient and simple ensemble learning algorithm widely used in many prediction tasks. However, the training of AdaBoost only focuses on reducing the average loss of whole population, which can result in potential discrimination of different groups of samples if the training data is biased or imbalanced. Although there are a few fairness-aware AdaBoost models, none of them can guarantee the convergence of the algorithms. To mitigate this gap, this project proposes a new fairness-constrained objective function for AdaBoost and designs a novel mechanism to estimate the parameters, so that the fairness-constrained objective function is minimized. The proposed algorithm is applied to a cardiovascular disease prediction problem and its effectiveness is demonstrated.

Recent Methodological Advances for Large-Scale Learning and Inference

Community Committee Choice Session

Session Chair: Trambak Banerjee, University of Kansas, Lawrence, KS

1 Decision-Aware Denoising for Linear Optimization

Michael Huang[1], Vishal Gupta[2], Paat Rusmevichientong[3], [1]University of Southern California, Seattle, WA, [2]University of Southern California, Los Angeles, CA, [3]USC Marshall School of Business, Los Angeles, CA

Many modern problems in urban planning, climate change, and healthcare leverage large-scale geospatial data to make decisions. In most settings, such data is noisy and challenging to analyze with out-of-the-box machine learning methods, resulting in low quality decisions. We propose a decision-aware denoising approach that integrates information about underlying decision problem into the training of out-of-the-box machine learning methods. We prove our approach can learn the best-in-class decision-making policies for a large-class of linear optimization problems and highlight its effectiveness in a case-study about placing speed humps to reduce fatalities in NYC.

2 The Doctor Knows Best: Model-Agnostic Physician-In-The-Loop Explainability via Counterfactually-Guided Deep Reinforcement Learning

Michael Lash, University of Kansas, Lawrence, KS, Contact: michael.lash@ku.edu

In recent years machine learning models have been increasingly integrated into high-stakes decision-making domains, such as healthcare. Yet, physicians and other healthcare professionals are reluctant to rely on and trust such models since they do not understand their inner workings. Machine learning explainability (MLX) promises to bridge this gap by showing *why* a prediction was made. Yet, many past MLX methods do not consider healthcare practitioners' domain knowledge and may thus produce counter-intuitive explanations. In this work, we propose a novel physician-in-the-loop machine learning explainability method that explicitly considers a physician's preferences when producing explanations. We embed these preferences in a novel counterfactually-guided off-policy reinforcement learning scheme to synthesize a physician-specific prediction explainer.

3 Unrestricted Hypothesis Testing

Bradley Rava, University of Sydney Business School, Sydney, Australia. Contact: bradley.rava@sydney.edu.au

We present a novel multiple hypothesis testing approach that improves upon existing state-of-the-art benchmarks by directly utilising p-values to preform calibration in order to control the local FDR. Our methodology has broad applications across multiple fields and works in a variety of settings. In this presentation, we will discuss the key insights and findings of our research.

4 Optimal Nonparametric Inference with Two-Scale Distributional Nearest Neighbors

Emre Demirkaya, University of Tennessee, Knoxville, TN

The weighted nearest neighbors estimator has been popularly used as a flexible and easy-to-implement nonparametric tool for mean regression estimation. The bagging technique automatically chooses weights to form the distributional nearest neighbors (DNN) estimator. We provide an in-depth technical analysis of the DNN, based on which we suggest a bias reduction for the DNN estimator by combining two DNN estimators, resulting in the novel two-scale DNN estimator. We prove that the two-scale DNN estimator enjoys the optimal nonparametric rate of convergence and asymptotic normality. For the practical implementation, we provide variance estimators and a distribution estimator using the jackknife and bootstrap techniques. These estimators can be exploited for constructing valid confidence intervals for nonparametric inference of the regression function.

Data Mining for Power System Resilience and Reliability

Community Committee Choice Session

Session Chair: Feng Qiu, [1</sup]

1 Monitoring and Novelty Detection in Energy Assets, Applications in Battery and Solar Inverters

Mohammad Badfar, Murat Yildirim, Ratna Babu Chinnam, Wayne State University, Detroit, MI, Contact: hi8578@wayne.edu

Shrinking product development cycles and increasing complexity of assets necessitates a new generation of monitoring and diagnostic algorithms that can demonstrate more autonomy and adaptivity. In many real-world applications, available data doesn't conform to the strict assumptions of conventional approaches. We present the results for a novelty detection-based autonomous monitoring framework that flags anomalies under real-world data. Results from applying the proposed framework to 12-volt battery systems and solar inverters are promising.

2 Spatio-Temporal Wildfire Prediction Using Multi-Modal Data

Chen Xu, [1</sup]

Wildfire prediction using multi-modal sensing data is essential to a more informed understanding of wildfire activities. In this paper, we develop a flexible spatio-temporal wildfire prediction framework using multi-modal time series data. We first predict the wildfire risk (the chance of a wildfire event) in real-time, considering the historical events using discrete mutually exciting point process models. Then we further develop a wildfire magnitude prediction set method based on the time-series conformal prediction (CP) approach. Theoretically, we prove a risk model parameter recovery guarantee, as well as coverage and set size guarantees for the \rev{CP} sets. Through extensive real-data experiments with wildfire data in California, we demonstrate the effectiveness of our methods, as well as their flexibility and scalability in large regions.

3 Diagnosis and Prognosis of Multivariate Battery State of Health

Susan Babinec, Noah Paulson, Argonne National Lab, Lemont, IL, Contact: sbabinec@anl.gov

Batteries are a cornerstone technology for deep decarbonization and the fight of climate change. Li-ion dominates all markets due to its excellent performance and cost but remains challenged due its complex degradation behaviors. *In this presentation we described state-of-the-art capabilities to predict advanced Li-ion state of health characteristics for thousands of cycles over years of use after several days' characterization.*

Digital Economy and Emerging Technologies

Community Committee Choice Session

Session Chair: Leting Zhang, University of Delaware, Bear, DE

1 AI Opponents in Online Gaming: Evidence from a Quasi-Field Experiment

Qinglai He[1], Haoyu Yuan[2], Lingli Wang[3], Jiayin Zhang[2], Nina Huang[4], Qiang Wei[2], [1]University of Wisconsin - Madison, Madison, WI, [2]Tsinghua University, Beijing, China; [3]Beijing University of Posts and Telecommunications, Beijing, China; [4]University of Miami, Miami, FL

There is a growing trend in the online gaming industry of introducing AI agents as virtual opponents (AI opponents) to create better gaming experiences and boost player engagement. Leveraging a large-scale quasi-field experiment in a multiplayer online racing game, we employ difference-in-differences (DID) analyses and find that the adoption of AI-powered virtual opponents can result in reduced player engagement and lower performance. Remarkably, the mechanism exploration further reveals that introducing AI opponents increases competition intensity and immersion in the game. These two factors exhibit opposing influences on players' subsequent behavior. A more competitive game hinders players' further engagement, whereas a more immersive experience encourages more gaming participation and better performance.

2 Peer Data Breaches and Cyber Risk Disclosure Quality: Evidence from U.S. Public Firms

Leting Zhang[1], Taha Havakhor[2], Sunil Wattal[3], [1]University of Delaware, Newark, DE, [2]McGill University, Montreal, QC, Canada; [3]Temple University, Philadelphia, PA

Public firms' cyber risk disclosure (CRD) is valuable in reducing information asymmetry in the financial market. However, there is limited understanding of whether and how data breach incidents affect a bystander firm's cyber risk disclosure (CRD) quality. To explore the question, we leverage textual data on more than 3,000 US public firms' CRD from 2011 to 2017 and perform empirical analyses. We find that bystander firms strategically lower their CRD quality after a firm's breach. The result is robust to instrumental variable analysis, different model specifications, and alternative measurements. We further show that the quality of CRD decreases at a larger magnitude if public attention to data breaches is higher, or a firm spends more on advertising, or is more vulnerable to cyber risks. Lastly, peer breaches lower the positive association between CRD quality and a firm's market returns but exert no significant impact on the association between CRD quality and a firm's breach likelihood. We discuss the implications for research and practice.

Financial Technologies

Community Committee Choice Session

Session Chair: Rich Zhu, Georgia Institute of Technology

1 Beyond the Financial Value of Crowdfunding: Evidence from an Interpretable Machine Learning Approach

Jiayu Yao[1], Mingfeng Lin[1], Xuan Wei[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]University of Arizona, Tucson, AZ

The paper studies the nonfinancial value of crowdfunding for entrepreneurs' success in mass markets. While previous literature has primarily focused on the financial impacts of crowdfunding, our study examines the value of crowdfunding in validating innovative ideas and accessing early feedback. Using data from a US reward-based crowdfunding platform, we build explanatory machine learning models to predict entrepreneurs' market performance. Our study highlights the critical role of early market feedback.

2 The Effect of Merger and Acquisition Rumors on Investor Behaviors

Ruiqi Rich Zhu[1], Hailiang Chen[2], Yinghua Li[3], Yu Jeffrey Hu[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]The

University of Hong Kong, Hong Kong, Hong Kong; [3]Arizona State University, Tempe, AZ, [4]Georgia Institute of Technologuy, Atlanta, GA

Investors increasingly rely on social media platforms as crucial sources of information for making investment decisions. While these platforms offer a wealth of insights, it is essential to acknowledge the prevalence of misinformation, such as merger and acquisition (M&A) rumors, can lead to irrational choices. While M&A information is valuable in predicting future stock movements, M&A rumors circulating on social media may not always be reliable, potentially resulting in poor investment decisions. To investigate this phenomenon, we collect M&A rumors from both Seeking Alpha, a prominent social media website, and traditional news media. We compare the accuracy of these rumors against realized events, explore whether investors tend to follow these rumors, and examine how the content of the rumors influences their decision-making process.

3 The Egalitarian Tale of Decentralization in Automated Market Making

Allen Zhao[1], Zixuan Meng[1], Zhiqiang Eric Zheng[2], [1]The University of Texas at Dallas, Richardson, TX, [2]University of Texas-Dallas, Richardson, TX, Contact: allenz@utdallas.edu

Blockchain technologies have revolutionized the financial market with Decentralized Finance (DeFi), particularly decentralized automated market making (AMM). This study examines if AMM truly offers equal benefits to all participants. Findings reveal that profits still largely go to large, sophisticated liquidity providers (LPs), contradicting DeFi's intent. This disparity is partly due to individual LPs' lack of sophistication. Smart contracts have been used to aid LPs' decision-making, but low-performing LPs benefit less as they are less likely to adopt this technology. The study concludes that simply providing equal market access and tools isn't enough to create an egalitarian market.

4 Mobile Effects on Two-Sided Financial Decisions: Evidence from Field Experiments on Peer-To-Peer Lending Platforms

Sihan Fang[1], Hyeokkoo Eric Kwon[1], Tian Lu[2], Yingjie Zhang[3], [1]Nanyang Technological University, Singapore, Singapore; [2]Arizona State University, Tempe, AZ, [3]Peking University, Beijing, China. Contact: sihan001@e.ntu.edu.sg

We investigate how mobile channels shape the behaviors of both borrowers and lenders in peer-to-peer (P2P) lending platforms, as well as the corresponding impacts on credit risk management and economic return. Empirically, we collaborate with a leading P2P lending platform to launch two-sided field experiments, in which we randomly assign mobile treatments to borrowers and lenders. We illustrate that mobile borrowers are more likely to terminate loan submissions, especially during peak commuting hours. By contrast, mobile lenders have a higher tendency to approve loan applications within a shorter period. Surprisingly, we observe no change in the quality of submitted or approved loans. Considering the improved debt collection capability of the platform, we reveal that mobile adoption brings profit enhancement. We offer theoretical and managerial implications.

CC-West 106B

Consumer Credit

Community Committee Choice Session

Session Chair: Taylor Begley, University of Kentucky, Lexington, KY

1 Risk in the Shadows: Leverage and Liquidity in Nonbanks

Taylor Begley[1], Kardarp Srinivasan[2], [1]University of Kentucky, Lexington, KY, [2]Northeastern University, Boston, MA

Nonbank mortgage companies (NMCs) use high levels of short-term leverage, leading to concerns about their individual fragility and systemic risk. We find that NMCs also hold very risky assets, with revenue growth ranging from -30% to +100% at the 10th-90th percentile. Surprisingly, we also observe extremely low bankruptcy rates. We address this puzzle by examining the dynamics of NMCs' costs following negative shocks. Our findings show that NMCs have the flexibility to quickly and substantially reduce both their operating expenses and financing costs (interest expense and debt levels). These dynamics lower their credit risk compared to what static measures of leverage and asset risk suggest. The collateralized nature of originators' borrowing plays a fundamental role in debt flexibility. Servicers, who lack high-quality collateral, compensate by holding more cash.

2 How Resilient is Mortgage Credit Supply? Evidence from the Covid-19 Pandemic

Andreas Fuster[1], Aurel Hizmo[2], Lauren Lambie-Hanson[2], James Vickery[2], Paul Willen[3], [1]Ecole Polytechnique Fédérale de Lausanne, Luasanne, Switzerland; [2]Federal Reserve Bank of Philadelphia, Philadelphia, PA, [3]Federal Reserve Bank of Boston, Boston, MA

We study the evolution of mortgage credit supply during the COVID-19 pandemic. The mortgage market experienced a historic boom in 2020, but a large increase in intermediation margins limited the pass-through of low rates to borrowers. This rise is only partially explained by the historical relationship between demand shocks and the price of intermediation. Labor market frictions and operational bottlenecks contributed to unusually inelastic credit supply, and technology-based lenders gained market share for difficult-to-process loans. Rising forbearance and default risk did not significantly reduce supply for "plain vanilla" conforming mortgages, but constrained credit availability for loans without government guarantees and mortgages to the riskiest borrowers. Federal Reserve bond purchases also supported credit supply in the conforming segment.

3 Fraud Litigation and FHA Mortgage Lending

Erik Mayer, University of Wisconsin-Madison, Madison, WI

We study the impact of recent increases in mortgage lenders' litigation risk on borrowers. In the last decade, the U.S. Department of Justice brought suits against many of the largest lenders in the FHA mortgage market, alleging fraud under the False Claims Act. These suits led to over $5.4 billion in settlements and caused targeted banks and their peers to precipitously exit the FHA market. A combination of difference-in-differences and triple differences tests exploiting geographic variation in exposure to exiting banks show a 19% reduction in aggregate FHA lending in heavily affected areas. Smaller non-bank lenders with higher historical misconduct rates partially filled the void in the FHA market, highlighting potential unintended consequences of aggressive consumer financial protection litigation.

4 The Rise of Non-Banks in Servicing Household Debt

Brittany A. Lewis[1], Erica Jiang[2], Manisha Padi[3], Avantika Pal[1], [1]Washington University in St. Louis, St Louis, MO, [2]USC, LA, CA, [3]Berkeley, San Francisco, CA, Contact: lewis.b@wustl.edu

Over the past two decades, the mortgage industry has been transformed from the traditional bank-centered deposit taking, lending, and servicing model to a fragmented market with high non-bank participation. We document a novel mechanism for this unbundling -- mortgage servicing transfers -- and study the role of bank regulation in transforming servicing. Using a near universe of consumer credit records, we show that banks increase transfers of mortgage servicing rights (MSRs) to non-banks following the announcement of Basel III's higher regulatory costs of holding MSR assets for banks. Based on predictions of a simple model of servicing transfers, we demonstrate which types of banks and loans experience the highest transfer rates. We find that banks selectively transferred below-median income, subprime, and 60+ day delinquent MSRs to non-banks. Loans subject to transfer due to regulatory pressure experienced more foreclosures and personal bankruptcies. Our results suggest that growth in the unbundling of mortgage servicing increased existing disparities in financial risks across households.

Learning and Mechanism Design

Community Committee Choice Session

Session Chair: Michael Albert, University of Virginia, Charlottesville, VA

1 Delegating Data Collection for Learning

Nivasini Ananthakrishnan, Stephen Bates, Michael Jordan, Nika Haghtalab, UC Berkeley, Berkeley, CA, Contact: nivasini@berkeley.edu

Motivated by the emergence of decentralized machine learning ecosystems, we initiate the study of the delegation of data collection. Taking the field of contract theory as our starting point, we design optimal and near-optimal contracts that deal with two fundamental machine learning challenges: lack of certainty in the assessment of model quality and lack of knowledge regarding the optimal performance of any model. We show that lack of certainty can be dealt with via simple linear contracts that achieve a $1-1/e$ fraction of the first-best utility, even if the principal has a small test set. We also discuss considerations in delegation over multiple rounds.

2 Competition, Alignment, and Equilibria in Digital Marketplaces

Meena Jagadeesan, Michael I. Jordan, Nika Haghtalab, UC Berkeley, Berkeley, CA, Contact: mjagadeesan@berkeley.edu

Competition between traditional platforms is known to improve user utility by aligning the platform's actions with user preferences. But to what extent is alignment exhibited in data-driven marketplaces? To study this question from a theoretical perspective, we introduce a duopoly market where platform actions are bandit algorithms and the two platforms compete for user participation. A salient feature of this market is that the quality of recommendations depends on both the bandit algorithm and the amount of data provided by interactions from users. Our main finding is that competition in this market does not perfectly align market outcomes with user utility. Interestingly, market outcomes exhibit misalignment not only when the platforms have separate data repositories, but also when the platforms have a shared data repository.

3 Imitative Buyer Deception in Repeated Posted-Price Auctions

Minbiao Han, University of Chicago

A ubiquitous learning problem in today's digital market is, during repeated interactions between a seller and a buyer, how a seller can learn optimal pricing based on the buyer's past purchase responses. A fundamental challenge of learning in such a strategic setup is that the buyer naturally has incentives to manipulate his responses in order to induce more favorable learning outcomes. To understand the limits of the seller's learning when facing such a strategic buyer, we study a natural yet powerful buyer manipulation strategy. That is, before the game starts, the buyer simply commits to imitate a different value function by pretending to always react optimally according to this imitative value function. We fully characterize the optimal imitative value function of the buyer as well as the resultant seller revenue and buyer surplus under this optimal buyer manipulation.

4 From Dynamic Pricing to Dynamic Stackelberg Games: Going Beyond the No Learning Theorem

Minbiao Han[1], Dawkins Quinn[2], Michael Albert[2], Haifeng Xu[1], [1]University of Chicago, Chicago, IL, [2]University of Virginia, Charlottesville, VA

In this work, we study dynamic Stackelberg games, i.e. games in which a leader and a follower repeatedly interact, where the follower's type is unknown and the follower is non-myopic. A natural question to ask is, can the leader learn the optimal strategy against the unknown follower through these repeated interactions? The No Learning Theorem from dynamic pricing, a particular type of dynamic Stackelberg game, would suggest that the leader cannot learn effectively from the follower. In contrast, we demonstrate that in general dynamic Stackelberg games, the leader can improve her utility through learning in repeated play. We show that this dynamic policy is provably nearly optimal, even when compared to stronger equilibrium concepts that permit communication between the leader and follower.

5 Scalable Strategyproof Mechanism Design via Differentiable Economics

Michael Curry, University of Zurich, Zurich, Switzerland

A recent approach to automated mechanism design, differentiable economics, represents auctions by rich function approximators and optimizes their performance by gradient descent. We present recent work in differentiable economics, including new architectures that can guarantee exact strategyproofness of the mechanism, and new extensions of the techniques of differentiable economics that can be applied to dynamic problems.

Collaborative Vehicle Routing and Network Design

Contributed Session

Session Chair: Himani Ananthula, Kellogg School of Management, Northwestern University, Evansotn, IL

1 Anticipatory Request Acceptance in Dynamic and Collaborative Vehicle Routing

Yannick Scherr[1], Margaretha Gansterer[2], Richard F. Hartl[3], [1]University of Klagenfurt & University of Vienna, Vienna, Austria; [2]Univiersity of Klagenfurt, Klagenfurt, Austria; [3]University of Vienna, Wien, Austria. Contact: margaretha.gansterer@aau.at

We consider the problem setting of serving stochastic customer requests that must be answered dynamically. Accepted requests are served in routes using a set of vehicles with limited load capacity and route duration. Multiple carriers participate in a combinatorial auction to exchange a subset of requests. After carriers place bids on bundles of requests, an auctioneer allocates the bundles to carriers in a cost-minimizing way. We consider overbooking policies for prior to the auction and the strategic rejection of requests in anticipation of more profitable new requests. Experiments show that carriers' request acceptance decisions impact their individual profits and the overall collaboration savings. The largest benefits can be achieved with an overbooking policy that is applied by all carriers and considers the locations of both the request and the carriers' depots.

2 Integrated Optimization of Auto-Carrier Loading and Routing Decisions in Automobile Shipping

Sajeeb Kirtonia, Yanshuo Sun, Florida State University, Tallahassee, FL

The underlying pickup and delivery problem in automobile shipping is interesting because of the special configuration of a roadway auto-carrier, which further leads to auto-carrier loading decisions to be intertwined with routing decisions. First, for given auto-carrier routes, we design a unified space-state network formulation for auto-carrier loading optimization. Then, we use supervised learning to predict the number of reloads for a given auto-carrier route, thus avoiding solving a lengthy loading optimization problem. This data-driven module can be plugged into an auto-carrier routing optimization engine based on a column generation approach, to evaluate the impact of routing decisions on loading in real-time. Eventually, we jointly optimize two interrelated decisions and demonstrate the proposed methods with a case study in the Southeastern U.S.

3 Gig Workers for Relay Network Model: Factors to Consider

Himani Ananthula, Kellogg School of Management, Northwestern University, Evansotn, IL, Contact: himani.ananthula@kellogg.northwestern.edu

A relay point is a physical location in the transportation network where shipments can be relayed. We study the optimal relay network design problem robust to labor(drivers/supply) shocks under a queuing framework. We discuss managerial insights and factors to consider while designing relay networks with such daily-level supply uncertainties.

1 Sustainable Multi-period Last-mile Delivery with Anticipatory Postponement

Tingting Chen[1], Jiantong Zhang[2], [1]Tongji University, Shanghai, China; [2]Tongji University, Shanghai, China. Contact: aryatt120999@gmail.com

E-retailing reshapes shopping habits, but raises sustainability issues and parcel growth strains couriers physically and mentally.This research pioneers simultaneous route and package workload balance in the context of multi-period last-mile delivery. An anticipatory postponement policy is proposed using Sample Average Approximation (SAA) and policy-gradient method to balance package workload and reduce costs. An enhanced multi-objective optimization algorithm combines NSGAII with hybrid Simulated Annealing and Variable Neighborhood Search (SAVNS) to achieve route workload balance and efficient distribution with respect to sustainability. Computational results based on realistic data show the effectiveness of our policy. Comparative experiments also validate the proposed optimization algorithm against other state-of-the-art methods.

2 Setting Customized Service Level Targets for Parts in a Repair Kit

Jingran Xu, John Maleyeff, Boston University, Boston, MA, Contact: xujr21@bu.edu

The presentation details a stochastic approach to determine the service level for a part contained in a repair kit, where the repair cannot be started until all parts are available. Our model features a unique cost structure that considers the shortage cost to be the cost of holding other parts in the repair kit while the part being ordered is in transit. Using data from a transportation company, a k-means clustering analysis showed the demand distribution to be Poisson for intermittent demand repairs. Sensitivity and joint effect analyses were used to evaluate the effects of lead time, part cost, and demand rate on optimal service levels. An important result is that a part with a higher unit cost should be assigned a lower service level.

3 Direct and Mitigation Factors of Crowdsourced Last-Mile Delivery Workers' Willingness to Work in a Rural Setting

Mingwei Guo[1], Joseph Gerard Szmerekovsky[2], [1]North Dakota State University, Fargo, ND, [2]North Dakota State University, Fargo, ND, Contact: mingweiguo@live.com

The motivation of the practitioners(drivers) in crowdsourced delivery is often neglected when more attention is given to the decision making and scheduling process. When temporary workers from phone APPs taking more third-party last-mile delivery tasks, the supply of practitioners may be in shortage if certain factors are not considered. This research aims to find and test the direct and mitigation factors for crowdsourced last-mile practitioners' willingness to work (WTW), with specialization and focus on the rural areas and commuting workers who might be potential last mile delivery workers. A combination of qualitative and quantitative research methods will be utilized, from which, descriptive and exploratory survey will be the main method. Phase I results will be expected by September. It will be the job market paper of the presenter.

Session Chair: Mostafa Amini, Oklahoma State University, Oklahoma City, OK

1 The Effect of Interpretable Artificial Intelligence on Repeated Managerial Decision-Making Under Uncertainty

Onur Altintas[1], Abraham Seidmann[2], Bin Gu[1], Nina Mažar[1], [1]Boston University, Boston, MA, [2]Boston University, NEWTON, MA, MA

Many business decisions, such as managing investment instruments, selecting medical care, and managing various supply chains, are being made repetitively in uncertain environments. At times, decisions under uncertainty could be perceived as wrong ex-post even though they are really ex-ante optimal. Therefore, decision-makers tend to intuitively resist taking algorithmic advice under high uncertainty. In our study, we empirically investigate the impact of various common interpretability formats on AI adoption and trust under uncertainty. Interestingly, we show that explaining the inner workings of a model in fact decreases AI adoption. On the other hand, frequently sharing the cumulative performance over time of both the users and the AI improves users' trust in the model. On the other hand, it had no negative impact on the AI adoption rate.

2 Valid Inequalities for Verification of Binarized Neural Networks

Woojin Kim[1], Jim R. Luedtke[2], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, Contact: wkim73@wisc.edu

Binarized neural networks(BNNs) are neural networks with binary weights, and activation functions are the sign function. Verification of BNNs against input perturbation is one way to measure robustness of BNNs. BNN verification can be formulated as a mixed integer linear optimization problem. The natural formulation is often difficult to solve due to large integrality gap induced by big-M constraints. We explore techniques for generating valid inequalities that improve the integrality gap. Numerical results will be presented.

3 High-Dimensional Parameter Estimation for Complex Chemical Reaction Networks Using a Hybrid Bayesian Optimization and Gradient Descent Approach

You Peng[1], Lingxun Kong[2], Ivan Castillo[3], Ricardo Rendall[4], [1]The Dow Chemical Company, Columbus, OH, [2]Dow Chemical Company, Lake Jackson, TX, [3]The Dow Chemical Company, Houston, TX, [4]The Dow Chemical Company, Terneuzen, Netherlands

Chemical processes often involve complex reaction networks. The rate for each reaction depends on various factors such as concentration and temperature. Each factor can have multiple parameters whose values are usually unknown and can only be estimated from data. For this work, we propose a hybrid approach that combines global and local optimization strategy to tackle such high-dimensional parameter estimation problem efficiently. The method involves using high-dimensional Bayesian Optimization (SAASBO) to search the full parameter space and then reduce problem dimension by eliminating the less sensitive parameters. Then the current best set of parameters found by SAASBO were further refined using gradient based methods which are computationally more efficient. Additionally, the posterior distribution was also quantified using a MCMC sampling approach.

4 A Hybrid AI and Optimization Framework to Address the Issue of Frequent Missing Values; the Case of a Clinical Decision Support System for Parkinson's Disease

Mostafa Amini[1], Ali Bagheri[2], Dursun Delen[3], [1]California State University Long Beach, Long Beach, CA, [2]Oklahoma State University, Stillwater, OK, [3]Oklahoma State University, Tulsa, OK

Analyzing electronic health record (EHR) data can improve clinical decision support systems (CDSS). However, the volume of data presents significant challenges, including handling missing values. Employing explainable AI techniques, optimization, and predictive analytics, we introduce a framework that addresses the issue of incompleteness in EHR data, enabling researchers to select the most critical variables at an acceptable level of missing data. We demonstrate the effectiveness of this framework by applying it to developing a CDSS for detecting Parkinson's disease, where in practice, Parkinson's disease is hard to diagnose, and even specialists' diagnoses can be inaccurate. Our results show that the framework improves the accuracy of predictive models and identifies patients with Parkinson's disease who might otherwise go undiagnosed.

Intersection of Optimization and Learning

Contributed Session

Session Chair: Zhiqiang Liao, Aalto University, Espoo, Finland

1 Carousel Greedy Algorithms for Feature Selection in Linear Regression

Jiaqi Wang[1], Bruce L. Golden[2], Carmine Cerrone[3], [1]University of Maryland-College Park, College Park, MD, [2]University of Maryland-College Park, Columbia, MD, [3]University of Genoa, Genoa, Italy. Contact: jqwang@terpmail.umd.edu

The carousel greedy algorithm (CGA) was proposed several years ago as a generalized greedy algorithm. In this paper, we implement the CGA to solve linear regression problems with a cardinality constraint on the number of variables. We compare this against stepwise regression and more sophisticated approaches, one using integer programming and a second using LASSO.

2 Consistency Regularization for Distortion-Robust Supervised Learning

Hyungu Kang, Seokho Kang, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: viamonoh@skku.edu

Convolutional neural networks (CNNs) have shown high accuracy in various image classification tasks. However, their performance can be significantly degraded for distorted images. To address this issue, we propose an improved training method for building a CNN robust to image distortions. It utilizes consistency regularization, a technique commonly used for semi-supervised learning, for supervised learning. By incorporating a consistency regularization term into the objective function, the CNN is encouraged to produce similar outputs for strong and weak transformations of the same input image, thereby enhancing the robustness against image distortions. Experimental results on image classification benchmarks demonstrate that the proposed method improves both classification accuracy and robustness against image distortions.

3 A Machine Learning-Based Warm Start Approach to Improve the Solvability of Lps

Jitamitra Desai, Ronit Neogy, Indian Institute of Management - Bangalore, Bangalore, India. Contact: jmdesai@iimb.ac.in

In this research, we explore the use of machine learning techniques, notably logistic regression and decision tree algorithms, for improving the solvability of optimization problems. Recognizing that the computational time required to solve a linear programming problem can be heavily influenced by the choice of a starting basis (referred to as “warm start”), we apply classification techniques to apriori decide the decision variables that are most likely to be part of the optimal basis. Problem parameters and their combinations that yield the most effective warm start basis are identified and our detailed computations show that the use of advanced ML techniques can significantly improve the solvability of optimization problems.

5 Overfitting Reduction in Convex Regression

Zhiqiang Liao, Aalto University, Espoo, Finland. Contact: zhiqiang.liao@aalto.fi

We study the problem of overfitting in multivariate convex regression. We investigate the inconsistency of the multivariate convex regression and the unboundedness of its subgradients near the boundary. To reduce overfitting, we propose the augmented Lipschitz convex regression and weight-restricted convex regression method. We identify their behavior near the boundary by providing the theoretical results of consistency and boundedness. A Monte Carlo study is performed to illustrate the advantage of the proposed methods. The proposed approaches are further applied to benchmark the operations efficiency of Finnish electricity companies.

Mixed Integer Linear Programming for Scheduling

Contributed Session

Session Chair: Nathan Adelgren, United States Naval Academy, Annapolis, MD

1 Robust Concurrent Algorithms for Unstructured Mixed Integer Linear Programs

Utku Koc, MEF University, Istanbul, Turkey. Contact: utku.koc@mef.edu.tr

In this study, we propose robust concurrent heuristics for Mixed Integer Linear Programs that runs in massively parallel platforms in distributed memory settings. Specifically, both feasibility pump and objective feasibility pump are run in parallel starting from alternative points in the feasible region. Information generated by a subroutine is

collectively used by all subroutines. The algorithm continues to provide good solutions even if some of the computing nodes are unreachable.

2 Finding Locally Maximal Boolean Patterns from Numerical Data

Sunung Kim, Hong Seo Ryoo, Korea University, Seoul, Korea, Republic of. Contact: tjsdndrla1@korea.ac.kr

This study proposes a metaheuristic procedure for discovering Pareto-optimal Boolean patterns from fuzzy numerical datasets. Toward this end, we first build an initial set of clusters of homogeneous data to obtain a set of literals for classifying different types of data without contradiction. Next, we sequentially expand each cluster in reference to clusters nearby via the determination of a direction for expansion and through the generation of new literals. This yields a set of Pareto-optimal patterns that best describe the local traits of the data that they contain. With preliminary experiments on public machine learning datasets, we test efficacy and efficiency of the proposed algorithm in comparison with approaches from the literature.

3 A New Discrete-Time-Based Branch-And-Cut Strategy for Solving Single-Stage Scheduling Problems

Nathan Adelgren[1], Shamik Misra[2], Christos Maravelias[3], [1]Andlinger Center for Energy and the Environment, Princeton University, Princeton, NJ, [2]Indian Institute of Technology Tirupati, Tirupati, India; [3]Princeton University, Princeton, NJ, Contact: na4592@princeton.edu

We present a new hybrid MILP/CP approach for solving single-stage scheduling problems. In contrast to existing hybrid MILP/CP approaches for these problems, all of which have been proposed within a continuous-time framework, the technique we present is designed within a discrete-time framework. The proposed approach builds upon the so-called Discrete-Continuous Algorithm by embedding it within a branch-and-cut solution strategy. Several variants of the proposed approach will be presented together with computational results that demonstrate their utility. All computational tests also include comparisons with current state-of-the-art approaches.

Live Stream Ecommerce

Contributed Session

Session Chair: Sung Hyun Kwon, University of Maryland, College Park, MD

1 Supply Chain Strategies in the Presence of Livestream E-Commerce: Channel Leadership and Low-Carbon Promotion

Wei Liu[1], Xinyan Cao[2], Xueqi Niu[1], Xiang Fang[3], Jason Choi[4], [1]Dongbei University of Finance and Economics, Dalian, China; [2]Northern Illinois University, Chicago, IL, [3]University of Colorado Denver, Denver, CO, [4]University of Liverpool, Liverpool, United Kingdom. Contact: xiang.fang@ucdenver.edu

Livestream e-commerce is an emerging phenomenon, and its impacts on supply chains are largely unknown. Motivated by this important growing market, we propose an analytical model to study a decentralized supply chain with an upstream manufacturer (he) selling his product to a downstream retailer (she) via a wholesale price contract. We solve the equilibrium solutions under both the traditional e-commerce mode and the livestream mode. Our results show that the traditional e-commerce mode is always dominated by the livestream mode such that both parties are more profitable when participating in the livestream e-commerce. However, when the wholesale price is sufficiently high, the livestream e-commerce is no longer feasible for both parties such that the market becomes manufacturer-monopolistic.

2 The Role of Live-Streaming Commerce in Dual-Channel Supply Chain

Haiying Yang[1], Zhuang Qian[2], Zhengping Wu[3], [1]Missouri State University, Springfield, MO, [2]Pennsylvania State University, Dunmore, PA, [3]Syracuse University, Syracuse, NY

Live-streaming shopping has become a significant sales force and it allows viewers to watch and shop through real-time interactions over the phone. We investigate how a supplier responds to the fast-growing live-streaming commerce. We examine multiple centralized settings when a supplier builds his own live-streaming teams and hosts live sessions. We also design a two-stage game to formulate one decentralized case that the supplier offers a revenue-sharing contract and sells products through a key opinion leader's stream. Our results show that the supplier and the key opinion leaders may be discouraged compared with the centralized models, which might decrease the supplier's expected profit eventually.

3 Live-Stream Platform Strategies: Drive Traffic or Not?

Yuhan Yan[1], Rongyi Huang[2], [1]School of Business, Renmin University of China, Beijing, China; [2]School of Economics and Management, Fuzhou University, Fuzhou, China. Contact: rmbsyuhanyan@ruc.edu.cn

Live-stream, with its diverse content and real-time interaction with the audience, has become a powerful means of boosting online traffic. In order to benefit from the massive traffic, live-stream platforms have begun to encourage live promotions driving potential consumers to traditional e-commerce platforms, while attempting to incorporate e-commerce features into themselves. We develop a stylized model consisting of a third-party seller, a live-stream platform and a traditional e-commerce platform to investigate their strategic interactions, and consumer's switching behavior between traditional and live-stream channels. We share managerial insights in live-stream platform design, and channel strategies for third-party sellers.

4 Catching the Viewer's Eye: Examining Exploration and Exploitation Strategies in the Live Streaming Market

Sung Hyun Kwon, Il-Horn Hann, University of Maryland, College Park, MD

More and more creators are competing on live streaming platforms like Twitch to maximize the attention they receive from viewers. To attract and maintain attention, it is crucial for content creators to effectively develop innovative content that captures consumer interest and facilitates the discovery of their content. We examine how these content creators employ an exploration-exploitation strategy to design their content and attract viewership. We combine traditional methods with recent NLP techniques to measure exploration, exploitation, and learning from viewers and streamers to assess the positioning of content creators. Utilizing our proposed metrics, we estimate consumer utility derived from the varying strategies using the BLP model. Our findings hold implications for content creators, platform businesses, and several streams of literature.

Topics in Finance

Contributed Session

Session Chair: Pedro Júdice, ISCTE Business Research Unit, Lisbon, Portugal

1 Credit Line and Interest Rate Optimization

Wenyou Wang, Yao Yang, Sirong Luo, Shanghai University of Finance and Economics, Shanghai, China. Contact: luo.sirong@mail.shufe.edu.cn

Interest rate and credit line are critical decisions in lending industry, which need to consider the market acceptance, credit loss and interest income. We propose a model for joint interest rate and credit line optimization. We find the optimality conditions for credit line and interest rate when either interest rate or credit line is given. We show that the optimal credit line is decreasing with loss given default and risk-free rate and the optimal interest rate is decreasing with loss given default and credit line. Then, we extend the analysis by considering the market acceptance. We prove the optimality conditions with respect to credit line and interest rate separately. We show that the optimal interest rate is increasing with risk-free rate. And we prove that the optimal credit line is higher and the optimal interest rate is lower when considering the market acceptance.

2 Leveraging Dynamic Multilayer Networks for Modelling Credit Risk Contagion in Smes

Sahab Zandi[1], Kamesh Korangi[2], María Óskarsdóttir[3], Christophe Mues[2], Cristián Bravo[1], [1]Western University, London, ON, Canada; [2]University of Southampton, Southampton, United Kingdom; [3]Reykjavík University, Reykjavík, Iceland. Contact: szandi@uwo.ca

Researchers in the field of credit risk management have recently focused on improving the performance of these models by incorporating alternative data sources such as network data. This study uses complex, multilayer network data on SMEs from a large financial institution to estimate credit risk. We propose a novel model leveraging dynamic graph attention networks to predict SME default, with two sources of connections, namely shared ownership of companies and financial transactions between them, resulting in a two-layer network. We show how this information, when combined with traditional structured data, contributes to application credit scoring performance, and explicitly models contagion risk across companies.

3 Simulation-Optimization for Dynamic Bank Asset Allocation

Pedro Júdice, ISCTE Business Research Unit, Lisbon, Portugal. Contact: pedro.judice@iscte-iul.pt

Bank asset allocation is a major determinant of banks' long-term performance and financial sustainability. Current bank asset allocation models fail simultaneously to use realistic scenarios and produce time-dependent asset allocations, so do not take advantage of the changes in business cycles. Using a multi-objective genetic algorithm, we develop a simulation-optimization method that uses variable selection and determines dynamic optimal asset allocation rules based on environment variables such as interest rates. We conduct a performance analysis in a separate testing set, indicating the algorithm's superior performance compared to other established methodologies, namely optimizing constant allocations or choosing equal-weight policies. The method can thus be used in practice to support banks' senior management dynamic decisions.

Opioid Crisis and Other Health Systems Management

Contributed Session

Session Chair: Justin Rist, The Pennsylvania State University, State College, PA

1 Data-Driven Resource Allocation for the Opioid Crisis in Chicago

Rashid Anzoom[1], Rakesh Nagi[2], Chrysafis Vogiatzis[3], Hyojung Kang[4], [1]University of Illinois Urbana-Champaign, Urbana, IL, [2]Industrial Enterprise Systems University of Illinois, Urbana, IL, [3]University of Illinois at Urbana-Champaign, Urbana, IL, [4]University of Illinois at Urbana-Champaign, Champaign, IL, Contact: ranzoom2@illinois.edu

The opioid crisis has emerged as a serious problem across the USA, with fatalities from opioid overdoses soaring rapidly over time. This necessitates a careful evaluation of allocation strategies for different resources (e.g., NARCAN) to help individuals with opioid overdose and misuse. In this talk, we discuss a data-driven approach to accurately forecast the demands for such resources and design an integer programming-based allocation scheme to ensure fairness of benefits across different regions. We illustrate the efficacy of our approach in the context of Chicago's neighborhood communities.

2 Access Versus Physical Access: An Examination of Telehealth Adoption

Eric Xu, Mississippi State University, Mississippi State, MS

While our current conception of telemedicine has existed for half a century, beginning with the Space Technology Applied to Rural Papago Advanced Health Care (STARPAHC), only recent telecommunication advancements have increased the pace of adoption amongst patients and practitioners. Therefore, we examine the impact of telemedicine adoption on primary care use, specifically examining the conditions by which telehealth consultations become a substitute for in-person care or a compliment to in-person care. Using a unique dataset of insurance claims for primary care visits, we examine in-person, asynchronous, and synchronous primary care visits.

3 Identifying Access and Attendance Disparities to Opioid- Related Prevention Programs in Pennsylvania

Justin Rist, Pennsylvania State University, State College, PA, Contact: jsr5605@psu.edu

The opioid epidemic is a significant public health crisis in the United States, with rural areas experiencing greater challenges in access to prevention programs. This study examines the impact of county population density on access and attendance to opioid-related prevention programs in Pennsylvania. Using data from four counties and multilevel OLS regression models, the analysis reveals that rural counties have reduced access and attendance compared to urban counties. Findings suggest the need for targeted strategies to improve access and attendance in rural areas, thereby reducing the burden of opioid overdoses.

Economic Analysis of Supply Chains

Contributed Session

Session Chair: Wangsheng Zhu, University of Texas at Dallas, Plano, TX

1 Value Allocation in Make-To-Order (MTO) and Make-To-Stock (MTS): An Experimental Study

Wei-Shiun Chang[1,2], Sarah Ereneo[3], [1]Institute of International Management, National Cheng Kung University, Tainan City, Taiwan; [2]Center for Innovative FinTech Business Models, NCKU, Tainan City 701, Taiwan; [3]National Cheng Kung University, Tainan City, Taiwan. Contact: wschang@mail.ncku.edu.tw

We explore the value allocation in two major production procedures, Make to Order (MTO) and Make to Stock (MTS). Weighing in the preference of value creation associated with producers' technology, we posit that the producers' selection of cost for production out of the price in MTO is influenced by the level of producers' technology. This preference is absent in MTS when producers negotiate the price with the customers. Holding value creation constant, we test the value allocation between MTO and MTS with a series of experiments and we find producers' spitting rate would favor customers more when their technology is more advanced in MTO while the splitting rate remains constant in MTS.

2 A Novel Way Based on Behavioral Cognition and Human-Machine Collaboration: The Stochastic Adaptation Method for Beer Game

Gong Yu, Yu Hui, Chongqing University, ChongQing, China. Contact: gongyu_96@163.com

The beer game is a classic problem in inventory management and is widely used to demonstrate the bullwhip effect. Given bounded rationality, it makes sense to explore behavioral cognition. We propose the Stochastic Adaptation(SA) method to play the beer game. It originates from the characterization of similar behaviors between humans and AI algorithms. The SA provides a unified framework, allowing players to decide with limited options under partial information. Experiments show that the SA achieves stable operation in different supply chain scenarios. Each player develops a policy around its local adaptation but ultimately can realize global adaptability. Under certain conditions, the SA can exhibit a smaller cost and the bullwhip effect than other methods. Human-machine collaboration helps further optimize its performance.

3 Managing Ad Campaigns On Digital Billboards Under Supply Disruptions

Wangsheng Zhu[1], Shaojie Tang[2], Vijay S. Mookerjee[3], [1]University of Texas at Dallas, Plano, TX, [2]University of Texas-Dallas, Mckinney, TX, [3]University of Texas- Dallas, Richardson, TX, Contact: zhuws199211@gmail.com

The digitization of billboards has facilitated the sale of advertising slots through real-time auctions, leading to a rise in agents who assist advertisers in bidding and acquiring slots. These agents enter into contracts with advertisers to secure a specific number of slots within designated time periods. However, accepting numerous contracts may require the agent to place higher bids in auctions, potentially impacting their profitability. Therefore, it is crucial to strike a balance between contract acceptance and the bidding strategy employed. This study addresses two key aspects: (1) identifying the optimal set of advertisers for the agent to contract with, and (2) determining the appropriate bidding strategy. We formulate a two-stage optimization problem for agents, followed by the proposal of a near-optimal solution to the bidding optimization problem.

Optimization in Supply Chain Management

Contributed Session

Session Chair: Abdurrezzak Sener, Penn State University, Pittsburgh, PA

1 Who Gets the Whip? How Supplier Diversification Influences Bullwhip Effect in a Supply Chain

Tyler Burrows, Max Hamilton, David Grimsman, Brigham Young University, Provo, UT, Contact: tnburrows@me.com

Emergent technologies, such as the 'blockchain,' are enabling unprecedented coordination across firms in Supply Chains (SC). Firm decision-makers ultimately are going to need to understand how they can control (and optimize) such a network of relationships. However, current approaches to the study of SC-level behavior typically assume a focal firm, and the modeling of SC behavior is usually limited to single-product serial networks. This paper aims to understand how the 'bullwhip effect' propagates and intensifies throughout a SC with multiple suppliers. We find that SC the structure has to be accompanied with a dynamic policy to see changes in demand disturbances. We also explicate a novel SC model that can be used to test the implications of our main result: diversifying a firm's supplier-base has the potential to amplify disturbances more quickly.

2 Newsvendor's Supplier Selection Problem with Correlated Supply and Demand Uncertainties

Liao Wang[1], Jin YAO[2], Sean Zhou[3], [1]University of Hong Kong, Hong Kong, Hong Kong; [2]The University of Hong Kong, Hong Kong, Hong Kong; [3]Chinese University of Hong Kong, New Territories, China. Contact: lwang98@hku.hk

It is established in literature (Dada et al., A Newsvendor's Procurement Problem when Suppliers Are Unreliable, M&SOM, 2007, 9(1), 9-32) that for a newsvendor facing multiple suppliers, the optimal selection rule ("DPS's rule") is that the cheaper ones are always selected first. Two crucial assumptions are made: the demand and supply risks are independent, and the newsvendor is risk neutral. In this research, we relax these assumptions. We first study the supplier selection problem with correlated supply and demand risks and identify conditions that preserve or do not preserve the DPS's rule . We find that a positive demand-supply relationship can lead to violation of the rule. With a

CVaR objective, we find that risk aversion per se does not affect DPS's rule and study the impact of supply-demand correlation on the selection rule.
*This research is supported by the GRF of HK RGC.

3 Analyzing Trade Agents Decisions in B2B Transactions
Itir Z. Karaesmen, Ozden Engin Cakici, American University, Washington, VA
We formulate and analyze the procurement decisions of a trade agent in B2B markets. We cast the problem as a new type of newsvendor problem where the trade agent bids to purchase a predetermined supply from seller(s). We analyze the conditions under which the optimal bids are monotonic. We also show the effect of yield uncertainty on optimal bids and that it may not be optimal for the trade agent to prefer a more reliable seller when all other supply parameters are the same.

4 Modeling Purchase Premium Using Binomial Tree Options
Mei-Ting TSAI, Hau-Cheng WEN, National Chung Hsing University, Taichung, Taiwan. Contact: mtsai@dragon.nchu.edu.tw
In 2020, black swan events, such as Covid-19 and the Ukrainian-Russian War, cause serious uncertainty in the supply chain. To share risks between suppliers and manufactures, this study designs a purchase premium contract. By paying the premium in advance, the manufacturer has a right to terminate or continue the purchase contract with the supplier according to the actual needs. On the other hand, the supplier could diminish inventory risks. We develop the pricing model using the binomial tree options method. For the numerical analysis, we collect sales data from a technology company in Taiwan and analyze the effects of the proposed contract design on three different periods--before, during and after Covid-19. The differences in cost sharing under the current contract and the premium contract are discussed.

5 Flow of Information and Its Preservation
Abdurrezzak Sener[1], Alparslan Ersoz[2], [1]Penn State University, Pittsburgh, PA, [2]Carnegie Mellon University, Pittsburgh, PA
In this research, we investigate flow of information among members of a supply chain and preservation of shared and used information. Simulation of our theoretical model is also discussed.

JMP/AIZOTH
Technology Tutorial

1 Exploring Unstructured Text Data to Extract Meaning and Sentiment
Kevin J. Potcner, JMP Statistical Discovery, SAS, San Francisco, CA, Contact: kevin.potcner@jmp.com
Asking students what data they are most familiar with will inevitably result in the answer: "Text Data" From social media posts, texting, product and movie reviews, among so many others, this generation of students live in a world of constantly sending, receiving, and looking at unstructured text data. Requiring no prior experience in the concepts of formal statistical analyses (confidence intervals, p-values, models, etc.), extracting meaning from a large collection of text can be successfully done by a wide range of students including those with just a basic knowledge of data analysis. Due to today's students being intimately familiar with this type of data, the value of exploring text data to extract meaning is easily appreciated by students, with most finding it quite fun and engaging. Using JMP statistical software, the presenter will step through examples of analyzing text data in a "No Code" interactive environment.

2 Multi-Sigma: An Integrated AI Platform of Prediction and Optimization for Multiple Target Objectives Simultaneously
Kotaro Kawajiri, AIZOTH, Tsukuba-shi, Japan. Contact: kotaro.kawajiri@aizoth.com
AIZOTH provides AI services such as Multi-Sigma, AI consulting, spot support to optimize manufacturing conditions, and commissioned R&D. Multi-Sigma is the cloud-based AI software for R&D to reduce the effort of experiment drastically and also to help researchers finding the innovative solutions for their actual problems with minimum experimental dataset. Multi-Sigma was already introduced by large manufacturing enterprises and top universities. We will demonstrate how a Multi-Sigma can be used with sample datasets.
Key feature of Multi-Sigma: •Numerical analysis using deep learning: Deep learning techniques of both neural network and Bayesian optimization can be used with minimum dataset. High precision prediction of multiple objective variables. Factor analysis using sensitivity analysis for explainable AI. Multi-objective optimization in trade-off (maximization, minimization, target value, tailor-made optimization, constraint of explanatory variables). It can handle a large number of explanatory variables (up to 200)

and objective variables (up to 100), •No-code cloud-based software: Multi-Sigma is the advanced cloud-based AI platform which can be used with no-code on the browser. Anyone can use Multi-Sigma anytime, anywhere, and by any hardware (even by smartphones). •Innovative Design of Experiment using Artificial Intelligence (AI-DOE): Researchers can utilize our 'AI-DOE' techniques easily on Multi-Sigma. AI-DOE is developed by incorporating AI techniques into the traditional DOE basing on statistics. It can guides researchers to find the optimal solution for multi-input and multi-objective systems. •Versatility: Multi-Sigma can be utilized for any issue of R&D. Main users are manufacturing companies such as automobile, chemical, pharmaceutical companies. Also it can be used for management issues such as prediction of sales, marketing, and inventory management. Tailor-made optimization is the brand-new techniques with great potential in the field of medical care, material science, and sales management.

Learning in Games and Applications

Community Committee Choice Session

Session Chair: S. Rasoul Etesami, University of Illinois at Urbana-Champaign, Champaign, IL

1 Optimizing in the Presence of Strategic Behavior

Eric Mazumdar, California Institute of Technology, CA

Machine learning algorithms are increasingly being deployed into environments in which they must contend with other strategic agents with potentially misaligned objectives. The presence of these other agents breaks many of the underlying assumptions on which machine learning algorithms are built and can cause non-stationarity in the environment that can give rise to surprising dynamics and behaviors. In this talk, we will discuss two facets of this problem. In the first, we will describe a new approach for learning in zero-sum Markov games based on Q-learning and best-response-type dynamics which is independent, pay-off based, rational, and provably convergent.

2 Impacts of Different Information Sharing Modalities on Multi-Agent Reinforcement Learning

Parinaz Naghizadeh, University of California, San Diego, San Diego, CA

We explore the impacts of different information sharing modalities, namely parameter sharing vs. observation sharing, on the performance of multi-agent RL algorithms. We are specifically interested in the impacts of information sharing delay and intermittency (e.g., due to an underlying communication network) on the effectiveness of information sharing in enhancing learning in cooperative tasks. We provide analytical and numerical experiments to support our findings.

3 Dynamic Information Provision in Bayesian Exploration

Tianyi Lin, University of California, Berkeley, Berkeley, CA

We consider the dynamic information provision in Bayesian exploration. The principal controls the information flow to incentivize the agents, to coordinate them toward a socially optimal balance between exploration and exploitation. Each agent is self-interested, which necessitates the design of incentive-compatible policies for the principal. Notably, our setting features two considerations: 1) there are multiple agents interacting in a common environment; 2) the realized state is evolving over time. The first one has been studied before, while the second one, though making the problem more realistic, poses significant technical challenges, as the uncertainty of the agents not only comes from the actions of other agents, but also from the dynamics of the game. Our contribution is to show that the principal achieves constant regret for deterministic utilities.

4 Learning Stationary Nash Equilibrium Policies in N-Player Stochastic Games with Independent Chains

S. Rasoul Etesami, University of Illinois Urbana-Champaign, Champaign, IL

We consider a subclass of n-player stochastic games, in which players have their own independent chains while they are coupled through their payoff functions. Moreover, players can receive only realizations of their payoffs, and cannot observe each other's states/actions. We first show that finding a stationary Nash equilibrium (NE) policy without any assumption on the reward functions is interactable. However, for general reward functions, we develop polynomial-time learning algorithms based on dual averaging and dual mirror descent, which converge in terms of the averaged Nikaido-Isoda distance to the set of epsilon-NE policies almost surely or in expectation. In particular, under extra assumptions on the reward functions such as social concavity, we derive polynomial upper bounds on the number of iterates to achieve an epsilon-NE policy with high probability.

Designing Online Marketplaces

Community Committee Choice Session

Session Chair: Neha Sharma, Kellogg School of Management, Evanston, IL

1 Rating System Design: Structure, Incentives, and Fees

Titing Cui[1], Michael L. Hamilton[2], Su Jia[3], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, [3]Cornell, Ithaca, NY, Contact: mhamilton@katz.pitt.edu

We model a two-sided online platform which facilitates interactions between workers and customers, and where workers can receive reviews after completing jobs. In this ecosystem we design and analyze rating systems which must process the sequence of reviews, including cases where no review is given. Specifically, we propose a class of ARMA inspired rating systems that down-weight older reviews. We demonstrate that this approach creates an incentive constraint that prevents workers from disintermediating on the platform, and characterize the achievable fees the platform can collect under these constraints.

2 Spatial Matching with Resource Competition

Alireza Amanihamedani[1], Ali Aouad[1], Daniel Freund[2], [1]London Business School, London, United Kingdom; [2]MIT, Cambridge, MA

Motivated by ride-hailing marketplaces, we present a model of two-sided matching platforms in a duopoly market with spatial frictions. Both platforms face disjoint streams of rider requests, but they share the same resources on the supply side, i.e., drivers multi-home. Due to spatial frictions, supply efficiency requires an admission control to maintain a buffer of available drivers to balance matching distances with other supply costs. For both controls, we find that a duopoly equilibrium entails at least one platform undercutting, by accepting all requests, to gain market share. When both platforms undercut, the supply buffer is not maintained and inefficiencies ensue. We provide a classifier of market characteristics that delineates the two regimes and allows us to characterize the prices of anarchy and stability in these settings.

3 Near-Optimal Control in Ride-Hailing Platforms with Strategic Servers

Sushil Varma[1], Francisco Castro[2], Siva Theja Maguluri[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]UCLA Anderson School of Management, Los Angeles, CA, [3]ISyE Georgia Tech, Atlanta, GA, Contact: sushil@gatech.edu

Motivated by applications in online marketplaces such as ride-hailing, we study how strategic servers impact the system's performance. We consider a discrete-time process in which heterogeneous types of customers and servers arrive. Each customer joins their type's queue, while servers might join a different type's queue depending on the prices posted by the system operator and an inconvenience cost. Then the system operator, constrained by a compatibility graph, decides the matching. The objective is to design an optimal control (pricing and matching scheme) to maximize the profit minus the expected waiting times. We develop a general framework that enables us to analyze a broad range of strategic behaviors. In particular, we encode servers' behavior in a properly defined cost function that can be tailored to various settings. Using this general cost function, we introduce a novel probabilistic fluid problem and show that it provides an upper bound on the achievable net profit. We then study the system under a large market regime in which the arrival rates are scaled by ￼ and present a probabilistic two-price policy and a random matching policy which results in a net profit-loss of at most O(￼1/3). Under a maximally probabilistic fluid model condition, we show that the net profit-loss can be further improved to O(1). We conclude the discussion by underlining the necessity of the probabilistic fluid model by showing that the classical fluid model can result in arbitrarily low profit compared to the probabilistic fluid model.

Causal Machine Learning in Operations Management (Ruomeng Cui and Zhikun Lu)

Community Committee Choice Session

Session Chair: Ruomeng Cui, Emory University, Decatur, GA

Session Chair: Zhikun Lu, Emory University, Decatur, GA

1 Deep-Learning-Based Causal Inference for Large-Scale Combinatorial Experiments: Theory and Empirical Evidence

Zikun Ye[1], Zhiqi Zhang[2], Dennis Zhang[3], Heng Zhang[4], Renyu Zhang[5], [1]University of Illinois, Urbana-Champaign,

Urbana, IL, [2]Washington University in St. Louis, St. Louis, MO, [3]Washington University in St Louis, ST LOUIS, MO, [4]Arizona State University, Tempe, AZ, [5]The Chinese University of Hong Kong, Hong Kong, China. Contact: zikunye2@illinois.edu

We develop a framework combining deep learning and double machine learning to estimate and infer the causal effect of any treatment combination of multiple treatments when observing only a small subset of treatment combinations. Our proposed framework exploits Neyman orthogonality and combines interpretable and flexible structural layers in deep learning. To empirically validate our method, we collaborated with a large-scale video-sharing platform and implemented our framework for three experiments involving three treatments where each combination of treatments is tested.

2 The Value of Last-Mile Delivery in Online Retail

Zhikun Lu[1,2], Ruomeng Cui[1], Tianshu Sun[3], Lixia Wu[2], [1]Emory University, Decatur, GA, [2]Cainiao Network, Hangzhou, China; [3]University of Southern California, Los Angeles, CA

We study the value of last-mile delivery in the context of online retail. Leveraging a quasi-experiment with Alibaba's logistics arm, Cainiao, we evaluate the causal impact of last-mile home delivery on customers purchasing behaviors. Our difference-in-differences analysis shows that last-mile home delivery significantly increases customer spending at Alibaba's online retail platform, and the effects are highly heterogeneous across customers. Motivated by such heterogeneity, we propose a causal machine learning approach to optimally allocate the limited delivery capacity. We demonstrate that our approach can further increase the value of last-mile delivery without incurring additional labor costs.

3 Learning from a Biased Sample

Roshni Sahoo[1], Lihua Lei[2], Stefan Wager[2], [1]Stanford University, Stanford, CA, [2]Stanford GSB, Stanford, CA

The empirical risk minimization approach to data-driven decision making assumes that we can learn a decision rule from training data drawn under the same conditions as the ones we want to deploy it in. However, we may be concerned that our training sample is biased, and that some groups may be under- or over-represented relative to the general population; and in this setting empirical risk minimization may fail to yield rules that perform well at deployment. We propose a model of sampling bias called □-biased sampling, where observed covariates can affect the probability of sample selection arbitrarily much but the amount of unexplained variation in the probability of sample selection is bounded by a constant factor. We then develop a method for learning a decision rule that minimizes the worst-case risk incurred under this model via augmented convex risk minimization.

4 Does the Seller's Response Time Affect the Buyer's Concession? Evidence from Online Bargaining

Guihua Wang[1], Wen Zhang[2], [1]The University of Texas at Dallas, RICHARDSON, TX, [2]Baylor University, Waco, TX, Contact: Wen_Zhang1@baylor.edu

In this paper, we study the effect of the seller's response time on the buyer's concession in online-marketplace bargaining. In the average treatment effect analysis, we employ an instrumental variable (IV) approach and find the seller's response time has a nonlinear effect on the buyer's concession. In the heterogeneous treatment effect analysis, we develop a multi-treatment instrumental variables forest (MT-IVF) approach that incorporates multiple treatment effects into the IV forest approach. We find the treatment effects are heterogeneous across item categories and conditions. We also find that using the thread-average best response time from the average treatment effect analysis could increase the buyer's offer price in each item category or condition, and using the thread-specific best response time from the MT-IVF can achieve additional increases.

Information, Learning and Incentive Design in Societal Scale Systems

Community Committee Choice Session

Session Chair: Manxi Wu, Cornell University, ORIE, Ithaca, NY

1 Information Design for Spatial Resource Allocation

Ozan Candogan[1], Manxi Wu[2], [1]University of Chicago, Chicago, IL, [2]Cornell University, ORIE, Ithaca, NY, Contact: manxiwu@cornell.edu

We study platforms where resources and jobs are spatially distributed, and resources have the flexibility to strategically move to different locations for better payoffs. The price of the service at each location depends on the number of resources and the market size, which is a random state. We focus on how the platform can utilize information about the underlying state to influence resource repositioning decisions and increase commission revenues. We establish that in many practically relevant settings a simple monotone partitional information mechanism is optimal. This mechanism reveals state realizations below a threshold and above a second (higher) threshold, and pools all states in between to create a unique signal. We also provide algorithmic approaches for obtaining (near-)optimal information structures that are monotone partitional in general settings.

2 Markov α-potential Games: A New Framework for Multi-agent Reinforcement Learning

Chinmay Maheshwari[1], Manxi Wu[2], Druv Pai[1], Shankar Sastry[1], Xin Guo[3], Xinyu Li[4], [1]University of California Berkeley, Berkeley, CA, [2]Cornell University, ORIE, Ithaca, NY, [3]University of California-Berkeley, Piedmont, CA, [4]UC Berkeley, Berkeley, CA, Contact: chinmay_maheshwari@berkeley.edu

We propose a new framework to study multi-agent interaction in Markov games -- Markov α-potential games. Markov potential games are special case of Markov α-potential games, so are two important and practically significant classes of games: Markov congestion games and perturbed Markov team games, which cannot be studied through existing MARL frameworks. We introduce two algorithms - the projected gradient-ascent and the sequential smoothed best response - for approximating the stationary Nash equilibrium in Markov alpha-potential games. We show that Nash-regret scales sub-linearly in time horizon. For the special case of Markov potential games, we present a independent and decentralized learning algorithm which requires minimal coordination and communication between agents, and asymptotically converges to Nash equilibrium.

3 Market Design for Dynamic Pricing and Pooling in Capacitated Networks

Saurabh Amin[1], Patrick Jaillet[1], Haripriya Pulyassary[2], Manxi Wu[2], [1]MIT, Cambridge, MA, [2]Cornell University, ORIE, Ithaca, NY, Contact: hp297@cornell.edu

We study a market mechanism that sets edge prices to incentivize strategic agents to organize trips that efficiently share limited network capacity. This market allows agents to form groups to share trips, make decisions on departure times and route choices, and make payments to cover edge prices and other costs. We develop a new approach to analyze the existence and computation of market equilibrium, using ideas from combinatorial auctions and dynamic network flows. We provide sufficient conditions on the network topology and agents' preferences that ensure the existence and polynomial-time computation of market equilibrium. We also identify a particular equilibrium that maximizes agent utilities. Finally, we extend our results to general networks with multiple populations and apply them to compute dynamic tolls for efficient carpooling in San Francisco Bay Area.

4 Capacity Allocation and Pricing of High Occupancy Toll Lane Systems with Heterogeneous Travelers

Haripriya Pulyassary[1], Ruifan Yang[1], Zhanhao Zhang[2], Manxi Wu[3], [1]Cornell University, Ithaca, NY, [2]Cornell University, Ithaca, NY, [3]Cornell University, ORIE, Ithaca, NY, Contact: zz564@cornell.edu

We study the optimal design of High Occupancy Toll (HOT) lanes. In our setup, the traffic authority determines the road capacity allocation between HOT lanes and ordinary lanes, as well as the toll price charged for travelers who use the HOT lanes but do not meet the high-occupancy eligible criteria. We build a game-theoretic model to analyze the decisions made by travelers with heterogeneous values of time and carpool disutilities, who choose between paying or forming carpools to take the HOT lanes, or taking the ordinary lanes. Travelers' payoffs depend on the congestion cost of the lane they take, the payment and the carpool disutilities. We provide a complete characterization of travelers' equilibrium strategies for any capacity allocation and toll price. Additionally, we characterize the equilibria that yield minimum total emissions or maximum revenue.

Ride-Hailing and Platform Operations

Community Committee Choice Session

Session Chair: Yuexing Li, Johns Hopkins Carey Business School, Baltimore, MD

Session Chair: Nur Sunar, UNC Kenan-Flagler Business School, Chapel Hill, NC

1 Recommender Systems Under Privacy Protection

Can Kucukgul[1], Ozalp Ozer[2], Shouqiang Wang[3], [1]Rutgers University - Camden, Philadelphia, PA, [2]Amazon, Richardson, TX, [3]The University of Texas at Dallas, Richardson, TX, Contact: can.kucukgul@rutgers.edu

The hallmark feature of digital platforms is their capability of keeping track of users' online browsing activities and using this information to personalize recommendations. Various regulations are established to grant users of these

platforms the right to privacy, i.e., they can choose whether to share their personal data with the platforms for product recommendation purposes. Using an information design framework, we study how an online platform should design its recommender policy under such regulatory provisions. We show that when the platform and users' incentives are sufficiently aligned, it is optimal for the platform to adopt a personalized recommender policy. Perhaps surprisingly, when the incentives are sufficiently misaligned, we find that the right to privacy may in fact reduce the overall user surplus.

2 Rating and Service Quality Prediction in Online Labor Markets: Models and Implications

Guanting Wu[1], Hai Wang[2], Peter Zhang[3], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Singapore Management University, Singapore, Singapore; [3]Carnegie Mellon University, Pittsburgh, PA, Contact: guantingwu@cmu.edu

Online labor markets (OLMs) are experiencing rapid growth, in which online labor platforms provide search functions that enable clients and workers to find each other. Numerical ratings for workers serve as crucial metrics of service quality, the prediction of which plays a significant role in numerous platform operation decisions. In this study, we employ a data-driven approach to predict service quality based on various features of projects, workers, and their interactions. Using a large and unique dataset from a leading online labor platform, we apply our method to gain insights into how different features influence service quality. Subsequently, we offer actionable insights for enhancing service quality in OLMs, including designing effective recommendation systems, implementing soft-skills training programs, and using project decomposition.

3 Greening Ride-Hailing: Impact on Environment and Consumers

N. Bora Keskin[1], Yuexing Li[2], Nur Sunar[3], [1]Duke University, Durham, NC, [2]Johns Hopkins Carey Business School, Baltimore, MD, [3]UNC Kenan-Flagler Business School, Chapel Hill, NC

Rapidly growing ride-hailing platforms offer customers convenience while raising concerns about their environmental impact. Many ride-hailing platforms have launched green initiatives, but their impact on the environment and customers is unclear. To our knowledge, we are the first to analyze this impact theoretically. We build a model with drivers deciding between local rides and repositioning, and we find that adding green vehicles may increase emissions and decrease the surplus of less environmentally sensitive consumers. Besides, for minimizing total emissions, the optimal price margin for green vehicles over gas-fueled ones can be positive or negative. We also study several extensions and confirm the robustness of our findings. These results emphasize the need for prudent decision-making to reduce emissions and avoid unintended consequences.

4 Courier Dedication vs. Sharing in On-Demand Delivery

Arseniy Gorbushin[1], Ming Hu[2], Yun Zhou[3], [1]Rotman School of Management, Toronto, ON, Canada; [2]University of Toronto, Minneapolis, MN, [3]McMaster University, Hamilton, ON, Canada. Contact: zhouy185@mcmaster.ca

On-demand delivery platforms have grown rapidly. To study whether courier sharing contributes to the reduction of delivery costs, we consider a spatial queueing model and compare the performance of a dedicated courier policy where couriers work for a single vendor and a sharing policy where couriers can be shared between different vendors and travel to the closest vendor. Surprisingly, we find that the dedicated policy can often perform better than the sharing one. Under the "growth target" strategy, if the market is sufficiently large, the sharing policy achieves a higher profit than the dedicated; if the market is small, the dedicated policy is more profitable. Under the "profit maximization" strategy, it is even more likely the dedicated policy is optimal: in addition to the market size condition, a high service value is required for the sharing policy to be optimal.

Control in Stochastic Processing Networks

Community Committee Choice Session

Session Chair: Mendelson Gal, Faculty of Data and Decision Sciences, Technion, Adi, Israel

1 Exponential Tail Bounds on Queue Length in Heavy Traffic

Prakirt Raj Jhunjhunwala[1], Daniela Hurtado-Lange[2], Siva Theja Maguluri[3], [1]Georgia Institute of Technology, Atlanta, GA, [2]William & Mary, Williamsburg, VA, [3]ISyE Georgia Tech, Atlanta, GA, Contact: prakirt@gatech.edu

A popular approach to computing performance measures of queueing systems (such as delay and queue length) is studying the system in an asymptotic regime. However, these results are only valid in the limit and often provide bounds for the pre-limit systems that are not optimized and, hence, give loose bounds for the tail probabilities. In this work, we provide optimized bounds for the tail probabilities of the scaled total queue length in a load-balancing system under Join the Shortest Queue (JSQ). Our bounds characterize the rate of convergence of the tail probabilities to the corresponding heavy traffic values. For the tail probability of the JSQ system, our bounds yield a multiplicative error that arises from three factors: pre-limit errors, pre-exponent errors, and State-Space Collapse (SSC) error.

2 Optimal Rate-Matrix Pruning for Large-Scale Heterogeneous Systems

Zhisheng Zhao, Debankur Mukherjee, ISyE Georgia Tech, Atlanta, GA, Contact: zzhao388@gatech.edu

We consider large-scale load balancing systems where processing time distribution of tasks depend on both task and server types. We analyze the system in the asymptotic regime where both the number of task and server types tend proportionally to infinity. In such heterogeneous setting, popular policies like JFIQ, JFSQ are known to perform poorly and they even shrink the stability region. Moreover, to the best of our knowledge, in this setup, finding a scalable policy with provable performance guarantee has been an open question prior to this work.In this paper, we propose and analyze two asymptotically delay-optimal dynamic load balancing policies. Exploiting a framework inspired by the graphon literature and using the mean-field method and stochastic coupling arguments, we prove that both policies above achieve asymptotic zero queueing.

3 Sizing and Scheduling Flexible Resources

Jinsheng Chen[1], Jing Dong[2], [1]Singapore Institute of Manufacturing Technology, Singapore, Singapore; [2]Columbia University, New York, NY, Contact: jc4823@ columbia.edu

Flexible resources are an important part of many service and manufacturing systems. In this work, we study the problem of jointly sizing and scheduling flexible resources when they may incur a higher cost or a loss of efficiency. We consider different degrees of demand uncertainty and obtain asymptotically optimal joint staffing and sizing policies.

4 A Hierarchical Approach to Robust Stability of Multiclass Queueing Networks

Feiyang Zhao[1], Itai Gurvich[2], John Hasenbein[1], [1]The University of Texas at Austin, Austin, TX, [2]Northwestern University, Kellogg School of Management, Evanston, IL, Contact: feiyang_zhao@utexas.edu

The focus of this research is on the robust stability of stochastic processing networks, under a wide class of control policies. A framework for robust stability is developed, in which the resources are given freedom to decide their own priority policy, under some general constraints. We offer a new approach for determining sufficient conditions for robust stability, which builds on, and makes connections to, suitable robust optimization problems, with the collection of priority policies as the uncertainty set. We also show how robust stability of a family of policies is inherited from the stability of some special policies, i.e., static-priority policies.

Navigating the Use of Technology in Stochastic Service Systems

Community Committee Choice Session

Session Chair: Yue Hu, University of Chicago, Chicago, IL
Session Chair: Yueyang Zhong, The University of Chicago Booth School of Business, Chicago, IL

1 Multi-Channel Healthcare Operations: The Impact of Video Visits on the Usage of In-Person Care

Tan (Suparerk) Lekwijit[1], Hummy Song[2], Christian Terwiesch[3], Krisda Chaiyachati[4], [1]W. P. Carey School of Business, Arizona State University, Tempe, AZ, [2]The Wharton School, University of Pennsylvania, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]The Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, Contact: tan.lekwijit@asu.edu

The impact of a new digital channel on care demand within existing physical channels has not been thoroughly investigated in the primary care context of a traditional healthcare organization. We study a large healthcare system that made video visits available to a subset of its patients for primary care needs and find that the introduction of video visits increases the demand for in-person PCP visits by 20% and the demand for ED visits by 30%. We also find that patients who have poorer access to in-person care are more likely to initiate care via a video visit rather than an in-person visit, and that the increase in in-person demand arises primarily from patients who live farther from their place of care and who seek an appointment with a PCP who is busier than usual. Furthermore, compared to in-person visits, we find that video visits are less likely to provide definitive care.

2 The Effects of Information on Abandonment and Congestion in Non-Stationary Priority Queues

Philipp Afèche[1], Junqi Hu[2], Rouba Ibrahim[3], Vahid Sarhangian[4], [1]University of Toronto, Toronto, ON, Canada;

[2]University of Illinois Urbana-Champaign, Champaign, IL, [3]University College London, London, United Kingdom; [4]University of Toronto, Toronto, ON, Canada. Contact: junqihu@illinois.edu

Motivated by empirical studies on the impact of information on abandonment in service systems, we study novel queueing models with abandonment rates that depend on the system state, customers' consumed waiting time, and the granularity of customers' state information.
We provide insights on the effects of information on the average queue length and abandonment rate, and how these effects depend on time-varying arrivals and priority service.

3 AI and Incentives and Agency, Oh My! Incentive Design in the Age of Generative Artificial Intelligence

Tinglong Dai[1], Terry Taylor[2], [1]Johns Hopkins University, Baltimore, MD, [2]U.C. Berkeley, Berkeley, CA, Contact: dai@jhu.edu

The advent of generative artificial intelligence (AI) has significant transformative implications for autonomous work ecosystems, where the client's visibility into the contractor's efforts and instrumental choices is minimal. This paper proposes a theoretical framework to capture the impact of generative AI on incentive design, and extrapolates scenarios in which a client may seek to limit the contractor's AI toolbox options. It also discusses scenarios in which generative AI could potentially mitigate traditional principal-agent challenges, thereby facilitating welfare enhancement.

4 Is Telemedicine Here to Stay? Equilibrium Analysis of an Outpatient Care Queueing Game

Xiaole (Alyssa) Liu, Mor Armony, New York University Stern School of Business, New York, NY, Contact: xiaole.liu@stern.nyu.edu

Current trends suggest that telemedicine will continue to play a key role in post-pandemic care delivery. As observed in some empirical studies, however, the use of telemedicine can trigger more demand for in-person visits and overcrowd the clinic. We develop a queueing game model to assess the impact of telemedicine in equilibrium. Analyzing this model allows us to characterize the optimal resource allocation for outpatient clinic and characterize the conditions under which introducing telemedicine is beneficial.

Community Detection in Networks

Community Committee Choice Session

Session Chair: Anirudh Sridhar, Princeton University, Issaquah, WA

1 Community Detection with Censoring

Souvik Dhara, Brown University, Providence, RI

Recovering latent communities is a key unsupervised learning task in network data with applications spanning across a multitude of disciplines. For example, identifying communities in web pages can lead to faster search, classifying regions of the human brain in communities can be used to predict onset of psychosis, and identifying communities of assets can help investors manage risk by investing in different communities of assets. However, the scale of these massive networks has become so large that it is often impossible to work with the entire network data. In this talk, I will talk about some theoretical progress for community detection in a probabilistic set up especially when we have missing data about the network. Based on joint works with Julia Gaudio, Elchanan Mossel and Colin Sandon.

2 Fundamental Limits of Spectral Clustering in Stochastic Block Models

Anderson Ye Zhang, University of Pennsylvania, Philadelphia, PA, Contact: ayz@wharton.upenn.edu

We give a precise characterization of the performance of spectral clustering for community detection under Stochastic Block Models by carrying out sharp statistical analysis. We show spectral clustering has an exponentially small error with matching upper and lower bounds that have the same exponent, including the sharp leading constant. The fundamental limits established for the spectral clustering hold for networks with multiple and imbalanced communities and sparse networks with degrees far smaller than $\log n$. The key to our results is a novel truncated ℓ_2 perturbation analysis for eigenvectors and a new analysis idea of eigenvectors truncation.

3 Graph Matching and Robust Community Recovery in Correlated Stochastic Block Models

Anirudh Sridhar, Princeton University, Princeton, NJ

We consider the problem of learning latent community structure from multiple edge-correlated stochastic block models (SBMs). We show that community recovery from a single graph can be improved by combining the correlated networks via an appropriate graph matching algorithm and applying a *robust* community recovery algorithm to the synthesized network. In the case where the average degree of the correlated stochastic block models is constant with respect to the number of vertices, we show that community detection beyond the Kesten-Stigum threshold for single graphs is possible. When the average degree is slowly growing in the number of vertices, graph matching followed by robust community recovery attains the optimal error rate for community recovery. This is based on joint work with Julia Gaudio and Miklós Rácz.

4 Differentially Private Community Detection in Networks: Algorithms and Fundamental Limits

Mohamed Mohamed, Andrea Goldsmith, H. Vincent Poor, Princeton University, Princeton, NJ, Contact: mseif@princeton.edu

Community detection is a fundamental problem arising in graph mining and machine learning. The goal of community detection over graphs is to recover underlying labels/attributes of users (e.g., political affiliation) given the connectivity information between users. There has been significant recent progress on understanding the fundamental limits of community detection when the graph is generated from a stochastic block model (SBM). In this talk, we will present some of our recent work on differentially private (DP) community detection for SBM. Focusing on edge-differential privacy, we will present results that highlight fundamental tradeoffs between SBM parameters, privacy budget and computational efficiency and their impact on community recovery. If time permits, I will conclude with several open problems and challenges in this topic.

Simulation Flash Talks

Flash Session

Session Chair: Enlu Zhou, ISyE Georgia Tech, Atlanta, GA

1 Does Regret-Based Dro Minimize Regret?

Arindam Roy Chowdhury, Columbia University, New York, NY, Contact: ar4445@columbia.edu

Distributionally Robust Optimization (DRO) is a popular methodology for decision-making under uncertainty that advocates minimizing the worst-case loss. While it advantageously provides protection on the attained objective value, it does not guarantee a good performance regarding the regret, or equivalently the optimality gap with respect to the oracle true solution. To this end, one could formulate the protection on the worst-case regret, giving rise to the so-called regret-based DRO (R-DRO). We show that, in terms of local behavior, R-DRO could not outperform even simple empirical optimization in terms of regret both from a statistical view when data are i.i.d., and a robust view when distribution shift is present. Our assertions appear to be in complete contrast to the natural belief on the advantage of R-DRO.

2 Data-Driven Ranking and Selection

Enlu Zhou, ISyE Georgia Tech, Atlanta, GA

We consider ranking and selection with streaming input data, which arrive in batches, possibly of varying sizes, sequentially over time. We develop a sequential elimination framework for the fixed confidence setting, where the goal is to achieve a specified probability of correct selection (PCS) with as few simulation replications as possible. We also develop procedures based on optimal computing budget allocation for the fixed budget setting, where the goal is to achieve a PCS as high as possible with a given simulation budget.

3 Actively Learning a Bayesian Matrix Fusion Model with Deep Side Information

Yangyang Yu, Stevens Institute of Technology, Hoboken, NJ, Contact: yyu44@stevens.edu

High-dimensional deep network representations of images and concepts can be aligned to predict human annotations of diverse stimuli. However, such alignment requires the costly collection of behavioral responses, such that, in practice, the deep-feature spaces are only sparsely sampled. Here, we propose an active learning approach adaptively sampling experimental stimuli to efficiently learn a Bayesian matrix factorization model with deep side information. We observe a significant efficiency gain over a passive baseline. Moreover, with a sequential batched sampling strategy, the algorithm is applicable not only to small datasets collected from traditional laboratory experiments but to settings where large-scale crowdsourced data collection is needed to accurately align the high-dimensional deep feature representations derived from pre-trained networks.

4 Flash Paper Submission (5-Minute Presentation)

Haoting Zhang, University of California, Berkeley, Berkeley, CA, Contact: haoting_zhang@berkeley.edu

Contextual Bayesian optimization problems have extensive applications such as healthcare and autonomous vehicles, where the core challenge is to select a suitable surrogate model for unknown objective functions. In this work, we propose a neural network-accompanied Gaussian process (NN-AGP) model, which leverages neural networks to approximate the unknown objective function regarding contextual variables, and maintains a Gaussian process with the decision variable. Our model outperforms existing approaches by offering better approximation accuracy thanks to the neural networks and possessing explicit uncertainty quantification from the Gaussian process. We prove the regret bounds for the optimization algorithm associated with our model. We also conduct experiments on both synthetic and real problems, demonstrating the effectiveness of our approach.

5 Flash Paper Submission (5-Minute Presentation)

Dilara Aykanat[1], Nian Si[2], Zeyu Zheng[3], [1]University of California at Berkeley, Berkeley, CA, [2]The University of Chicago Booth School of Business, Chicago, IL, [3]University of California, Berkeley, Berkeley, CA

One approach to construct or calibrate simulators, when representative real data exist, is to ensure that the synthetic data generated by the simulated match the empirical distribution of the real data. However, such approach to construct simulators does not take into consideration where the constructed simulators will be used. For some applications, there are clear tasks (such as performance evaluation of different decisions) in users' mind where the simulated data will serve as input to the tasks. In this work, we propose an approach to use the knowledge of these tasks to guide the construction of simulators, in addition to the distribution match of simulated data and real data. We conduct a preliminary numerical study of this approach to illustrate the effectiveness compared to not taking into consideration the specific tasks of the simulators.

6 Parameter Optimization with Conscious Allocation (POCA)

Joshua Inman, Arizona State University

The performance of machine learning algorithms depends upon the selection of a set of hyperparameters. Independently from the specific ML model, the budget used to evaluate potential hyperparameter configurations is a critical decision to the performance of a hyperparameter optimization algorithm. Here, we introduce a hyperparameter optimization algorithm, Parameter Optimization with Conscious Allocation (POCA), that focuses on how the overall budget is allocated to hyperparameter configurations and on how the data collected are used to update the posterior distribution to select novel configurations. We introduce the algorithm and compare POCA to its nearest competitor at optimizing the hyperparameters of an artificial toy function and a convolutional neural network, finding that POCA discovers strong configurations faster in both settings.

Districting for Modern Service Systems

Community Committee Choice Session

Session Chair: Yao Xie, Georgia Institute of Technology, Atlanta, GA

Session Chair: Woody Zhu, Carnegie Mellon University, Pittsburgh, PA

1 Generalized Hypercube Queuing Models with Overlapping Service Regions

Shixiang Zhu[1], Yao Xie[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Carnegie Mellon University, Atlanta, GA

We present a generalized hypercube queue model, building upon the original model by Larson, with a particular focus on its application to overlapping service regions such as police beats. The traditional hypercube queue model is constrained to light-traffic operations, where officers are either ``busy'' or ``not busy''. However, contemporary service operations often experience saturation, necessitating the inclusion of heavy-traffic operations with queue lengths greater than one. The motivation to address the heavy-traffic regime stems from the increased workload and staff shortages prevalent in modern service systems. The design of overlapping regions is inspired by boundary effects in crime incidents, which require overlapping patrol regions for efficient resource allocation. Our proposed model addresses these issues using a Markov model with a large state space represented by integer-valued vectors. By leveraging the sparsity structure of the transition matrix, where transitions occur between states whose vectors differ by 1 in the ℓ distance, we can accurately solve the steady-state distribution of states. This solution can then be used to evaluate general performance metrics for the service system. We demonstrate the reasonable accuracy of our model through simulation.

2 A Comparative Analysis of School District Design Formulations

Aysu Ozel, Karen Smilowitz, Northwestern University, Evanston, IL, Contact: AysuOzel2025@u.northwestern.edu

We revisit the school districting problem, introducing a stream-based approach that incorporates multiple assignment decisions simultaneously. This leads to a compact formulation building on advances in the literature and extending the capabilities of such models. We create benchmark school districts that represent the range of public school districts throughout the U.S. and compare the performances of the existing formulations and the stream-based formulation.

3 Heterogeneous Multi-Agent Reinforcement Learning for Joint Patrol and Dispatch

Matthew Repasky, He Wang, Yao Xie, Georgia Institute of Technology, Atlanta, GA, Contact: mwrepasky@gatech.edu

Multi-agent patrol is concerned with learning the policies of a group of patrollers, often employing methods such as reinforcement learning. A separate but related problem is the dispatch of spatially-distributed servers, which has mostly been studied in the context of police operations from the perspective of multi-server priority queues. Such works often use rudimentary patrol policies paired with dispatch. We propose a method to jointly optimize multi-agent patrol and dispatch and learn policies yielding rapid response times. We exploit similarity in patrol policies by treating the patrollers as independent Q-learners with a shared deep Q network. The dispatcher uses mixed-integer programming to select actions from a combinatorial action space. This approach is capable of learning joint policies which outperform those optimized for patrol or dispatch alone.

4 Districting With Overlapping Service Regions

Wenqian Xing[1], Shixiang Zhu[2], [1]Stanford University, Palo Alto, CA, [2]Carnegie Mellon University, Pittsburgh, PA, Contact: wxing@stanford.edu

Districting is a crucial problem for modern service systems, such as transportation, healthcare, and emergency response. The goal is to partition a geographical region into districts to provide efficient and effective services to the population. However, traditional non-overlapping districting schemes may suffer from inefficient service delivery when the demand is not evenly distributed across the district. In this talk, we highlight the importance of overlapping districting, which allows for a more flexible and responsive allocation of resources based on the actual service demand. We investigate heuristic algorithms and Bayesian optimization to address the overlapping districting problem under realistic constraints. We hope our research could raise awareness of overlapping districting and stimulate novel research in the modern world.

5 Demand Learning and Supply Optimization of Last-Mile Transportation Services

Yidi Miao, Peter Zhang, Carnegie Mellon University, Pittsburgh, PA

We consider the problem of designing service modes facing the unknown and evolving travel demands for a non-profit mobility provider. Firstly we learn from the past data to capture the underlying evolving travel demands; then we incorporate the forecasted demand ambiguity set into our distributionally robust optimziation models for different service modes, and determine the worst demand distribution; finally we adopt heuristics and numerical experiments to propose districting decisions for the service modes to encounter the worst scenarios. Through this research, we aim to enable the provider to adapt their service modes to unknown and evolving demands. By leveraging various methods, we enhance the provider's ability to anticipate, respond to, and effectively serve the dynamic mobility needs, and hence improve the equity of transportation resource allocations.

6 Data-Driven Optimization for Police Staffing Schedule

Weiqing Xu, Georgia Institute of Technology, Atlanta, GA

We present a data-driven optimization framework to determine the police staffing schedule in Atlanta, in a way that maximizes resource use while minimizing incident response time. We particularly focus on floating "umbrella" units that cover multiple police beats. Using 911 call data from the Atlanta Police Department, we estimate travel time between patrol units and incident locations. We then develop a two-stage stochastic optimization formulation of the staffing problem, where staffing decisions are made in the first stage and dispatch decisions in the second stage.

Emerging Topics in Social Operations Management

Community Committee Choice Session

Session Chair: Junhao Vincent Yu, Miami University, Oxford, OH

Session Chair: Tim Kraft, NC State - Poole College of Management, Raleigh, NC

1 The Effects of CSR Performance and Price on Consumer Purchase Decisions: A Moderated Mediation Analysis

Junhao Vincent Yu[1], Tim Kraft[2], Robert Handfield[2], Rejaul Hasan[2], Marguerite Moore[2], [1]Miami University, Oxford, OH, [2]NC State University, Raleigh, NC

We use controlled experiments in an online purchase context to examine how consumers' willingness to buy is influenced by a retailer's disclosure of a manufacturer's CSR performance. We show that disclosing CSR performance is more challenging (and potentially riskier) with consumers who typically pay a higher price.

2 Examining Sustainability as a Service Model in Retail

Huseyn Abdulla[1], Seulchan Lee[2], Hankyul Oh[3], [1]University of Tennessee, Knoxville, TN, [2]Michigan Technological University, Houghton, MI, [3]Tilburg University, Utrecht, Netherlands. Contact: slee12@mtu.edu

As the pressure from investors, government institutions, and consumers on firms to improve environmental sustainability performance increases, new business models emerge to facilitate the firms' sustainability efforts while generating profit. One such model, Sustainability as a Service (SaaS), helps retailers offset emissions from the delivery and return shipments of online orders in real time by offering a "green shipment" option to consumers for a fee. In this paper, we analytically examine this new business model in the context of an online retailer who has made a sustainability commitment to become carbon neutral and a SaaS provider.

Assortment Planning

Contributed Session

Session Chair: Young-San Lin, Melbourne Business School, Carlton, Australia

1 Assortment Planning Under History-Dependent Utility

Yating Zhang, Taotao He, Huan Zheng, Shanghai Jiao Tong University, Shanghai, China. Contact: ytzhang20@sjtu.edu.cn

This paper studies a multiperiod assortment planning problem where consumers' utility depends on previous assortments. For instance, repeated exposure to the same product satiates consumers. We formulate this problem as a large-scale integer programming model involving a nonlinear history-dependent utility function. We show that a cyclic policy is asymptotically optimal. In the non-asymptotical regime, we characterize the envelope of the history-dependent utility function to obtain a strong integer programming formulation. A case study on a catering service dataset shows our model has good fitness and potentially increases revenue.

2 Seasonal Assortment and Allocation Planning at Target

Timothy Murray, Shobhit Jain, Target Corporation, Minneapolis, MN, Contact: shobhit.jain@target.com

As a Fortune 50 company and one of America's 10 largest retailers, the Target Corporation has a complex supply chain with a wide range of product offerings. In this talk we discuss how Target makes decisions for seasonal assortment and allocation planning related to our in-store apparel items. The problem is first formalized as a non-convex Bilinear Integer Program before we explore our solution method, which follows a pattern of initialization, solution iteration, and final greedy heuristic improvements.

3 In-Store Product Planning of Multichannel Retailer with Product-Fit Uncertainty and Competition

Raunak Joshi[1], Sumanta Basu[2], Balram Avittathur[2], Sreelata Jonnalagedda[3], [1]O.P. Jindal Global University, Delhi, India; [2]Indian Institute of Management Calcutta, Kolkata, India; [3]Indian Institute of Management-Bangalore, Bangalore, India

We address the problem of in-store assortment planning, service level determination and pricing when the product-fit is uncertain, and the multichannel retailer faces competition. The consumers decide whether to purchase based on online information or visit the store for verification, with uncertain product availability in store.

4 Pricing and Convenience Consideration in Omnichannel Assortment Planning

Joshua Gladstone[1], Ahmed Ghoniem[2], Bacel Maddah[3], [1]University of Massachusetts Amherst, Amherst, MA, [2]Isenberg School of Management, UMass Amherst, Amherst, MA, [3]American University of Beirut, Beirut, Lebanon. Contact: jdgladstone@umass.edu

We address the problem of assortment planning and pricing optimization for omnichannel grocery retailers. In the proposed mixed-integer nonlinear program, the decision-maker jointly optimizes channel assortments and prices, endogenously driven by consumer price and convenience preferences, while accounting for limited brick-and-mortar shelf space. Linearizing our model enables computational analysis and provides managerial insights for optimizing online and in-store product lines.

5 Assortment Optimization with Customer Information Exploration

Young-San Lin[1], YALCIN AKCAY[2], Gerardo Berbeglia[3], [1]Melbourne Business School, Carlton, Australia; [2]MBS, CARLTON, Australia; [3]Melbourne Business School - Centre for Business Analytics, carlton, Australia. Contact: nilnamuh@gmail.com

We introduce a general assortment optimization problem for the Random Utility Model (RUM) when the seller is inattentive to the customer's utility. The firm strives to maximize its objective, the expected revenue deducted by an entropy-based information processing cost.
Our framework is based on the seminal work of Matejka and Mckay (American Economic Review, 2015). Towards the extremals, our model captures the traditional assortment optimization problem when processing information is expensive, and the scenario that the seller is clairvoyant when processing information is free.
We present structural results for specific RUMs. There is a closed-form optimal seller solution with two products. For Multinomial Logit, a mixed strategy on revenue-ordered offer sets might not be optimal. With two or three revenue values, the problem can be reduced by an aggregate property.

Optimization Approaches to Modeling Fairness

Community Committee Choice Session

Session Chair: David B. Shmoys, Cornell University, Ithaca, NY

1 Bicriteria Approximation Algorithms for Priority Matroid Median

Tanvi Bajpai, Chandra Chekuri, University of Illinois at Urbana-Champaign, Urbana, IL, Contact: tbajpai2@illinois.edu

Fairness considerations have motivated new clustering problems and algorithms in recent years. In this talk we consider clustering under the Priority model, which recently resurfaced as a means of creating clusterings with individual fairness. In this model, the clustering is required to ensure that no individual travels farther than their desired radius (given as part of the input specification). In previous work we gave algorithms for Priority Supplier problems with outliers. We now study the Priority Matroid Median problem, a generalization of the recently studied Priority k-Median problem. We obtain the first bicriteria approximation algorithms for this problem, and obtain improved bounds for the special case of uniform radii. We explore various cost and fairness tradeoffs that can be accomplished via our algorithm, and discuss avenues for further study.

2 Fair Submodular Maximization

Ashkan Norouzi Fard, Google Research, Zurich, Switzerland. Contact: ashkannorouzi@google.com

Recent studies have shown that automated data-driven methods can have unintended biases and discriminatory effects. Our proposed algorithms aim to prevent these issues in applications which can be modeled as a submodular maximization over a cardinality or matroid constraint problem. Such applications arise in a variety of contexts, including selection of political representatives, committees, candidates for outreach programs, and content selection for search engines and news feeds.

3 Fair Joint Replenishment with Bounded Outliers

Varun Suriyanarayana[1], Varun Sivashankar[2], Siddharth Gollapudi[2], David B. Shmoys[3], [1]Cornell University, Ithaca, NY, [2]Microsoft Research, Bengaluru, India; [3]Cornell University, Ithaca, NY, Contact: vs478@cornell.edu

The joint replenishment problem (JRP) is a classical inventory management problem. We consider a natural generalization with outliers,where we are allowed to reject (that is, not service) a subset of demand points. In this paper, we are motivated by issues of fairness - if we do not serve all of the demands, we wish to ``spread out the pain'' in a balanced way among customers, communities, or any specified market segmentation.One approach is to constrain the rejections allowed, and to have separate bounds for each given customer. In our most general setting, we consider a set of C features, where each demand point has an associated rejection cost for each feature, and we have a given bound on the allowed rejection cost incurred in total for each feature. This generalizes a model of fairness introduced in earlier work on the Colorful $k-$Center problem in which (analogously) each demand point has a given color, and we bound the number of rejections of each color class. In the JRP, we seek to balance the cost incurred by a fixed ordering overhead with the cost of maintaining on-hand inventory over a longer period in advance of when it is needed. More precisely, there a given set of item types, for which there is specified demand over a finite, discrete-time horizon, and placing any order at a given time incurs a general ordering cost and item-specific ordering costs (independent of the total demand serviced); in addition, for each unit of demand held in inventory for an interval of time, there is a corresponding item-specific holding cost incurred; the aim is to minimize the total cost.
We give the first constant approximation algorithms for the fairness-constrained JRP with a constant number of features; specifically, we give a 2.86-approximation algorithm in this case. Even for the special case in which we bound the total (weighted) number of outliers, this performance guarantee improves upon bounds previously known for this case. Our approach is an LP-based algorithm that splits the instance

into two subinstances. One is solved by a novel iterative rounding approach and the other by pipage-based rounding. The standard LP relaxation has an unbounded integrality gap, and hence another key element of our algorithm is to strengthen the relaxation by correctly guessing key attributes of the optimal solution, which are sufficiently concise, so that we can enumerate over all possible guesses in polynomial time - albeit exponential in C, the number of features.

4 Fairness in Algorithmic Combinatorial Optimization

Aravind Srinivasan, University of Maryland, College Park, MD

We discuss a family of approaches to provable fairness in combinatorial optimization, with an emphasis on clustering problems. One primary idea here is to let randomization be an inherent part of the algorithm, and to develop efficient randomized algorithms that satisfy a traditional global objective (such as the maximum cluster radius in k-center clustering) and deliver probabilistic per-user or per-demographic-group guarantees for the quality of service obtained. This talk will present joint work with several colleagues who will be acknowledged in the presentation.

Behavioral Aspects in Humanitarian, Non-profit and Retail Operations with Societal Impact

Community Committee Choice Session

Session Chair: Pelin Pekgun, University of South Carolina, Columbia, SC

1 Volunteering Experience and Monetary Donation

Mahyar Eftekhar, Chao Wu, Arizona State University, Tempe, AZ, Contact: eftekhar@asu.edu

Charities are cautioned against providing volunteer opportunities to potential donors because volunteers are considered as unreliable source of labor supply, and volunteering is assumed to crowd out monetary donation. In this study, we examine the causal relationship between individuals' volunteering and their subsequent donation decisions through two sets of experiments.

2 Balancing Act: How Nonprofit Organizations Can use Cause Marketing for Effective Fundraising

Vinit Tipnis[1], Sebastian Villa[2], fei gao[3], Alfonso J. Pedraza-Martinez[4], [1]Kelley School of Business, Indiana University Bloomington, Bloomington, IN, [2]University of New Mexico, Albuquerque, NM, [3]Indiana University Bloomington, Bloomington, IN, [4]Indiana University, Bloomington, IN, Contact: svillab@unm.edu

In cause marketing campaigns, firms donate a percentage of their sales revenue to partnering non-governmental organizations as a strategy to increase sales. We investigate how and when earmarked (i.e., restricted) and flexible (i.e., unrestricted) donations affect consumers' purchase intent. Our study provides clear recommendations both to firms and NGOs.

3 Enhancing Fundraising Productivity Through Strategic Staffing and Revenue Diversification Decisions: Evidence from Food Banks

Yingru Han, Luv Sharma, Pelin Pekgun, University of South Carolina, Columbia, SC, Contact: yingru.han@grad.moore.sc.edu

Food banks, a major solution to close this gap between food supply and demand and relieve hunger, are non-profit organizations that rely on fundraising to support operations. The success of fundraising, a labor-intensive process, relies heavily on staffing strategies and how to allocate them to different fundraising tasks. We use data from 105 food banks within Feeding America to better understand the role of staffing levels and revenue concentration levels on fundraising productivity. We also study the moderating roles of passive vs active solicitation methods as well as team composition in the above relationships.

4 Food Surplus Management: A Global Perspective

Arzum E. Akkas, Boston University, Boston, MA

In this study, we explain varying approaches to grocery retailers' management of food surplus. Through two round interviews with 20 retailers from the US, UK, European Union, Africa, and Australia, we identify how practices related to food repurposing, markdowns, donations, composting and anaerobic digestion vary across different geographies.

Data-driven Decision Making in Healthcare

Community Committee Choice Session

Session Chair: Maria Esther Mayorga, North Carolina State

University, Raleigh, NC
Session Chair: Erik Rosenstrom, North Carolina State University, Raleigh, NC

1 Interpretable Predictions for Unplanned Hospitalization of Urinary Tract Infection

Nasrin Alizadeh, Kimia Vahdat, Osman Ozaltin, Sara Shashaani, Julie L. Swann, North Carolina State University, Raleigh, NC

This research introduces two risk scores for predicting unplanned hospitalizations due to urinary tract infections. These scores were trained and tested on elderly patients aged 65 years and above using data from the Centers for Medicare and Medicaid Services. Both approaches utilize logistic regression models, but they differ in terms of coefficient scaling. The strengths and weaknesses of each score are thoroughly discussed. Furthermore, the study demonstrates how these scores offer insights into the significant features and their impacts on the risk of unplanned hospitalization for urinary tract infections.

2 Identifying Clinical Characteristics of Patients at Risk of Cardiovascular Events with Prescription Stimulants Use: A Machine Learning Approach

Yifang Yan[1], Qiushi Chen[1], Wen-Jan Tuan[2], Paul Griffin[1], [1]The Pennsylvania State University, University Park, PA, [2]The Pennsylvania State University, Hershey, PA, Contact: yvy5478@psu.edu

With the rapidly growing use of prescription stimulants in the US, concerns have been raised about major adverse cardiovascular events (MACEs) as side effects associated with the use of prescription stimulants. However, there is a lack of research in predicting the risk of MACEs with stimulants use and identifying the characteristics of the patients who are more adversely affected by stimulants use. To fill the gap, we first developed machine learning models to predict MACEs based on individual's stimulants use, demographics, and comorbidities using large real-world health records data. We computed the added risk of MACEs when using prescription stimulants for each patient and applied Association Rule Mining approach to characterize the comorbidity profiles of patients with higher added risk, which were further validated with an independent set of data.

3 Hybridized Genetic Algorithm to Solve Large Multi-Model Markov Decision Process Problems for Sepsis Treatment

Erik Rosenstrom[1], Julie Simmons Ivy[2], [1]North Carolina State University, Raleigh, NC, [2]University of Michigan, Ann Arbor, MI, Contact: erosens@ncsu.edu

The multi-model Markov decision process (MMDP) extends the traditional Markov decision process (MDP) to account for uncertainty. This combinatorial optimization problem is NP-hard. Most existing solution methods are exact and thus do not scale well to large problems. The success of a local search heuristic (LSH) motivates the exploration of other metaheuristic methods to solve large instances. We adapted the genetic algorithm (GA) to solve infinite horizon MMDP problems. Additionally, we hybridize the GA and the LSH. Experiments are conducted comparing the metaheuristics' performance with the extensive form MILP solver, the local search heuristic and random search. Study of the computation time indicates that metaheuristics become more computationally efficient than LSH as the number of actions or states increases without degradation in performance.

International Healthcare
Community Committee Choice Session
Session Chair: Kraig Delana, University of Oregon, Eugene, OR

1 Cost-Effectiveness of Seroprevalence Based Covid-19 Vaccination Strategies in India

Sripad K. Devalkar[1], Sarang Deo[1], Abhishek Reddy[1], Nimalan Arinaminpathy[2], Sandip Mandal[3], Hiral Shah[4], [1]Indian School of Business, Hyderabad, India; [2]Imperial College London, London, United Kingdom; [3]ICMR, New Delhi, India; [4]GSK, London, United Kingdom. Contact: sripad_devalkar@isb.edu

Identifying and prioritising vaccination strategies based on cost-effectiveness evidence can aid in understanding how to allocate limited supply and resources in the face of heterogeneity and uncertainty in the transmission of a pandemic. In this work, we use COVID-19 as the context to determine the cost-effectiveness of seroprevalence-based vaccination strategies by combining epidemiological and supply chain modeling. We develop a supply chain model based on the resources available to support COVID-19 vaccination and determine the appropriate allocation of these resources to support differentseroprevalence-based vaccination strategies to estimate the cost of vaccine administration. We use an epidemiological model of transmission dynamics to determine health outcomes for the vaccination strategies and estimate their cost-effectiveness.

2 International Vaccine Allocation: An Optimization Framework

Michael H. Veatch[1], Susan E. Martonosi[2], [1]Gordon College, Wenham, MA, [2]Harvey Mudd College, Claremont, CA

In addition to the moral issues, vaccine nationalism during a pandemic could contribute to new variants of the virus. Assuming that variants are more likely to emerge among the unvaccinated in low-income countries, we identify scenarios where donating vaccines before distributing them locally can reduce donor country deaths. An epidemiological model based on COVID-19 is embedded in an optimization framework. We find that vaccine distribution is not a zero-sum game between donor and nondonor countries: changing the objective function can achieve dramatic reduction in total deaths with only a small increase in donor-country deaths.

3 Last-Mile Strategies for Delivery of Health Interventions in Sub-Saharan Africa

Robert Montgomery, Baris Ata, University of Chicago, Chicago, IL, Contact: rmontgo0@chicagobooth.edu

We study the inventory management of medical products in two settings. We examine the last-mile supply chain for malaria vector controls in villages in the Democratic Republic of the Congo, and the distribution of Integrated Community Case Management (iCCM) medications between central locations and community care providers in Liberia. Our models attempt to minimize system costs by strategically distributing treatments between health facilities and households while accounting for the frequent disruptions encountered while operating in these unstable contexts.

4 Multichannel Delivery in Healthcare: The Impact of Telemedicine Centers in Southern India

Kraig Delana[1], Sarang Deo[2], Kamalini Ramdas[3], Ganesh-Babu Subburaman[4], Thulasiraj Ravilla[4], [1]IE Business School, Madrid, Spain; [2]Indian School of Business, Hyderabad, India; [3]London Business School, London, United Kingdom; [4]Aravind Eye Care System, Madurai, India

We empirically study the impact of rural telemedicine centers on patients' access, outcomes, and costs at the Aravind Eye Care System in Southern India. Using a quazi-experimental difference-in-differences approach, we find that telemedicine centers increase visit rates 30%, of which 60% is driven by new patients, demonstrating improved patient access. Telemedicine centers also increase the prescription rate for glasses by 18.5% while decreasing travel costs for patients by 30%. The findings show telemedicine centers are effective in providing healthcare to rural communities of developing countries.

Optimal Resource Allocation in Healthcare Operations

Community Committee Choice Session

Session Chair: Vahid Sarhangian, University of Toronto, Toronto, ON, Canada

1 Implementation of Interpretable Placement Decision Support in Community Corrections

Xiaoquan Gao, Griffin Carter, Pengyi Shi, Nicole Adams, Purdue University, West Lafayette, IN, Contact: shi178@purdue.edu

The incarceration population in the U.S. has grown significantly over the past three decades, and there is a pressing need to resolve the overcrowding issue. One viable approach is to divert individuals from jail to community corrections (CC). However, simply sending all eligible individuals to CC may shift the crowding from jail to CC and cause negative societal consequences. Therefore, analytics-informed decision support is essential to help determine the priority on whom to divert to CC while taking into account various system- and individual-level factors that are balanced against intricate tradeoffs. We collaborate with our community partner to co-develop and implement an interpretable analytics-enabled decision support tool that combines theoretical advancement with tangible impact.

2 Location-Allocation of Emergency Service Systems in Light Traffic: Application to Lift-Trap Rescue

Xin Wang[1], Weiliang Liu[2], Zhisheng Ye[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: xinwang99@u.nus.edu

This study investigates the location-allocation problem for emergency service systems (ESSs) in light traffic conditions. Given the time sensitivity, the performance metric for an ESS location-allocation problem is usually a function of response time for emergency calls. The complex response time distribution for queued emergency calls makes computing performance metrics challenging, resulting in intractable optimization. To address this, we examine the asymptotic behavior of spatial queuing systems and derive a closed-form approximation for performance metrics under light traffic.

We then apply this approximation to two ESS schemes, demonstrating significant reductions in coverage loss using real lift-trap rescue data from Singapore.

3 Vaccination for Endemic Diseases: Optimal Allocation of Initial and Booster Vaccine Doses

Isabelle Jueli Rao, Margaret L. Brandeau, Stanford University, Stanford, CA, Contact: isarao@stanford.edu

For some communicable endemic diseases such as COVID-19, vaccination is an effective means of control but must be augmented with booster doses due to waning immunity from vaccination. We consider an SIS model with interacting population groups, an allocation over time of limited vaccines (initial and booster doses), and four objectives: minimize new infections, deaths, life years lost, and quality-adjusted life years lost due to death. We develop intuitive analytical solutions by approximating epidemic dynamics. We then extend the analysis to the case of an SEIS model. In both cases vaccines are allocated as much as possible to groups in order of priority until no vaccines remain. Numerical simulations show that our method achieves near-optimal results and outperforms simple allocation rules. Our unique model provides interpretability while still being accurate.

4 Individualized Dynamic Patient Monitoring Under Alarm Fatigue

Hossein Piri[1], Tim Huh[2], Steven Shechter[3], Darren Hudson[4], [1]Haskayen School of Business-University of Calgary, Calgary, AB, Canada; [2]University of British Columbia, Vancovuer, BC, Canada; [3]University of British Columbia, Vancouver, BC, Canada; [4]Department of Critical Care Medicine, University of Alberta, Edmonton, AB, Canada. Contact: hossein.piri@ucalgary.ca

Hospitals are rife with alarms, many of which are false. This leads to alarm fatigue, in which clinicians become desensitized and may inadvertently ignore real threats. We develop a partially observable Markov decision process model for recommending dynamic, patient-specific alarms in which we incorporate a cry-wolf feedback loop of repeated false alarms. Our model takes into account patient heterogeneity in safety limits for vital signs and learns a patient's safety limits by performing Bayesian updates during a patient's hospital stay. We develop structural results of the optimal policy and perform a numerical case study based on clinical data from an intensive care unit.We find that compared with current approaches of setting patients' alarms, our dynamic patient-centered model significantly reduces the risk of patient harm.

Innovations in Healthcare Operations for Improved Patient Outcomes

Community Committee Choice Session

Session Chair: Kejia Hu, Vanderbilt University

Session Chair: Zhenzhen Jia, Shanghai, China

1 Will Centralized Procurement of Drugs Reduce the Innovation Investment of Enterprises? Observations from the Chinese Pharmaceutical Industry

Kang Sun[1], Kejia Hu[2], Hongmin Li[3], Xiande Zhao[4], [1]Shanghai Jiao Tong University, Shanghai, China; [2]Vanderbilt University, Nashville, TN, [3]Arizona State University, Tempe, AZ, [4]China Europe International Business School, Shanghai, China

OM-public-policy is a cutting-edge area of operations management research. Major public policies of-ten have a significant impact on business operations. Yet there is a lack of focused research in this area. We hand-curated a database of 500 pharmaceutical companies against the backdrop of the Centralized Procurement of Drugs policy being implemented in China's pharmaceutical industry. Based on this, we analyze the impact of the Centralized Procurement of Drugs policy on firms' R&D investment and the moderating effects of organizational slack and generic R&D intensity. Based on new institutional theory, it is proposed that the Centralized Procurement of Drugs policy can act as a market-based coercive pressure from the government. Our study finds that the Centralized Procurement of Drugs policy does not have a significant effect on firms' R&D investment in generic drugs and R&D investment in innovative drugs. We also find that the effect of the Centralized Procurement of Drugs policy on firms' R&D investment is moderated by organizational slackness and generic R&D intensity. Specifically, firms with higher organization slackness have no significant impact on generic R&D investment after centralized procurement, and R&D investment in innovative drugs decreases. Firms with stronger generic R&D intensity will see an increase in generic R&D investment and an increase in innovative R&D investment after centralized procurement. The Centralized Procurement of Drugs policy does not have a significant impact on firms' R&D investment in general. This is because firms' behavioral choices in the face of market-based coercive pressures are multiple, creating a neutralizing effect in the aggregate. The heterogeneous effects of centralized drug purchasing policies through organizational slack and generic R&D intensity can provide insights into the different response behaviors of firms in the face of market-based coercive pressures, which are moderated by the resource base of the organization.

2 Simultaneous Imputation and Prediction with High-Dimensional Data (SIP-HD): A Deep Learning Model for Disease Diagnosis

Zhenzhen Jia[1], Jianqiang Hu[1], Kejia Hu[2], Qingchen Wang[3], Ning Zhang[4], [1]Fudan University, Shanghai, China; [2]Vanderbilt University, Nashville, TN, [3]Opendoor, New York, NY, [4]Shanghai Jiao Tong University, Shanghai, China. Contact: 18110690011@fudan.edu.cn

Advanced medical tests can be financially costly or infeasible for some patients, leading to limitations in doctors' diagnostic accuracy. To address this, we propose SIP-HD, a deep learning model that simultaneously performs imputation and prediction with high-dimensional data. Our one-step approach reduces errors compared to two-step models, with imputation serving the goal of better prediction. Our meaningful graph construction enhances the model's capacity to handle high-dimensional data, resulting in superior performance compared to similar one-step approaches. Evaluations demonstrate that our model outperforms two-step models, one-step models, and doctors' preliminary diagnoses in ACC, AUC, and F1 score. We recommend our model to healthcare institutions where advanced tests may not be available to improve doctors' diagnostic practices.

3 Shortening Emergency Medical Response Time with Unmanned Aerial Vehicle-Ambulance Joint Operations

Xiaoquan Gao[1], Nan Kong[1], Paul Griffin[2], [1]Purdue University, West Lafayette, IN, [2]The Pennsylvania State University, University Park, PA, Contact: nkong@purdue.edu

Unmanned aerial vehicles (UAVs) can improve emergency medical service (EMS) logistics by quickly delivering medical interventions with the help of bystanders. We formulate a large-scale MDP model to jointly optimize the dispatching and redeployment of UAVs and ambulances in real time. To tackle the curse of dimensionality, we adopt an approximate dynamic programming (ADP) approach with neural network-based value function approximations. We construct a set of basis functions based on queueing and geographic properties of the UAV-augmented EMS system to design the approximation. Our approach outperforms existing benchmarks and provides guidance for effectively incorporating UAVs into EMS operations. By highlighting the potential advantages of using UAVs, we hope to encourage their wider adoption in the EMS field.

4 Performance Tradeoff Under Vbp Program Structure

Xin Ding, Rutgers University, Neward, NJ

In this study, I examine how hospitals trade off various performance metrics under the ongoing value-based purchasing program structure. The longitudinal study supports performance tradeoffs and also suggests that the tradeoff effect varies by different types of hospitals and is also subject to market conditions.

Tuesday, October 17, 4:00 PM - 5:15 PM

Healthcare in Supply Chains

Community Committee Choice Session

Session Chair: Junghee Lee, University of Notre Dame, Notre Dame, IN

1 The Generic Competition Paradox in the Prescription Drug Market

Qinquan Cui, Kenan Arifoglu, Dongyuan Zhan, UCL School of Management, University College London, London, United Kingdom. Contact: qinquan.cui.21@ucl.ac.uk

The generic competition paradox (GCP) is the increase in the price of a branded drug when the competition emerges by introducing a new generic drug to the market. To explain the GCP, we build a game-theoretic model with signalling where the brand-name firm (incumbent) and the generic firm (entrant) have asymmetric information on consumers' relative price sensitivity to the branded drug. We show that the brand-name firm uses limit pricing to deter the entry of the generic firm and the limit pricing can be another rationale behind GCP. Also, we show that GCP can benefit consumers and the limit pricing may increase or decrease the social welfare.

2 Promoting Generics: Effects on Pharmaceutical Quality

In Joon Noh[1], Hessam Bavafa[2], Christian Blanco[3], [1]Pennsylvania State University, University Park, PA, [2]Wisconsin School of Business, Madison, WI, [3]Ohio State University, Columbus, OH, Contact: ikn5003@psu.edu

Generic drugs are a cornerstone of affordable healthcare. In this study, we empirically examine the pharmaceutical quality effects of Generic Drug User Fee Amendments (GDUFA), a hallmark legislation enacted by Congress in 2012 that armed the FDA with resources to improve the timeliness of generic drug application reviews. While GDUFA succeeded in shortening total application review times, its impact on drug quality, as measured by drug recalls, has not been considered. This study bridges this gap.

3 Time to Recover Market Share: Lasting Effects of Supply Chain Disruptions on Firm Performance

Minje Park[1], Anita Carson[2], Rena Conti[2], [1]Columbia Business School, New York, NY, [2]Boston University, Boston, MA, Contact: minje.park@columbia.edu

This study investigates the enduring effects of supply chain disruptions on firms' market share. Specifically, we examine the impact of supply-side disruptions on pharmaceutical products, measuring the extent to which lost market share persists even after the product has resumed production. Our results indicate that market share loss due to supply chain disruptions is not entirely recovered even after production has been restored. These findings underscore the significance of investing in supply chain resilience and prompt recovery as a means of mitigating the long-term effects of supply chain disruptions on market share.

4 From Black to Grey: Improving Access to Antimalarial Drugs in the Presence of Counterfeits

Jiatao Ding[1], Michael Freeman[1], Sasa Zorc[2], [1]INSEAD, Singapore, Singapore; [2]University of Virginia, Darden School of Business, Charlottesville, VA, Contact: jiatao.ding@insead.edu

In malaria-endemic countries, the limited availability of affordable antimalarial medication has contributed to the widespread distribution of inferior counterfeit drugs. We study such markets to determine how philanthropic donors can best allocate limited funds to subsidize the purchase or sales of antimalarial drugs via private-sector distribution channels. We also evaluate five strategies that have been employed to combat counterfeit drugs (improving consumer awareness, increasing the cost of sourcing counterfeits, adopting traceability technology, cracking down on the supply, and imposing price controls) and identify the conditions under which these approaches can either improve or worsen outcomes. Our paper provides guidance as to how to improve outcomes in the presence of counterfeit drugs.

Supply Chain Digitization and Sustainability

Community Committee Choice Session

Session Chair: Li Chen, Cornell University, Ithaca, NY
Session Chair: Shiqing Yao, Monash University, Melbourne, Australia

1 Waste Not Want Not? the Environmental Implications of Quick Response and Upcycling

Xiaoyang Long[1], Luyi Gui[2], [1]University of Wisconsin-Madison, Madison, WI, [2]The Paul Merage School of Business, UC Irvine, Irvine, CA, Contact: luyig@uci.edu

Overproduction is often cited as the fashion industry's biggest environmental issue, as textile production is notoriously resource intensive and pollutive, and much of the textile produced may end up as "deadstock" fabric or finished products that do not sell. In this paper, we study two major approaches commonly adopted by the fashion industry to address this issue: quick response, whereby finished product inventory is replenished on demand, and upcycling, whereby deadstock fabric is reused to make new clothes.

2 Distrust and Dishonesty: An Application to the Ethical Goods Market

Sytske Wijnsma, UC Berkeley, Berkeley, CA

An important issue for the production and sale of ethical goods is that consumers are not able to assess whether a good promoted as ethical has indeed those attributes, even after consumption. This credence attribute may incentivize the seller to cheat on the consumer and sell a mere traditional good promoted as ethical for a premium. This paper sets out to uncover the effects of dishonesty and distrust on market outcomes.

3 Impact of Social Learning on Consumer Subsidies and Supplier Capacity for Green Technology Adoption

Hang Ren[1], Tingliang Huang[2], Georgia Perakis[3], [1]George Mason University, Fairfax, VA, [2]The University of Tennessee-Knoxville, Knoxville, TN, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: thuang7@utk.edu

Due to the innovative nature of green-technology products (e.g., electric vehicles and solar panels), customers are usually a priori uncertain about their purchasing benefits and typically consult user experiences via online product reviews and word-of-mouth communications. Despite the critical role of this social learning behavior for customers' adoption decisions, its implications for consumer subsidies aimed at facilitating adoption are not well-understood. In this paper, we investigate how social learning affects the government's optimal consumer subsidies considering a supplier's capacity decision and examine the welfare impact overall.

4 Ultra-Fresh Fashion: Creating Demand with Freshness and Agility

Li Chen[1], Hau Leung Lee[2], Shiqing Yao[3], [1]Cornell University, Ithaca, NY, [2]Stanford University, Stanford, CA, [3]Monash University, Melbourne, Australia. Contact: shiqing.yao@monash.edu

Using agile supply chains, fast fashion companies have been viewed as best-practice examples in industries. Prior research has focused on how agility can equip such companies with strong "sense and respond" capabilities to identify and fulfill unpredictable customer demands. There is another powerful dimension of agility—the ability to create new products frequently—that has enabled recent market success of companies such as Shein. We seek to model this dimension of agility as an operational strategy for demand creation. Our model enables us to explore the impacts through the lens of profit to the firm, consumer surplus, and environmental performances.

Multi-channel Retail Operations Strategy

Community Committee Choice Session

Session Chair: Yimin Wang, Arizona State University, Tempe, AZ

Session Chair: Rui Yin, Arizona State University, Kowloon

1 Inventory and Supply Chain Management Withauto-Delivery Subscription

Junfei Lei, University of Washington, WA

Auto-delivery is a subscription model widely employed in supply chains, whereby a supplier delivers products to a buyer (or multiple buyers) according to the buyer's choice of a constant shipping quantity to be delivered at prescheduled dates. The buyer enjoys discounts on auto-delivery orders and other benefits, including free subscription and cancellation. Because these benefits seem to all accrue to the buyer at the supplier's expense, the rationale for the supplier's decision to offer auto-delivery and its impact on the profitability of both parties is an intriguing concern. We develop models that consist of a supplier and a single buyer (multiple buyers), whereby the supplier offers a discount for the auto-delivery orders, and the buyer chooses the auto-delivery quantity with the flexibility of canceling the subscription.

2 When Persuasion is Too Persuasive: An Empirical Analysis of Product Returns in Livestream E-commerce

Xiaojing Feng[1], Ying Rong[2], Xin Tian[3], Mengmeng Wang[2], Oliver Yao[4], [1]Southwestern University of Finance and Economics, Chengdu, China; [2]Shanghai Jiao Tong University, Shanghai, China; [3]University of Chinese Academy of Sciences, Beijing, China; [4]Lehigh University, bethlehem, PA, Contact: yrong@sjtu.edu.cn

Livestream e-commerce features live social interactions that enable real-time, face-to-text communications among a streamer and many customers. We posit such live social interactions generate persuasion effect that eventually leads to higher product returns. Using data from a leading livestream e-commerce firm, we compare the product returns between live sessions with rerun sessions where the only difference is the presence of live social interactions in live sessions but not in rerun sessions, and develop econometric models to estimate the effect of live social interaction intensity on product returns. We find that product returns are higher for the live sessions than for the rerun sessions, and that the magnitude of the effect increases with live social interaction intensity, confirming the adverse persuasion effect in livestream e-commerce.

3 Two-Sided Dynamic Pricing for an Online Used-Car Platform

Meichun Lin[1], Tim Huh[2], Harish Krishnan[1], [1]University of British Columbia, Vancouver, BC, Canada; [2]University of British Columbia, Vancovuer, BC, Canada. Contact: meichun.lin@sauder.ubc.ca

We consider an online platform that sets prices for buying and selling used cars. The platform adjusts purchase and selling prices to match supply with demand and maximize total profit. We show that a fixed price policy is asymptotically optimal as the time horizon grows to infinity. When the supply and demand functions are unknown *a priori*, the platform needs to learn from the purchase and sales data, and dynamic pricing is necessary. This leads to the classical learning and earning trade-off. We propose a pricing policy to achieve this goal.

4 Donation and Pricing Decisions for a Socially Responsible Firm with Prosocial Customers

Xinyue Cai[1], Yongbo Xiao[1], Tony Haitao Cui[2], Chen Hu[3], [1]Tsinghua University, Beijing, China; [2]University of

Minnesota, Minneapolis, MN, [3]Xi'an Jiaotong-liverpool University, Jiangsu, China. Contact: caixy21@mails.tsinghua.edu.cn

In the context of widely advocated ESG concept, we study a business that concerns both its profit and customer welfare. The firm conducts donations to boost customers' wellbeing. In return, donation amount affects the desire of socially conscious customers to purchase. We examine the firm's decision on selling price and donation amount in the case where donations are prioritized to high-value and empty-handed customers. The result is contrasted with the benchmark model where no donation is made. In addition, we examine three extensions, where the firm donates randomly, the firm has exogenous capacity, and the firm's objective function includes the so-called ``warm glow effect," respectively. Our study uncovers some intriguing managerial insights for socially responsible firms in balancing their profits and customer welfare in the presence of prosocial customers.

5 The Interaction Between CSR Labeling and Realized Quality of a CSR Product

Hyunsuk Baek[1], Yimin Wang[1], Sanghak Lee[1], Rui Yin[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Kowloon

We conducted a survey on 383 college students to investigate the post-purchase behavior for a CSR product. Given a hypothetically assumed environment, the survey asked three choices in purchase, return, and future purchase. We identify how the realized quality of a CSR product, which is revealed after purchase, interacts with CSR labeling effect, and how it affects the consumer behavior in return and future purchase. We then show the insights on the CSR practice adoption.

Interpretable Models for Health & Treatment Management and Policy Design

Community Committee Choice Session

Session Chair: Fernanda Bravo, UCLA Anderson School of Management, Los Angeles, CA

1 Test-Retest and Quarantining Policies: A Pomdp Approach

Zack (Ziqian) Zhu[1], Steven Shechter[2], Tim Huh[3], [1]UBC, [2]University of British Columbia, Vancouver, BC, Canada; [3]University of British Columbia, Vancovuer, BC, Canada

Motivated by recent debates on Covid quarantining policies, we model test-retest and quarantining policies as a partially observable Markov decision process. Costs include testing, quarantining, and spreading the virus, while the state of Covid (truly "positive" or "negative") is partially observable. Daily decisions involve whether to test and/or quarantine. We derive structural results of the optimal cost function and optimal testing/quarantining policy under different modeling assumptions. We discuss how individuals, workplaces, and governments may differ in their preferred policies.

2 Predicting Long-Term Opioid use via Interpretable Machine Learning

Jingyuan Hu, Fernanda Bravo, Elisa Frances Long, UCLA Anderson School of Management, Los Angeles, CA, Contact: jingyuan.hu.phd@anderson.ucla.edu

Long-term prescription opioid use (i.e., more than 90 days of opioid use within a 180-day period) can lead to drug abuse, addiction, and overdose. Predicting who is most likely to become a long-term opioid user could provide opportunities for early intervention by the prescribing physician or dispensing pharmacist. In this study, we examine the effectiveness of an opioid patient alert system currently used by the California Department of Justice (DOJ), and develop a novel risk-scoring rule to predict whether a patient will become a long-term opioid user, based on their historical prescription data and other characteristics. The scoring rule's inputs and assigned points are derived using an interpretable machine learning model.

3 Peer Influence and Spread of Opioid Epidemic: A Data Driven Social Network Analysis Approach Using Facebook's Social Connectedness Index

Kushagra Tiwari[1], M. Amin Rahimian[2], Mark S. Roberts[2], Mary G Krauland[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: kut20@pitt.edu

The Opioid Epidemic (OE) is a major concern in the US causing over 100,000 deaths due to overdose last year. Despite multiple studies that document the role of peer influence in the spread of OE, our current understanding of social network effects in the spatial spread of OE remains limited. We employ Facebook's Social Connectedness Index (SCI) to quantify social network strength across locations. Using Negative Binomial Regression we assess the SCI 's effect on Opioid Overdose Deaths corroborating our results with robustness checks: Linear Regression, Spatial Autocorrelation, Network Autocorrelation and a Two-way Fixed effect model. Our results suggest that peer influence, as captured by SCI, significantly contributes to OE's spread, highlighting the importance of social networks in public health interventions.

Empirical Research in Service Operations Management

Community Committee Choice Session

Session Chair: Jing Dong, Columbia University, New York, NY

Session Chair: Carri Chan, Columbia Business School, New York, NY

1 Data-driven Decisions in Supply Chains: Contracts, Algorithms and Efficiency

Karan Girotra[1], Xiaoyue Yan[2], Elena Belavina[3], [1]Cornell Tech/Johnson Cornell University, New York, NY, [2]Cornell, Ithaca, NY, [3]Cornell University, New York, NY, Contact: girotra@cornell.edu

We study the performance of revenue sharing and wholesale price contracts in supply chains where firms make data-driven inventory/pricing decisions. In these supply chains, each tier uses historical and contemporaneous data on demand and demand-relevant covariates to directly arrive at their optimal decisions, as opposed to the traditional paradigm where demand estimates are first exogenously specified, followed by a separate optimization stage. We find that when there is a lot of historical data, or there are several covariates that tend to have positive skew and high variance, wholesale-price contracts tend to unexpectedly yield higher supply chain profits than revenue-sharing contracts—a stark contrast with well-known findings in the supply chain literature.

2 Waiting Online Versus In-Person in Outpatient Clinics: An Empirical Study on Visit Incompletion

Jimmy Qin[1], Carri Chan[1], Jing Dong[2], Shunichi Homma[3], Siqin Ye[3], [1]Columbia Business School, New York, NY, [2]Columbia University, New York, NY, [3]Columbia University Irving Medical Center, New York, NY, Contact: qqin23@gsb.columbia.edu

To better manage telemedicine visits and effectively integrate them with in-person visits, we need to better understand patient behaviors under the two modalities of visits. Utilizing data from two large outpatient clinics, we take an empirical approach to study service incompletion for in-person versus telemedicine appointments. Our estimation results show that intra-day delay increases the telemedicine service incompletion rate by 7.40%, but it does not have a significant effect on the in-person service incompletion rate. We conduct counterfactual experiments to optimize the intra-day sequencing rule when having both telemedicine and in-person patients. Our analysis indicates that not correctly differentiating the types of incompletions due to intra-day delays from no-show can lead to highly suboptimal patient sequencing decisions.

3 Analyzing Illegal Psychostimulant Trafficking Networks Using Noisydata

Margret V. Bjarnadottir, Greg Midgette, Siddharth Chandra, University of Maryland, College Park, MD, Contact: mbjarnad@umd.edu

We apply analytical approaches to map illegal psychostimulant (cocaine and methamphetamine) trafficking networks in the US using data from the System to Retrieve Information from Drug Evidence. We adopt a two-step analytical approach: we formulate the data aggregation problem as an optimization problem to maximize learning, then construct an inferred network of connected states. Our network reveals a number of phenomena, some aligning with what is known and some previously unobserved. Our findings show that an optimally aggregated dataset can provide a more accurate picture of an illicit drug network than can suboptimally aggregated data.

Platform/Policy Design for Social Good

Community Committee Choice Session

Session Chair: Vahideh Manshadi, Yale University, New Haven, CT

1 Farm Equipment Sharing in Emerging Economies

Olufunke Adebola[1], Priyank Arora[2], Can Zhang[3], [1]Hello Tractor, Abuja, Nigeria; [2]University of South Carolina, Columbia, SC, [3]Duke University, Durham, NC, Contact: priyank.arora@moore.sc.edu

In emerging economies, there is a growing number of farm equipment sharing platforms that connect smallholder farmers with tractor owners who fulfill farmers' requests for mechanization services. Due to the small farm sizes and the low digital literacy in rural areas of emerging economies, these platforms often rely on the so-called “booking agents” to collect demand from individual farmers and submit the aggregated demand on the platform. This paper studies how the presence of such booking agents affects the platform’s optimal pricing and wage decisions and the equilibrium outcomes. Our findings also shed light on the effectiveness of government/donor interventions to promote agricultural mechanization, such as increasing the number of tractors on such platforms and reducing booking agent’s cost for aggregating demand.

2 Optimal Timing for Screening Tests to Identify Children with Reading Disabilities

Akshaya Suresh[1], Edward H. Kaplan[1], Edieal J. Pinker[1], Jeffrey R. Gruen[2], [1]Yale School of Management, New Haven, CT, [2]Yale School of Medicine, New Haven, CT

Reading disabilities (RD) affect 10-15% of US students. Untreated RD students struggle in school, falling behind peers and facing long-term issues. Neuropsychological evaluations identify RD students, and instructional interventions help them catch up. Early intervention is vital as benefits decline with age, but costly evaluations strain school budgets. Thus, schools use cheap screening tests to flag at-risk students or rely on parents to request evaluation, creating disparities in treatment. Screening accuracy increases with age, creating a trade-off between screening too early (wasting evaluations) or too late to provide effective intervention. Here we design optimal screening policies to maximize benefit and minimize disparity given budget constraints. We also calibrate our model using data on 1.5 million Florida students to provide managerial insights.

3 Empowering Collective Impact: Introducing the Swap System for Resource Sharing

Weixiao Huang[1], Elise J. Deshusses[1], Jennifer A. Pazour[2], Yunus Telliel[1], Sarah Stanlick[1], Alexander Teytelboym[3], Andrew C. Trapp[1], [1]Worcester Polytechnic Institute, Worcester, MA, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]University of Oxford, Oxford, United Kingdom. Contact: whuang2@wpi.edu

Nonprofit organizations (NPOs) lack resources, hindering their service delivery. At the same time, NPOs have underutilized resources due to the mismatch between their assets and temporally shifting service demands. Motivated by these observations, we propose what we believe to be the first auction-based resource sharing system: SWAP. SWAP facilitates resource exchanges through integer optimization, enabling NPOs to obtain resources by offering their own. Empirical and simulated experiments reveal: 1. SWAP can address temporal resource needs in practice; 2. optimal exchange outcomes can be generated even for large-scale SWAP markets; and 3. solid evidence to inform the progression for future versions of SWAP. SWAP is implemented in Howard County, Maryland, with ongoing enhancements and strong potential for future expansion.

4 Counterbalancing Learning and Strategic Incentives in Allocation Markets

Jamie Kang[1], Faidra Monachou[2], Moran Koren[3], Itai Ashlagi[4], [1]Stanford, Redwood City, CA, [2]Harvard University, Cambridge, MA, [3]Ben gurion University of the Negev, Beer Heva, Israel; [4]Stanford University, Stanford, CA, Contact: korenmor@bgu.ac.il

Motivated by the high discard rate of donated organs in the US, we study an allocation problem in the presence of learning and strategic incentives. A benevolent social planner decides on the allocation of a single indivisible, common value object to a queue of strategic agents. Each agent holds an informative, yet noisy, private signal about the quality. To make a correct allocation decision, the planner must elicit agents’ true signals. Under the sequential offering mechanism, learning is hampered as herding may emerge. This can result in incorrect allocation. We propose a novel class of incentive-compatible mechanisms that involve a batch-by-batch, dynamic voting process using a majority rule. We prove that the proposed voting mechanisms improve the probability of correct allocation. Particularly, we show that such an improvement can be achieved via a greedy algorithm.

Frontiers in Revenue Management

Community Committee Choice Session

Session Chair: Huanan Zhang, University of Colorado Boulder, Boulder, CO

Session Chair: Chengyi Lyu, 1</sup

1 Online Learning for Pricing in On-Demand Vehicle Sharing Networks

Saif Benjaafar[1], Xiangyu Gao[2], Xiaobing Shen[1], Huanan Zhang[3], [1]University of Minnesota, Minneapolis, MN, [2]The Chinese University of Hong Kong, Hong Kong, Hong Kong; [3]University of Colorado Boulder, Boulder, CO

We consider the pricing decisions for on-demand vehicle sharing networks in an online learning setting. We use a search subroutine to approximately locate the price with a desired demand for each trip and estimate the gradient information at this price point. We develop an ellipsoid based online learning algorithm with provable theoretical performance guarantees.

2 No Algorithmic Collusion in Two-Player Blindfolded Game with Thompson Sampling

Yi Xiong[1], Ningyuan Chen[2], Xuefeng Gao[1], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]University of Toronto, Toronto, ON, Canada

When two players are engaged in a repeated game, they may be completely unaware of the existence of each other and use multi-armed bandit algorithms to choose the actions, which is referred to as the ``blindfolded game'' in this paper. We show that when the players use Thompson sampling, the game dynamics converges to the Nash equilibrium, under a general condition. Therefore, algorithmic collusion doesn't arise in this case despite the fact that the players do not intentionally use competitive strategies.

3 Approximation Schemes for the Joint Inventory Selection and Online Resource Allocation Problem

Jacob Feldman[1], Panos Kouvelis[2], Xingxing Chen[3], Seung Hwan Jung[4], [1]Olin Business School, Saint Louis, MO, [2]Washington University in St. Louis, Saint Louis, MO, [3]University of Richmond, Richmond, VA, [4]Washington University in St. Louis, Brentwood, MO, Contact: chen@richmond.edu

In this paper, we introduce and study the joint inventory selection and online resource allocation problem, which is characterized by two sequential sets of decisions that are irrevocably linked. First, a decision maker must select starting inventory levels for a set of available resources. Subsequently, the decision maker must match arriving customers to available resources in an online fashion so as to maximize expected reward. We first study the problem in its most general form, before focusing on a specific version that arises at ABI. This particular application of our general setting is referred to as the ABI Trailer Problem, and it considers how ABI ships its beer to vendors via third party delivery trucks. In this problem, ABI must select the weights of preloaded trailers of beer, which are then matched in an online fashion to arriving third party delivery trucks.

4 Assortment Optimization with Multi-Item Basket Purchase Under the Multivariate Mnl Model

Chengyi Lyu[1], Stefanus Jasin[2], Sajjad Najafi[3], Huanan Zhang[1], [1]University of Colorado Boulder, Boulder, CO, [2]University of Michigan, Ann Arbor, MI, [3]HEC Paris, VERSAILLES, France

Assortment selection is one of the most important decisions faced by retailers. Most existing papers in the literature assume that customers select at most one item out of the offered assortment. While this is valid in some cases, it contradicts practical observations in many shopping experiences, both in online and brick-and-mortar retail, where customers may buy a basket of products instead of a single item. In this paper, we incorporate customers' multi-item purchase behavior into the assortment optimization problem. We consider both uncapacitated and capacitated assortment problems under the so-called Multivariate MNL (MVMNL) model, which is one of the most popular multivariate choice models used in the marketing and empirical literature.

5 Schedule-Based Revenue Management with Unknown Demand

Zechao Li[1], Anyan Qi[2], Yining Wang[3], [1]Tsinghua University, Beijing, China; [2]The University of Texas at Dallas, Richardson, TX, [3]University of Texas at Dallas, Richardson, TX

We analyze a class of revenue management problems where a firm provides a service over a selling horizon. Any combination of consecutive periods during the horizon is called a schedule and is available to consumers subject to capacity constraints. The firm must learn about the demand for each schedule on the fly. We introduce learning-while-doing algorithms and quantify the performance of our algorithms using regret analysis.

Advances in Sustainable Operations

Community Committee Choice Session

Session Chair: Vibhuti Dhingra, Schulich School of Business, York University, Toronto, ON, Canada

1 A Model of International Trade in Carbon Mitigation Outcomes: Analyzing the Impact of Article 6 of the Paris Agreement

Manish Tripathy[1], Sanjith Gopalakrishnan[2], Harish Krishnan[1], [1]University of British Columbia, Vancouver, BC, Canada; [2]McGill University, Montreal, QC, Canada

Article 6, of the ParisAgreement, proposes a mechanism, Internationally Transferred MitigationOutcomes (ITMOs), to allow countries to transfer mitigation outcomes, i.e.reduction of emissions in one country can be credited to another.

In thispaper, we present a theoretical and stylized model for the implementation ofITMOs between two countries, one producing a low-carbon fuel and the otherreliant on a high-carbon fuel. Essentially, we show that with trade and ITMOs,countries can reduce global GHG emissions. We also outline the impacts of ITMOson domestic energy prices and the energy consumption mix in the two countries.

2 Toward Stormwater Resilient Cities: Robust Planning Against Extreme Rainfalls

Sheng Liu[1], Wei Qi[2], Aiqi Zhang[1], [1]University of Toronto, Toronto, ON, Canada; [2]Tsinghua University, Beijing, China. Contact: aq.zhang@rotman.utoronto.ca

We are experiencing prolonged and intensified rainfalls in our cities due to climate change. Unfortunately, existing efforts on urban stormwater infrastructure planning, typically based on empirically predetermined rainfall scenarios, fails to capture the worst scenarios that should be planned against. Leveraging robust optimization techniques, this paper identifies the worst-case rainfall scenarios that cause the most severe flooding losses. The use of robust optimization goes beyond existing literature by constructing a new type of uncertainty set using IDF curves directly. Our analysis reveals that cities should be savvy in balancing their investments in green and grey infrastructures. Under a budge constraint, green infrastructures may have to give way to grey ones in exchange for a larger retention capacity to withstand the increasingly severe rainfalls.

3 Beyond Technical Merits:An Analysis of the Perceived Legitimacy of Small Modular Reactors

Goran Calic[1,2], [12]McMaster University, Hamilton, ON, Canada

Small modular reactors (SMRs) are a promising low-carbon energy technology. This study examines audience perceptions of SMRs' legitimacy using media and policy documents, where legitimacy signifies an SMR's right to exist within society. Audiences utilize analogous concepts to understand SMRs and evaluate their merits and demerits. Findings show that people's bounded rationality results in reliance on heuristics when forming legitimacy perceptions. This insight uncovers cognitive processes and highlights practical implications, such as potential miscommunication and unintended outcomes. We stress that "one-size-fits-all" approaches are unsuitable for promoting SMRs as a climate change solution. Grasping legitimacy perceptions is vital for novel technologies, such as SMRs, successful integration into society.

Emerging Market Retail Operations

Community Committee Choice Session

Session Chair: Jiwen Ge, Institute of Supply Chain Analytics (ISCA), Dongbei University of Finance and Economics, Karlstad, Sweden

1 A Competitive Facility Location Model to Mitigate Food Insecurity in Emerging Markets

Gonzalo Mejia[1], Raul Aranguiz[2], Julian Espejo[3], Daniela Granados[3], Christopher Mejia[4], [1]Universidad de los Andes, Miami, FL, [2]Pontificia Universidad Catolica de Valparaiso, Valparaiso, Chile; [3]Universidad de La Sabana, Chia, Colombia; [4]Massachusetts Institute of Technology, Cambridge, MA, Contact: cmejia@mit.edu

This research explores the sustainability of street markets to grant access to fruits and vegetables, F&Vs, to underserved communities. Specifically, this paper studies the impact of adding street markets to satisfy the demand of consumers. We developed a non-linear mathematical model to establish the location and number of street markets. This variant of the competitive facility location problem includes specific features of street markets (i.e., itinerant nature, dynamic shopping behavior). To feed the model, we collected data from main competitors of the street markets (i.e., nanostores) to investigate their market share and purchasing habits. The results suggest that street markets can provide better access to F&Vs to food-insecure households to some extent. Still, their operational complexity may limit their applicability in the long term.

2 The Differential Impact of Lead Time Uncertainty and Review Period Uncertainty on Nanostore Ordering Behavior

Simone Balvers, Eirini Spiliotopoulou, Jan C. Fransoo, Tilburg University, Tilburg, Netherlands. Contact: s.balvers@tilburguniversity.edu

Nanostores, or mom-and-pop stores, face different forms of supply uncertainty when making ordering decisions. Besides lead time uncertainty, shopkeepers rely on irregular in-person sales visits to place orders. This paper focuses on two forms of supply uncertainty: lead time uncertainty and review period uncertainty (i.e., uncertainty in the time between two sales agent visits). Using an experimental design, we find that subjects order more under lead time uncertainty than under review uncertainty, for both high and low margin products. We identify as an underlying mechanism the tendency of decision makers to underestimate the expected lead time, while this is not necessarily the case for the expected review period.

3 Value of Exclusive Doorstep Delivery in the Last-100-Meter Distribution

Yang Zhan[1,2], Zheng Zhang[3], Jiwen Ge[4], [1]Zhejiang University of Technology, Hangzhou, China; [2]Cainiao Network, Hangzhou, China; [3]Zhejiang University, Hangzhou, China; [4]Dongbei University of Finance & Economics, Dalian, China

This paper investigates the value of the last-100-meter distribution service on e-commerce sales via a natural experiment. In the experiment, the last-100-meter distribution service is organized by self-pickup points, and doorstep delivery is provided exclusively for Alibaba packages. By leveraging difference-in-differences models and using data from more than 1.5 billion packages, we show that the exclusive doorstep delivery service brought significant sales growth (decline) of Alibaba (Non-Alibaba) and reversed sales growth trends. We uncover cross-channel negative and positive spillover effects that are induced by service capacity sharing and shifting. We reveal how self-pickup points with different service-quality metrics affect sales and competitive position. Our results suggest how to customize business efforts to maximize the Alibaba benefit.

4 Nanostore-Supermarket Supply Chain Competition

Jiwen Ge[1], Brian Tomlin[2], [1]Institute of Supply Chain Analytics (ISCA), Dongbei University of Finance and Economics, Dalian, China; [2]Tuck School of Business, Hanover, NH, Contact: mojietuzi@gmail.com

Nanostores are mom-and-pop stores prevalent in emerging markets. We study the competition between a cluster of nanostores and a supermarket located on a circle. We model a manufacturer as the common supplier to both retailers as a Stackelberg leader in the nanostore retail supply chain, while the manufacturer engages in a Nash Bargaining game with the supermarket.

Advances in Vehicle Routing

Contributed Session

Session Chair: Maichel Aguayo, Universidade de Concepcion, Concepcion, Chile

1 Efficient Routing and Cargo Transfer Strategies with Heuristic Algorithm in Two-Truck Vehicle Routing Problem

Hyungjoo Cha, Taesu Cheong, Korea University, Seoul, Korea, Republic of. Contact: hyungjoo_cha@korea.ac.kr

In this talk, we address the optimization of waste collection in a two-truck vehicle routing problem by proposing efficient routing and cargo transfer strategies utilizing a heuristic algorithm. The problem involves two trucks, where a smaller vehicle with higher speed collects waste and transfers it to a larger vehicle with slower speed. Utilizing a heuristic algorithm, the objective is to minimize total collection time by optimizing routes and managing cargo transfer. The algorithm considers varying vehicle speeds, generating routes that minimize distances and ensure timely transfer. Results show significant improvements in waste collection time, offering a promising approach for enhancing efficiency and promoting sustainable waste management practices.

2 A Reinforcement Learning Approach for Vehicle Routing Problem with Drones

Aigerim Bogyrbayeva, Bissenbay Dauletbayev, Meraryslan Meraliyev, Suleyman Demirel University, Almaty, Kazakhstan. Contact: b.dauletbayev@sdu.edu.kz

Many exact algorithms, heuristics, and metaheuristics have been proposed to solve the *Vehicle Routing Problem with Drones* (VRPD), which involves using a fleet of heterogeneous vehicles to fulfill customer orders in last-mile delivery. We formulate this problem using the *Markov Decision Process* (MDP) and propose a *Reinforcement Learning* (RL) model to solve it, aiming to obtain high-quality solutions for both small and large instances. Our RL model is based on an attention-based encoder-decoder architecture, enabling us to capture every action taken by any agent in the environment. This approach enhances coordination, determining which vehicles should visit specific customers and where vehicles can rendezvous to effectively leverage drones and reduce the overall completion time. Our experiments produce competitive results when compared to benchmark algorithms.

3 The Generalized Critical Node Problem

Vaidehi S. Karajgikar[1], Chrysafis Vogiatzis[2], [1]UNIVERSITY OF ILLINOIS, URBANA -CHAMPAIGN, Urbana, IL, [2]University of Illinois at Urbana-Champaign, Contact: vaidehi5@illinois.edu

In this talk, we introduce the Generalized Critical Node Problem (GCNP). Given a simple, undirected, and unweighted graph with disjoint clusters, the objective is to minimize global pairwise connectivity while satisfying a minimum damage requirement for each cluster, subject to a global budget. This problem is motivated by previously proposed generalizations of combinatorial optimization problems like the traveling salesman problem and minimum spanning tree problem among others. Our formulation is based on transitive constraints at the global and cluster level. We propose a reformulation into a main problem and subproblem to separate the global and local connectivity requirements and develop a solution method inspired by Benders decomposition. We finish this talk with a comparison of runtimes between our approach and commercial solvers for random instances.

4 A Two-Index Formulation for the Fixed-Destination Multi-Depot Asymmetric Travelling Salesman Problem and Some Extensions

Maichel Aguayo[1], Francisco Aviles[1], Subhash C. Sarin[2], Hanif Dostmahomed Sherali[3], [1]Universidad San Sebastián, Concepción, Chile; [2]Virginia Polytechnic Institute, Blacksburg, VA, [3]Virginia Polytechnic & State University, Blacksburg, VA, Contact: maichel.aguayo@uss.cl

We introduce a compact formulation for the fixed-destination multi-depot asymmetric travelling salesman problem (FD-mATSP). It consists of severañ salesmen distributed among depots who depart from and return to their respective origins after visiting a set of customers. The proposed model exploits the multi-depot aspect of the problem by labelling the arcs to identify the nodes that belong to the same tour. Our experimental investigation shows that the proposed-two index formulation is versatile and effective in modelling new variations of the FD-mATSP compared with existing formulations.

Recent Advances in Optimization Methods for Constrained Machine Learning Problems

Community Committee Choice Session

Session Chair: Sen Na, 1</sup

Session Chair: Vivak Patel, 1</sup

1 Stochastic Algorithms with Adaptive Parameters for Solving Constrained Optimization Problems

Frank E. Curtis, Lehigh University, Bethlehem, PA, Contact: frank.e.curtis@gmail.com

I will discuss some challenges that arise in the design and analysis of stochastic algorithms for solving constrained optimization problems. In particular, I will focus on challenges that arise due to the presence of adaptive algorithmic parameters when their updates are based on stochastic gradient information. I will also present some solutions that my collaborators and I have reached for addressing these challenges in the context of sequential quadratic optimization and interior point methodologies.

2 Physics-Constrained Machine Learning with Differentiable Solvers

Aditi Krishnapriyan, UC Berkeley, Berkeley, CA

Machine learning (ML) has achieved success in a wide variety of applications. While there have also been some successes in the scientific domain, many challenges remain. It is often the case that there is limited data in these settings, as well as ML methods that are not explicitly incorporating information about the physical setting. Examples of such information include conservation laws corresponding to the laws of physics that are known to hold true. I will discuss how we can have stronger control over incorporating conservation laws into neural networks through differentiable optimization and via using the implicit function theorem. Using this, we are able to much more accurately and efficiently converge to the right spatiotemporal solutions, while needing minimal training data.

3 Stochastic Optimization with Constraints: Algorithm, Convergence, and Statistical Inference

Sen Na, 1</sup

Constrained stochastic optimization problems appear widely in numerous applications in statistics, machine learning, and engineering. These include constrained maximum likelihood estimation, constrained deep neural networks, physics-informed machine learning, and optimal control. In this talk, I will describe how to design adaptive algorithms for solving constrained stochastic nonlinear optimization problems based on sequential quadratic programming (SQP). The algorithms employ an exact augmented Lagrangian as the merit function and adaptively select suitable merit parameters. Numerical results are provided.

Advances in Large Scale Optimization

Community Committee Choice Session

Session Chair: Miaolan Xie, Cornell University, Ithaca, NY

1 Online Learning Guided Curvature Approximation: A Quasi-Newton Method with Global Non-Asymptotic Superlinear Convergence

Ruichen Jiang[1], Qiujiang Jin[1], Aryan Mokhtari[2], [1]University of Texas at Austin, Austin, TX, [2]University of Texas at Austin, Austin, TX, Contact: rjiang@utexas.edu

Quasi-Newton methods are among the most popular iterative methods for unconstrained minimization problems due to their favorable superlinear convergence property. However, existing results for these methods are limited, as they provide either an *asymptotic* superlinear convergence rate or a *local* non-asymptotic superlinear rate. In this talk, we present the first globally convergent quasi-Newton method with an explicit non-asymptotic superlinear rate. Unlike classical quasi-Newton methods, we build our algorithm on the hybrid proximal extragradient method and propose a novel online learning framework for updating the Hessian approximation matrices. Specifically, guided by the convergence analysis, we formulate an online learning problem in the space of matrices and relate the bounded regret of the online problem to the superlinear convergence of our method.

2 Extra-Gradient Method with Adaptive Stepsize for Monotone Equations

Yang Luo[1], Michael O'Neill[2], [1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC

First-order methods with adaptive step size have obtained significant attention over decades due to their auto-tuning properties, including AdaGrad, Adam, RMSProp and so on. Yet, even for very simple convex-concave minimax problems, these single step adaptive gradient methods may fail to converge. In this work, inspired by the auto-tuning properties of these adaptive gradient methods, we would like to incorporate AdaGrad techniques into Extra-gradient framework to propose a new scheme called AdaEG-Norm for solving monotone equations which can cover convex-concave saddle point problems. We technically establish the sub-linear convergence rate on the squared norm of the operator and show its robustness to the choice of hyper-parameters.

3 Understanding Low-Dimensional Representation Learning via Neural Collapse

Peng Wang, University of Michigan, Ann Arbor, MI

In this work, we study the recently discovered neural collapse phenomenon in training over-parameterized deep neural networks for classification tasks. As feature normalization in the last layer becomes a common practice in modern representation learning, we theoretically justify the neural collapse phenomenon with normalized features. Based on an unconstrained feature model, we simplify the empirical loss function in a multi-class classification task and obtain a nonconvex optimization problem over the Riemannian manifold by constraining all features and classifiers over the sphere. In this context, we analyze the nonconvex landscape of the Riemannian optimization problem over the product of spheres. Moreover, we also establish linear convergence of neural collapse based on the error-bound condition.

4 Robustly Learning a Single Neuron via Sharpness

Puqian Wang[1], Nikos Zarifis[2], Ilias Diakonikolas[1], Jelena Diakonikolas[1], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI

We study the problem of learning a single neuron with respect to the L_2^2-loss in the presence of adversarial label noise. We give an efficient algorithm that, for a broad family of activations including ReLUs, approximates the optimal L_2^2-error within a constant factor. Notably, our algorithm applies under much milder distributional assumptions compared to prior work. The key ingredient enabling our results is a novel connection to local error bounds from optimization theory.

Algorithmic Foundation in Minimax Optimization

Community Committee Choice Session

Session Chair: Jiajin Li, 1</sup

Session Chair: Jiawei Zhang, MIT, Cambridge, MA

1 Decentralized Methods for Composite Nonconvex Strongly-Concave Minimax Problems

Yangyang Xu, Wei Liu, Rensselaer Polytechnic Institute, Troy, NY

Minimax problems arise in several applications that have attracted a lot of research interests. Many efforts have been made on designing algorithms for solving such problems. A majority of existing algorithms are non-distributed or centralized. In this talk, I will first present a deterministic gradient-type method for non-convex strongly-concave

(NCSC) minimax problems, which can include nonsmooth regularizers for both primal and dual variables. Several existing decentralized methods for NCSC minimax problems only applies to smooth cases. In addition, I will present variance-reduction based stochastic gradient methods for stochastic or finite-sum structured minimax problems. Numerical results will also be shown.

2 Oracle Complexity of Single-Loop Switching Subgradient Methods for Non-Smooth Weakly Convex Functional Constrained Optimization

Yankun Huang[1], Qihang Lin[2], [1]Tippie College of Business, The University of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, IA

We consider a non-convex constrained optimization problem, where the objective function is weakly convex and the constraint function is either convex or weakly convex. To solve this problem, we consider the classical switching subgradient method, which is an intuitive and easily implementable first-order method whose oracle complexity was only known for convex problems. This paper provides the first analysis on the oracle complexity of the switching subgradient method for finding a nearly stationary point of non-convex problems. Our results are derived separately for convex and weakly convex constraints. Compared to existing approaches, especially the double-loop methods, the switching gradient method can be applied to non-smooth problems and achieves the same complexity using only a single loop, which saves the effort on tuning the number of inner iterations.

3 From Halpern's Fixed-point Iterations to Nesterov's Accelerated Interpretations for Root-finding Problems

Quoc Tran-Dinh, The University of North Carolina at Chapel Hill, NC

We derive an equivalent form of Halpern's fixed-point iteration scheme for solving a co-coercive equation (also called a root-finding problem), which can be viewed as a Nesterov's accelerated interpretation. We show that one method is equivalent to another via a simple transformation, leading to a straightforward convergence proof for Nesterov's accelerated scheme. Alternatively, we directly establish convergence rates of Nesterov's accelerated variant, and as a consequence, we obtain a new convergence rate of Halpern's fixed-point iteration. Next, we apply our results to different methods to solve monotone inclusions, where our convergence guarantees are applied. Since the gradient/forward scheme requires the co-coerciveness of the underlying operator, we derive new Nesterov's accelerated variants for both recent extra-anchored gradient and past-extra anchored gradient methods in the literature. These variants alleviate the co-coerciveness condition by only assuming the monotonicity and Lipschitz continuity of the underlying operator. Interestingly, our new Nesterov's accelerated interpretation of the past-extra anchored gradient method involves two past-iterate correction terms. This formulation is expected to guide us developing new Nesterov's accelerated methods for minimax problems and their continuous views without co-coericiveness. We test our theoretical results on two numerical examples, where the actual convergence rates match well the theoretical ones up to a constant factor.

Global Optimization in Robust Decision-making and Optimal Control

Community Committee Choice Session

Session Chair: William Haskell, Purdue University, West Lafayette, IN

1 Supply Chain Contracts in the Small Data Regime

Xuejun Zhao[1], William Haskell[2], Guodong Yu[3], [1]Purdue University, [2]Purdue University, West Lafayette, IN, [3]Shandong University, Shandong, China

We study supply chain contract design under uncertainty. In this problem, the retailer has full information about the demand distribution, while the supplier only has partial information drawn from historical demand realizations and contract terms. The supplier wants to optimize the contract terms, but she only has limited data on the true demand distribution. We show that the classical approach for contract design is fragile in the small data regime, and we combine the historical demand and retailer data to improve the supplier's contract design terms. Our framework sheds light on the value of information from interactions between agents in a game-theoretic setting and suggest that such information should be utilized in data-driven decision-making.

2 Sequential Quadratic Programming for Optimal Transport

Zihe Zhou, Purdue University, West Lafayette, IN, Contact: zhou408@purdue.edu

The Monge optimal transport (OT) problem seeks an optimal measure that transforms a source probability measure to a target, by minimizing a given cost function. Deviating from the growing literature that focuses on the dual, we formulate the Monge problem as a nonlinear functional optimization problem subject to a nonlinear operator constraint, and develop a sequential quadratic programming (SQP) operator recursion for solution. We first show that the Monge problem, under some reasonable regularity conditions, satisfies the conditions of Alt's SQP formulation over Banach spaces, immediately yielding local convergence. We then discuss embedding the structure provided by Brenier's theorem into the SQP, and also globalizing the SQP recursion. To the best of our knowledge this is the first attempt at a globally convergent SQP operator recursion over function spaces.

3 Preference Robust Optimization with Quasi-Concave Choice Functions for Multi-Attribute Prospects

Jian Wu[1], William Haskell[1], Wenjie Huang[2], Huifu Xu[3], [1]Purdue University, West Lafayette, IN, [2]The University of Hong Kong, Hong Kong, Hong Kong; [3]The Chinese University of Hong Kong, Southampton, United Kingdom. Contact: wbhaskell@gmail.com

In stochastic optimization, the decision maker's (DM's) preferences are expressed by a choice function. Preference robust optimization (PRO) is concerned with the situation where DM's preferences are ambiguous and a precise choice function cannot be specified. The current preference robust choice models are mostly single-attribute and are built upon von Neumann-Morgenstern expected utility theory, the theory of convex risk measures, or Yaari's dual theory of choice. In this paper, we extend the PRO approach to the broader class of monotone and quasi-concave multi-attribute choice functions. We show how to efficiently solve our new class of PRO problems by solving a sequence of convex optimization problems. We test our scheme on a single-attribute portfolio optimization problem and a multi-attribute capital allocation problem.

Understanding Generalization of Optimization Algorithms in Machine Learning

Community Committee Choice Session

Session Chair: Jiawei Zhang, MIT, Cambridge, MA
Session Chair: Kaiqing Zhang, MIT, Cambridge, MA
Session Chair: Asuman Ozdaglar, Massachusetts Institute of Technology, Cambridge, MA

1 An (Empirical) Law of Data Separation in Deep Learning

Weijie Su, Wharton School, University of Pennsylvania, Philadelphia, PA

The law of equi-separation is a pervasive empirical phenomenon that describes how data are separated according to their class membership from the bottom to the top layer in a well-trained neural network. We will show that, through extensive computational experiments, neural networks improve data separation through layers in a simple exponential manner. This law leads to roughly equal ratios of separation that a single layer is able to improve, thereby showing that all layers are created equal. We will conclude the talk by discussing the implications of this law on the interpretation, robustness, and generalization of deep learning, as well as on the inadequacy of some existing approaches toward demystifying deep learning. This is based on joint work with Hangfeng He (arXiv:2210.17020).

2 On the Role of Attention in Prompt-Tuning

Mahdi Soltanolkotabi, [1]</sup

Prompt-tuning is an emerging strategy to adapt large language models (LLM) to downstream tasks by learning a (soft-)prompt parameter from data. Despite its success in LLMs, there is limited theoretical understanding of the power of prompt-tuning and the role of the attention mechanism in prompting. In this talk I will demystify this phenomenon by characterizing the generalization properties of the trajectory of gradient descent for such problems.

3 Optimization and Generalization for Contrastive Self-Supervised Learning

Tianbao Yang, [1]</sup

In this presentation, I will talk about our recent works about contrastive self-supervised learning. I will highlight the challenges for optimization and present our solutions for addressing the challenges. I will then present the generalization results and discuss their limitations and offer potential path for addressing these limitations in future work.

4 Transformers are Support Vector Machines

Samet Oymak, University of Michigan, Ann Arbor, MI

Recent advances in language modeling, such as ChatGPT, have revolutionized our society within a short timeframe. These large language models are based on the transformer architecture which uses the self-attention mechanism as their central component. However, the theoretical principles underlying the attention mechanism are poorly understood, especially its nonconvex optimization dynamics. In this talk, we establish a formal equivalence between the optimization geometry of self-attention and a linear hard-margin SVM problem that separates the optimal input tokens within the input sequence from non-optimal tokens (e.g. selecting the optimally-relevant words within a sentence). Through this, we characterize the inductive bias of 1-layer transformers optimized with gradient descent and prove that optimization of self-attention weights converges in direction to a max-margin token-separator minimizing either nuclear norm or Frobenius norm objective depending on the parameterization. We also highlight that convergence can occur in locally-optimal directions rather than global ones. Our findings apply to general datasets and allow for a final neural-net layer. Finally, we demonstrate the practical validity of our hard-margin SVM equivalence via thorough numerical experiments. These findings on self-attention inspire a new perspective, interpreting multilayer transformers as a hierarchy of SVMs that separates and selects optimal tokens.

First-order Methods and Large-scale Optimization

Community Committee Choice Session

Session Chair: Jonathan Eckstein, 1</sup

Session Chair: Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ

1 Stochastic Approximation Methods in the Presence of Biased Oracles

Sam Davanloo, Yin Liu, The Ohio State University, Columbus, OH, Contact: davanloo.1@osu.edu

Motivated by multiple emerging applications, e.g., stochastic composition optimization, we consider a general optimization problem where the gradient of the objective is only available through a biased stochastic oracle where the bias magnitude can be controlled by a parameter; however, lower bias requires higher computation. Without exploiting a specific bias decay structure, we propose a couple of adaptive and nonadaptive stochastic algorithms to solve the underlying problem. We analyze the nonasymptotic performance of the proposed algorithms in the strongly convex and nonconvex regimes. The numerical performance of the proposed methods over two applications on composition optimization and policy optimization for infinite-horizon Markov decision processes will be presented.

2 Dish: A Distributed Hybrid Primal-Dual Optimization Framework to Utilize System Heterogeneity

Xiaochun Niu, Ermin Wei, Northwestern University, Evanston, IL, Contact: xiaochunniu2024@u.northwestern.edu

We consider solving distributed consensus optimization problems over multi-agent networks. Current distributed methods fail to capture the heterogeneity among agents' local computation capacities. We propose DISH as a distributed hybrid primal-dual algorithmic framework to handle and utilize system heterogeneity. Specifically, DISH allows those agents with higher computational capabilities or cheaper computational costs to implement Newton-type updates locally, while other agents can adopt the much simpler gradient-type updates. Theoretically, we show that DISH achieves a linear (Q-linear) convergence rate to the exact optimal solution for strongly convex functions, regardless of agents' choices of gradient-type and Newton-type updates. Finally, we perform numerical studies to demonstrate the efficacy of DISH in practice.

3 Defbal: The ADMM Meets Proximal Gradient Methods

Jonathan Eckstein[1], Felipe Atenas[2], Paulo J. S. Silva[3], [1]Rutgers University, Piscataway, NJ, [2]University of Melbourne, Melbourne, Australia; [3]University of Campinas, Campinas, Brazil

The ADMM algorithm is an application the Douglas-Rachford splitting method for monotone operators. However, a connection also exists between the ADMM and proximal gradient (forward-backward) algorithms. This talk will explain the connection and show how it can be exploited to develop new ADMM-like augmented Lagrangian algorithms for convex optimization.

4 DEFBAL, Part II: Some ADMM-Like Algorithms Derived from Forward-Backward Methods

Chang Yu, Jonathan Eckstein, Rutgers University, Piscataway, NJ, Contact: cy301@business.rutgers.edu

The connection between the proximal gradient (forward-backward) algorithm and the ADMM allows one to derive new ADMM-like methods by substituting related methods such as FISTA for the ordinary proximal gradient procedure. This talk describes some examples of such algorithms and their potential applications.

New Advance in Solving Vehicle Routing Problems Exactly

Community Committee Choice Session

Session Chair: Yu Yang, University of Florida, Gainesville, FL

1 Maximum Throughput Dispatch for Shared Autonomous Vehicles Including Vehicle Rebalancing

Jake Robbennolt, The University of Texas at Austin, Austin, TX

Shared autonomous vehicles (SAVs) provide on demand point-to-point transportation for passengers. This service has been extensively studied using dispatch heuristics and agent-based simulations of large urban areas. However, these approaches make no mathematical guarantees of passenger throughput for the SAV network. This study uses a dynamic queuing model for passengers and includes rebalancing of empty vehicles to regions of high demand. The dispatch policy is proven to maximize throughput. Simulation results show that including rebalancing in the dispatch policy reduces waiting times (between vehicle dispatch and passenger pickup). However, vehicle time traveling empty increases in some scenarios. Simulation results also show that rebalancing reduces passenger waiting times unless many vehicles rebalance at once and are not available for dispatch.

2 A New Exact Algorithm for Single-Commodity Vehicle Routing with Split Pickups and Deliveries

Jiliu Li[1], Zhixing Luo[2], Roberto Baldacci[3], Hu Qin[4], Zhou Xu[5], [1]School of Management, Northwestern Polytechnic University, Xi'an, China; [2]School of Management and Engineering, Nanjing University, Nanjing, China; [3]Hamad Bin Khalifa University, Doha, Qatar; [4]Huazhong University of Science and Technology, Wuhan, China; [5]Department of Logistics and Maritime Studies, Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: zhou.xu@polyu.edu.hk

Based on a pattern-based mathematical formulation and a novel label-setting procedure. we develop a new branch-price-and-cut algorithm to solve a vehicle routing problem with split pickups and deliveries. Extensive computational results on different classes of benchmark instances show that our new exact algorithm solves several open instances and significantly outperforms state-of-the-art algorithms.

3 Elementary Branch-Price-And-Cut for Solving Stochastic Vehicle Routing Problems

Alexandre Florio, Amazon, Bellevue, WA

We consider the vehicle routing problem with stochastic demands (VRPSD), a stochastic variant of the VRP in which demands are only revealed upon arrival of the vehicle at each customer. We focus on the VRPSD under the restocking-based perspective, which means that vehicles are allowed to replenish at the depot to guarantee enough capacity to serve all customers. We present a branch-price-and-cut (BP&C) algorithm for the VRPSD under optimal restocking. The distinctive feature of this algorithm is that it operates with elementary routes, that is, it does not apply any route relaxation strategy. We provide intuition as to why the elementary pricing strategy is more efficient for a wide class of stochastic routing problems. Computational experiments show that the BP&C method outperforms previous state-of-the-art algorithms on several sets of literature instances.

4 Deluxing: Deep Lagrangian Underestimate Fixing for Column-Generation-Based Exact Methods

Yu Yang, University of Florida, Gainesville, FL, Contact: yu.yang@ise.ufl.edu

In this paper, we propose an effective variable fixing strategy called deep Lagrangian underestimate fixing (DeLuxing). It is widely applicable to remove unnecessary variables in column-generation-based exact methods for solving various challenging discrete optimization problems. DeLuxing employs a novel LP formulation, which is theoretically guaranteed to yield qualified dual solutions for computing Lagrangian underestimates. We extend the fundamental concept underpinning the new formulation to contexts beyond variable fixing, namely cutting plane addition and variable type relaxation. We demonstrate DeLuxing brings the performance of the state-of-the-art branch-price-and-cut methods to the next level via an extensive numerical study on three important classes of VRPs: the CVRP, VRPTW, and CMTVRPTW.

Tuesday, October 17, 4:00 PM - 5:15 PM

Collaboration and Cooperation in City Logistics Systems

Community Committee Choice Session

Session Chair: Julia Lange, RPTU Kaiserslautern-Landau, Kaiserslautern, Germany

1 Resource and Cost Allocation in Cooperative Two-Tier City Logistics Systems

Johannes Gückel[1], Pirmin Fontaine[2], Teodor Gabriel Crainic[3], [1]KU Eichstaett-Ingolstadt, Ingolstadt School of Management, Inglstadt, Germany; [2]KU Eichstaett-Ingolstadt, Ingolstadt School of Management, Ingolstadt, Germany; [3]Université du Québec à Montréal, Montréal, QC, Canada

We introduce a new tactical planning problem for the resource and cost allocation of a two-tier city logistics system with cooperative logistics service providers. Therefore, we present a new mathematical formulation that combines a service network design formulation on the first tier with a capacitated vehicle routing problem with release and due dates on the second tier. Our model accommodates different cooperation scenarios, such as full sharing of resources and customers, partial sharing of customers, and exclusive sharing of resources. This model is used in adapted cost allocation methods, including proportional methods and more complex game theoretical methods. To solve larger instances, we propose a problem-specific iterated local search metaheuristic.

2 Machine Learning for Last-Mile Delivery and Third-Party Logistics

Maria Elena Bruni[1], Edoardo Fadda[2], Stanislav Fedorov[3], Guido Perboli[4], [1]University of Calabria, Rende, Italy; [2]Politecnico di Torino, Turin, Italy; [3]Politecnico di Torino, Turin, Italy; [4]Politecnico di Torino, Turin, Italy. Contact: guido.perboli@polito.it

Third-party logistics is an essential component of efficient delivery systems, enabling companies to purchase carrier services instead of an expensive fleet of vehicles. However, carrier contracts must be booked in advance without knowing what orders will be available for dispatch, while reducing the total service costs. This problem becomes more challenging in satellite-based two-tier systems. In this paper, we present a new heuristic algorithm able to do so based on machine learning techniques able to tackle large-sized instances. Several numerical experiments show that the proposed method performs well in a short computational time. In addition, we present an application of the method to a real case study.

3 A Bi-Level Approach for Last-Mile Delivery with Multiple Satellites

Maria Elena Bruni[1], Sara Khodaparasti[2], Guido Perboli[2], [1]University of Calabria, Rende, Italy; [2]Politecnico di Torino, Turin, Italy

Last-mile delivery is regarded as an essential, yet challenging problem in city logistics. One of the most common initiatives, implemented to streamline and support last-mile activities, are satellite depots, intermediate logistics facilities used to decouple last-mile activities from the rest of the distribution chain. In this paper, the interplay and the hierarchical relation between the problem agents are modeled by a bi-level optimization framework. Two mathematical models and an exact solution approach, properly customized for the problem, are presented. To assess the validity of the proposed formulations and the efficiency of the solution approach, we conduct an extensive set of computational experiments on benchmark instances. In addition, we present managerial insights for a case study on parcel delivery in Turin, Italy.

4 Learning Last-Mile Delivery Drivers' Behavior Using Machine Learning and Spatial Tessellation

Hesam Rashidi[1], Mehdi Nourinejad[2], Matthew Roorda[1], [1]University of Toronto, Toronto, ON, Canada; [2]York University, Toronto, ON, Canada. Contact: hesam.rashidi@mail.utoronto.ca

Delivery drivers develop tacit knowledge about their daily operating environment, enabling them to navigate the service region more efficiently over time. For instance, drivers may avoid neighborhoods during peak congestion periods or when parking availability is limited; these factors may be challenging to predict or incorporate into traditional optimization models. This study develops a human-centric optimization formulation for the Traveling Salesman Problem, aiming to incorporate the expertise and familiarity of in-field drivers. The framework integrates a Machine Learning classifier into a mathematical program to generate routes more likely to be taken by delivery drivers.

5 Coalition-Based Urban Delivery Network Design for the Hyperconnected City Logistics

Simon S. Kwon[1], Johan Leveque[2], Walid Klibi[3], Gautier Stauffer[4], Benoit Montreuil[5], [1]Georgia Institute of Technology, Atlanta, GA, [2]La Poste Group, Paris, France; [3]KEDGE Business School, Talence, France; [4]University of Lausanne, Lausanne, Switzerland; [5]Georgia Tech, Atlanta, GA, Contact: skwon82@gatech.edu

Motivated by the hyperconnected city logistics initiatives, this work addresses the design of hyperconnected urban parcel delivery networks engaging multiple independent delivery actors, modeling it as a coalition-formation game. The objective is to design coalition parcel delivery networks among multiple delivery actors such that the actors within the same coalition may cooperatively share resources (e.g., hubs/vehicles) to achieve their service levels (i.e., timely

origin-destination deliveries) robustly and efficiently. We develop a case study of major delivery actors within a major French urban area to understand the impact of coalitional decisions and different cost-allocation methods on the global and individual network design cost.

Applications of Optimization - 2

Contributed Session

Session Chair: Junyao Yang, Auburn University, Auburn, AL

1 Economic Lot Sizing Problem with Tank Scheduling

Mehmet Önal[1], Wilco van den Heuvel[2], Erinç Albey[3], Ihsan Yanikoglu[4], [1]Özyeğin University, İstanbul, Turkey; [2]Erasmus University Rotterdam, Rotterdam, Netherlands; [3]Özyeğin University, istanbul, Turkey; [4]Özyegin University, Alemdag, Turkey. Contact: mehmetonal@gmail.com

We introduce a multiple-item economic lot sizing problem where items are produced through the fermentation of some raw materials. Fermentation takes place in specialized tanks that have finite capacities, and duration of the fermentation process is item dependent. When fermentation starts, the tanks are not available for the duration of the fermentation process. We analyze the complexity of this problem under various assumptions on the number of items and tanks. In particular, we show that several cases of the problem are (strongly) NP-hard, and we propose polynomial time algorithms to some single item cases. In addition, we propose a quick and simple heuristic approach for one of the multiple item cases.

2 Quick Mods: Shelf Space Optimization on the Fly

Mohit Batham[1], Rishi Bhatia[2], Khosro Pichka[3], Navina Kaur Sethi[4], Saipraveen Vabbilisetty[4], Apoorva Modali[3], [1]Walmart, Bangalore, India; [2]Walmart, BENTONVILLE, AR, [3]Walmart, Sunnyvale, CA, [4]Walmart, Dallas, TX

Deciding how to assign products to limited shelf space is one of the most challenging decisions for retailers. This can affect retailers' profit directly and help them to be more competitive. With supply disruptions and change in buyer preferences, merchants need the ability to make minor updates in store. We developed two optimization models to address this problem, for shelf & pegboards/bars. It tries to minimize the modular alterations per merchant's request and maximize the space allocation. The manual modular draw process requires weeks of lead time and engagement from multiple support teams. But this approach is an efficient solution for merchants to remove, add or even update shelf capacity for a number of products in stores. Quick Mods reduces the cost significantly by reducing the lifecycle of an update from 2 weeks to under an hour and bring sales through updates.

3 Network Design Model for Walmart's Omni-Channel Last Mile Delivery

Xinyue Peng, Yao Luo, Walmart, Sunnyvale, CA, Contact: xpeng37@wisc.edu

To support the design of Walmart's last mile delivery network for different types of offerings (scheduled and unscheduled delivery), we developed a scalable optimization model that generates the optimal last mile network configurations, including the location of delivery stations, catchment areas, and fleet mix. A novel aspect is the unified last-mile catchment design for various assets, such as stores, delivery stations, and market fulfillment centers. This integration minimizes total system costs while ensuring operational efficiency. The model adeptly handles different demand channels, promoting spatial optimization and efficient handling of scheduled and unscheduled deliveries.

4 Portfolio Optimization with Probability Estimated CVaR Objective and Return Constraints

Junyao Yang[1], Alexander Vinel[2], [1]Governors State University, University Park, IL, [2]Auburn University, Auburn, AL, Contact: jyang3@govst.edu

Business intelligence analysis for Financial asset management is well-developed with many applications nowadays. Portfolio optimization is traditionally stimulated by adequately modeling the requirements, including risks, returns, and computational efficiency. However, the optimization framework strictly relies on statistical principles and distribution assumptions, which contain no future information. In this work, we propose a three phases predict-then-optimize framework using AI and CVaR optimization. In particular, the approach can be used for maximizing expected predicted returns while minimizing the risk measured by the CVaR objective simultaneously. A case study for the portfolio of multiple US stocks is performed to demonstrate this new technique can be implemented.

1 Policy Finetuning in Reinforcement Learning via Design of Experiments Using Offline Data

Andrea Zanette, UC Berkeley, Berkeley, CA

In some applications of reinforcement learning, a dataset of pre-collected experience is already availablebut it is also possible to acquire some additional online data to help improve the quality of the policy.However, it may be preferable to gather additional data with a single, non-reactive exploration policyand avoid the engineering costs associated with switching policies.

In this paper we propose an algorithm with provable guarantees that can leverage an offline dataset to design a single non-reactive policy for exploration. We theoretically analyze the algorithm and measure the quality of the final policy as a function of the local coverage of the original dataset and the amount of additional data collected.

2 Settling the Sample Complexity of Model-based Offline Reinforcement Learning

Yuting Wei, University of Pennsylvania, Philadelphia, PA

This paper studies multi-agent reinforcement learning in Markov games, with the goal of learning Nash equilibria or coarse correlated equilibria (CCE) sample-optimally. All prior results suffer from at least one of the two obstacles: the curse of multiple agents and the barrier of long horizon, regardless of the sampling protocol in use. We take a step towards settling this problem, assuming access to a flexible sampling mechanism: the generative model. Focusing on non-stationary finite-horizon Markov games, we develop an algorithm that can learn the equilibrium with optimal sample complexity.

3 Reinforcement Learning in Continuous Time: Learning Hamiltonian and Temperature Control

Wenpin Tang, Columbia University, New York, NY, Contact: wt2319@columbia.edu

Reinforcement Learning (RL) has been successfully applied to wide-ranging domains in the past decade. Recent years have witnessed a fast growing body of research that has extended the frontiers of continuous RL such as designing model-free methods and algorithms. In this talk, I will discuss the recently introduced "q-learning" through the lens of distributional control. Various problems such as policy optimization, Boltzmann exploration and temperature control will also be discussed.

4 When is Agnostic Reinforcement Learning Statistically Tractable?

Ayush Sekhari, Massachusetts Institute of Technology

We study the problem of agnostic PAC reinforcement learning (RL): given a policy class Π, how many rounds of interaction with an unknown MDP (with a potentially large state and action space) are required to learn an ϵ-suboptimal policy with respect to \(\Pi\)? Towards that end, we introduce a new complexity measure, called the \emph{spanning capacity}, that depends solely on the set \(\Pi\) and is independent of the MDP dynamics. With a generative model, we show that the spanning capacity characterizes PAC learnability for every policy class Π. However, for online RL, the situation is more subtle. We show there exists a policy class Π with a bounded spanning capacity that requires a superpolynomial number of samples to learn. This reveals a surprising separation for agnostic learnability between generative access and online access models (as well as between deterministic/stochastic MDPs under online access). On the positive side, we identify an additional \textit{sunflower} structure which in conjunction with bounded spanning capacity enables statistically efficient online RL via a new algorithm called POPLER, which takes inspiration from classical importance sampling methods as well as recent developments for reachable-state identification and policy evaluation in reward-free exploration.

Scheduling & Demand Modeling in Aviation

Community Committee Choice Session

Session Chair: Alex Estes, 1</sup

1 Integrated Network Planning and Schedule Design for a Regional Airline

Alberto Santini[1], Vikrant Vaze[2], [1]University of Bologna, Caltanissetta, Italy; [2]Dartmouth College, Hanover, NH, Contact: vikrant.s.vaze@dartmouth.edu

We propose a new mixed-integer optimization formulation for jointly optimizing frequency planning, timetabling and fleet assignment decisions with endogenous passenger demand for a regional airline carrier. We develop a column generation-based approach for solving this joint optimization problem within reasonable runtime budgets. We also present a heuristic acceleration strategy for generating high quality solutions quickly for larger scale problems. Computational results demonstrate that our approach outperforms existing benchmark approaches, leading to significant gains in solution quality.

2 Airline Alliances and Schedule Convenience - Evidence from the Transatlantic Market

Volodymyr Purdue Bilotkach, 1</sup

3 Impact Assessment of Capacity Reduction Policies at Major Hubs: Network and Societal Implications

Sebastian Birolini, Nicolò Avogadro, Paolo Malighetti, University of Bergamo, Dalmine (BG), Italy. Contact: sebastian.birolini@unibg.it

We develop an airport⍰centric multi-objective flight scheduling and fleet assignment optimization model to assess the impact of capacity reduction initiatives at major hubs, aimed at alleviating congestion and improving their environmental footprint at short notice, possibly at little expense of passenger surplus. We deploy our model to address three main research questions: (i) investigate the impact of capacity reductions on the hub carrier's network connectivity and profitability; (ii) investigate trade⍰offs between airline profits, local passenger surplus, and CO2 emissions; (iii) investigate the impact and policy implications of different policies, i.e., the setting of air transport movements vs. CO2 limits.

4 Nonmonetary Allocation Under Congestion

Alexander Stewart Estes[1], Ankur Mani[2], [1]University of Maryland-College Park, Ellicott City, MD, [2]University of Minnesota - Twin Cities, Minneapolis, MN, Contact: aestes@umd.edu

We study the problem of allocating a finite set of resources to a finite set of agents with unit demand without monetary transfers. Agents may share a resource and bear a congestion cost, so that the utility that an agent derives from a resource is decreasing in the number of agents sharing that resource. One problem exhibiting similar characteristics is that of allocating arrival slots at an airport. We show that there does not exist a nonmonetary mechanism that produces a stable assignment and that incentivizes truthful revelation by all coalitions. We introduce an nonmonetary mechanism similar to an ascending auction, but where a specified level of congestion takes the place of a price. We find that the mechanism produces a stable assignment. In addition, we prove that this mechanism provides the smallest possible incentives for agents to deviate from truthful behavior.

1 Modeling Hub Dynamics in Long-Haul Aviation Markets

Nuno Ribeiro[1], Mingmei Li[1], Sebastian Birolini[2], [1]Singapore University of Technology and Design, Singapore, Singapore; [2]University of Bergamo, Dalmine (BG), Italy

We look at the strategic hub competition problem in long-haul markets at a global scale. We identify itinerary attributes affecting passengers' choices and integrate them into demand generation and allocation models to analyze the sensitivity of competition across airport hubs in the world.

AI-driven Healthcare Analytics: Opportunities and Challenges

Community Committee Choice Session

Session Chair: Zheng Zeng, Rutgers University, Edison, NJ

1 An Integrated Framework of Multifaceted Machine Learning, Metaheuristics, and Braden Scale to Predict Hospital-Acquired Pressure Injuries (Bedsores)

Odai Dweekat, State University of New York at Binghamton, Binghamton, NY, Contact: odweeka1@binghamton.edu

Hospital-Acquired Pressure Injuries (HAPIs), known as bedsores, are the second most common diagnosis in healthcare system billing records in the US. The Braden Scale, commonly used to identify HAPIs, is limited by the number of factors that a caregiver can reasonably assess during patient care. Moreover, it identifies a large percentage of hospitalized patients as being at risk for developing HAPIs. This research aims to develop an integrated framework of multifaceted machine learning, metaheuristics, and Braden scale to predict if and when HAPI occurs. The proposed research achieves better performance than Braden and reduces the number of patients identified as at-risk. The research outcomes will provide guidance on early target intervention when it is needed most and will help reduce unnecessary burden on patients and care teams when patients are at lower risk.

2 Modeling Semantic Compositions for Clinical Risk Prediction

Weiting Gao, NJ

Clinical notes are valuable resources for clinical risk prediction. In clinical notes, medical terms commonly co-occur with modifiers, thereby providing additional information that indicates the clinical status or imposes specific constraints. Without capturing the modifiers, the model is likely to capture partial information or incorrectly comprehend the note. In order to learn semantics of the clinical notes correctly and comprehensively, the compositions of medical terms and their modifiers, referred to as medical facts, should be considered as important information units when making predictions. In this work, to enhance the models on capturing the *medical terms-modifiers* compositions, we propose a method to learn the representations of semantic compositions for medical facts and model the impact of medical facts on the predictive outcome.

3 How Does Insurance Coverage Affect Unclaimed Prescriptions and Physician's Behavior?

Zheng Zeng[1], Xiaowei Xu[1], Lian Qi[2], [1]Rutgers University, Piscataway, NJ, [2]Rutgers Business School, Piscataway, NJ, Contact: zzeng@business.rutgers.edu

China implements continuous health reforms for a universal health insurance system, improving affordability and accessibility. National Healthcare Security Administration (NHSA) regularly adjusts the insurance coverage rates for various drugs and services on the basic medical insurance list to dynamically and reasonably allocate the budget and offer patients the most needed support.
This study examines the effects of insurance coverage rates on unclaimed prescription rates and physicians' prescribing behaviors based on outpatient data from one of the largest regional hospitals in Liaoning, China. The results can aid NHSA and other decision-makers in adjusting insurance coverage rates for different drugs and services, managing the government medical budget, and optimizing the insurance system.

4 Trading One Evil for Another? - Analyzing Users' Attitude Towards E-Cigarettes

Anindita Bandyopadhyay, University of Iowa, Iowa City, IA

Sentiment analysis on publicly available content from BecomeAnEX, a smoking cessation platform, is used to understand users' perceptions of e-cigarettes. Through the evaluation of blog posts, group discussions, and comments from 2017 to 2022, we assess users' views on e-cigarettes as smoking cessation aids and factors leading to prolonged addiction. Employing a BERT-based multi-stage classifier model for sentiment classification, our research contributes to public health strategies by offering a comprehensive understanding of e-cigarette sentiments. It also aids in designing effective interventions by elucidating users' misconceptions and perspectives about e-cigarette usage, its role in addiction, and its effectiveness/non-effectiveness as a smoking cessation tool.

Nonlinear Learning and Optimization

Contributed Session

Session Chair: Mehmet Kolcu, Norfolk Southern Corp., Atlanta, GA

1 A Quadratic Surface Support Vector Machine for Imbalanced Classification

Xinyu Xu[1], Fengming Lin[1], Zheming Gao[2], Shu-Cherng Fang[1], [1]North Carolina State University, Raleigh, NC, [2]Northeastern University, Shenyang, China. Contact: xxu37@ncsu.edu

This paper studies the problem of constructing a robust nonlinear classifier when the data set is imbalanced. Utilizing the hidden moment information embedded in the data points, a distributionally robust chance-constrained kernel-free quadratic surface support vector machine model is proposed. The proposed model is reformulated as a fractional programming problem with second-order cone constraints. Extensive computational experiments using synthetic and public benchmark data support the superior performance of the proposed model over other state-of-the-art models, particularly for classifying the imbalanced datasets. The proposed model also has dominating performance on a real-world application to battery failure prediction with highly imbalanced data.

2 Data-Driven Preference Learning Methods for Multiple Criteria Sorting with Temporal Criteria

Mengzhuo Guo[1], Yijun Li[2], Qingpeng Zhang[3], [1]SiChuan University, Cheng Du, China; [2]City University of Hong Kong, Kowloon Tong, Hong Kong; [3]City University of Hong Kong, Kowloon, Hong Kong. Contact: mengzhguo@outlook.com

This study presents a novel preference learning method for multiple criteria sorting problems with temporal information. Existing methods lack consideration of temporal dynamics.

Our approach utilizes additive piecewise-linear value functions as the basic preference model for each time point, employing a fixed time decay rate to aggregate values over the time series. By formulating the problem as a quadratic programming model, the solution relies on a subset of training samples. To enhance generalization, we incorporate arbitrary time decay rates and introduce a monotonic recurrent neural network (mRNN) to learn preference model parameters. The proposed mRNN ensures monotonicity and automatically adapts the time decay rate for extensive temporal data. We demonstrate the efficacy in evaluating the value of mobile game users, addressing a real-world problem.

3 Column Generation Methods for Solving Lot Sizing and Scheduling Problems with Sequence Dependent Setup Times

Kai-Yi Lin, Sheng-I Chen, National Yang Ming Chiao Tung University, Hsinchu, Taiwan. Contact: t311704038.mg11@nycu.edu.tw

The lot-sizing and scheduling problem with sequence-dependent setup times is a common and challenging problem in manufacturing industries. The problem complexity arises from the exponential number of possible production sequences to be considered and the weak relaxation solutions of its mixed-integer linear programs. This study reformulates the problem based on the Dantzig-Wolfe decomposition. We propose heuristics to obtain columns of production sequence decisions for each machine. Additionally, a compact formulation is used to reduce the number of binary decision variables and constraints in the mathematical programming model. Computational results display our approach performances using benchmarking problem instances.

4 Debugging Nonlinear Optimization Problems with the Dulmage-Mendelsohn Decomposition

Robert Parker[1], Bethany Nicholson[2], John Siirola[2], Lorenz Biegler[3], [1]Los Alamos National Laboratory, Los Alamos, NM, [2]Sandia National Laboratories, Albuquerque, NM, [3]Carnegie Mellon University, Pittsburgh, PA

Modeling a complex, nonlinear process can be a time-consuming and error-prone task. In nonlinear optimization, modeling errors often appear as rank deficiencies, which can violate assumptions made by the optimization solver or the model. The Dulmage-Mendelsohn partition helps debug such modeling errors by identifying unique subsystems of variables and constraints that are structurally over, under, or well-constrained. In this talk, we describe the Dulmage-Mendelsohn partition in the context of nonlinear optimization problems, give several examples of its application to problems from the IDAES process modeling framework, and present implementations for debugging optimization models in the Pyomo and JuMP algebraic modeling languages.

5 Integrated Learning of Predictive and Prescriptive Tasks

Mehmet Kolcu[1], Alper E. Murat[2], [1]Norfolk Southern Corp., Atlanta, GA, [2]Wayne State University, Detroit, MI, Contact: mehmetkolcu06@hotmail.com

Traditional decision problems rely on constrained optimization, and real-world problems often contain uncertain parameters. In the presence of feature data pairs for uncertain parameters, a decision-maker can make prescriptions by solving the optimization problem with the pre-estimated parameters. This work proposes a two-stage neural network framework integrating predictive and prescriptive tasks to provide high-quality decisions, especially by capturing non-linearity between uncertain parameters and feature data pairs. While the predictive neural network feeds the decisions, the prescriptive neural network evaluates the decisions by minimizing the objective function and satisfying all the constraints. Overall, this work emphasizes the importance of neural networks in improving decision-making in uncertain and competitive environments.

Data-driven Decision-making for Interconnected Systems

Community Committee Choice Session

Session Chair: Andi Wang, Arizona State University, Mesa, AZ

1 Fast Personalization for Heterogeneous Condition Monitoring Signals Using Neural Processes

Seokhyun Chung, Raed Al Kontar, University of Michigan, Ann Arbor, MI, Contact: seokhc@umich.edu

Personalization is crucial in modeling condition monitoring (CM) signals, as it provides personalized analysis for individual units while retaining population-level features. This study presents a neural process-based approach that enables fast personalization. Our method learns a distribution over signals and a mapping between a set of context points and the corresponding signal's distribution. This allows the model to rapidly infer the future evolution of CM signals by using available observations as contexts. Our model builds upon latent representation based on a mixture of Gaussians, parameterized by deep networks, to effectively handle the heterogeneity present in CM signals. Experiments show that our proposed model achieves faster personalization and improves predictive accuracy, particularly in scenarios involving heterogeneous CM signals.

2 Robust Generalized Scalar-On-Tensor Regression

Elif Konyar[1], Mostafa Reisi[1], Ruizhi Zhang[2], [1]University of Florida, Gainesville, FL, [2]University of Georgia, Athens, GA, Contact: elif.konyar@ufl.edu

High-dimensional (HD) data, such as images and profiles, are commonly collected from complex systems and contain significant explanatory information for systems monitoring and control. Therefore, developing accurate and robust predictive models based on HD data is crucial. In literature, various methods including scalar-on-tensor regression are developed to model a complex system based on HD data. However, they ignore the presence of outliers and are prone to biased estimations. This paper proposes a robust scalar-on-tensor regression framework that handles HD input data when the data contain outliers. Our proposed estimation method is constructed using maximum Lq-likelihood estimation instead of the classical maximum likelihood estimation. Several simulations and case studies evaluate the proposed method's efficacy compared to several benchmark methods.

3 Process Monitoring for Covariance Matrices with Latent Structures

Qing Zou[1], Jian Li[2], Dong Ding[3], Fugee Tsung[4], [1]Xi'An Jiaotong University, Xian, CN, China; [2]Xi'an Jiaotong University, Xian, CN, China; [3]Xi'An Polytechnic University, Xian, CN, China; [4]HKUST(GZ), Kowloon, Hong Kong. Contact: zouqing277@stu.xjtu.edu.cn

Principal component analysis (PCA) based monitoring methods are efficient for detecting additive faults. However, as faults occurring in the covariance matrix are not additive, conventional PCA based methods cannot detect them effectively. To this end, this paper aims to develop a series of efficient monitoring statistics for detecting covariance matrices with latent variables and sensor errors. They include two statistics in the principal component and residual subspaces, respectively, as well as a combined one. The proposed indices do not require knowledge of the remaining near-zero eigenvalues of PCA decomposition, and their detectability analyses and theoretical control limits are also provided. Furthermore, simulations have demonstrated their superiority over existing methods for detecting process/sensor covariance faults.

4 Two-Stage Infill Error Compensation for Cloud Printing

Hui Wang[1], An-Tsun Wei[2], [1]Florida A&M University-Florida State University College of Engineering, Tallahassee, FL, [2]Florida A&M University-Florida State University College of Engineering, Tallahassee, FL, Contact: hwang10@fsu.edu

Infill patterns in 3D printed parts crucially affect structure functionality. Yet, quality control can hamper productivity due to calibration and printing speed. This presentation proposes a cloud-based compensation method to maintain infill quality during rapid printing, optimizing productivity. The method adjusts extruder deposition volume at non-uniform printing locations, allowing high-speed printing with localized slower adjustments. The learning process consists of two stages: the pre-trained stage co-learns group patterns of non-uniformity probability and local conditions from cloud printers, and the fine-tune stage shapes individual infill pattern belief based on minimal data, referencing group patterns. This method enhances productivity and print quality for interconnected printers and practitioners with limited experience and data.

Surrogate Models for Complex Systems

Community Committee Choice Session

Session Chair: Ashif Iquebal, Arizona State University, Tempe, AZ

Session Chair: Bo Shen, New Jersey Institute of Technology, Newark, NJ

1 An Improved Data-Driven Sequential Learning Framework Guided by Surprise Observations in Autonomous Experimentation Platforms

Ahmed Shoyeb Raihan, Imtiaz Ahmed, West Virginia University, Morgantown, WV, Contact: ar00065@mix.wvu.edu

Autonomous experimentation platforms (AEPs) can revolutionize the traditional material discovery process by searching intelligently for optimal material properties. While machine learning (ML) algorithms are great at identifying the complex relationship between the inputs and the target

property, they initially require a large amount of data to be trained. They are not feasible for use in AEPs. Bayesian optimization (BO) with a sequential learning framework, although effective in determining the optimal design points, is more exploitative and performs poorly in approximation tasks. We propose a surprise-guided framework which addresses all these challenges. Driven by the element of surprise, our proposed approach follows a sequential experiment design policy showing superior prediction performance with fewer data when compared to BO and popular ML methods.

2 Community/Committee's Choice Submission

Ridwan Olabiyi, Arizona State university, Tempe, AZ

3 Hierarchical Active Learning for Defect Localization in 3D Systems

Jianxin Xie[1], Bing Yao[2], [1]University of Tennessee, Knoxville, TN, [2]The University of Tennessee Knoxville, Knoxville, TN

Advanced sensing and imaging enable rich information retrieval from complex systems for personalized simulation and defect localization. This paper presents a Hierarchical Gaussian Process (HGPAL) framework for reliable defect localization in 3D systems. It combines advanced sensing and imaging with physics-based simulations to personalize models for detecting internal system defects. The HGPAL framework uses a two-step process: GP regression on 2D geometry embedding for capturing geometric info, and a Hierarchical GP-based active learning approach to account for system heterogeneity and estimate spatial-varying parameters. We evaluate the performance of the proposed HGPAL framework in a 3D body-heart system to identify and localize infarct in the heart. Numerical experiments demonstrate the effectiveness of our HGPAL framework for 3D defect localization.

4 Heterogeneity-Aware Federated Learning for Quality Control in Distributed Additive Manufacturing

Anyi Li[1], Jia Liu[2], [1]Auburn University, Auburn, AL, [2]Auburn University, Auburn, AL, Contact: azl0082@auburn.edu

Federated learning (FL) is a promising technique enabling privacy-preserving, collaborative learning with a network of distributed additive manufacturing (AM) manufacturers. However, the data among manufacturers are often heterogenous (i.e., non-IID) due to distinct machine specifications, hindering the FL deployment of distributed AM quality control. To alleviate this issue, we propose a heterogeneity-aware FL model to examine fabricated parts' quality in distributed AM, which handles non-IID data across distributed AM manufacturers. During training, it regulates and balances the model weights between global FL and local individual manufacturers' models to mitigate the non-IID constraints while maintaining their model performance. This model is evaluated by a simulation and case studies for quality control of the parts built by distributed 3D printers.

Advancements in Spatial-temporal Analytics

Community Committee Choice Session

Session Chair: Fenglian Pan, University of Arizona, Tucson, AZ
Session Chair: Jian Liu, University of Arizona, Tucson, AZ

1 Decomposition Methods for Spatio-Temporal Hotspot Detection

Hao Yan, Arizona State University, Tempe, AZ, Contact: haoyan@asu.edu

Spatiotemporal hotspot detection is important in many applications such as pandemic monitoring, manufacturing process monitoring and video imaging data. In general, the goal for hotspot detection is not only detect when the hotspot happens but also localize the hotspot when it happens. In this talk, I will summarize existing works and some of our recent progress on the data decomposition methods for hotspot detection such as Bayesian extension, tensor extension, handling non-Gaussian data, etc.

2 An Integrated Uncertainty Quantification Model for Longitudinal and Time-To-Event Data

Ye Kwon Huh[1], Minhee Kim[2], Kaibo Liu[3], Shiyu Zhou[1], [1]University of Wisconsin-Madison, Madison, WI, [2]University of Florida, Gainesville, FL, [3]UW-Madison, Madison, WI, Contact: yhuh8@wisc.edu

We present a novel joint prognostic framework for the integrated analysis and uncertainty quantification of longitudinal data and time-to-event data. Specifically, the proposed integrated uncertainty quantification (IUQ) method models longitudinal data using functional principal component analysis, while the time-to-event data is characterized by a Bayesian neural network-based Cox model. The IUQ model achieves the following advantages: 1) Accurate remaining useful life predictions while seamlessly integrating the uncertainties of both sub-models; 2) Great flexibility in modeling both data types; 3) Real-time updates of the RUL distribution of in-service units; 4) Reliable RUL predictions under limited data availability. Numerical evaluations on synthetic and real-world battery data demonstrate the advantages of the IUQ model.

3 Spatter Trajectory Detection Using Tracking Methods in Laser Powder Bed Fusion Process for Quality Purposes

Mehrdad Moradi, Georgia Institute of Technology, Atlanta, GA, Contact: mehrdadmoradi@gatech.edu

Laser powder bed fusion (LPBF) has emerged as a promising additive manufacturing technique. However, its widespread industrial use faces a significant obstacle due to the lack of robust real-time monitoring techniques for detecting defects and anomalies. Recent research has extensively focused on utilizing spatter-related information for this purpose. Building upon this emerging literature, we propose an algorithm based on Kalman filter to track individual spatters in images and extract relevant statistics such as trajectory length, size, velocity, and more. By detecting the initial and landing points of spatters, one might be able to adjust the manufacturing process to prevent spatters from creating defects in the final part. We validate the proposed method using simulation and real data from an LPBF process.

4 Spatial-Temporal Triggering Pattern Recovery Using Large-Scale Recurrent Event Data

Fenglian Pan, Jian Liu, University of Arizona, Tucson, AZ, Contact: fenglianpan@arizona.edu

The triggering pattern embedded in spatial-temporal (ST) recurrent events provides valuable insight of the mechanism underlying event occurrences. It is of significant research value, yet methodological challenge, to accurately estimate such latent patterns from high-dimensional recurrent event data with complex ST structure. To tackle such challenges, this research proposes a ST latent triggering pattern representation by modeling the ST events as a multi-dimensional Hawkes processes. During the estimation procedure, regularization techniques are employed to learn the ST triggering pattern. A modified likelihood-based algorithm which combines techniques of EM and ADMM are proposed. The performance of the proposed model is demonstrated by a real-world case study.

Advanced Data Analytics and Data-driven Sensor-based Modeling, Prediction, and Control for Complex Systems

Community Committee Choice Session

Session Chair: Phat Huynh, University of South Florida, Tampa, FL

Session Chair: Trung Le, University of South Florida, Tampa, FL

1 Noise-Robust Optimal Sampling Strategy for Multi-Scale Complex Systems Using Deep Reinforcement Learning

Phat Huynh[1], Trung Le[2], Dang Nguyen[3], [1]University of South Florida, Tampa, FL, [2]University of South Florida, Tampa, FL, [3]University of South Florida, Tampa, FL, Contact: huynh105@usf.edu

We propose a reinforcement learning framework that integrates multi-scale complex dynamics to define the reward signals for the agent and uses a deep Q-learning agent to determine the optimal data sampling strategy for capturing multi-scale and/or multi-physics dynamics. We employed the sparse identification of nonlinear dynamical systems (SINDy) algorithm for systems dynamics discovery and prediction, and validated the method using three case studies. The proposed method enables data-efficient reinforcement learning for multi-scale complex systems, facilitates the integration of different modeling techniques, and provides a principled approach for optimizing the data sampling strategy for controlling multi-scale systems.

2 Model Preditive Control in Optimal Interventional of the Covid-19 with Mixed Epistemic-Aleatoric Uncertainty

Jinming Wan[1], Changqing Cheng[1], Saeideh Mirghorbani[2], N. Eva Wu[3], [1]Binghamton University, Binghamton, NY, [2]Binghamton University, Binghamton, NY, [3]Binghamton University, Binghamton, NY, Contact: jwan8@ binghamton.edu

Non-pharmaceutical interventions (NPI) have been proven vital in the fight against the COVID-19 pandemic before the massive rollout of vaccinations. Considering the uncertainty of parameters, accurate simulation and modeling of the interplay between the NPI and contagion dynamics is critical to the optimal design of intervention policies. We propose a modified SIRD-MPC model, which combines a modified stochastic Susceptible-Infected-Recovered-Deceased (SIRD) compartment model with mixed epistemic-aleatoric parameters and Model Predictive-Control (MPC), to develop robust NPI control policies in containing the infection of the COVID-19 pandemic with minimum economic impact. The simulation result indicates that our proposed model can significantly decrease the infection rate compared to the practical result under the same initial conditions.

3 Semiparametric Evaluation of First-Passage Distribution for Step-Stress Accelerated Degradation Tests

Hon Keung Tony Ng[1], Lochana Palayangoda[2], Ling Li[3], [1]Bentley University, Waltham, MA, [2]University of Nebraska Omaha, Omaha, NE, [3]Xi'an Microelectronic Technology Institute, Xi'an, China

In reliability engineering, different types of accelerated degradation tests have been used for the reliability evaluation of highly reliable or expensive products. Step-stress accelerated degradation test (SSADT) is an experimental scheme that can be used to save the resources of an experiment. Motivated by the SSADT data for operational amplifiers collected at Xi'an Microelectronic Technology Institute, we propose a semiparametric approach for SSADT data analysis that does not require strict distributional assumptions. Specifically, the empirical saddlepoint approximation method is proposed to estimate the items' lifetime (first-passage time) distribution at both stress levels included and not included in the SSADT experiment. Monte Carlo simulation studies are used to evaluate the performance and illustrate the advantages of the proposed approach.

4 Feature Subspace Selection for High-Dimensional Data

Di Bo, Hoon Hwangbo, Stephanie TerMaath, University of Tennessee, Knoxville, Knoxville, TN, Contact: dbo@vols.utk.edu

This paper presents a novel feature selection approach that can identify important features and interactions in the form of feature subspaces. This identification is challenging as it requires intensive computations and complex model structures. To tackle this problem, the proposed method applies XGBoost that involves random generations of trees (each forming a feature subspace) and integration of significant base learners created for particular feature subspaces. The XGBoost outcomes are further fed into a partially-connected neural network to adjust the linkages within the subspaces and explore more unseen subspaces. Comparative studies demonstrate the advantages of the proposed method in predictions and feature (subspace) selections.

Regional-scale, Community-informed Models for Electric Power System Resilience to Climate Change

Community Committee Choice Session

Session Chair: Ana Dyreson, Michigan Technological University, Houghton, MI

Session Chair: Mostafa Sahraei-Ardakani, University of Utah, UT

1 Resilience Oriented Optimization of Energy Storage and Solar Energy Sharing Systems in Residential Communities

Farzane Ezzati[1], Sasha Zhijie Dong[2], Qingyang Xiao[1], [1]University of Houston, Houston, TX, [2]University of Houston, Houston, TX, Contact: fezzati@cougarnet.uh.edu

This study proposes optimized energy sharing solutions for solar and energy storage technologies in residential communities to enhance their energy resilience during outages. A conditional value at risk stochastic programming is developed to optimally plan and schedule the devices while capturing normal and contingency uncertainties and ensuring the model robustness. Meanwhile, a multi objective optimization approach is utilized to maintain a balance between various resilience metrics. Lastly, mixed integer programming with scenario decomposition is explored for modeling and solution techniques. The proposed model's efficiency is evaluated using real case studies in Houston and Austin, paving the way for widespread adoption of renewable energy and increased energy resilience in residential areas.

2 Robust and Sustainable Power System Planning: Insights from Mexico and Ghana

Erin Baker, Univ of Massachusetts-Amherst, Amherst, MA

We combine work from Mexico and Ghana to indicate a way forward for community-informed models for electric power system resilience to climate change. We combine multiple Integrated Assessment Models with a single capacity planning model to derive robust climate mitigation pathways. We combine that with Value Focused Thinking to evaluate the sustainability of the pathways.

3 Toward More Energy Resilient Communities in Los Angeles

Kwami Senam A. Sedzro[1], Kapil Duwadi[1], Bryan Palmintier[2], Sherin Ann Abraham[1], Gayathri Krishnamoorthy[1], Greg Bolla[1], Jane Lokshin[1], Patricia Romero-Lankao[1], Nicole Rosner[1], [1]National Renewable

Energy Laboratory, Golden, CO, [2]National Renewable Energy Laboratory, Golden, CO

Equitable community energy resilience has not always been part of energy planning requirements. But as Los Angeles (LA) transitions toward 100% renewables, it is vital to understand and compare how resilient the city's neighborhoods are, to make sure that disadvantaged communities (DACs) are not left behind. Energy resilient communities keep reasonable access to critical services despite low-probability energy service disruptions. We investigate, for selected neighborhoods in LA, the impact of resilience events on access to key services such as electricity, grocery, hospital, shelter, and banking. Preliminary findings indicate that DACs are more vulnerable to energy service disruptions than non-DACs. We also found that resilience profiles vary by event type and that programs such as energy backups and microgrids can enhance equity in community energy resilience.

4 Pathways and Barriers to an Equitable Blue Economy

Jasmine McAdams, University of California, Berkeley, Berkeley, CA

The growth in demand for ocean-based resources such as food, materials, and energy reflect the growing importance of the blue economy in today's society. In particular, increased attention is being paid to marine renewable energy as key solution for mitigating the climate crisis. The equitable integration of marine renewable energy into local economies requires an understanding of the local economic impacts. This presentation will share some preliminary research findings of a marine energy jobs analysis evaluating forecasted workforce needs, the economic impact of new job opportunities, and the implications for frontline communities.

5 Balancing Wildfire Risk and Demand in Power Systems Expansion

Saeed Manshadi, Reza Bayani, San Diego State University, San Diego, CA

This presentation introduces an innovative approach to address the emergency measure of Public Safety Power Shut-off (PSPS) in wildfire-prone areas. We focus on the challenge of balancing wildfire ignition risk with energy supply continuity. We propose a quantified, robust optimization problem for long-term resilient expansion planning of power systems. The model offers a trio of expansion strategies: addition of new lines, modification of existing ones, and installation of Distributed Energy Resources (DERs). It integrates the uncertainties of DERs and wildfire risk, ensuring resilience against adverse events. Our case studies illustrate the model's ability to balance between customer shut-offs, DER installations, and line modifications while mitigating wildfire ignition risk.

Modeling Aspects Towards Demand Response

Community Committee Choice Session

Session Chair: Victoria C. p. Chen, The University of Texas at Arlington, Arlington, TX

Session Chair: Jie Han, University of Texas at Arlington, Arlington, TX

1 Probabilistic Day-Ahead Electricity Price Forecasting with Transformer-Based Models

Jie Han[1], Shouyi Wang[1], Wei-Jen Lee[1], Jay Michael Rosenberger[2], Victoria Chen[1], [1]University of Texas at Arlington, Arlington, TX, [2]University of Texas-Arlington, Arlington, TX, Contact: jie.han@mavs.uta.edu

Electricity price forecasting is an essential task for market participants to make management decisions for day-ahead and intra-day energy markets. However, electricity price forecasting has become more and more challenging given the increasing penetration of stochastic renewable energy in recent years. In this study, we developed a new probabilistic deep learning model to achieve long-sequence multivariate time series modeling and forecasting. Our model is an integration of quantile regression and a multivariate time series transformer model. The developed probabilistic deep learning model has been applied to the day-ahead energy price forecasting of the Electric Reliability Council of Texas (ERCOT). The proposed method achieved superior forecasting performance compared with the state-of-the-art methods.

2 Demand Response Optimization Using Bi-Level Adaptive Dynamic Programming

Bahareh Nasirian, Victoria C. P. Chen, Jay Michael Rosenberger, The University of Texas at Arlington, Arlington, TX

In this research, we propose a bi-level stochastic dynamic programming model for an electricity market demand response problem in the residential sector. Three types of customers are represented: load serving entity, dynamic pricing customers, and fixed pricing customers. State variables consist of exogenous deterministic, exogenous stochastic, and endogenous stochastic. Additionally, the model incorporates multiple groups of energy sources, namely renewable energy (wind, solar), the grid, battery, and pre-purchased electricity. The objective is to minimize the cost of demand response decisions while satisfying electricity market needs. Due to the high dimensional state space, we utilize the Design and Analysis of Computer Experiments (DACE) based infinite horizon adaptive dynamic programming solution method.

3 Integer Programming for Non-Intrusive Load Monitoring Using Data-Driven Appliance Signatures

Marina Materikina[1], Eshan Singhal[1], Jay Michael Rosenberger[2], Victoria C. P. Chen[1], Wei-Jen Lee[3], [1]The University of Texas at Arlington, Arlington, TX, [2]University of Texas-Arlington, Arlington, TX, [3]The University of Texas at Arlington, Arlington, TX, Contact: marina.materikina@mavs.uta.edu

Rapidly developing renewable energy sources pose new challenges for utility companies' production and demand response (DR) planning. Studying customers' electricity consumption behavior can enhance the effectiveness of DR programs. Non-intrusive load monitoring (NILM) enables the analysis of individual appliance electricity patterns, fostering the connection between customers and energy providers. An integer programming algorithm utilizing data-driven appliance signatures was developed for NILM. The detailed signatures for modern state-based appliances (EV, AC, solar, washer, dryer) were studied using nonlinear programming and piecewise functions that depend on mode shapes. This approach, applied to low-frequency data, significantly improved load detection accuracy during the disaggregation phase.

4 Optimizing a System of Electric Vehicle Charging Stations Using Mixed Integer Linear Programming Computer Experiments

Ukesh Chawal, University of Texas at Arlington, Arlington, TX, Contact: ukesh.chawal@uta.edu

This paper formulates a mixed-integer linear programming model to optimize a system of EV charging stations, locations of EV charging stations, the number of charging slots to be opened, and expected profits from satisfying demand and electricity trading with the power grid. Then, a two-stage framework is considered that integrates the first-stage system design problem and second-stage control problem of the EV charging stations using a design and analysis of computer experiments based system design optimization approach. The first stage specifies the design of the system that maximizes expected profit. This approach generates a meta-model to predict revenue from the control problem using multivariate adaptive regression splines, fitted over a binned Latin hypercube design. Using the revenues from the control problem, the system design problem is then solved.

Optimization for Efficient and Resilient Operation of Electric Grids

Community Committee Choice Session

Session Chair: Christine Chen, The University of British Columbia, Vancouver, BC, Canada

Session Chair: Antoine Lesage-Landry, Polytechnique Montréal, Montréal, Canada

2 Assessing Network Resilience Under an Optimal Water Pumping Control Strategy to Provide Frequency Regulation

Anna Stuhlmacher, Seth Guikema, Johanna L. Mathieu, University of Michigan, Ann Arbor, MI, Contact: akstuhl@umich.edu

Recent research has proposed optimizing the operation of the drinking water network and power grid jointly. However, it is critical that new operational strategies do not degrade network performance of the coupled power-water system. In this work, we investigate the impact of optimally scheduling and controlling water pumps in the drinking water distribution network to provide frequency regulation services to the bulk transmission system. We evaluate how changes in operational strategy from a traditional rule-based operation to an optimal pump scheduling operation may impact network resilience during and after a hazard event. In a case study, we demonstrate our approach by comparing the resilience metrics of three operational strategies.

3 Measurement-Based Locational Marginal Pricing in Active Distribution Networks

Roohallah Khatami[1], Severin Nowak[2], Christine Chen[3], [1]Southern Illinois University at Carbondale, Carbondale, IL, [2]Lucerne University of Applied Sciences and Arts, Lucerne, Switzerland; [3]The University of British Columbia, Vancouver, BC, Canada. Contact: roohallah.khatami@siu.edu

The use of distribution locational marginal prices (DLMPs) represents a promising solution to establish distribution-level real-time electricity markets. However, calculating DLMPs is more challenging than their transmission-level counterparts due to solving an optimal power flow (OPF) with nonlinear constraints. Further, accurate distribution network models that reflect the up-to-date operating point are often not available. As a solution, we propose a measurement-based method for calculating real-time DLMPs that relies only on online measurements collected at a subset of distribution system buses to estimate a linear sensitivity model mapping bus voltages to injections, which in turn is embedded in the OPF problem as an equality constraint. The proposed method is computationally efficient and obviates the need for an accurate distribution network model.

4 Online Dynamic Submodular Optimization for Power Systems

Antoine Lesage-Landry, Julien Pallage, Polytechnique Montréal, Mila & GERAD, Montréal, QC, Canada

We propose new algorithms with provable performance for online binary optimization subject to general constraints in dynamic settings. We consider submodular objective functions. We propose the online submodular greedy algorithm (OSGA) which solves to optimality an approximation of the previous round loss function to avoid the NP-hardness of the original problem. We extend OSGA to a generic approximation function. We show that OSGA has a dynamic regret bound similar to the tightest bounds in online convex optimization. For instances where no approximation exists or a computationally more efficient implementation is desired, we design the online submodular projected gradient descent by leveraging the Lovász extension. We obtain a regret bound that is akin to the online gradient descent. Finally, we numerically test our algorithms in two power system applications.

5 Topology-Aware Neural Networks for Power Systems

Agnes M. Nakiganda, Spyros Chatzivasileiadis, Technical University of Denmark, Lyngby, Denmark

Presently, most Machine Learning (ML) methods applied to complex power systems problems cannot capture changes in the grid topology. If an ML model has the capability to account for topology changes, it could handle the combinatorial explosion of *N-k* scenarios involved in the security analysis of power networks faster than conventional methods. This work presents physics-informed topology-aware Neural Network (NN) architectures (Graph NN, Guided dropout, One-hot encoded NN) for power flow computation and investigates their generalization capabilities in handling *N-k* security analyses. Furthermore, performance comparisons to the traditional Newton Raphson solver on various grid sizes are discussed. Finally, the interpretability of models based on graph theoretic principles is examined to foster the confidence needed for their adoption in real systems.

Is the Environmental Impact as Primary Moderator of Sustainability?

Community Committee Choice Session

Session Chair: Biswajit Sarkar, [1</sup]

1 A New Moderator for Sustainable Supply Chain Management Towards Environmental Benefits

Rekha Guchhait, Biswajit Sarkar, Yonsei University, Seoul, Korea, Republic of. Contact: bsbiswajitsarkar@gmail.com

Almost every supply chain management sector moves toward a dual-channel policy because of the changing sustainable nature. This study designs a fourth-party logistics managed closed-loop dual-channel supply chain management that manages the product flow of reverse logistics. Fourth-party logistics formulates an integrated structure that takes the order from the manufacturer for recycled spare parts and finally delivers those required spare parts. The fourth-party service provider manages the execution of this entire process of reverse logistics with random demand for both the new products and recycled spare parts. The collected recycled spare parts through the proposed system are found to be more than the expected demand for spare parts. If 4PL can reduce the purchasing cost of used products from the collection center by 50%, the system can gain 55% more profit.

2 A Game Theoretic Approach for Evaluating and Pricing Alternative Business Models for Clean Technology Adoption: Applications to Solar Panels

J. Lemuel Martin[1,2], S. Viswanathan[3], [1]Cambridge CARES, Singapore, Singapore; [2]Nanyang Technological University, Singapore, Singapore; [3]Nanyang Technological University, Singapore, Singapore. Contact: jesuslj.martin@ntu.edu.sg

We model the interaction between a firm that manufactures and/or sells and installs solar panels and its customers under alternative business models from conventional sales to third-party ownership models such as leasing or power-purchasing agreement. Using price and solar panel maintenance level as decision variables, we look at the distinguishing factors that influence business model choice and develop pricing algorithms to account for customer heterogeneity. We also look at leasing models with minimum energy commitments and buyback policies.

Machine Learning for Optimization

Community Committee Choice Session

Session Chair: Geunyeong Byeon, Arizona State University, Tempe, AZ

1 Learning to Optimize with Stochastic Dominance Constraints

Bo Dai, Georgia Institute of Technology, Atlanta, GA, Contact: bodai@cc.gatech.edu

In real-world decision-making, uncertainty is important yet difficult to handle. Stochastic dominance provides a theoretically sound approach to comparing uncertain quantities, but optimization with stochastic dominance constraints is often computationally expensive, which limits practical applicability. We develop a simple yet efficient approach for the problem, Light Stochastic Dominance Solver (light-SD). We recast the inner optimization in the Lagrangian as a learning problem for surrogate approximation, which bypasses the intractability and leads to tractable updates or even closed-form solutions for gradient calculations. We prove convergence of the algorithm and test it empirically. The proposed light-SD demonstrates superior performance on several representative problems ranging from finance to supply chain management.

2 Learning to Design Circuits

Vinod Nair, Google, Bangalore, India

Designing efficient hardware circuits from specification for modern chips is a challenging discrete optimization problem involving a large number of decision variables, with complex constraints and objectives. In this talk we present a machine learning-based approach to the problem that decomposes it into two sub-problems -- 1) optimizing for correctness with respect to specification, and 2) optimizing for hardware efficiency. Results show that our approach outperforms classical optimization techniques across a broad set of circuit design problems. It also enables better design flexibility by naturally allowing to trade off correctness for efficiency.

3 Accelerating Benders Decomposition via Exploration

Kaiwen Fang, Geunyeong Byeon, Arizona State University, Tempe, AZ, Contact: kfang11@asu.edu

We propose a Benders decomposition method that accelerates its convergence rate empirically through learning via statistical approaches that balance exploration and exploitation. Specifically, we present a novel algorithmic variant that strategically enriches and exploits information exchanged between decomposed problems for acceleration. A computational study on facility location problems demonstrates the computational benefits of the proposed method over state-of-the-art solution approaches.

4 Learning to Generate Columns

Minseok Ryu, Geunyeong Byeon, Arizona State University, Tempe, AZ, Contact: minseok.ryu@asu.edu

We propose an approach for randomized column generation (CG) that maintains the convergence characteristics of the classic CG technique, while simultaneously improving speed by learning from iterative information. To achieve this, we have modified the CG method to enhance information sharing between decomposed problems, which helps to generate effective columns. By conducting a computational analysis on mixed-integer linear problems, we have shown that our proposed method outperforms current solution approaches in terms of computational efficiency.

Infrastructure Planning to Address Climate Change

Contributed Session

Session Chair: Ashkan Zare Hadesh, George Mason University, Fairfax, VA

1 The Fuels and Industry Integrated Optimization Model (FINITO)

Merve Olmez Turan, Maxwell Brown, Daniel Steinberg, National Renewable Energy Laboratory, Golden, CO, Contact: merve.olmezturan@nrel.gov

The evolution of the industrial sectors plays a crucial role on mitigating climate change and reaching net-zero emissions targets by 2050 in the United States yet detailed modeling efforts remain sparse. Therefore, discussion on industrial decarbonization strategies should consider economic and environmental objectives as well as relations with fuel and power sectors. In this presentation, we discuss the Fuels and Industry Integrated Optimization Model (FINITO) which is a spatially explicit, long-term capacity expansion model for the industrial and fuel supply sectors. We demonstrate both the methods of and implications on industrial, fuel supply, and power sector evolution by linking with the Regional Energy Deployment System (ReEDS), the National Renewable Energy Laboratory's flagship electricity capacity expansion model.

2 Managing Physical Assets: A Systematic Review and a Sustainable Perspective

Amir-Behzad Samii[1,2], Georgiana Sandu[1], [1]Vlerick Business School, Brussels, Belgium; [2]Zaragoza Logistics Center, Zaragoza, Spain. Contact: behzad.samii@vlerick.com

Physical Asset Management (PAM) has shifted from the negative image of asset failure and expensive maintenance to an enabler of sustainability that creates value from extended lifetime and renewed functions. We follow a systematic reviewing process enabled by text analytics methods to identify the approaches to building a sustainable perspective for PAM. Statistics and critical features extracted from over 2800 journal articles support our key contributions and insights. We particularly emphasize the research footprint and trends of the asset-intensive construction and energy sectors represented as barriers and enablers of sustainable development. We propose a conceptual framework that adopts an asset-within-a-system perspective, recognizes the links between the stakeholders, and holistically integrates the extracted research trends.

3 Sustainability-Aware Asset Investment Optimization

Nianjun Zhou[1], Pavankumar Murali[2], Dzung Phan[2], Anuradha Bhamidipaty[3], [1]IBM, Chappaqua, NY, [2]IBM Research, Yorktown Heights, NY, [3]IBM, Yorktown Heights, NY, Contact: jzhou@us.ibm.com

Sustainability-aware asset replacement has taken a prominent role in Energy & Utilities, supply chain, transportation, and other industries to meet the clean energy and zero emissions targets set by the 2030 Paris Agreement. This talk introduces a novel approach for asset replacement planning using sustainability scores together with asset health metrics. We prioritize assets to be replaced based on failure risk and criticality while aiming for the highest overall sustainability benefits. Our four-step approach includes computing asset sustainability posture, forecasting this posture over a planning horizon, enhancing the asset risk matrix with sustainability scores, and optimizing asset investment planning by incorporating these scores. We demonstrate the application of our methodology to distribution transformers in the Energy & Utilities industry.

4 Optimal Transportation Infrastructure Protection Investment Timing for Climate Change

Ashkan Zare Hadesh[1], Elise Miller-Hooks[2], [1]George Mason University, Fairfax, VA, [2]George Mason University, Fairfax, VA, Contact: azarehad@gmu.edu

Actions to protect transportation infrastructure against uncertain coastal flooding events and other risks from a changing climate involve major capital investments and long-term implementation schedules. Whether these investments will pay off or could be postponed to allow near-term investment in alternative community needs depends on the outcome of low-probability, but high-consequence events and their timing. This talk will describe OR-based methods to determine a best protective investment strategy and implementation timing toward protecting our transportation systems.

Models for Energy Supply Chains

Contributed Session

Session Chair: Hyunhong Choi, Kyung Hee University, Yongin, Korea, Republic of

1 A Two-stage Spatiotemporal Predictive Framework to Forecast Mobility Patterns to Gas Stations

Zhiyuan Wei[1], Sayanti Mukherjee[2], [1]University at Buffalo, Buffalo, NY, [2]University at Buffalo - The State University of New York, Buffalo, NY, Contact: zwei7@buffalo.edu

Accurate demand forecasts for gas stations are fundamental to providing essential services to people, yet have received little attention in the literature due to data unavailability and lack of sophisticated predictive tools. Thus, we provide a new perspective for demand forecasts at gas stations leveraging large-scale human mobility data, and propose a novel two-stage data-driven framework mobility prediction. The first stage is to decompose the mobility patterns into spatial and temporal components, whereas the second stage is to model temporal dynamics using multivariate time series analysis. The results show that our model demonstrates the best predictive performance over multiple benchmark models for varying forecast horizons. The stability and reliability of the framework are also investigated through sensitivity analysis and robustness checks.

2 A Nationwide Hydrogen Supply Chain Deployment Plan for a Short-Term Hydrogen Supply Shortage

Seungyeop Lee[1], Hyunjoon Kim[2], Byung-In Kim[1], [1]Pohang University of Science and Technology (POSTECH), Pohang, Korea, Republic of; [2]Gachon University, Seongnam, Korea, Republic of. Contact: sylee1509@postech.ac.kr

A nationwide hydrogen supply chain deployment problem for mobility involves determining the sites and capacities of hydrogen refueling stations (HRSs), considering production, physical state, transportation, refueling, and demand. Short-term solutions entail on-site HRS installation to overcome supply shortages from existing facilities. To tackle this problem, we propose a two-stage optimization approach that includes demand and supply stages using mixed-integer linear programming models. In the demand stage, the optimal locations and capacities of HRSs are determined, along with demand allocation. In the supply stage, the installation of additional on-site production facilities for HRSs to be deployed and the supply allocation are determined. Realistic assumptions and high-resolution data are utilized to evaluate our proposed approach for 2025 and 2030.

3 Investigating Development Trends and Emerging Technological Topics in Hydrogen Sector Using Patent Data

Hyunhong Choi, Kyung Hee University, Yongin, Korea, Republic of. Contact: hongchoi@khu.ac.kr

As a promising alternative for the future energy system, hydrogen technology has been gaining significant attention, particularly recently. This study aims to investigate both the long-term development trends and recent emerging technological topics in the hydrogen technology sector. Specifically, using a structural topic model and patent data collected from the US Patents and Trademarks Office, we examine which topics led the previous key uptakes in the sector and which are likely to drive the next surge in hydrogen technology in the near future. Moreover, we provide a national-level comparison and decision-making tools for policymakers, enabling them to better understand and classify hydrogen technology.

Perspectives on Adoption of Emerging Technologies

Contributed Session

Session Chair: Segev Wasserkrug, IBM Research - Israel, Haifa, Israel

1 Pride and Program: How Overconfidence Drives Crypto Asset Adoption

Dominik M. Piehlmaier, Emanuela Stagno, Maria Restuccia, University of Sussex, Brighton, United Kingdom

Despite large and persistent volatility, crypto assets have become an important investment tool over the past decade. However, little is known about the drivers of adoption of such assets and the reasons why some investors choose to bank on crypto assets in an early market with a lack of information and high volatility. We show that overconfident investors drive the expansion of crypto assets by expecting higher returns than mass-market investors. Using data from approximately 2,000 investors, 800 experimental participants, and more than 5.5 million transactions, we show that confidence in investment knowledge significantly increases the chances of investing in an early crypto market. However, objective knowledge has the opposite effect. Furthermore, overconfident early investors overtrade crypto assets and hurt their bottom line with every additional transaction.

2 Straying or Staying: The Impact of Token Incentives on User Defection and Retention

Jian Li[1], Xinyu Zang[2], Xiang(Shawn) Wan[3], Xi Zhao[1], Kenny Cheng[2], [1]Xi'an Jiaotong University, Xi'an, China; [2]University of Florida, Gainesville, FL, [3]Santa Clara University, Santa Clara, CA, Contact: xinyu.zang@warrington.ufl.edu

The prosperity of cryptoeconomics in recent years has highlighted the need for reliable crypto exchange platforms. Due to the significant issues associated with centralized exchanges, decentralized exchanges (DEXs), which are two-sided on-chain platforms without intermediaries, have emerged as a viable alternative. Based on a series of competitive events between two leading DEXs in the blockchain ecosystem, we empirically investigate the impact of tokenized incentives on user defection and retention. Our study provides valuable insights into motivating user engagement for DeFi applications and the broader blockchain community.

3 Leveraging the Internet of Things and an Understanding of Human Behavior in Condition-Based Preventive Maintenance

Mateus J do Rego F. Lima[1], Elliot Bendoly[2], Nathan C. Craig[3], [1]The Ohio State University, Columbus, OH, [2]The Ohio State University, Worthington, OH, [3]Ohio State University, Columbus, OH, Contact: doregoferreiralima.1@osu.edu

We investigate settings where the Internet of Things augments condition-based preventive maintenance. Inspired by field case data and on-site observations, we observe work behaviors that undermine the full potential of this technical benefit and consider mitigation options. We delve into these issues through the use of a multimethod empirical perspective.

4 The Usage of Robotics, AI and Sensor Fusion to Meet Sustainability Goals in Technology Companies

Stavan Dholakia[1], Shivani Shukla[2], [1]Microsoft Corp, Seattle, WA, [2]University of San Francisco, San Francisco, CA

This paper investigates the integration of robotics, AI, sensor fusion and warehouse automation and order fulfillment to achieve sustainable operations. The aim is to drive sustainable practices, reduce resource consumption and enhance environmental performance. AI algorithms contribute to sustainability by optimizing processes and minimizing environmental impact. Metrics such as a 25% decrease in energy consumption, a 20% reduction in carbon emissions, and a 15% improvement in equipment uptime highlight the positive outcomes achieved through accurate demand forecasting, energy management, optimization and predictive maintenance facilitated by AI technologies. We compare the metrics of such an implementation in the context of a real-world application.

5 Who Benefits from Multi-Cloud? A Game Theoretic Analysis

Segev Wasserkrug[1], Shaul Rosner[2], Takayuki Osogami[3], [1]IBM Research - Israel, Haifa, Israel; [2]Reichman University - Israel, Herzeliya, Israel; [3]IBM Research - Tokyo, Tokyo, Japan. Contact: segevw@il.ibm.com

The benefits of cloud computing, along with its limitations such as provider lock in and geographical restrictions on data, are leading to the formation of a new multi-cloud market in which cloud users will be able to distribute their workloads easily and dynamically across different clouds. While this is expected to be beneficial to users, providers' income may reduce from such a move.
In this work, using trading networks, we formally analyze the multi-cloud market and show that, surprisingly, users may also pay more in such a market. Moreover, we show that with a centralized broker, it is almost always possible to create a multi-cloud market beneficial to all when assuming truthful revelation. Finally, we show that it many cases, using automated mechanism design, it is possible to learn mutually beneficial mechanisms where truthful value reporting is the dominant strategy.

Network Analytics for Smart and Resilient Urban Systems

Community Committee Choice Session

Session Chair: Jinzhu Yu, 1</sup

1 Networked Systems: Going Beyond Topological Relations

Jürgen Hackl, Princeton University, Princeton, NJ, Contact: hackl@princeton.edu

Network science offers robust techniques for analyzing complex systems like power grids, transportation, communication infrastructures, and social networks. With increased access to data on networks with more than just dyadic relations, we can also understand when, where, and in which order these relations occur. Despite advances in data analytics and machine learning, applying these techniques to real-world data with complex characteristics remains challenging.
Novel approaches in network science are needed to address this challenge. This presentation introduces formal methods in network science for complex dynamic processes in transportation networks and spatially embedded systems. The focus is on space and time-aware network analytic methods that consider both temporal and topological dimensions of complex systems.

2 A Simulation-Based Optimization Approach for Resource Allocation Decisions Considering Organizational Dynamics

Shima Mohebbi, Pavithra Sripathanallur Murali, George Mason University, Fairfax, VA, Contact: psripath@gmu.edu

Traditional resource allocation models focus on centralized approaches, where there is a single decision maker, one set of resources, and one aggregated goal. However, many complex systems such as infrastructure systems are governed by several sectors working together. The collective performance of such systems is affected by various factors such as financial decision-making and communication protocols between sectors. We develop a hybrid simulation-based optimization model for decentralized resource allocations with applications in infrastructure systems. Dynamics of communication and financial decisions at organizational levels are captured by a system dynamics model while maintenance decisions and network performance are captured by an agent-based model. The proposed model is applied to water and transportation networks in the City of Tampa, FL.

3 An Optimal Control Approach for Additive Manufacturing Production with Waste Recycling Process

Shuo Linda Wang[1], Arian Sarrafan[2], [1]UT Arlington, Arlington, TX, [2]UT Arlington, ARLINGTON, TX

Economic damage due to the supply chain turmoil in the past few years has been more severe than the pandemic. The primary cause of such a crisis is that the current supply chain analysis tool, relying heavily on static optimization, is insensitive to non-eligible changes such as policy changes due to the pandemic. In this talk, the primary purpose is to achieve agile sustainability supply chain management through dynamic system modeling and control for such networks' production processes, which involves theoretical and numerical analysis. Several numerical cases are presented to demonstrate the applicability of this developed dynamic system and further discuss the potential optimal production.

4 Reconstructing Sparse Multiplex Networks with Application to Covert Networks

Jinzhu Yu[1], Jianxi Gao[2], Felipe Aros-Vera[3], Gisela Bichler[4], Mincheng Wu[5], [1]UT Arlington, Arlington, TX, [2]RPI, Troy, NY, [3]Ohio University, Athens, OH, [4]California State University, San Bernardino, San Bernardino, CA, [5]Zhejiang University of Technology, Hangzhou, China. Contact: yujinzhu88@gmail.com

The complete structure of real-world networks is often unavailable, thus it is crucial to develop approaches to infer a more complete structure of networks. To this end, we integrate the configuration model for generating random networks into an Expectation-Maximization-Aggregation (EMA) framework to reconstruct the complete structure of multiplex networks. We validate the proposed EMA framework against the Expectation-Maximization (EM) framework and random model on several real-world multiplex networks. It is found that the EMA framework generally outperforms the EM framework and the random model. The inferred multiplex networks can be leveraged to inform the decision-making on monitoring covert networks as well as allocating limited resources for collecting additional information to improve reconstruction accuracy.

5 Revealing Water Distribution Network Robustness to Link Failures Using a Novel Topological-Physical Measure

Xiangnan Zhou, Leonardo Duenas-Osorio, Rice University, Houston, TX, Contact: xz68@rice.edu

The functionality of a water distribution network (WDN) depends on multiple features including topology structure, element profile, and physical constraints. We propose a novel topological-physical measure, the weighted average source-terminal shortest path length ⍰, to approximate a WDN's capability to deliver water from sources to demand nodes. We use variations of ⍰ to estimate the impacts of pipe failures on a WDN's functionality revealing its robustness. We validate this measure with computational experiments, where pipe rankings using our approach are compared to those by hydraulic analysis, on four WDN test cases. A high correlation was identified between ranking results by the two approaches for all WDNs under single-link and two-link failure scenarios. Also, the critical pipe set identified by hydraulic analysis is always a subset of that by our approach.

Session Chair: Birsen Karpak, Youngstown State University, Canfield, OH

Session Chair: Ilker Topcu, Istanbul Technical University, Istanbul, Turkey

1 Rank Voting: The Closest to Voting with Intensity of Preferences

Luis G. Vargas, University of Pittsburgh, Pittsburgh, PA

Voting is the essence of democracy. One person one vote. It is also known that not everybody likes a candidate with the same intensity. So, how do we enter into the voting process the intensity with which we feel our support for a candidate, or our like/dislike for a candidate? In this paper we show using rank voting with an eigenvector method, that when all the candidates running for an election are ranked, as in Australia, the percent of votes captured by the candidates is close to the values one would obtain if each voter were allowed to express how strongly they prefer one candidate versus another. We show though simulations the convergence of both approaches.

2 Best Worst Method and Data Envelopment Analysis

Dariush Khezrimotlagh, Pennsylvania State University - Harrisburg, Middletown, PA

The challenge for decision makers is to choose appropriate weights for criteria despite their personal preferences. To address this issue, this study develops a linear procedure that balances decision makers' preferences with appropriate weights for criteria.

3 Modeling the IoT Adoption Barriers in Indian Micro, Small & Medium Enterprises Using an Integrated BWM-DEMATEL Approach

Sorokhaibam Khaba[1], Dibyajyoti Ghosh[2], [1]Institute of Management Technology, Dubai, United Arab Emirates; [2]Vellore Institute of Technology, Vellore Tamil Nadu, India. Contact: prinskhaba@gmail.com

The purpose of this study is to identify the ranking of the IoT implementation barriers in the Indian MSME industry and to develop the causal relationships among these barriers. The study has identified 19 barriers to IoT implementation in the Indian MSME industry, grouped into 4 main barriers from literature review and expert opinion. An integrated MCDM technique combining the BWM and the DEMATEL is used to evaluate the barriers. The study found that Technical Challenges and Socio-Environmental Challenges are the most important and the least important barriers respectively. The result from the causal relationship implied that 9 sub-barriers come under the cause group while the effect group includes 10 sub-barriers. The findings would give guidance and deeper insights into potential barriers to IoT adoption and take better strategies for successful IoT adoption.

1 K-12 Outreach: Early Introduction to Operations Research

Afrooz Jalilzadeh, The University of Arizona, Tucson, AZ

There is a lack of awareness among middle and high school students about the benefits of Operations Research (OR) and how it can lead to better decision-making. Our project aims to address this gap by introducing OR to middle and high school students in Tucson, Arizona. Our approach involves a variety of interactive activities, informative presentations on OR applications, career paths, and the significance of diversity in STEM. In this talk, we will summarize our project's progress and share insights gained from our work with Tucson schools.

2 Guided Discussions on How Women Can Thrive

Aineth Torres, Fractal.ai, Austin, TX

This presentation will describe my experience facilitating the series of "Guided discussions on how women can thrive" which main objective is to critically explore within the INFORMS community what science says about the factors that drive women to suceed in their professional career as well as the obstacles they face, especially in STEM fields. A summary of the content exchanged during each session and the points of view shared by the participants will be included, as well as an overall assessment of the experience and potential extensions or future activities.

Andrea Hupman[1], Gul E. Kremer[2], Allison C. Reilly[3], Jun Zhuang[4], Amy Russ[5], Vivian Nwadiaru[6], Mubarak Iddrisu[7], Dayu Wu[8], Anh Phuong Ngo[9], Hamid Arzani[10], [1]University of Missouri - St. Louis, Saint Louis, MO, [2]University of Dayton, Dayton, OH, [3]University of Maryland, College Park, MD, [4]University at Buffalo, Buffalo, NY, [5]Synchrony, Duluth, GA, [6]University of Massachussetts Amherst, Amherst, MA, [7]University of Massachusetts Boston, Boston, MA, [8]University of Wisconsin, Madison, WI, [9]NCAT, Greensboro, NC, [10]Rotman School of Management, University of Toronto, Toronto, ON, Canada

Value focused thinking advocates beginning any decision-making process by carefully specifying values. The Decision Analysis Society (DAS) DEI Subcommittee is endeavoring to begin its efforts by focusing on values. This project teaches five graduate student fellows about value focused thinking. The student fellows and team members have developed and deployed a survey of INFORMS and DAS members' perspectives and values as they relate to activities promoting diversity and improving a sense of inclusion among all members in order to guide future programming activities and efforts. This talk summarizes the survey instrument and its findings.

4 To Future Medical Failures: Racial and Gender Bias in Research

Behshad Lahijanian, Gian-Gabriel P. Garcia, Nicoleta Serban, Georgia Institute of Technology, Atlanta, GA, Contact: blahijanian3@gatech.edu

Diversity, equity, Inclusion (DEI) is an inherently complex issues, and everyone makes their trade-off between perfect equality and dealing with historical inequality. Researchers always suffer from these biases between different genders, races, and under-represented minorities. This gender bias is more critical in human life. What's missing is an in-depth understanding of how women and men of different races respond differently to medications and other therapies, as well as other variables that profoundly influence human health. In this panel discussion, we will discuss these biases in healthcare research.

5 Active Engagement with DEI Students from Data-Related Master's Programs in the INFORMS Data Mining Society and Beyond

Ying Lin[1], Chun-An Chou[2], Nathan B. Gaw[3], [1]University of Houston, Houston, TX, [2]Northeastern University, Boston, MA, [3]Air Force Institute of Technology, Wright-Patterson AFB, OH, Contact: ylin58@uh.edu

Data science (DS) has drawn increasing attention in academia and every conceivable industry. As a result, there is ever-increasing motivation for students of diverse backgrounds to learn data mining and decision analytics (DMDA) skillsets for their future career. However, it brings apparent difficulties and barriers to train and foster students who were not in DS-related majors. As one of largest professional communities dedicated to OR and analytics research, we are responsible to provide a channel to consider diversity, equity, and inclusion (DEI) for students to participate in INFORMS events. This project conducted by the INFORMS Data Mining Society will contribute to furthering DEI of INFORMS within the data-related communities through attracting students from diverse backgrounds to participate in online seminars, workshops/conferences, and data challenges.

6 Well Informed Mentorship Program

Jessye Talley, Morgan State University, Baltimore, MD, Contact: jessye.bemleytalley@morgan.edu

Wellness and self-care are recognized as an essential part of optimal health and well-being. Creative interventions, seminars and the like are being incorporated in every system (corporate, non-profits, private practice and industry) to promote wellness. This movement is slowly being integrated into the academic setting. Wellness should be considered more than the latest trend; it should also be seen as a tool that prevents non-productivity, self- sabotage or conflict with self and others. The need for education, creative interventions and social support in the academy is vital for the success of all college students and professors. In this session we will highlight our DEIC project that showcases the self-care and wellness practices that we cultivated with OR/MS PhD students on the doctoral journey.

7 A Portal for Diverse OM/MS Teaching Resources

Margret Bjarnadottir[1], Jason Acimovic[2], [1]University of Maryland at College Park Robert H Smith School of Business, College Park, MD, [2]Penn State University, State College, PA, Contact: margret@rhsmith.umd.edu

The goal of this project is to make it easy for faculty to search for inclusive classroom materials by systematically collecting information about DEI cases and MS/OM cases with diverse actors and make them available through an online portal.

8 Adding Wings to the "Pride Forum" at INFORMS

Priyank Arora[1], Dwaipayan Roy[2], [1]University of South Carolina, Columbia, SC, [2]University of Virginia Darden School of Business, Charlottesville, VA, Contact: priyank.arora@moore.sc.edu

This project aims to help the new PRIDE Forum at INFORMS take-off and gain momentum ("add wings") in its initial phase. The PRIDE Forum comprises of individuals with self-identified interest in supporting or championing the interests of LGBTQ+ members.

9 Informs High School Outreach Strategic Initiative

Veronica White[1], Carmen Haseltine[2], Mary Ogidigben[3], [1]University of Wisconsin Madison, Madison, WI, [2]University of Wisconsin-Madison, Madison, WI, [3]Penn State University, State College, PA, Contact: vmwhite@wisc.edu

In 2022, we developed a workshop to introduce high school students to the field of Operations Research. The workshop was delivered to 28 students and was designed to increase student awareness, confidence, and contemplation of OR/MS using a motivational example of choosing social media influencers. Building upon the success of last year's project, we established yearly outreach workshops hosted by the UW-Madison and Penn State INFORMS student chapters that engage underrepresented minority students in OR/MS fields. Additionally, we created a comprehensive informational packet for INFORMS Student Chapters that serves as a standalone guide for student chapters to engage in high school outreach consistently. This talk will discuss the workshops held in 2023, the informational packet, and how to access it.

10 Informs DEI Research: How Can Your Research Help to Promote DEI?

Bing Si, State University of New York at Binghamton, Binghamton, NY

This project proposes a Diversity, Equity, and Inclusion Research (DEIR) initiative to showcase and highlight how the OR/MS research can help to promote DEI through the Research Pathway. The proposed DEIR initiative is inspired by the continued contribution on DEI promotion from our INFORMS researchers who have demonstrated that OR/MS research can help promote DEI in society by directly tackling challenges faced by under representative populations. Under this initiative, a DEIR-featured session is organized in the 2023 INFORMS Annual Meeting, jointly listed by Quality, Statistics, and Reliability (QSR) and Data Mining (DM), to recognize and promote the contribution of OR/MS research on addressing real-world challenges in public health and policy to better serve the diverse population of individuals.

Health Delivery Challenges in Low-Income Settings

Community Committee Choice Session

Session Chair: Jérémie Gallien, London Business School, London, United Kingdom

1 Optimal Geographic Assignment Guidelines for Maternity Waiting Homes in Resource-Limited Environments

George Chen[1], Yuhang Du[1], Jérémie Gallien[1], Jody Lori[2], [1]London Business School, London, United Kingdom; [2]University of Michigan, Ann Arbor, MI, Contact: ydu@london.edu

Maternity waiting homes (MWH) constitute an effective intervention for reducing maternal mortality where timely access to a skilled birth attendant is difficult. MWH operations present challenges due to limited accommodation capacity and delivery date uncertainty however. We consider the problem of whether and when a pregnant woman should go to a local MWH with given capacity based on her health profile and living location. We use variational calculus to derive closed-form assignment policies within an MWH catchment area, perform numerical experiments to evaluate the impact of potential associated interventions in the country of Liberia, and develop related recommendations.

2 When Should Fractional-Dose Vaccines be Used?

Naireet Ghosh[1], Jérémie Gallien[1], Francis de Véricourt[2], [1]London Business School, London, United Kingdom; [2]European School of Management and Technology, Berlin, Germany. Contact: nghosh@london.edu

Fractional-dose vaccines constitute a potential epidemic intervention when available vaccine stockpiles are limited. While fractional-dose vaccines help expand coverage, they are less efficacious and hence lead to a slower buildup of population immunity when the speed of vaccine administration is constrained. We use an optimal control model to analyze this tradeoff and derive a simple and easily implementable vaccination policy relying on a combination of full and fractional-dose vaccines. We perform extensive numerical experiments to investigate the population health benefits and risks associated with this policy relative to single-dose alternatives, and develop policy recommendations based on the available stockpile and maximum vaccination speed.

3 Empowering the Frontline Health Workers to Tackle Stock-Outs: Empirical Evidence from Indonesia

Amir Karimi[1], Anant Mishra[2], Karthik V. Natarajan[2], Kingshuk K. Sinha[2], [1]Alvarez College of Business, The University of Texas at San Antonio, San Antonio, TX, [2]Carlson School of Management, University of Minnesota, Minneapolis, MN, Contact: a.karimi@utsa.edu

In low and middle-income countries, frontline health workers are frequently tasked with the non-clinical responsibility of inventory management for which they are not adequately trained. While training programs can improve the skills of frontline health workers in managing inventories, we have a limited understanding of the conditions under which the benefits from such trainings are more or less pronounced. To address this gap, we analyze novel and proprietary field data from a large-scale training program of frontline health workers in Indonesia, comprising more than 2 million observations from nearly 18,000 health facilities.

4 Managing Essential Gatherings During the Pandemic: The Case of Agricultural Procurement During Covid-19 in India

Hemanshu Das[1], Sarang Deo[2], Sripad K. Devalkar[3], Nimalan Arinaminpathy[4], [1]Yale University, New Haven, CT, [2]Indian School of Business, Hyderabad, India; [3]Indian School of Business, Hyderabad, India; [4]Imperial College,

London, United Kingdom. Contact: sarang_deo@isb.edu
Certain multi-day events of social and economic importance must be held during a pandemic despite their transmission risk. Limiting crowding may reduce transmission at these events within a day but may end up prolonging the overall event duration thereby increasing the overall disease transmission due to the growth of the pandemic in the community over this period. We explore this trade-off using a stochastic, compartmental model in the context of agricultural procurement centres in Punjab, India. We find that the impact of event duration depends on the local epidemiological context. Specifically, counter to intuition, shorter duration is preferred if the event is held in the period of rising infections in the surrounding community.

CC-West 102A

Scheduling Theory and Its Contemporary Applications

Community Committee Choice Session

Session Chair: Zhixin Liu, University of Michigan - Dearborn, MI

1 Scheduling Chains Using Sublinear Time or Sublinear Space

Hairong Zhao, Purdue University Northwest, Hammond, IN

We study the problem of minimizing makespan on identical parallel machines with precedence constraints. We specifically consider precedence graphs composed of chains. Our goal is to develop approximation algorithms for this problem that utilize sublinear space or sublinear time. These algorithms have practical applications in big data modeling. The techniques used in this research can provide insights for developing algorithms for other problems.

2 Human-Machine Collaboration Scheduling with Serial and Parallel Jobs

Gongjie Xu, Jun-Qiang Wang, Chenmin Liu, Northwestern Polytechnical University, Xi'an, China. Contact: pacpos.gjxu@gmail.com

We study a human-machine collaboration scheduling problem with parallel and serial jobs to minimize the makespan. A parallel job is simultaneously processed by a human and a machine. A serial job is first processed by a human and then processed immediately by a machine. For the problem with parallel jobs, we design an approximation algorithm and analyze its performance. For the problem with serial jobs, we design two heuristic algorithms and verify the effectiveness of the algorithms by experiments.

3 Scheduling for Patient-Centered Care and Outcomes for Chronic Conditions: Challenges and Opportunities

Charu Chandra[1], Zhixin Liu[2], [1]Univ of Michigan- Dearborn, Dearborn, MI, [2]University of Michigan-Dearborn, Dearborn, MI, Contact: charu@umich.edu

The Institute of Medicine defines patient-centered care as “Providing care that is respectful of, and responsive to, individual patient preferences, needs and values, and ensuring that patient values all clinical decisions.” A segment of patients requiring this care regime are elderly with chronic conditions, such as Alzheimer, and congestive heart failure. Due to the nature of their care, these patients are frequently treated by a cadre of caregivers, ranging from a PCP, specialists, nurses, nurses' aides, therapists, etc., often with overlapping and/or coordinated schedules. To accommodate these special care needs, a linear schedule is not feasible. We look at what challenges and opportunities exist for such scheduling and investigate a viable multi-tiered, flexible, and dynamic constrained scheduling solution.

4 Research on Optimization of Material Dispensing Path Selection at the Front End of Production Line

Wei Si[1], Jianbin Li[2], [1]Huazhong University of Science & Technology, Wuhan, China; [2]Huazhong University of Science & Technology, Wuhan, China

With the improvement of productivity level, the competition between enterprises is increasing. Meticulous production is gradually becoming the inevitable trend of enterprise survival and development. In such an economic environment, enterprises rely on manual experience. A lack of scientific guidance in decision-making will substantially increase costs while reducing operational efficiency. In order to achieve cost reduction and increase efficiency and improve enterprise competitiveness, this paper considers inventory cost and material backflow, establishes a material distribution path selection model for the front-end material distribution link in intra-enterprise logistics, and uses a two-stage heuristic algorithm based on local search to solve it.

5 Dynamic Seat Assignment with Social Distancing

Zikang Li, Xiangtong Qi, Qian Liu, The Hong Kong University of Science and Technology, Hong Kong, China

This study addresses the dynamic seat assignment problem with social distancing, which arises when groups arrive at a venue and need to be seated together while respecting minimum physical distance requirements. To tackle this challenge, we develop a scenario-based method for generating seat plans and propose a seat assignment policy for accepting or denying arriving groups. We also explore a relaxed setting where seat assignments can be made after the booking period. The results provide insights for policymakers and venue managers on seat utilization rates and offer a practical tool for implementing social distancing measures while optimizing seat assignments and ensuring group safety.

Recent Developments in Digital Platform Operations

Community Committee Choice Session

Session Chair: Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong

Session Chair: Bharadwaj Kadiyala, University of Utah, Salt Lake City, UT

1 Sponsored vs. Programmatic: A Theoretical Analysis of Advertising Strategy on Digital Content Platforms

Kun Qian, Southern University of Science and Technology

Advertisers can reach online content audiences through two channels: programmatic advertising, which involves delivering ads through digital bidding for ad spots controlled by the platform (e.g., YouTube), and sponsored advertising, which involves ad directly sponsoring content creators who include paid product placements or endorsements in their content. The platform may lose revenues if advertisers choose to sponsor creators instead of delivering programmatic ads. This paper employs a game-theoretic model to examine the platform's incentives for allowing or disallowing sponsored advertising and the implications of its advertising strategy on online content innovation, profits, and surpluses.

2 Search in Omnichannel Operations via Information Design

Ailing Xu[1], Qiao-Chu He[2], Ying-Ju Chen[3], [1]The Hong Kong University of Science and Technology, HongKong, China; [2]Southern University of Science and Technology, ??, ??, China; [3]The Hong Kong University of Science and Technology, Kowloon, Hong Kong. Contact: axuaj@connect.ust.hk

This paper examines how firms manage consumer search and purchase behaviors in omnichannel operations via information design. We propose a sequential search model, where consumers are allowed to search either channel or both and choose to purchase or leave at any stage of the search process. By fine-tuning information structures, we can synergize both channels to navigate consumer search and coordinate channel competitions. The optimal signal structure is either a two-interval or three-interval policy online, which is shaped by the complementarity effect between two channels and the tension between the persuasion incentive and the attraction incentive. Especially, when product values are perfectly correlated, firms obfuscate extreme (low-end and high-end) match values and mix intermediate match values to differentiate consumer search patterns in two channels.

3 The Value of Customer-Related Information on Service Platforms: Evidence from a Large Field Experiment

Zhiyu Zeng[1], Nicholas Clyde[2], Hengchen Dai[3], Dennis Zhang[4], Zuo-Jun Max Shen[5], [1]Tsinghua University, Beijing, China; [2]Washington University in St. Louis, SAINT LOUIS, MO, [3]UCLA Anderson School of Management, Los Angeles, CA, [4]Washington University in St Louis, ST LOUIS, MO, [5]University of California Berkeley, Berkeley, CA, Contact: nsclyde@wustl.edu

We conducted a field experiment on a live-streaming platform that connects hundreds of millions of viewers with individual broadcasters. When viewers entered shows, we provided viewer-related information to broadcasters who were randomly assigned to the treatment condition (but not to control broadcasters). Our analyses, involving a random subsample of 49,998 broadcasters, demonstrate that relative to control broadcasters, treatment broadcasters expanded service capacity by 12.62% via increasing both show frequency (3.31%) and show length (7.10%), thus earning 10.44% more income, based on our conservative estimate. Moreover, our intervention increased service enjoyment (measured by viewer watch time) by 4.51%. Additional analyses about the field experiment and two surveys involving 1,229 broadcasters shed light on the mechanisms.

4 The Economics of Ghosting

James Siderius[1], Mohamed Mostagir[2], [1]Dartmouth College, Hanover, NH, [2]University of Michigan, Ann Arbor, MI, Contact: jpsiderius@gmail.com

Ghosting is a phenomenon where communication between two parties abruptly stops after one side becomes deliberately unresponsive. This occurs in a variety of settings and applications, but the term entered the mainstream after its usage to describe an important aspect of the online dating experience that, surprisingly, has been sparsely studied. Both online dating platforms and users report that ghosting is one of the primary drivers hurting user experience and preventing good outcomes. We develop a model of ghosting and study the optimal communication policies that platforms can implement. Interestingly, we show that no structure on communication, or alternatively, eliminating ghosting altogether, can both result in lower welfare for users.

Resource Management in Services

Contributed Session

Session Chair: Xi Shan, Bemidji State University, Bemidji, MN

1 Dynamic Resource Sharing in Private 5g Networks with Slicing

Demet Batur[1], Jennifer K. Ryan[2], Mehmet C. Vuran[1], [1]University of Nebraska-Lincoln, Lincoln, NE, [2]University of Nebraska - Lincoln, Lincoln, NE, Contact: dbatur@unl.edu

We propose a Markov Decision Process model to study the decision problem faced by the operator of a private 5G network, known as a private cell, who must allocate available capacity to meet the resource needs of the primary user of the network, but who may also lease excess capacity to external secondary users to generate additional revenue. Private cells are privately-owned, local wireless networks independent of commercial or public 5G networks. Such networks have recently been implemented in factories, warehouses, hospitals, ports, and campuses. Network slice instances are units of demand from the primary user, requiring specific resource combinations, such as spectrum, computation, or storage. We use the model to characterize the optimal real-time admission decisions for the slice instances, and leasing and cancellation decisions for the secondary user demands.

2 Optimizing the Call Center Headcount of the Largest Bank in Perú, BCP

Alvaro Evangelio, Alfonso Barriga, Cynthia Yacel Fuertes, Banco de Crédito de Perú, Lima, Peru. Contact: alvaroevangelio@bcp.com.pe

We combine machine learning and optimization to determine the optimal number of call center operators in a call center of BCP, the largest bank of Peru. We use empirical data to calibrate the service level as a function of the number of operators. We applied these methods and achieved a 10% reduction in the number of call operators combined with an improvement of service level.

3 Satiation and Motivation for the Long Run: What Motivates Physicians in Online Communities?

Panpan Wang[1], Jifeng Luo[2], Zhiyan Wu[3], [1]Zhejiang University of Finance and Economics, Hangzhou, China; [2]Shanghai Jiao Tong University, Shanghai, China; [3]Shanghai University of International Business and Economics, Shanghai, China

A variety of incentives have been adopted to encourage voluntary contributions in online communities. However, the majority of related research either examines the effect of incentives over the short run or ignores the interplay between supply-side contributions and demand-side requests in multisided platforms. From a two-sided perspective, our study investigates the time-varying effects of different incentives on physician contributions in a doctor-patient interaction platform. The main challenge faced when addressing this problem is a simultaneity and reverse causality issue. We adopt simultaneous equation model to cope with this problem. Our results verify the existence of satiation and the time-varying effects of different incentives on the examined physicians' efforts.

4 Consequences Of Long Lead Time - Evidence From The Israeli Court System

Shany Azaria[1], Noam Shamir[2], [1]Tel Aviv University, Tel-Aviv, Israel; [2]Tel Aviv University, Tel Aviv, Israel. Contact: azaria.shany@gmail.com

This paper describes a data-driven approach to study negative consequences of congestion, demonstrated in court system environment. Combining two extensive and unique datasets from the Israeli court system, we aim to econometrically estimate the effect of long lead times, an outcome of congestion, on real demand for judges' effort caused by changes in work content induced by the customers. We propose a rigorous analysis to deal with the empirical challenges of reverse causality between lead time and effort using the two exogenous shocks to lead time as IVs. Our findings suggest that delay causes a significant increase in judges' effort and in the probability of cases ending with judgments on merits, thus increases demand. These findings contribute to understanding judicial system dynamics and offer insights for enhancing efficiency.

5 Vertical Contracting with Information Asymmetry: Do Secret Offers Hurt a Channel?

Xi Shan[1], Lixin Ye[2], Chenglin Zhang[3], [1]Bemidji State University, Bemidji, MN, [2]The Ohio State University, Columbus, OH, [3]Southwestern University of Finance and Economics, Chengdu, China

We consider the issue of contract confidentiality in a decentralized supply chain, where a manufacturer produces for two downstream competing retailers. When the contracts are observed secretly, we follow the vertical contracting literature by assuming that agents hold "passive beliefs" about the other agent's contract terms. Surprisingly, secret contracts may improve channel profit as they can involve either downward or upward distortion, and channel coordination can be achieved under certain conditions. Our analysis highlights the interplay between the distortion caused by the principal's lack of commitment and the distortion resulting from the agents' private information. Additionally, our findings offer an explanation for the importance and prevalence of protecting agents' contract confidentiality in practice.

Managing in Innovative Environments

Community Committee Choice Session

Session Chair: John N. Angelis, University of Lynchburg, Lynchburg, VA

Session Chair: Juliana Hsuan, Copenhagen Business School, Frederiksberg, Denmark

1 Advancing Digital Servitization Strategies for Sustainability

Juliana Hsuan, Copenhagen Business School, Frederiksberg, Denmark. Contact: jh.om@cbs.dk

The ongoing efforts by manufacturing companies to embrace sustainability requirements into their product-service-software offerings entail development of innovative solutions to integrate and share information among the stakeholders in the ecosystem. Potential pitfalls and traps when embarking on digital servitization journey as well as measurement considerations are shared. Opportunities for inter-disciplinary research are proposed.

2 Building Emotion Vectors Using Twitter Data

Nitin Mayande[1], Charles M. Weber[2], [1]Tellagence, Naperville, IL, [2]Portland State University, Portland, OR

Emotion Vectors represents a valuable framework for analyzing and modeling human emotional states. By capturing the multidimensional nature of emotions, these vectors provide a structured and quantitative approach to understanding emotional experiences. In this empirical research, we gathered Twitter data for 8 basic emotions (joy, fear, trust, surprise, sadness, disgust, anger and anticipation). We built multiple Emotion Vectors with varied-time data aggregations (1 week, 2 weeks, 3 weeks,4 weeks, 6 weeks, 8 weeks, and 12 weeks). In this presentation, we present our initial results regarding the viability of varied-time Emotion Vectors in predicting the emotions of future data sets.

3 A Leadership Model for Volatile, Uncertain, Complex, and Ambiguous Organizational Environments

Charles M. Weber, Dahm Hongchai, Portland State University, Portland, OR, Contact: webercm@pdx.edu

The organizational environment of the 21st Century is becoming increasingly volatile, uncertain, complex, and ambiguous (VUCA). This paper shows that successful leadership in a VUCA environment requires approaches that focus on problem solving, relationships, empathy, and motivation (PREM), as well as integrating three traditional perspectives: authentic leadership, servant leadership, and adaptive leadership. This paper presents a model for PREM and a research agenda from which best practices for leadership in technology management in a VUCA world will hopefully emerge.

4 Exploring the Impact of Increased Resources on Preventing Customer Data Breaches

John N. Angelis[1], Rajendran Murthy[2], [1]University of Lynchburg, Lynchburg, VA, [2]Rochester Institute of Technology, Henrietta, NY, Contact: angelis@lynchburg.edu

Data breaches represent a significant threat to consumer privacy and financial well-being. Previous studies have shown that the firm is sometimes better off shifting blame or justifying their actions rather than fully apologizing for the data breach. We explore whether customers would be more concerned about the damage from data breaches if they were more empowered to prevent data breaches. However, we find that cybersecurity education, prior experience, and other improvements did not result in meaningful change to customer behavior as expected. Thus, data breaches would not diminish, and customers are highly susceptible to privacy fatigue.

5 Impact of Industry 4.0 Technologies on Operator Learning Curves: A Comparative Study in a Manufacturing Environment

Flavio Fogliatto, Universidade Federal do Rio Grande do Sul, Brazil

We examine the effect of Industry 4.0 (I4.0) technologies adoption on the learning process of operators modeled by learning curves. Data from the training of twenty new operators in a quality inspection workstation of an auto parts manufacturer was collected under two scenarios: before and after the adoption of I4.0 technologies to support the operation. A 2-parameter hyperbolic model was used to model the learning process. Results indicated that operators supported by I4.0 technologies had a significantly higher learning rate than those without I4.0 support. No significant difference was found in the final performance level between groups.

Behavior-based Data Analytics

Community Committee Choice Session

Session Chair: Yuqian Xu, UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC

1 Incentivizing Healthy Food Choices Using Add-On Bundling: A Field Experiment

Nymisha Bandi, McGill University

Retailers can use price, convenience, and taste to incentivize customers to make healthier food choices, but these options are often expensive and infrequently promoted. Recent efforts in deploying healthy nudges to incentivize customers toward healthier food choices have been observed. We conducted a field experiment with a global convenience store chain to better understand how different add-on bundle promotions influence healthy food choices. We considered three types of add-on bundles: (i) an unhealthy bundle, (ii) a healthy bundle, and (iii) a choice bundle. In addition to our field experiment, we conducted an online lab study to strengthen the validity of our results.

2 On the Granularity of Wait Time Information: A Large-Scale Field Experiment on a Major Ride-Sharing Platform

Yiming Zhang[1], Qiuping Yu[2], Yong-Pin Zhou[3], [1]Chinese University of Hong Kong, Shenzhen, China; [2]Georgetown University, Washington, DC, [3]University of Washington, Seattle, Seattle, WA, Contact: zhangyiming@cuhk.edu.cn

Collaborating with a ride-sharing platform, we study whether and how the granularity of wait time information (WTI) impacts customers abandonment behavior through a randomized field experiment on our partner platform. In the experiment, we consider a point estimate, a narrow interval, and a wide interval of WTI. To uncover the fundamental mechanism, we propose a structural model to explore the impacts of granularity of WTI on customers' prior beliefs and waiting cost-reward ratios. We also discuss the managerial implication of our findings.

3 Impact of Workload and Task Complexity on Psychological Counsellors in Appointment Scheduling

Yuchen Liang[1],

The growing demand for mental health services, exacerbated by the COVID-19 pandemic, has placed significant strain on psychological counsellors, posing unique challenges for counselling clinic operations. This paper focuses on the impact of mental stress on counsellor performance and clinic operations within the appointment scheduling setting. Utilizing a data-set from a counselling clinic in a Singaporean university, we examine the effects of workload and task complexity on counsellor behavior. Our findings indicate that higher workload and task complexity are associated with increased likelihood of follow-up appointments and longer intervals between sessions. To improve clinic operations, we propose a scheduling policy that integrates workload and task complexity considerations, and develop a discrete-event simulation model to compare the results.

4 A Self- and Mutual-Exciting Model for Discrete-Time Data: Case Study on Online Money Market Fund

Yuqian Xu[1], Lingjiong Zhu[2], Haixu Wang[3], [1]UNC-Chapel Hill Kenan-Flagler Business School, Chapel Hill, NC, [2]Florida State University, Tallahassee, FL, [3]Citi, Tampa, FL, Contact: lz465@nyu.edu

This paper proposes a novel stochastic model in discrete time to capture two essential features of general event data motivated by the practice: the dependence on the past event arrivals and associated sizes (i.e., self-exciting) and the behavioral interdependence between multiple activities (i.e., mutual-exciting). To illustrate the applicability of our model and validate its performance, we calibrate it with a customer deposit and withdrawal data set from one leading online money market fund. We analytically quantify the churn probability and expected activity level of customers as an illustration of performance measures and then compare our model with classic time-series and machine-learning models and show that our model can achieve high prediction accuracy.

Doing Analytics for Good and Good Analytics

Community Committee Choice Session

Session Chair: Joseph Cazier, Arizona State University, Tempe, AZ

1 Expanding Ethical Awareness in Analytics with the INFORMS CAP Ethics Course

Joseph Cazier[1], Bill Griffin[2], Terry Rawls[3], [1]Arizona State University, Tempe, AZ, [2]INFORMS, Catonsville, MD, [3]Vulcan Academics, Durham, NC

This session introduces a new Ethics Course produced at the request of INFORMS recently. It was created to help prepare CAP and aCAP candidates for the Certified Analytics Practitioner designation. The course is part of an effort by INFORMS to ensure that Associate and full CAP candidates have access to ethical training in the official INFORMS Ethics guidelines before beginning their journey as an aCAP/CAP. The course features several prominent INFORMS Subject Matter Experts (SMEs) sharing their wisdom, insight and stories around each of the core INFORMS Ethics Guidelines. This course is scheduled to launch in late spring of 2023. This presentation will share an overview of the course, providing key insights garnered and lessons learned from the production process and the first cohort to complete the program.

2 Improving Analytics Education and Giving Back with the ***Data and Analytics for Good Journal***

Ronald Freeze[1], Joseph Cazier[2], [1]University of Arkansas, Fayetteville, AR, [2]Arizona State University, Tempe, AZ, Contact: rfreeze@walton.uark.edu

Thispresentation introduces the *Data andAnalytics for Good Journal.* The goal of this journal is to collect,document and share data that has value to society by supporting ESG(Environmental, Social and Governance) objectives, as illustrated by the U.N.Sustainable Development Goals. Each dataset will be made freely available to the public to encourage practitioners andlearners of analytics to analyze and use the data and share insights withothers anywhere they can, including in reports in this journal. Each data set is peer reviewed and madeavailable for download and in a state of the art analytics ecosystem allowinganyone, anywhere to use and play with the data. This is a great resource for educators and anyone wishing to give back,but making data with a social purpose available to use, learn from and sharealongside the tools needed to analyze it.

3 Stories and Lessons from Leading Analytics for Good Communities and Initiatives

Beverly Wright, Burtch Works, Atlanta, GA

Many data professionals spend their time, and careers, helping companies improve their financials. Improving market presence, optimizing operations, developing products, and decreasing expenses all help their companies run more effectively and efficiently. Recognizing the value of their skills, data professionals want to contribute these capabilities to the greater good, going beyond improving profit for companies to doing something to contribute to society. Saving and improving lives, reducing societal challenges such as addiction, home insecurity, hunger, human trafficking, and other issues are but some of the contributions that analytics professionals can provide.

Learn what you can do to become a part of a community that leverages data science for social good. This session will share tips and a framework for starting, developing, improving, and really contributing to social good via data science and analytics in a way that helps those in need.

4 Succeeding in Analytics by Leading in Analytics

Joseph Cazier[1], Terry Rawls[2], [1]Arizona State University, Tempe, AZ, [2]Strategic Transitions Group, LLC, Durham, NC

Inspired by the INFORMS ABOK, this presentation focuses on how to succeed in analytics by leading in analytics. Expanding on Karl Kempf's framework of the 5 Manageable Tasks (Ch. 2 of the ABOK), we interviewed dozens of experts to develop best practices of how to do analytics well, ultimately developing a book and companion professional educational course in partnership with INFORMS and the Professional Development Academy. This short presentations highlights the findings and how to learn more.

Decision-making and Machine Learning

Community Committee Choice Session

Session Chair: Michael Lash, University of Kansas, Lawrence, KS

1 Large-Scale Multiple Testing of Composite Null Hypotheses Under Heteroskedasticity

Trambak Banerjee, University of Kansas, Lawrence, KS

For simultaneous testing of composite null hypotheses, the conventional practice of standardizing or re-scaling heteroskedastic test statistics may severely affect the power of the underlying multiple testing procedure. Additionally, when the inferential parameter of interest is correlated with the variance of the test statistic, methods that ignore this dependence may fail to control the type I error at the desired level. We propose a new Heteroskedasticity Adjusted Multiple Testing (HAMT) procedure that avoids data reduction by standardization, and directly incorporates the side information from the variances into the testing procedure. HAMT is asymptotically valid and optimal for FDR control. Simulation results demonstrate that it outperforms existing procedures with substantial power gain across many settings.

2 Mitigating Label Bias via Decoupled Confident Learning

Yunyi Li, The University of Texas at Austin, Austin, TX, Contact: yunyi.li@mccombs.utexas.edu

Algorithmic fairness has received increasing attention, but methodologies to mitigate bias largely assume that observed labels constitute a "ground truth". In reality, bias in labels is a pervasive problem across important domains. While the presence of labeling bias has been discussed conceptually, there is a lack of methodologies to address this problem. We propose decoupled confident learning (DeCoLe), a pruning method specifically designed to mitigate label bias. Theoretically, we present sufficient conditions under which the DeCoLe algorithm accurately identifies corrupted labels and reduces label bias. Empirically, we illustrate the benefits of the proposed approach in the context of hate speech detection.

3 Corporate Probability of Default: A Single-Index Model with Multiple-Link Approach

Shun Dong, University of Kansas School of Business, Lawrence, KS, Contact: shun.dong@ku.edu

Accurately predicting the Probability of Default (PD) for corporations is crucial for effective risk management and precise asset pricing. In this paper, we present a novel approach for PD prediction by constructing a nonparametric single-index model with multiple link functions for binary response variables. Our proposed model can capture the shape of the PD changes in different industries and model the relationship between corporations and PD for various industries based on significant financial characteristics of companies.

4 Modeling the Transition of Human-AI Collaboration

Wensu Li[1], Neil Thompson[1], Kaizhi Qian[2], Maja Svanberg[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]IBM (International Business Machines Corporation), Cambridge, MA, [3]MIT, cambridge, MA

Traditionally, job replacement is seen as a threat when AI systems match human capabilities, often assessed without considering AI-human collaboration. However, the transition will be smoother, with AI initially complementing humans. In hybrid modes, AI excels where it's strong, while humans fill in the gaps. To understand this nuanced transition, we propose to better understand the quality metrics like accuracy and cross-entropy loss from computer vision models to map out the progression. Using information theory, we developed a groundbreaking economics model estimating patterns of human-machine collaboration and reliance on AI. By examining confidence scores and their distribution with AI performance, along with survey data on task error tolerance, we evaluate cooperation levels and predict tangible economic benefits from AI performance improvements.

Advances in Modeling and Statistical Methods for Analyzing Complex Networked Systems

Community Committee Choice Session

Session Chair: Babak Ahmadi, University of Florida, Gainesville, FL

Session Chair: Mostafa Reisi, University of Florida, Gainesville, FL

1 Bayesian Semi-Non-Negative Matrix Factorization: A Technique for Estimating Bank Holdings and Systemic Risk

Shawn Mankad, North Carolina State University, Raleigh, NC, Contact: smankad@ncsu.edu

We propose a novel methodology to estimate the portfolio composition of banks as a function of daily stock returns. Building on a model where individual bank balance sheets connect through common holdings, we derive and solve a constrained semi-non-negative matrix factorization problem where the rows (corresponding to banks) of one latent matrix factor are subject to probability constraints. We develop a Markov chain Monte Carlo estimator that resolves the well-known issues of scale and rotational invariance in non-negative matrix factorization models. Our method allows analysts to understand the interconnectedness of banks and measure the risk from contagion and undiversified bank holdings.

2 Recurrence Network Representation Learning for Quality Control of Additive Manufacturing

Yujing Yang[1], Chen Kan[2], [1]The University of Texas at Arlington, Arlington, TX, [2]University of Texas-Arlington, Arlington, TX, Contact: yxy9663@mavs.uta.edu

Additive manufacturing (AM) is widely adopted in the production of mechanical metamaterials with complex geometries. However, geometric defects largely occur during fabricating, which could compromise the mechanical properties of fabricated parts. It is of great interest to characterize the complex geometries and identify defects, where 3D point clouds are increasingly utilized to represent the geometries of AM builds. In this study, first, we develop a recurrence network-based approach to represent the 3D point cloud, which considers both spatial closeness and geometric similarity. Second, a graph-based one-class classification approach is integrated to detect the presence of geometric defects. Experimental results highlight the effectiveness of the developed framework in detecting AM-induced geometric defects in mechanical metamaterials.

3 Efficient Model Fitting and Two Sample Testing for Large Networks via Subsampling

Kaustav Chakraborty, IL

In recent years, large networks are routinely used to represent data from many scientific fields. Statistical analysis of these networks, such as model fitting and hypothesis testing, has received considerable attention. However, most of the methods proposed in the literature are computational expensive for large networks. In this paper, we propose a subsampling-based method to reduce the computational cost of estimation and two-sample hypothesis testing. The idea is to divide the network into smaller subgraphs, draw inference based on each subgraph, and combine the results together. We first develop the subsampling method for random dot product graph models, and establish theoretical consistency of the proposed method. We demonstrate the performance of our methods through simulation experiments and real data analysis.

4 Anomaly Detection in Temporal Multilayer Networks Using GLMs and Tensor Decomposition

Mahya Qorbani, Kamran Paynabar, ISyE Georgia Tech, Atlanta, GA, Contact: mqorbani3@gatech.edu

Our study aims to improve anomaly detection in complex systems by applying a combination of generalized linear models (GLMs) and tensor decomposition to temporal multilayer networks (MLNs). We apply GLMs and space state models to provide one-step ahead prediction for adjacency tensors of MLNs. To improve the accuracy of our predictions, we leverage the EM algorithm and tensor decomposition methods. We validate our method using simulations and a case study. Our proposed approach provides a more effective means of detecting anomalies in complex systems and has the potential to be applied in a wide range of fields such as, transportation, communications, and marketing.

5 Change Detection in Multi-Layer Dynamic Networks

Babak Ahmadi[1], Mostafa Reisi[2], [1]University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, Contact: Babak.Ahmadi@ufl.edu

With the advancement of data collection systems, collecting entity-level data has become highly feasible. Having any kind of relationship between the entities, the data can be modeled as a network. In certain intricate networks, entities exhibit multiple forms of relationships with each other, as seen in the case of multi-layer networks. In this work, each multi-layer network is presented as an adjacency tensor, and using a modified CP decomposition method, the tensor is decomposed to its factor matrices and features over time. Then, using the extracted features from the data, the one-step-ahead features are predicted over time. Then, to detect the change in temporal multi-layer networks, the residuals are monitored over time. Finally, the proposed modeling and monitoring approach is examined through a simulation and a compelling case study, establishing its validity.

User Behavior in Online Platforms

Community Committee Choice Session

Session Chair: Chenhui Guo, Michigan State University, East Lansing, MI

1 Effects of Exploration and Exploitation on Mobile App Evolution

Qiang Gao, Baruch College, City University of New York, New York, NY

To ensure market success, mobile app developers need to satisfy their user base by incorporating users' reviews and feedback on the one hand and exploring new features and content that allows them to stay competitive on the other. Drawing on the organizational learning and innovation literature, this research studies how these two activities of exploitation and exploration in consequent app updates affect the app's success

2 Promote Safe Driving: Spread Out Promotions on Telematics App

Jiaoping Chen, Li Zhang, Quan Zhang, Michigan State University, East lansing, MI, Contact: chenj107@broad.msu.edu

Monitoring driving behaviors by telematics is shown effective in improving driving safety in usage-based insurance (UBI). However, the use of telematics in non-UBI settings is insufficiently investigated. We fill the gap by empirically studying the effect of a promotion campaign that incentivizes the engagement of a telematics app. First, participants of the promotion campaign drive more safely during the promotion period. Second, the promotion type and sign-up time moderate the effect. Third, promotion participants with high baseline risk improve more, and fatigue has less negative impact among the participants. The findings reveal insights into use of telematics in non-UBI settings and suggest promotion strategies to improve road safety.

3 The Spillover Effect of a No-Tipping Policy on Competitors' Online Reputation

Naveen Kumar[1], Xiahua Wei[2], [1]University of Oklahoma, Norman, OK, [2]University of Washington, Bothell, Bothell, WA

This paper examines the externality of a no-tipping policy by restaurants on their local competitors' online reviews. Using the testing field of a restaurant chain that introduced a no-tipping policy in different locations, we analyze the customer reviews of these locations' local rivals with a panel data model. In our study, a treatment is the introduction of no-tipping at each location of the restaurant with no-tipping, and an outcome is the sentiment of customer reviews for their competitors in the same zip code. We find that no-tipping leads to negative externalities on the customer sentiment of the local, direct competitors in the same cuisine category. Further, this negative spillover effect is heterogenous along several other dimensions of the rivals, including their review influencers, linguistic features of the reviews, and the local competition intensity.

4 Visualizing the Competitive Market Structure: A Dynamic Latent Factor Model for Mapping Products and Brands Using Online Reviews

Yifan Zhang[1], Ning Zhong[2], [1]Kennesaw State University, Kennesaw, GA, [2]Penn State University, University Park, PA

Online reviews have become an essential tool for businesses to learn about consumer perception of their brand and products. In this research, we develop a dynamic latent factor model that generates a joint spatial mapping of products and brands to provide insights into the underlying competitive market structure. The proposed model combines review text with review rating through a topic model and simultaneously performs market segmentation and brand positioning.
We apply our model to car review data and show how the model may be used by managers to identify changes in consumer perception in online platforms and visualize the competitive market structure.

Session Chair: Paramveer Dhillon, 1</sup

1 Explainable AI Helps Bridge the AI Skills Gap: Evidence from a Large Bank

Jonathan Hersh[1], Selina Carter[2], [1]Chapman University, Orange, CA, [2]CMU, Pittsburgh, PA, Contact: hersh@chapman.edu

This paper examines the 'AI skills gap' in firms, focusing on the role of trust in AI for predicting significant events and the impact of explainable AI (XAI) on this trust. In collaboration with a major bank, we developed AI predictions for loan disbursement delays, incorporated into a dashboard tool, and surveyed 685 employees pre- and post-exposure to the tool. Additionally, some participants received an XAI treatment explaining model decisions and performance.
Our findings reveal: i) XAI enhances perceived usefulness but not understanding of AI predictions; ii) Senior managers and those less familiar with AI are more reluctant to trust

AI predictions; iii) Greater loan complexity fosters more trust in AI predictions; iv) AI-skeptical groups show stronger responses to XAI. These insights inform the design of ML models for more equitable workplace benefits.

2 Conversation and User-To-User Networks for Product Innovation

Kristen Altenburger, Meta, CA

Technological innovations have fundamentally transformed information flow and social behavior. This talk will provide an overview of how we measure online conversations at Meta, new methods for addressing interference in A/B tests on networks, and ongoing work including studying conflict in groups. The talk will conclude with thoughts on the future of studying online conversations and will discuss the unique role of human-centered machine learning in this space.

3 Occupational Skills and AI Exposure: Evidence from 350 Million Online Job Postings

Sebastian Steffen, Boston College, MA

I study how much occupational skill compositions changed over the last decade, how these skill changes relate to recent AI exposure scores, and what the implications for the values of skills are. To do so, I create a novel occupation-level panel of skill compositions based on the detailed skill demands of over 350 million US online job postings since 2010 and calculate how much occupational skill compositions changed. Recent AI exposure scores only weakly correlated with each other, which raises doubts about their insightfulness; the vast majority of skill, wage, and employment changes can also not be explained by AI. Finally, I estimate the impact of technological change on the market returns of skills and identify several skill groups with high and stable returns that may offer feasible future career opportunities for the workers that are most exposed to AI.

Predictive Analytics and Game Theoretic Techniques for Smart Network Grids

Community Committee Choice Session

Session Chair: Ming Jin, Virginia Tech, Blacksburg, VA
Session Chair: Harshal D. Kaushik, Bayer, St Louis, MO

1 System-Constrained Multi-Agent Reinforcement Learning for Smart Grid Applications

Daniel Tabas[1], Ahmed Zamzam[2], Baosen Zhang[1], [1]University of Washington, Seattle, WA, [2]National Renewable Energy Laboratory, Golden, CO

Constrained multiagent reinforcement learning (C-MARL) is gaining importance as MARL algorithms find new applications in real-world systems. Most C-MARL algorithms use a primal-dual approach to enforce constraints through a penalization approach. In this talk, we discuss the structural effects of the primal-dual approach on the constraints and value function. We discuss the shortcomings of using the constraint evaluation as the penalty, hence, we propose enforcing meaningful probabilistic safety constraints by simple penalty modifications. Then, we exploit the structural effects of primal-dual methods on value functions, leading to improved value estimates. We use simple energy management environments to demonstrate meaningful guarantees of the proposed constraints reformulations, and the improved convergence behavior of the proposed algorithms

2 Pricing and Economic Impact of Convex Relaxations for Power Flow on Electricity Spot Markets

Johannes Knörr[1], Martin Bichler[2], [1]Technical University of Munich, Munich, Germany; [2]Technical University of Munich, Garching B. München, Germany. Contact: knoerr@cit.tum.de

Welfare maximization problems on electricity spot markets should ideally consider constraints that reflect the physics of the power grid. As this leads to an intractable non-convex and non-linear optimization problem, linearized power flow models are currently used in practice. Tighter non-linear convex relaxations have been developed, but most research focuses on their optimality and scalability. We study the impact of different relaxations on prices, required side-payments by the market operator, and redispatch costs, while also considering non-convexities in the preferences of buyers and sellers. Large-scale numerical experiments indicate that currently used linearized models can lead to unjustifiably high prices and biased investment signals, while tighter convex relaxations set better incentives and reflect the physics of the grid more accurately.

3 Enhancing Power Grid Resilience: Co-Optimizing Repair Crew Routing and Network Reconfiguration for Effective Management of Power Outages

Haneul Kim, Myungseok Yoon, Hyungjoo Cha, Dongkyun Kim, Hyeon Woo, Yongju Son, Sungyun Choi, Taesu Cheong, Korea University, Seoul, Korea, Republic of.

Contact: rgs6827@korea.ac.kr
The increasing occurrence of natural disasters necessitates the effective management of power outages in distribution networks. This study focuses on two key tasks: offline repair crew routing and online distribution reconfiguration. The objective is to co-optimize the visit sequence of repair crews and reconfiguration tasks, aiming to maximize the supply loads during power grid recovery. A mixed-integer programming model is proposed for repair crew routing and network reconfiguration in a discrete event system. Furthermore, deep reinforcement learning is used to address potential changes in repair plans based on actual repair time. The proposed methodology is experimentally evaluated using modified IEEE bus distribution systems.

4 Study the Effect of Weather Uncertainty and Future Scenarios on the U.S. Power Grid
Amir Zeighami, North Carolina State University, Raleigh, NC, Contact: mzeigha@ncsu.edu
This talk will examine how multiple sources of uncertainty influence short term operations of bulk power systems. The first part of the talk focuses on how stationary weather uncertainty affects the distribution of power plant air pollution damages among different demographic groups. The second part investigates how grid decarbonization will influence the response of power system and air quality impacts during extreme events (droughts and heat waves). Both aim to identify effective solutions to mitigate the negative effects of air pollution on public health while also addressing issues of social justice.

Information Search and Finance

Community Committee Choice Session

Session Chair: Ryan Israelsen, Michigan State University

1 Regulators at the Gate: SEC Visits and Insider Trading
William Gerken[1], Steven Irlbeck[2], Marcus Painter[3], Guangli Zhang[3], [1]University of Kentucky, Lexington, KY, [2]University of New Hampshire, Durham, NH, [3]Saint Louis University, St. Louis, MO, Contact: marc.painter@slu.edu
The Securities and Exchange Commission (SEC) plays a crucial role in maintaining the integrity of financial markets. Yet, the dynamics of how SEC officers meet with firms is little understood, as these meetings have historically been unobservable. We study the dynamics of the Security and Exchange Commission's face-to-face interactions with firms using individually-linked smartphone geolocation data. This data allows us to identify phones that ``ping'' regularly in SEC offices and in firm headquarters. We characterize the nature of SEC visits, finding these regulator-devices visit firms located both near to and far from SEC offices. On average, insiders are less likely to trade in the week surrounding an SEC-device visit. However, insiders that do sell before a visit outperform the market significantly.

2 Do Mutual Funds Walk the Talk? Evidence from Fund Risk Disclosure
Jinfei Sheng[1], Lu Zheng[2], Nan Xu[3], [1]University of California, Irvine, Irvine, CA, [2]University of California, Irvine, Irvine, CA, [3]Nankai University, Tianjin, China. Contact: jinfei.sheng@uci.edu
Do risk disclosures by mutual funds reflect funds' actual investment risks? In this paper, we examine the quality of risk disclosures in funds' summary prospectus. We first document what types of risk are disclosed by mutual funds and how the disclosed risks relate to academic risk factors, such as size and value. We then develop fund-level measures to evaluate the relevance, conciseness and order of the risk disclosures. We find that disclosed risks explain about 50% of variations in fund returns; funds tend to overdisclose by reporting insignificant risks; the order of disclosure does not imply importance. We also find that funds improve their disclosure relevance after receiving SEC comment letters concerning their prospectus. Furthermore, we explore the implications of risk disclosure for fund flow, risk taking and performance.

3 Community/Committee'S Choice Submission
Huseyin Gulen, Purdue University, West Lafayette, IN
Eye movements reflect biases inherent in decision-making. We conduct an eye-tracking experiment to measure how subjects allocate attention over a price chart while predicting future stock returns. We confirm that the attention allocation reflects how subjects form expectations from past price information. The measure of expectation based on eye-tracking quantitatively fits the actual forecasts submitted by subjects. Easily recognizable patterns in data receive disproportionately more attention: Subjects spend much more time reading recent as well as extreme trends and price levels. Such heuristics in information acquisition are heterogeneous across subjects and lead to inferior forecast precision. Overall, the results provide direct evidence for investor beliefs hypothesized by theories of return extrapolation.

4 All in a Day's Work: What Do We Learn from Analysts' Bloomberg Usage?

Ryan Israelsen[1], Azi Ben-Rephael[2], Zhi Da[3], Bruce Carlin[4], [1]Michigan State University, East Lansing, MI, [2]Rutgers University, Newark, NJ, [3]University of Notre Dame, Notre Dame, IN, [4]Rice University, Houston, TX, Contact: israels4@broad.msu.edu

We use minute-by-minute Bloomberg online status data to characterize two important dimensions of sell-side equity analysts' work habits: we estimate the average workday length (AWL) to proxy for analysts' general effort provision and we use the percentage away day (PAD) to proxy for their soft information production. Controlling for coverage, AWL is positively related to the quantity and the timeliness of analyst forecasts, while PAD is negatively related to quantity. Both are positively related to forecast accuracy. COVID lockdown provides further causal evidence. Traveling analysts experience a significant reduction in forecast accuracy during the lockdown. Using pre-COVID analyst commute time to instrument increased AWL during the lockdown, we find a higher AWL to significantly increase output and improve the accuracy of the forecasts

Maintenance Planning

Contributed Session

Session Chair: Mehdi Dadfarnia, National Institute of Standards & Technology, Bethesda, MD

1 Deep Reinforcement Learning for Optimal Planning of Multi-Assembly Line Maintenance with Resource Constraints

Michael Geurtsen, Eindhoven University Of Technology, Arnhem, Netherlands

Discovering the optimal maintenance planning strategy can have a massive impact on production efficiency, yet this aspect is often overlooked in favor of production planning. Our study emphasizes the significance of maintenance planning in the dynamic context of an assembly fab consisting of multiple assembly lines. By maximizing the average production rate and considering factors such buffer contents, machine production states, planning windows and scarce resources, we address a unique problem involving the planning of maintenance on the final machine of multiple serial assembly lines. We employ novel average-reward deep reinforcement learning techniques and compare them to generic dispatching methods. Through experiments using a digital twin with real-world data, we demonstrate the immense potential of this new deep reinforcement learning technique.

2 Maintenance Optimization of Inland Waterway Transportation System via Simulation and Machine Learning

Maryam Aghamohammadghasem[1], Jose Azucena[2], Haitao Liao[3], Shengfan Zhang[3], Heather Nachtmann[3], [1]University of Arkansas, Faytteville, AR, [2]University of Arkansas-IE Department, Fayetteville, AR, [3]University of Arkansas, Fayetteville, AR, Contact: maghamoh@uark.edu

Maintenance optimization is critical in minimizing the negative impact of natural and man-made disruptions on inland waterway transportation systems. This research takes advantage of agent-based simulation and machine learning to enable efficient maintenance for the continued operation of inland waterway transportation systems.

3 Estimation of Remaining Useful Life of Complex Systems Based on Bayesian Autoencoder Latent Variable Extraction

Sun Geu Chae[1], Suk Joo Bae[2], [1]Hanyang University, Seoul, Korea, Republic of; [2]Hanyang University, Seoul, Korea, Republic of

Data-driven approaches are progressively employed in state-based maintenance due to the limitations of physically-based models. Nonetheless, constructing models with minimal failure data poses a significant challenge. Advancements in sensor technology necessitate the management of considerable data and variables, thus highlighting the importance of autoencoders for dimensionality reduction. In this research, we propose a Bayesian Autoencoder for uncertainty quantification-based Virtual Health Index (VHI) development to estimate time-dependent deterioration in complex systems. This approach addresses the need to capture degradation over time in the presence of scarce failure data. Lastly, we validate the proposed methodology using a turbofan degradation dataset, demonstrating its potential for real-world applications.

4 Simulation Manufacturing Operations and Condition-Based Maintenance Policies to Support Condition Monitoring Tool Adoption

Mehdi Dadfarnia, National Institute of Standards & Technology, Gaithersburg, MD, Contact: mehdi.dadfarnia@nist.gov

Condition Monitoring Systems (CMSs) can improve manufacturing performance by helping maintenance detect and diagnose product faults and machine failures. However, measuring CMS impact on manufacturing can be difficult. Though CMS abilities can be assessed using detection or diagnosis metrics and compared to manufacturing performance indicators, manufacturing performance also depends on the configuration of machinery and the implemented maintenance policy. We developed a simulator to analyze manufacturing scenarios across various machinery configurations and maintenance policies, emphasizing CMS-enabled policies. We observe CMS impact on manufacturing performance and consider how machinery configuration and maintenance policy limits or facilitates CMS impact. We also discuss aligning CMS-level metrics and manufacturing performance indicators.

Session.Location:CC-West 208B

New Topics in Grocery Retailing

Contributed Session

Session Chair: Haoran Yu, Syracuse University, Syracuse, NY

1 Understanding the Relationship Between Customers' Segments and Their Short-Term Goals: A Bayesian Approach

Xiexin Liu[1], Xinwei Chen[2], [1]the Pennsylvania State University - Abington, Abington, PA, [2]Bucknell University, Lewisburg, PA, Contact: xpl5357@psu.edu

Analyzing customers' grocery shopping baskets has long been a critical topic research topic. The abundance of data makes it challenging to extract useful insights, and customers' complex purchasing behaviors make it hard to identify their preferences. This research develops a hierarchical Bayesian model to summarize customers' decision-making processes, where it assumes that a customer tends to wait for a period before shopping again in any specific segment. We use customers' product purchases to derive the probability distribution of their short-term shopping goals, and then further infer the long-term segment distribution. We use real data analysis to demonstrate that the proposed model 1) can be used to understand customer heterogeneity and facilitate personalized recommendations, and 2) predict customers' purchases and assist with product stock management.

2 Title: Order-Picking Strategies and Efficiency Models for the Fulfillment of Multi-Line Ecommerce Grocery Orders

Zijia Wang, Sanchoy Das, New Jersey Institute of Technology, Newark, NJ

The fulfillment process for Buy Online Pickup from Store grocery orders (BOPS-Grocery) is challenging, given the large item count per order and the low-profit margins. This research investigates the BOPS-Grocery model and pursues the following objectives: (i) Defining and specifying the grocery order picking problem. Identifying performance objectives and characterizing the problem variance and resource utilization function. Three classes or sections of grocery ordering picking, straight aisle, Island stocking and counter service; (ii) Modeling and developing of order picking algorithms specific to the straight aisle section. Formulated as an order batching problem with picker movement minimization and no order splitting. Simulation results will be presented.

3 Why Fruit Salads Complicate Ordering: Building Grocery Pipelines for Handling In-Store Transformations

Andrew S. Chen, Afresh Technologies, San Francisco, CA, Contact: andy@afresh.com

Grocery stores are seeing a growing demand for items prepared in store, including fruit bowls, salads, cut meats, ready-to-eat meals, and more. These transformations pose challenges for inventory management solutions, as they significantly change the perishability of the items. For example, cutting a ribeye might drop its shelf life from 30-90 days to 3-4 days. We present a full ML-to-OR pipeline for ordering the ingredients for these in-store transformations. We discuss the modeling decisions and tradeoffs when evaluating data quality, forecasting consumer demand, and ultimately recommending order decisions.

4 Retailing Strategies of Imperfect Produce and the Battle Against Food Waste

Haoran Yu[1], Burak Kazaz[1], Fasheng Xu[2], [1]Syracuse University, Syracuse, NY, [2]Syracuse University, Long Island City, NY, Contact: hyu143@syr.edu

Edible but cosmetically substandard produce is often not sold in stores, leading to substantial food waste. This study investigates how a grocery retailer should choose from three popular retailing strategies: discarding imperfect produce, bunching with perfect produce, and selling perfect and imperfect produce separately at different prices. We first derive conditions under which each retailing strategy is optimal and show that increasing consumers' valuation of imperfect produce can actually lead to more food waste. Next, we investigate the implications of the full-shelf ordering policy where retailers simply order up to their available shelf space, and show that this policy might not necessarily increase food waste. Lastly, we show that our main results remain valid when the imperfect proportion is random.

AI for Healthcare

Contributed Session

Session Chair: Maxim Terekhov, University Of Florida, Gainesville, FL

1 Interpretable Treatment Effect Prediction Using Optimal Trees

Jack Dunn, Interpretable AI, Cambridge, MA

Policy trees are a recent approach that combine interpretable machine learning and causal inference techniques to generate interpretable prescription policies from observational data. However, this approach is designed with the goal of finding the simplest policy for optimal treatment assignment. In many problem settings, particular in medicine, treatments may have side effects that are difficult to quantify, and so instead of simply prescribing the best treatment, our goal is to understand and predict personalized treatment effects in an interpretable way. We propose an approach that combines causal inference techniques with Optimal Regression Trees to generate interpretable treatment effect predictions. This new approach has many applications, including medical scenarios where over-treatment issues are suspected.

2 A Hybrid Approach to Veterinary Clinical Decision Support Systems

DoHoon KIM[1,2], Sangyong Lee[2], [1]Yonsei University, Seoul, Korea, Republic of; [2]Okestro, Seoul, Korea, Republic of

Veterinary CDSSs are crucial for high-quality animal care. A key challenge is unstructured medical records and no direct animal communication. We present a novel method combining rule-based models and LLMs for record insights and use XAI for decision clarity. Evaluations with dog kidney disease data suggest our approach might outdo traditional CDSSs in accuracy and transparency. Integrating cloud SaaS could harness data from multiple veterinary hospitals, fast-tracking training and boosting accuracy. Adopting SaaS enhances performance, emphasizing its broad benefits for the veterinary field.

3 Predicting Cervical Cancer with Machine Learning Algorithms: A Study on the Effectiveness of Sampling Methods

Noreliz Alorico, ANAS HOURANI, Fort Hays State

University, Hays, KS, Contact: naalorico@mail.fhsu.edu
Machine learning algorithms have been studied to predict the likelihood of cervical cancer. The dataset was analyzed with under-sampling, over-sampling, and no-sampling. Logistic regression, SVM, and random forest were built to compare the prediction performance of four targets (biopsy, cytology, Hinselmann, and Schiller) with and without sampling techniques. The data has been preprocessed. The results showed that over-sampling had the best prediction performance, and no sampling and under-sampling need improvement. The machine learning models were capable of predicting the likelihood of cervical cancer in the future.

4 Study of Health Outcomes in a Technology Enabled Virtual Setting

Maxim Terekhov, University Of Florida, Gainesville, FL
This paper presents an empirical analysis of health insurance claims data to explore telemedicine outcomes. Specifically, I utilize causal forests and a retrospective matched case control study design to demonstrate statistically significant changes in costs, utilization, and medication adherence of telehealth users.

1 A Heuristic Approach to Liquidity Management at Ant Group's Global Currency Network

Xinyue Zhong[1], Zewei Dong[1], Ang Li[2], [1]Ant Group, Hangzhou, China; [2]Ant Group, Shanghai, China. Contact: xinyue.zhong@antgroup.com
Ant's International Business Group (IBG) currently manages a global foreign exchange (FX) and liquidity network to support its cross-border payment and money transfer businesses. The network consists of a hub-and-spoke structure, where certain main accounts are connected to and fulfill cashflow requests arising from their respective peripheral accounts. Based on forecasts, the network needs to make daily decisions on fund re-balancing in each country-level account, as well as route-picking in real time for each request, where different options may carry distinct levels of timeliness, failure rate and cost. This talk briefly describes our pioneer solution to this problem with heuristics. A few future work directions are discussed.

2 Strategic Liquidity Provision in Uniswap V3

Zhou Fan[1], Francisco J. Marmolejo-Cossío[1], Daniel Moroz[2], Michael Neuder[3], David C. Parkes[4], Rithvik Rao[5], [1]Harvard University, Cambridge, MA, [2]Chainlink Labs, New York, NY, [3]Ethereum Foundation, New York, NY, [4]Harvard University, Boston, MA, [5]Jump Crypto, New York, NY, Contact: fjmarmol@seas.harvard.edu
Uniswap is the largest decentralized exchange for digital currencies. In Uniswap v3, liquidity providers (LPs) can selectively allocate liquidity to trades that occur within specific price intervals. While prices remain in that interval, LPs earn fee rewards proportionally to the amount of liquidity allocated. This induces the problem of strategic liquidity provision: smaller intervals result in higher concentration of liquidity and larger rewards when prices remain in the interval, but with higher risk as prices may exit intervals where liquidity is allocated and thus fail to earn rewards. Dynamically re-allocating liquidity can mitigate these losses, but at a cost, as traders must expend gas fees to do so. We formalize the dynamic liquidity provision problem and provide an optimization framework to maximize LP earnings for a general class of LP strategies.

3 Selective Hedging Policies & Commodity Firms: Models and Evidence

Kamal Smimou, Ontario Tech University, Oshawa, ON, Canada. Contact: kamal.smimou@ontariotechu.ca
Commodity firms and their hedging activities are a prominent topic of interest in financial economics. Adding to the current wave of attention, this study advances two theoretical optimization models guided by *market depth* (as a proxy for hedging demand) and *liquidity* to (1) detect and select the most genuinely related and viable commodity futures pertinent to the price movement of commodity companies traded in the stock market, and (2) elucidate *when* and *how* these optimal search strategies can enhance and affect hedging positions of investors. Likewise, we empirically document the joint dynamic behavior of these groups of assets while assessing the effects of including an *optimal* number of hedging instruments. Our insights are valuable for corporate hedging; and this work carries worthwhile implications for portfolio management undertaken by institutional investors.

4 Factor Glut in Asset Pricing and Dodging a Zillion Regressions

John Crosby[1], Gurdip Bakshi[2], Tim Christensen[3], Xiaohui

Gao[2], [1]Old Dominion University, Strome School of Business, Norfolk, VA, [2]Temple University Fox School of Business, Philadelphia, PA, [3]New York University, New York, NY

The issue of the "zoo of factors" has garnered much attention in recent years (eg., Cochrane (2011, JF)) because of the proliferation of proposed factors for explaining asset (especially stock) returns. The principal question that we answer is: Even when the number of potential test factors is large, can we identify the best factors that enter the stochastic discount factor. We develop asset pricing and econometric approaches with three desirable features. First, the realities of bid-ask spreads in prices as well as short-sale constraints are accommodated. Second, stochastic discount factors are strictly positive. Third, the approach is disciplined by the absence of unreasonably high rewards-for-risk. We identify which (in addition to a constant factor) is the best one factor, the best two factors, the best three factors, ..., the best ten factors, etc.

Application of Discrete Optimization

Contributed Session

Session Chair: Fabian Torres, EPFL-ENAC-TRANSP-OR, Lausanne, Switzerland

1 Generating Robust Task Allocations by Distributing the Risk Among Agents

Raunak Sengupta[1], Rakesh Nagi[2], Ramavarapu S. Sreenivas[1], [1]University of Illinois, Urbana Champaign, Champaign, IL, [2]Industrial Enterprise Systems University of Illinois, Urbana, IL, Contact: raunaks2@illinois.edu

We address the problem of generating robust solutions for the makespan minimization problem on identical parallel machines. While there are various concepts of robustness in the literature, we show through pathological examples that they do not capture all the desirable properties. We make the simple observation that an allocation that balances the worst-case loads and uncertainties simultaneously can generate extremely robust allocations. This reduces the problem of finding a robust allocation to a two-dimensional load balancing problem. We introduce an efficient algorithm that guarantees an approximation factor of 2 on both dimensions simultaneously along with fair allocation properties. We substantiate our claims with interesting structural and existential results. Finally, we prove the efficacy of our approach using detailed numerical results.

2 Evaluation of Manual Assembly Line Balancing Problem in Flexible Manufacturing and Uncertain Operator Performance

Liam J. Cahalane[1], Thomas A. Mazzuchi[2], Shahram Sarkani[3], [1]The George Washington University, Charleston, SC, [2]George Washington University, Washington, DC, [3]The George Washington University, Washington, DC, Contact: lcahala@gwmail.gwu.edu

Uncertainty in manual assembly operations can significantly impact manufacturing processes, resulting in late deliveries and potential loss of revenue. This research addresses the challenge of optimizing uncertain task durations of a manual assembly line in flexible manufacturing to minimize lateness and maximize revenue. We propose an approach to assigning operators to assembly tasks, without prior knowledge of their performance, which is periodically reevaluated to ensure optimal assignment and balance of the assembly line. Our approach considers the uncertain and variable nature of manual assembly operations, and leverages the Assembly Line Balancing Problem framework to achieve optimal efficiency. We demonstrate the effectiveness of our approach through numerical simulations and provide recommendations for implementation in manufacturing processes.

3 Branch-And-Price for Static Elevator Dispatching

Fabian Torres, Michel Bierlaire, EPFL, Lausanne, Switzerland. Contact: fabian.torres@epfl.ch

The elevator dispatching problem (EDP) is a vertical transportation problem where passengers are transported to their desired floors. In a destination control system, destination floors are known the moment passengers make a call for elevators. We consider the static EDP where complete information about passenger arrivals is known. Solving the static EDP provides a lower bound on the dynamic EDP and gives insights about the value of complete information. We consider 3 common objectives, to minimize the average waiting and journey time of passengers and the total energy consumption of elevators. We present the first branch-and-price algorithm to solve this problem, adapt the dominance rules of the pricing algorithm to each objective and show that we can solve instances with up to 60 passengers, a 5-fold improvement from the network flow formulation.

Supply Chain Models for Ecommerce

Contributed Session

Session Chair: Sambit Rath, XLRI, Jhajjhar, India

1 Third-Party Providers in Food and Grocery Delivery Service

Jingran Zhang, Marshall University, Huntington, WV, Contact: zhangjin@marshall.edu

E-commerce has grown rapidly. During the Pandemic, consumers increasingly turned to e-commerce for all their needs, including food and grocery. Leading retailers has changed the traditional retailing models, along with the remarkable growth, to achieve fast fulfillment and delivery. Omni-channel retailers provide different ways to process and fulfill consumer orders, but one of the biggest challenges and expenses is last mile, or final mile delivery. A strategic decision model between self-own delivery or third-party providers is established by forecasting demand and the expense of delivery and quick response to customer orders to optimize cost-cut of retailers and order fulfillment performance.

2 Scattered Storage Assignment to Minimize Picking Travel Distances for Large Order Lines

Mauricio Gámez, Trijntje Cornelissens, Kenneth Sörensen, University of Antwerp, Antwerp, Belgium. Contact: mauricio.gamezalban@uantwerpen.be

E-commerce is changing the way people consume. Usually, only a few items are demanded in small quantities in these online stores. For this reason, many warehouses use the policy of scattered storage to place items in close proximity and speed up the picking process. However, the question is whether scattered storage is also a good strategy for an atypical order that involves large order lines, as in the omnichannel strategy where individual customers and physical stores need to be served from the same warehouse. The idea is to figure out up to what ratio of large order lines scattered storage is still a promising strategy. To enable storage of large quantities, an adaptation of scattered storage with pairwise minimization of distances (SSA-SPD) is presented. Picking routing results show that SSA-SPD is a good storage policy compared to traditional storage policies.

3 Compete or Cooperate: Analysis of Financing and Private Label Decisions in Online Retailing

Sambit Brata Rath[1], Preetam Basu[2], Prasenjit Mandal[3], [1]XLRI – Xavier School of Management, jhajjhar, India; [2]Kent Business School, Canterbury, United Kingdom; [3]NEOMA Business School Reims Campus, Reims, France

Online third-party (3P) retailers face a shortage of working capital and mainly depend on bank financing (BF) for loans. Online platforms such as Amazon and Alibaba have recently started cooperating with retailers by funding them through platform financing (PF). At the same time, they directly compete with the sellers by introducing a competing private label (PB). This study focuses on this fascinating coopetition scenario and jointly analyses the players' financing and operational decisions. We find that the retailer should not always choose BF, even in the presence of PB products (e.g., low referral fee products). The platform should not introduce PB if the product quality is perceived as low. Furthermore, we show with an increase in risk, the retailer prefers PF more, and the platform can introduce lower-quality PB. We also develop a product-based equilibrium strategy.

Digital Platform Applications

Contributed Session

Session Chair: Moonwon Chung, Cleveland State University, Cleveland, OH

1 Illegal Content and Monitoring Strategies on Digital Platforms

Tarun Jain[1], Jishnu Hazra[1], T.C.E. Cheng[2], [1]Indian Institute of Management Bangalore, Bangalore, India; [2]The Hong Kong Polytechnic University, Hong Kong, Hong Kong. Contact: hazra@iimb.ac.in

In this talk, we consider a scenario where a subscription-based legal content has to compete with free but illegal content on the same digital platform. In both these scenarios, the digital platform generates revenue for itself. We analyze different content monitoring strategies and identify conditions under which it is beneficial for the platform to exert higher monitoring efforts than the content provider. We also find content monitoring strategies that generate higher payoffs for the digital platform and the content provider.

2 Exploring the Role of Regret and Envy in Crowdfunding Investment Decisions: A Study on Aspiring Entrepreneurs and Funding Efficiency

Giovanni Visentin, Elena Fumagalli, INCAE Business School, Alajuela, Costa Rica

The democratization of new venture funding has created a tension between capital allocation efficiency and inclusivity. To address this, we propose better profiling of entrepreneurs and backers. Our study tests the hypothesis that many crowdfunders are aspiring entrepreneurs who struggle with regret and envy when making backing decisions. We are currently collecting data from prospective entrepreneurs to determine the significance of these mechanisms. Our findings can inform crowdfunding platforms on how to better match the needs of their diverse user base.

3 Cross-Platform Value Co-Creation and Co-Destruction: The Case of Information and Exploit Videos on Youtube

Moonwon Chung[1], Kyungmin Lee[2], Sanghoon Cho[3], Manoj Malhotra[4], [1]Cleveland State University, Cleveland, OH, [2]American University, Washington, DC, [3]Texas Christian University, Dallas, TX, [4]Case Western Reserve University, Cleveland, OH

We study the interactions between two digital platforms, mobile apps and YouTube, to show how content published on YouTube influences users' mobile app engagement and the app's revenue generation. Specifically, we identify two types of videos, information and exploit videos, that leads to value co-creation and co-destruction. We deploy econometric analysis on data collected from the mobile app market and YouTube that contains the longitudinal performance of apps and characteristics of related YouTube videos. Results show that Information videos increase user engagement and revenue streams, while exploit videos decrease revenue streams. Information videos also increase the likes and views of YouTube content creators. In post-hoc analyses, we show the asymmetric impacts on different revenue sources and the antecedents of video creation behavior.

Prediction Models for Medication and Health Care

Contributed Session

1 Prediction of Adverse Drug Reactions Using Demographic and Non-Clinical Drug Characteristics in Faers Data

Alireza Farnoush[1], Zahra Sedighi-Maman[2], Behnam Rasoolian[3], [1]University of South Carolina, Columbia, SC, [2]Adelphi University, Garden City, NY, [3]Auburn University, Auburn, AL, Contact: alireza.farnoush@moore.sc.edu

The presence of adverse drug reactions (ADRs) is a significant public health concern. However, current studies on ADR prediction primarily focus on non-clinical data, neglecting the potential of leveraging both demographic and non-clinical information. Additionally, the importance of individual features in ADR prediction remains unexplored. This study aims to fill these gaps by developing an ADR prediction model that incorporates demographic and non-clinical data, identifying the most influential factors. The deep learning and random forest models were used and evaluated using the area under the receiver operating characteristic curve and the mean average precision. Results showed that our random forest model with only the top 20 most important features offers similar ADR prediction performance compared to feature-rich model consisting of all features.

2 Identifying High Risk States and Medications in T2DM Patients Using Dead-Ends

Chanyoung Park[1], Ga Eun Nam[2], Hyo Kyung Lee[1], [1]Korea University, Seoul, Korea, Republic of; [2]Korea University Guro Hospital, Seoul, Korea, Republic of. Contact: chanyoungpark@korea.ac.kr

Patients with type 2 diabetes often require complex medication regimens and are likely to develop irreversible complications which significantly worsen their quality of life. We formulate diabetes medication management problem as a reinforcement learning framework by representing T2DM patient's diabetic status and its transition across a sequence of visit records. Dead-ends Discovery approach is used to identify high-risk patient conditions and medications to avoid that likely lead to dead-ends from which negative outcomes are unavoidable. We set negative outcomes for diabetes patients as developing diabetic complications and aim to identify health conditions from which diabetes complications are highly likely to develop and pinpoint medications that should be avoided.

3 Personalized Statin Treatment Plan Using Counterfactual Prediction and Optimization

Yue Liang[1], Chih-Lin Chi[2], Pui Ying Yew[3], [1]University of Minnesota, Twin Cities, Minneapolis, MN, [2]U of Minnesota, Minneapolis, MN, [3]University of Minnesota, Minneapolis, MN

Statins are a class of drugs that lower cholesterol levels in the blood. High cholesterol levels can cause Atherosclerotic Cardiovascular Disease (ASCVD). Statins can reduce the risk of ASCVD events while they might be associated with symptoms such as muscle pain, etc. This leads to a strong reason to discontinue statin therapy, which increase the risk of cardiovascular events and mortality. To solve this problem, we proposed a framework to produce a proactive strategy, called a personalized statin treatment plan (PSTP) using Overlap Weighting counterfactual prediction, to minimize the risks of statin-associative symptoms (SAS) and risk of discontinuation, and maximizing LDL-C reduction.

1 Judicial Centralization and Firms' In-House Production: Quasi-Experimental Evidence from China

Hua Cheng[1], Liangfei Qiu[2], [1]University of Texas at Austin, Austin, TX, [2]University of Florida, Gainesville, FL

Firm decisons regarding in-house production or outsourcing is a key source of economic growth but involve significant risk of hold-up and imperfect enforcement of contracts, which makes a sound judicial system highly important. Using a staggered difference-in-differences design, we find the introduction of the circuit tribunals in China, which alleviates local intervention on the judicial system, reduces firms' in-house production sharply. Judicial centralization has much stronger effects on small firms, private firms, and high-growth firms. Finally, we find that judicial centralization indeed increases firms' confidence in the judicial system as seen in an increase in both the number of firm-initiated lawsuits and the claimed amount of funds in the treated areas.

2 Chief Intellectual Property Officers: An Exploratory Analysis of Their Emergence and Effects

Masayo Kani[1], Yoichiro Nishimura[2], [1]Meijo University, Nagoya, Japan; [2]Chuo University, Tokyo, Japan

With the growing importance of intellectual property (IP) management in corporate strategy, Chief Intellectual Property Officers (CIPOs), senior management positions responsible for intellectual property activities, have been appointed. This paper examines the relationship between IP strategy and top management structures, using the Japanese firms' data that can identify the position responsible for IP management. Based on the Contingency Theory and the Institutional Theory, we analyze which factors influence the appointment of the CIPO and how the CIPO affects the strategic divergence in IP management, which is divided into protection and utilization strategies. We evaluate how the indicators of divergence for each type of strategy are affected by the appointment of the CIPO and show the effects of the CIPO with concurrent work status and prior work experience.

3 Modeling the Distribution and Transshipment of Refined Oil Products

Walid Matar, KAPSARC, Riyadh, Saudi Arabia. Contact: walid.matar@kapsarc.org

I have developed an optimization model to characterize long-term planning for the distribution of oil products after the refining stage. The model ensures that the demand for any group of refined oil products is simultaneously met while minimizing the social costs associated with the distribution system. The distribution system moves products from oil refineries or import terminals to petroleum bulk plants using multiple modes of transport. Then, the products are moved from bulk plants to customers via trucking or pipeline transport. The model features:•transport fuel by pipeline, truck or ship by minimizing costs.•capacity constraints for storage and loading and unloading trucks at bulk plants and pipelines across the network.•investments.•geographical coordinates of the locations of all the elements within the distribution system.

4 Supply Chain Model for Three-Echelon Supply Chain for Deteriorating Items

Sarbjit Singh, Institute of Management Technology Nagpur, Nagpur, India. Contact: sarbjitoberoi@gmail.com

This paper proposed three echelon supply chain models. In this study, we have considered that after production, the manufacturer supplies the perishable items to the supplier. Then the retailer receives the product from the supplier for sale to the customers. The retailer assumes the customer's seasonal demand and the supplier's uncertain lead time. In this model, the product expiration date is also considered. The model helps the complete supply stakeholders to optimize their profits by managing optimal inventory. The convexity of the model has been checked, and numerical illustrations have aided the model's suitability.

5 Cocova: A Digital Service Design Method for Continuously Co-Creating Value

Tuure Tuunanen[1], Juuli Lumivalo[1], Alexander Mädche[2], [1]University of Jyvaskyla, Jyvaskyla, Finland; [2]Karlsruhe Institute of Technology, Karlsruhe, Germany. Contact: tuure@tuunanen.fi

This paper scrutinizes the differences between digital service design (DSD) and traditional systems analysis and design (SAD). Whereas SAD methods emphasize gathering or discovering users' requirements for an information system, digital service design utilizes understandings of customers and service providers, their context, and social practices for designing services. However, what is largely absent in the literature is methodological guidance on how to support value co-creation with customers and mitigate potential suboptimal digital service experiences. Thus, we argue that incorporating the value co-creation/co-destruction perspective into a DSD method is essential. Our study aims to fill this research gap by developing the DSD method CoCoVa in a design science research study in collaboration with research clients from both the industry and public sector.

Supply Chain Optimization and Resiliency

Contributed Session

Session Chair: Ana Muriel, University of Massachusetts, Amherst, MA

1 Static and Dynamic Optimization for the Joint Replenishment Problem

Miguel Chastre, Albert Schrotenboer, Christina Imdahl, Tom Van Woensel, Eindhoven University of Technology, Eindhoven, Netherlands. Contact: m.chastre@tue.nl

Organizations frequently face Stochastic Sequential Decision Problems and must come up with decision policies. Those problems can be divided into static (made once, e.g. capacity, delivery schedule) and dynamic decisions (made frequently, e.g. replenishment, routing). The static decision is often made in isolation, not considering the future impact on the dynamic policy.

Our research revolves around combining static and dynamic problem-solving methods (Mathematical Programming, Approximate Dynamic Programming, Reinforcement Learning) and applying them on use-cases from retail operations and/or transportation. In this work, we aim to find the best delivery schedule in a Joint Replenishment Problem, one-warehouse-multiple-retailers setting.

2 A Comparison of Stock-Out Scenarios Considering the Risk Attitude of the Retailer

Doran Wood, Sila Cetinkaya, SMU, Dallas, TX, Contact: doranw@smu.edu

We evaluate two practically-common approaches for handling excess demand through the lens of a retailer (newsvendor) whose risk-attitude (risk-neutral vs. risk-averse) is modeled, explicitly. The differing stock-out policies are investigated for both types of risk attitudes utilizing the corresponding expected-profit-based and conditional value-at-risk-based methodologies. Depending on the risk attitude and particular cost parameter relationships, we explore settings that reveal the superior way for handling stock-out scenarios and present practical insights regarding the profitability of each scenario.

3 A Digital Twin Framework for Production Planning Optimization

Ana Muriel[1], Ron Mallach[2], Vivek Saxena[3], William Marrujo[3], [1]University of Massachusetts, Amherst, MA, [2]University of Massachusetts, Amherst, MA, [3]Advisory Aerospace OSC, Minnetonka, MN, Contact: muriel@umass.edu

We develop a Digital Twin framework that allows for practical testing, evaluation, and implementation of new production optimization approaches. The ultimate goal is to facilitate industry adoption of these techniques by bridging theory and practice. To illustrate the approach in collaboration with a software and data analytics firm supporting manufacturers in the aerospace supply chain, we build 1) a factory generator accurately representing large-scale production facilities; 2) a Multi-Level Capacitated Lot Sizing Problem (MLCLSP) approach to generate a production plan for an extended planning horizon with full traceability of customer sales orders; 3) heuristics capable of translating production plans into executable schedules; and 4) advanced analytics and visualizations for evaluating the resulting scenarios and schedules.

4 Smart Contract on Mitigating Returns Risk

Ao Zhuo, Wanshan Zhu, Renmin University of China, Beijing, China. Contact: zhuoao@ruc.edu.cn

A smart contract can be executed automatically based on predetermined terms in supply chain transactions. It has potential to reduce a retailer's returns risk due to a supplier's speculative behavior under a buyback contract. The returns risk occurs when the supplier incurs losses in speculative investment and thus does not have sufficient funds to buy back the retailer's leftover inventory returns. A smart contract specifies a part of the supplier's fund to be stored in the smart contract account only for buyback use. Thus, it may mitigate the returns risk. Our theoretical study shows that when the supplier's speculative investment has high uncertainty, the returns risk is high but can be eliminated by a properly designed smart contract. We extend the model to price-dependent newsvendor and price postponement to show the results are robust.

Advanced Air Mobility: Are We There Yet?

Keynote Session

1 Advanced Air Mobility: Are We There Yet?

Hamsa Balakrishnan, Massachusetts Institute of Technology, Cambridge, MA

Advanced Air Mobility (AAM)—characterized by electric and hybrid aircraft, and highly-automated operations—has the potential to dramatically transform the way in which we transport people and goods, as well as our ability to sense our world from the sky. The excitement around these vehicles and the services they could enable has led to the investment of billions of dollars in their development. However, the deployment of such new aircraft and fleet operators will increase competition for limited airspace resources. Furthermore, in contrast to conventional air traffic that is managed by centralized Air Navigation Service Providers like the FAA, AAM operations are expected to be managed by third-party service providers. In this talk, I will discuss some of the key traffic management challenges to realizing the promise of AAM, and our initial work in overcoming them.

Sequential Decision Making

Community Committee Choice Session

Session Chair: Azarakhsh Malekian, University of Toronto Joseph L Rotman School of Management, Toronto, ON, Canada

1 Opening Pandora’s Box: The Correlated Case

Evangelia Gergatsouli, University of Wisconsin Madison, Madison, WI, Contact: gergatsouli@wisc.edu

The Pandora’s Box problem and its variants capture sequential decision making settings with stochastic input. The algorithm given a set of random variables with known distributions, has to select one, after obtaining information about their instantiation by paying an “exploration” cost. The goal is to select a good enough variable while not paying too much in exploration cost. All previous work on this class of problems makes the, somewhat unrealistic, assumption that the random variables’ distributions are independent. What happens when we remove this assumption? We summarize the recent solutions given to this problem and some of the techniques used.

2 Pandora’s Problem with Nonobligatory Inspection: Optimal Structure and a Ptas

Hedyeh Beyhaghi, Carnegie Mellon University, Pittsburgh, PA

Weitzman’s “Pandora’s problem” furnishes the mathematical basis for optimal search theory in economics. Nearly 40 years later, Doval introduced a version of the problem in which the searcher is not obligated to pay the cost of inspecting an alternative’s value before selecting it. Unlike the original Pandora’s problem, the optimal solution to the nonobligatory inspection variant is proved to require adaptivity in inspecting the search alternatives and is shown to be NP-hard. Our first main result is a structural characterization of the optimal policy: We show there exists an optimal policy that follows only two different pre-determined orders of inspection, and transitions from one to the other at most once. Our second main result is a polynomial time approximation scheme (PTAS).
Based on joint papers with Linda Cai (STOC 2023) and Robert Kleinberg (EC 2019).

3 Multi-Player Zero-Sum Markov Games with Networked Local Interactions

Chanwoo Park, Massachusetts Institute of Technology, Cambridge, MA, Contact: cpark97@mit.edu

We introduce a new class of Markov Games (MG), the Multi-player Zero-sum Markov Games with networked local interactions (MZNMG), where the Q value of each stage game is represented by a multi-player zero-sum game with local interaction (MZNG). We first identify the necessary and sufficient conditions under which an MG can be classified as an MZNMG, and provide that the set of CCE collapse to the set of NE. Next, we proved that finding stationary Markov approximate coarse correlated equilibria (CCE) in gamma-discounted infinite-horizon MZNMGs is PPAD-hard unless the underlying network is a star shape. For finding nonstationary Markov approximate CCE, we provide an algorithm that uses optimistic multiplicative weight updates. Lastly, we examine the classical learning dynamics of fictitious play in MZNMGs converge to a NE when the interaction structure assumes a star shape.

4 Near-Optimal Prior-Independent Online Algorithms and the Ski-Rental Problem

Jason Hartline, Aleck Johnsen, Anant Shah, Northwestern University, Evanston, IL, Contact: AnantShah2026@u.northwestern.edu

The prior-independent setting of robust algorithms aims to identify an algorithm with expected performance close to optimal in worst case over a family of distributions. This paper gives a fully polynomial time approximation scheme (FPTAS) for the prior-independent optimization of a family of online algorithms problems. Prior-independent approximation can be viewed as a zero sum game. The FPTAS framework then identifies conditions under which the equilibria of this game, which give robust algorithms, can be solved for in polynomial time. A key step is a reduction to online learning. The paper applies the framework to the paradigmatic ski renter problem.

Recent Advances in Choice Models and Pricing Analytics

Community Committee Choice Session

Session Chair: Zhenzhen Yan, Nanyang Technological University, Singapore, Singapore

1 Screening with Limited Information

Zhi Chen[1], Zhenyu Hu[2], Ruiqin Wang[3], [1]CUHK Business School, The Chinese University of Hong Kong, Shatin, Hong Kong; [2]NUS Business School, National University of Singapore, Singapore, Singapore; [3]National University of Singapore, Singapore, Singapore

A seller seeks a selling mechanism to maximize the worst-case revenue obtained from a buyer whose valuation distribution lies in a certain ambiguity set. For a generic convex ambiguity set, we show via the minimax theorem that strong duality holds between the problem of finding the optimal robust mechanism and a minimax pricing problem where the adversary first chooses a worst-case distribution and then the seller decides the best posted price mechanism. The duality result connects prior literature that separately studies the primal (robust mechanism design) and problems related to the dual (e.g., robust pricing, buyer-optimal pricing and personalized pricing). We further provide a geometric approach to analytically solving the minimax pricing problem for several important ambiguity sets.The solutions are then used to construct the optimal robust mechanism.

2 Fare Price Ladder Optimization: Airlines in Volatile Environment

Changchun Liu, Hong Ming Tan, Chung Piaw Teo, Yan Chen, Tim Lee, National University of Singapore, Singapore, Singapore

A fare price ladder is a pricing strategy used by airlines to maximize revenue. While the price ladder is often determined using historical sales data, the COVID-19 pandemic has significantly impacted the airline industry and altered the traveling behavior of passengers, prompting a need for airlines to re-evaluate their pricing strategies in a much more volatile environment. This paper proposes an adaptive fare price ladder recommendation model for airlines that employs novel techniques for detecting anomalies in revenue management, which are integrated into existing business processes for forecasting sales and estimating demand elasticity in volatile environments. A field experiment is conducted across ten markets to evaluate the effectiveness of the proposed approach. The results show that the approach improves revenue by 9.4% compared to the control group.

Platforms and Regulation

Community Committee Choice Session

Session Chair: Yao Cui, Cornell University, Ithaca, NY
Session Chair: Wee Kiat Lee, Cornell University, Ithaca, NY

1 Reducing Traffic Incidents in Meal Deliveries: Penalize the Platform or Its Independent Drivers?

Wenchang Zhang[1], Chris S. Tang[2], Liu Ming[3], Yue Cheng[4], [1]Indiana University, Bloomington, IN, [2]University of California-Los Angeles, Los Angeles, CA, [3]Chinese University of Hong Kong, Shenzen, Shenzhen, China; [4]Peking University, Shenzhen, China. Contact: ycheng@phbs.pku.edu.cn

Fierce competition among on-demand meal-delivery platforms resulted in meal-delivery-related traffic violations and accidents. To improve public safety, there is an ongoing debate about whether the government should penalize platforms for delivery-related traffic incidents. Our analysis of a three-stage Stackelberg game yields three results regarding government penalties on drivers and the platform. First, imposing a higher incident penalty on drivers will backfire. It will push the platform to offer higher commissions to incentivize drivers to travel faster, resulting in more accidents and lower profit for the platform. Second, imposing a higher incident penalty on the platform will encourage it to lower commissions, which will induce drivers to travel at safer speeds. Third, penalizing only the platform (not the drivers) is a socially optimal policy.

2 Self-Preferencing and Consumer Choice: Evidence from a Field Experiment

Chiara Farronato[1], Andrey Fradkin[2], Alexander MacKay[1], [1]Harvard Business School, Boston, MA, [2]Boston University, Boston, MA

We study whether Amazon engages in self-preferencing on its marketplace by favoring its own brands (e.g., Amazon Basics) in search, and the welfare consequences of this behavior. To address this question, we collect new micro-level consumer search data using a custom browser extension installed by a panel of study participants. Using this methodology, we observe search positions, search behavior, and product characteristics, and alter the availability of Amazon branded products. We find that Amazon branded products are indeed ranked higher than observably similar products in consumer search results. The prominence given to Amazon brands is 30% to 60% of the prominence granted to sponsored products.

3 Do Predictive Scheduling Laws Work?

Wee Kiat Lee[1], Yao Cui[1], Karan Girotra[2], [1]Cornell University, Ithaca, NY, [2]Cornell Tech/Johnson Cornell University, New York, NY, Contact: wl639@cornell.edu

Workers in the service industry tend to have varying work schedules from week to week. Such unpredictable work schedules can be detrimental to their welfare. The advent of the predictive scheduling law in some areas serves to protect these workers from unpredictable work schedules. This law requires the firms to schedule the work in advance or they will be required to compensate the workers. Opponents of the law have argued that such an intervention may be harmful to both the firms and workers. We build a game theoretic model to analyze the effect of this law. We find that while the firm's hiring level may increase with the regulation, the contracted shift hours and social welfare can potentially decrease. We also find empirical evidence for the predictions from our model using data from the state-wide implementation of a predictive scheduling law in Oregon.

4 Subscription vs. Spot Pricing in On-Demand Economy

Ming Hu[1], Taojie Qin[2], Lu Wang[3], Zhoupeng (Jack) Zhang[2], [1]University of Toronto, Minneapolis, MN, [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada; [3]Shanghai University of Finance and Economics, Shanghai, China. Contact: taojie.qin@mail.utoronto.ca

In this research, we comparatively study the implications of two practically grounded pricing schemes in an on-demand service platform, the subscription and spot pricing. We develop a game-theoretic queueing framework to model the matching process between consumers and workers on a platform. When consumers' valuations for the services are homogeneous, we show that the subscription always yields a lower profit than the spot pricing for the platform operator; yet if the market size is not very high relative to the labor pool size, we find that the ratio of the subscription profit to the spot pricing profit is bounded below by certain constant. In addition, the transaction volume can be higher under the subscription than the spot pricing. The operational implications of these two pricing schemes change dramatically when consumers' valuations become heterogeneous ex post.

Algorithms with Predictions and Beyond

Community Committee Choice Session

Session Chair: Billy Jin, Cornell University, Ithaca, NY
Session Chair: Will Ma, Columbia University, New York, NY

1 Algorithms with Prediction Portfolios
Michael Dinitz[1], Sungjin Im[2], Thomas Lavastida[3], Benjamin Moseley[4], Sergei Vassilvitskii[5], [1]Johns Hopkins University, Baltimore, MD, [2]University of California, Merced, Merced, CA, [3]University of Texas at Dallas, Richardson, TX, [4]Carnegie Mellon University, Pittsburgh, PA, [5]Google Research, New York, NY
The research area of algorithms with predictions has seen recent success showing how to incorporate ML predictions into algorithm design to improve performance when the predictions are correct, while retaining worst-case guarantees when they are not. Previous work typically assumes that the algorithm has access to a single prediction. In this work we consider scenarios where multiple predictions are available to the algorithm and the question is how to best utilize them. We study the use of multiple predictions for the fundamental problems of weighted matching, online load balancing, and non-clairvoyant scheduling, which have been studied in the single predictor setting. For each of these problems we introduce algorithms that take advantage of multiple predictions and prove bounds on their performance.

2 Energy-Efficient Scheduling with Predictions
Eric Balkanski, Noemie Perivier, Cifford Stein, Hao-Ting Wei, Columbia University, New York, NY
In this paper, we consider a general setting for energy-efficient scheduling and provide a flexible learning-augmented algorithmic framework that takes as input an offline and an online algorithm for the desired energy-efficient scheduling problem. We show that, when the prediction error is small, this framework gives improved competitive ratios for many different energy-efficient scheduling problems, including energy minimization with deadlines, while also maintaining a bounded competitive ratio regardless of the prediction error. Finally, we empirically demonstrate that this framework achieves an improved performance on real and synthetic datasets.

3 Two-Stage Bipartite Matching with Advice
Billy Jin[1], Will Ma[2], [1]Cornell University, Ithaca, NY, [2]Columbia University, New York, NY, Contact: bzj3@cornell.edu
We study the two-stage vertex-weighted bipartite matching problem (Feng, Niazadeh, and Saberi (SODA '21)) in a setting where the algorithm has access to a suggested matching that is recommended in the first stage. We evaluate an algorithm by its robustness, which is its performance relative to that of the optimal offline matching, and its consistency, which is its performance relative to that of the advice. We characterize the tight robustness-consistency tradeoff for this problem.

4 Fully Dynamic Correlation Clustering in Sublinear Total Update Time
Andreas Maggiori[1,2], [1]EPFL, Lausanne, Switzerland; [2]EPFL, Lausanne, Switzerland
We consider the classic correlation clustering objective in fully dynamic vertex streams: At each time a new vertex is added to or deleted from the stream and the goal is to maintain a solution to correlation clustering, i.e.: a partition of the vertex set. Each vertex is connected to each other vertex with either a + or - edge and the goal is to maintain a partition of the vertices that minimizes the number of + edges across clusters plus the number of - edges within clusters, at each time throughout the update sequence. We show that one can maintain an O(1)-approximation with $\polylog n$ amortized update time in the sublinear regime (where we can make +-degree queries and sample + neighbors in O(1) time).

Pricing Innovations at Amazon
Community Committee Choice Session
Session Chair: Shima Nassiri, Amazon, San Bruno, CA

1 Estimating the Distribution of Customers' Willingness to Pay for Delivery Speed
Pau Pereira, Amazon, Seattle, WA
We propose a model of customers' shopping behavior with which we can estimate customer-level parameters that describe the distribution of preferences about different attributes of an offer. We use the model to calculate the distribution of customers' willingness to pay for delivery speed, which we then use to solve the problem of what Retail prices to set on SKUs with long-ship speed competitors that have very long delivery speeds and very low prices. To estimate the model, we use data on consumer search to construct consideration sets for each shopping session. We then model customer choices of which offer to buy using a hierarchical Bayesian multinomial logit model which we approximate the posterior distribution using Mean-Field Variational Inference.

2 Sigmoid Demand Function: An Alternative to Constant Elasticity Demand Function
Hyungjun Lee[1], Pau Pereira[2], [1]Amazon, Cupertino, CA, [2]Amazon, Seattle, WA, Contact: hleehlee@amazon.com

We present the Sigmoid demand function, an alternative to the constant elasticity demand function that is bounded in both price- and quantity-axes. The Sigmoid demand function can be made arbitrarily close to the constant elasticity demand function but does not diverge to infinity when price approaches zero or remain greater than zero when price approach infinity. The conservative demand assumptions at extreme prices lead to more stable price optimization outputs.

3 Choosing an Objective Function for Price Optimization

Joe Cooprider, Amazon, Seattle, WA

When optimally setting Amazon online prices for business to consumer products, we should not only consider the short-term profit, but also the long-term impact of price changes. We study a price optimization setting that aims to balance the short vs long-term impact of retail pricing strategies. Some of the components consider in this optimization setting are: 1) the effect of seeing a price on customers' future purchase behavior, 2) the effect of purchasing the product on customers' future purchase behavior, 3) the effect of additional sales on supply side factors, and 4) the spillover from additional sales on other customers and products.

4 Balancing Bias and Variance in Amazon's Pricing Experiments

Yigit Okar[1], Shima Nassiri[2], Mohsen Bayati[3], [1]University of Washington, Seattle, WA, [2]Amazon, San Bruno, CA, [3]Stanford University, Stanford, CA, Contact: yokar@uw.edu

One of the main challenges faced by Amazon's pricing experimentation platform is the spillover effect in the product-randomized experiments. Spillover effects, when one product's pricing impacts demand for similar products, can bias treatment effect estimation. To mitigate this, we cluster products with correlated demands. This, however, reduces the effective sample size and statistical power. We will present a novel technique optimizing cluster selection and treatment decisions over time, balancing bias and variance for accurate treatment effect estimation.

5 Post Launch Evaluation of Pricing Policies

Shima Nassiri[1], Mohsen Bayati[2], [1]Amazon, San Francisco, CA, [2]Stanford University, Stanford, CA, Contact: shmnas@amazon.com

Running experiments on all policies that have already been launched on a continuous basis is not feasible given that 1) a good control group is not available post launch, and 2) policies can potentially interfere and hence a limited number of initiatives can be tested simultaneously. In this study, we propose a robust way of assessing the performance of launched pricing initiatives at Amazon.

Causal Reinforcement Learning

Community Committee Choice Session

Session Chair: Anish Agarwal, Amazon, Newton, MA

1 Did We Personalize? Assessing Personalization by an Online Reinforcement Learning Algorithm Using Resampling

Raaz Dwivedi, Harvard and MIT, Cambridge, MA

There is a growing interest in using reinforcement learning (RL) to personalize sequences of treatments in digital health to support users in adopting healthier behaviors. However, the inclusion of an RL algorithm in an ``optimized'' intervention for real-world deployment, requires data evidence indicating that the RL algorithm is actually personalizing the treatments to its users. Due to the stochasticity in the RL algorithm, one may get a false impression that the RL is learning to provide specific treatments in certain states. We introduce a resampling-based methodology for investigating whether the personalization exhibited by the RL algorithm is an artifact of the RL algorithm stochasticity. We demonstrate how our approach enhances data-driven truth-in-advertising via a case study with data from a physical activity clinical trial, HeartSteps.

2 A Finite-Sample Analysis of Multi-Step Temporal Difference Estimates

Yaqi Duan, MIT, Cambridge, MA

We consider the problem of estimating the value function of an infinite-horizon ⍰-discounted Markov reward process (MRP). We establish non-asymptotic guarantees for a general family of multi-step temporal difference (TD) estimates, including canonical K-step look-ahead TD for $K = 1, 2, \ldots$ and the TD(⍰) family for ⍰ [0,1) as special cases. Our bounds capture the dependence of these estimates on both the variance as defined by Bellman fluctuations, and the bias arising from possible model mis-specification. Our results reveal that the variance component shows limited sensitivity to the choice of look-ahead defining the estimator itself, while increasing the look-ahead can reduce the bias term. This highlights the benefit of using a larger look-ahead: it reduces bias but need not increase the variance.

3 Adaptive Principal Component Regression: Applications to Panel Data

Justin Whitehouse, CMU, Pittsburgh, PA

Principal component regression (PCR) is a popular technique for fixed-design error-in-variables regression, a generalization of linear regression where covariates are corrupted with noise. We provide the first time-uniform finite sample guarantees for PCR whenever data is collected adaptively. The techniques used to obtain bounds for PCR in the fixed design setting don't readily extend to the online setting. Instead, our results rely on applying self-normalized martingale concentration to the error-in-variables setting. As an application, we provide a framework for counterfactual estimation of unit-specific treatment effects in panel data settings when interventions are assigned adaptively. Our framework may be thought of as a generalization of the synthetic interventions framework where data is collected via an adaptive intervention assignment policy.

4 Bayesian Ensembling Methods for Contextual Bandit Models

Joseph Lawson, Duke University, Durham, NC

Contextual bandit models are a primary tool for sequential decision making with applications ranging from clinical trials to e-commerce. While there are numerous bandit algorithms which achieve optimal regret bounds and show strong performance on benchmark problems, algorithm selection and tuning in any given application remains a major open problem. We propose the Bayesian Basket of Bandits (B3), a meta-learning algorithm which automatically ensembles a set (basket) of candidate algorithms to produce an algorithm which dominates all those in the basket. The method works by treating the evolution of a bandit algorithm as a Markov decision process in which the states are posterior distributions over model parameters and subsequently applying approximate Bayesian dynamic programming to learn an optimal ensemble. We derive both Bayesian and frequentist convergence results for the cumulative discounted utility. In simulation experiments, the proposed method provides lower regret than state-of-the-art algorithms including Thompson Sampling, upper confidence bound methods, and Information-Directed sampling.

2 Experimentation for Scaling Healthcare Service Interventions

Hannah Li[1], Justin J. Boutilier[2], Jonas Oddur Jonasson[3], [1]Columbia, New York, NY, [2]University of Wisconsin - Madison, Madison, WI, [3]MIT Sloan School of Management, Cambridge, MA

A concern about service interventions, commonly found in domains like public health, education, and vocational training, is that promising interventions at the randomized controlled trial (RCT) stage may not perform well at scale. Although many factors contribute to these difficulty in scaling, in this work we highlight and isolate the effects of one such factor: capacity constraints. We consider a case study of a mobile health platform designed to improve patients' adherence to treatment protocols. We model the dynamics as a queueing system and investigate patient adherence. Due to capacity constraints on the system, the effect observed in an RCT may diminish when servicing a larger population. We show that this has counterintuitive implications for the typical power analysis and that a joint power and capacity analysis should be implemented.

3 Treatment Effect Heterogeneity: What It Means for Your Study

Elizabeth Tipton, Northwestern University, Evanston, IL, Contact: tipton@northwestern.edu

Randomized control trials (RCTs) offer the ability to determine unambiguously if an intervention causes outcomes to change; these changes are summarized in terms of the average causal effect (ACE). But interventions may not improve outcomes to the same degree for every unit. Thus, when treatment effects vary, the ACE estimated in one sample or population may not generalize to another. Furthermore, the ACE may not be the parameter of interest; e.g., we may instead be in interested in understanding 'for whom' and 'under what conditions' such an intervention is effective. But what does this mean for how we plan studies? In this paper, I focus on how to best design RCTs when treatment effect heterogeneity is likely. I show that the optimal study designs for estimating average effects, subgroups effects, and unit specific effects can differ substantially.

Data-driven Decision Making
Community Committee Choice Session
Session Chair: Qiaomin Xie, University of Wisconsin-Madison, Madison, WI

1 Concentration of Contractive Stochastic Approximation: Additive and Multiplicative Noise
Zaiwei Chen[1], Siva Theja Maguluri[2], Martin Zubeldia[3], [1]California Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, [3]University of Minnesota, Minneapolis, MN, Contact: zubeldia@umn.edu
In this talk, we look at the concentration behavior of a stochastic approximation (SA) algorithm under a contractive operator with respect to an arbitrary norm. We consider two settings where the iterates are potentially unbounded: bounded multiplicative noise, and additive sub-Gaussian noise. We obtain maximal concentration inequalities on the convergence errors, and show that these errors have sub-Gaussian tails in the additive noise setting, and super-polynomial tails (faster than polynomial decay) in the multiplicative noise setting. In addition, we provide an impossibility result showing that it is in general not possible to achieve sub-exponential tails for SA with multiplicative noise.
To demonstrate the applicability of our theoretical results, we use them to provide maximal concentration bounds for a large class of reinforcement learning algorithms.

2 Bayesian Learning of Optimal Policies in Markov Decision Processes with Countably Infinite State-Space
Saghar Adler, Vijay Subramanian, University of Michigan, Ann Arbor, MI
Models of many real-life applications-queuing models of communication networks or computing systems-have a countably infinite state-space. Learning procedures to find optimal policies mainly focus on finite-state models. We study the problem of optimal control of a family of discrete-time countable state-space Markov Decision Processes (MDPs) on $\X=\mathbb{Z}_+^d$ with finite action space A, and an unbounded cost function, governed by an unknown parameter $\theta\in\Theta$. The random unknown parameter $\boldsymbol{\theta}^*$ is generated via a given fixed prior. To optimally control the unknown MDP, we propose an a Thompson sampling algorithm with dynamically-sized episodes. Ergodicity assumptions ensure stability of controls. The Bayesian regret is bounded as $\tilde O(\sqrt{|A|T})$.

3 New Improved Regret Bounds for Model-Free Reinforcement Learning
Priyank Agrawal, Shipra Agrawal, Columbia University, New York, NY
Model-free reinforcement learning (RL) algorithms have been established to be simpler to implement in various practical scenarios than their model-based counterparts. This work presents a new algorithm design and regret analysis for model-free RL, mainly focusing on the average reward setting.

4 Measurized Markov Decision Processes
Alba V Victoria Olivares Olivares Nadal[1], Daniel Adelman[2], [1]University of New South Wales, Sydney, Australia; [2]University of Chicago, Booth School of Business, Chicago, IL
We build a framework that facilitates the analysis of infinite horizon Markov Decision Processes (MDP's) by visualizing them as deterministic processes where the states are probability measures on the original state space, and the actions are stochastic kernels on the original action space. We call this to "measurize" the original stochastic MDP, and show that measured MDP's are in fact a generalization of stochastic MDP's. We demonstrate that this framework offers various advantages.

A Few High-dimensional Inference Problems
Community Committee Choice Session
Session Chair: Dana Yang, Cornell University, Ithaca, NY

1 Test of Significance for High-Dimensional Thresholds with Application to Individualized Minimal Clinically Important Difference
Jingyi Duan[1], Huijie Feng[1], Yang Ning[1], Jiwei Zhao[2], [1]Cornell Univeristy, Ithaca, NY, [2]University of Wisconsin-

Madison, Madison, WI, Contact: jd2222@cornell.edu
This work is motivated by learning the individualized minimal clinically important difference, a vital concept in biomedical studies. We formulate the scientific question into a high-dimensional statistical problem where the parameter of interest lies in a linear threshold. The goal is to develop a hypothesis testing procedure for a single element in this parameter. The difficulty dues to the high-dimensional nuisance, and also the fact that this high-dimensional threshold model is non-regular. To deal with these challenges, we construct a test statistic via a new bias-corrected smoothed decorrelated score approach, and establish its asymptotic distributions under both null and local alternative hypotheses. We propose a double-smoothing approach to select the optimal bandwidth in our test statistic and provide theoretical guarantees for the selected bandwidth.

2 Detection of Dense Subhypergraphs by Low-Degree Polynomials

Abhishek Dhawan, Georgia Institute of Technology, Atlanta, GA, Contact: abhishekdhawan@gatech.edu
Detection of a planted dense subgraph in a random graph is a fundamental statistical and computational problem that has been extensively studied in recent years. We study a hypergraph version of the problem. Let $G^r(n,p)$ denote the r-uniform Erdos-Renyi hypergraph model with n vertices and edge density p. We consider detecting the presence of a planted $G^r(n^{\square}, n^{-\square})$ subhypergraph in a $G^r(n, n^{-\square})$ hypergraph, where $0< \square < \square < r-1$ and $0 < \square < 1$. Focusing on tests that are degree-$n^{o(1)}$ polynomials of the entries of the adjacency tensor, we determine the threshold between the easy and hard regimes for the detection problem.

3 Nearly-Linear Time and Streaming Algorithms for Outlier-Robust Pca

Thanasis Pittas, UW-Madison, Madison, WI, Contact: pittas@wisc.edu
We study principal component analysis (PCA), where given a dataset in R^d from a distribution, the task is to find a unit vector v that approximately maximizes the variance of the distribution after being projected along v. Despite being a classical task, standard estimators fail drastically if the data contains even a small fraction of outliers, motivating the problem of robust PCA. Recent work has developed computationally-efficient algorithms for robust PCA that either take super-linear time or have sub-optimal error guarantees. Our main contribution is to develop a nearly linear time algorithm for robust PCA with near-optimal error guarantees. We also develop a single-pass streaming algorithm for robust PCA with memory usage nearly-linear in the dimension.

4 Entry-Specific Bounds for Low-Rank Matrix Completion Under Highly Non-Uniform Sampling

Xumei Xi[1], Christina Lee Yu[1], Yudong Chen[2], [1]Cornell University, Ithaca, NY, [2]University of Wisconsin, Madison, Madison, WI, Contact: xx269@cornell.edu
Low-rank matrix completion concerns the problem of estimating unobserved entries in a matrix using a sparse set of observed entries. We consider the non-uniform setting where the observed entries are sampled with highly varying probabilities, potentially with different asymptotic scalings. We show that under structured sampling probabilities, it is often better and sometimes optimal to run estimation algorithms on a smaller submatrix rather than the entire matrix. In particular, we prove error upper bounds customized to each entry, which match the minimax lower bounds under certain conditions. Our bounds characterize the hardness of estimating each entry as a function of the localized sampling probabilities. We provide numerical experiments that confirm our theoretical findings.

VoI, Pandemic Decision Making, and Disaster Response

Community Committee Choice Session

Session Chair: Ali E. Abbas, University of Southern California, Los Angeles, CA

1 Developing Optimal Testing Strategies with Decision Programming

Ahti Salo, Topias Terho, Fabricio Oliveira, Aalto University, Espoo, Finland. Contact: ahti.salo@aalto.fi
By converting influence diagrams into mixed-integer linear programming (MILP) problems, Decision Programming (Salo et al., EJOR 299/2, 2022) makes it possible to eliminate the usual ‘no-forgetting’ assumption and to handle many kinds of logical, resource, and resource constraints. In order to improve the computational performance of these MILP problems, we propose novel formulations for modeling information decisions that govern what information is obtained to support further decisions. Technically, information decisions are represented through binary variables that act as constraints on other decisions. We illustrate the approach with numerical examples on the development of testing strategies.

2 Optimal Strategies for Asset Maintenance with Decision Programming

Leevi Olander, Aalto University, Helsinki, Finland

Condition-based optimal maintenance strategies are needed to maximize the performance of assets such as transportation infrastructures while minimizing the costs of maintenance and the risks of disruptions due to external loads. In this talk, we explore the use of Decision Programming (Salo et al., EJOR 299/2, 2022) in determining efficient maintenance strategies with regard to the level of performance associated with different asset conditions, the risk of disruptions, and the costs and impacts of alternative maintenance actions. The results indicate that Decision Programming is computationally viable for developing risk-informed maintenance strategies, as illustrated by stylized examples for the Finnish Transport Infrastructure Agency.

OM Problems with Social Interactions

Community Committee Choice Session

Session Chair: Dongwook Shin, HKUST Business School, Clear Water Bay, Hong Kong

1 Online Combinatorial Optimization with Group Fairness Constraints

Negin Golrezaei[1], Rad Niazadeh[2], Kumar Kshitij Patel[3], Fransisca Susan[4], [1]Massachusetts Institute of Technology, Lexington, MA, [2]Chicago Booth School of Business, CHICAGO, IL, [3]Toyota Technological Institute at Chicago, Chicago, IL, [4]Massachusetts Institute of Technology, Cambridge, MA, Contact: kkpatel@ttic.edu

Online marketplaces are increasingly under pressure to cultivate and sustain a fair ecosystem for all their users. An essential aspect of this challenge involves incorporating group fairness constraints into these platforms' decision-making processes. These processes often must solve NP-complete problems with exponentially large decision spaces, such as sub-modular maximization. We provide a general framework to address this challenge by casting this problem as a max-min game between a primal player aiming to maximize the platform's objective and a dual player in charge of group fairness constraints. With this view, we present fair algorithms for offline and online settings to maximize the platform's objective. We provide theoretical guarantees for our method and empirically evaluate our approach on the MovieLens dataset, demonstrating its effectiveness.

2 Dynamic Expansions of Social Followings with Lotteries and Give-Aways

Jingtong Zhao, Renmin University of China, Beijing, China

We study a practice common on popular microblogging platforms such as Twitter of influencers' expanding their followings by running lotteries and giveaways. We are interested in how the lottery size and the seeding decisions will influence the information propagation process and the final reward for such a campaign. We construct an information-diffusion model based on a random graph, and show that the market demand curve of the lottery reward via the promotion of the social network is "S"-shaped. Second, we observe that 1) the propagation may slow down quickly and 2) with a fixed seeding budget, seeding at two fixed occasions is always better than seeding once at the beginning. These observations motivate us to further study the joint optimization of lottery size and adaptive seeding. We show that the adaptive seeding problem is solvable by modelingit as a tractable MDP.

3 Quality Design for Multi-Attribute Product in the Presence of Social Learning

Eunjee Kim[1], Sang Won Kim[2], Dongwook Shin[3], [1]University of Wisconsin-Madison, Madison, WI, [2]KAIST College of Business, Seoul, Korea, Republic of; [3]HKUST Business School, Clear Water Bay, Hong Kong. Contact: catalanumber@gmail.com

This paper studies a monopolist firm's choices of product quality and price. The product quality is a priori unknown, but customers can infer it from customer-generated reviews using Bayesian updating. This problem is studied using two different review systems: a multi-dimensional (MD) review system, where customers report their experience on multiple features of a product; and a single-dimensional (SD) review system, where customers only provide an overall rating. Our analysis yields two main insights. First, we find that the learning is successful with MD reviews, whereas SD reviews may obfuscate the learning. Second, we find that MD reviews relatively improve the product quality when customers' prior belief is sufficiently negative.

4 Social Learning with Polarized Preferences on Content Platforms

Dongwook Shin[1], Bharadwaj Kadiyala[2], [1]HKUST Business School, Clear Water Bay, Hong Kong; [2]University of Utah, Salt Lake City, UT

The focus of this research is to explore how polarized preferences affect content consumption and production on a digital platform that utilizes popularity metrics to facilitate social learning. Our analysis yields three main insights. First, we find that social learning under polarized preferences can mislead consumers into incorrectly perceiving low-quality content as higher-quality content; consequently, content providers may lower the content quality. Second, despite the negative effects of polarization, social learning improves content quality unless the polarization level is extreme. Third, our research suggests several levers that platforms can use to improve content quality, including implementing two-part compensation plans, suppressing content recommendation, censoring misinformation, and providing viewership information.

Pricing and Its Effects

Contributed Session

Session Chair: Banafsheh Behzad, California State University, Long Beach, Long Beach, CA

1 Free Freight or Not? Retail Platform Operations Under Reference Price Effect

Qiang Wang[1], Jie Wu[1], Xiang Ji[1], Nenggui Zhao[2], [1]University of Science and Technology of China, Hefei, China; [2]Hefei University of Technology, Hefei, China

We incorporate reference price effect into a Hotelling model to characterize the pricing and freight decisions of two competitive retail platforms. Our results find retail platforms prefer sequential pricing over simultaneous pricing, and free freight will not affect the platforms' operational decisions if the reference price effect is ignored.

2 Dynamic Pricing with Experimentation and Fairness Concerns

Ariit Sengupta[1], Himanshu Rathore[2], [1]Indian Institute of Management, Lucknow, Lucknow, India; [2]Indian Institute of Management Lucknow, Lucknow, India. Contact: ariitsengupta@gmail.com

Research on Dynamic Pricing with demand learning is increasingly gaining traction because of shortening product life cycles. This work subscribes to experimentation in demand learning and proposes a pricing policy that quantifies the impact of fairness concerns on customers. The proposed pricing policy incurs a regret of O(log^m(T)) and performs better than the proposed bounds of Kleinberg and Leighton (2003).

3 Dynamic Pricing with Procedural and Substantive Fairness

Jianyu Xu, Qiao Dan, Yu-Xiang Wang, University of California, Santa Barbara, Santa Barbara, CA, Contact: xu_jy15@ucsb.edu

We study the problem of online dynamic pricing with two types of fairness constraints: a procedural fairness which requires the *proposed* prices to be equal and a substantive fairness which requires the *accepted* prices to be equal in expectation among different groups. A policy that is simultaneously procedural and substantive fair is referred to as doubly fair. We show that a doubly fair policy must be random to have higher revenue than the best fixed-price policy. In a two-group setting, we propose an online learning algorithm for two groups that achieves $O(\sqrt{T})$ regret, zero procedural unfairness and $O(\sqrt{T})$ substantive unfairness over T rounds. We also prove its optimality with two matching lower bounds. To the best of our knowledge, this is the first dynamic pricing algorithm that learns to price while satisfying two fairness constraints at the same time.

4 Managing Presales with Two Payments and Return Policy when Consumers are Time-Inconsistent

Yunjuan Kuang, Li Jiang, The Hong Kong Polytechnic University, Hong Kong, China. Contact: yunjuan.kuang@connect.polyu.hk

We consider a firm using presales with two payments (an upfront deposit and a postponed arrear) to sell a product to time-inconsistent consumers under various return policies. With the passage of time, consumers decide whether to preorder the product by paying the deposit, whether to settle the balance by paying the arrear by the due date, and (when returns are allowed) whether to return a fully paid product for a refund after its fitness is revealed. Consumers exhibit time-inconsistency when making purchasing decisions. We characterize the firm's optimal pricing strategy and return policy.

5 Optimal Three Part Tariff Pricing

Jianqing Fisher Wu[1], Banafsheh Behzad[2], [1]California State University, Long Beach, Long Beach, CA, [2]California State University, Long Beach, Long Beach, CA, Contact: banafsheh.behzad@csulb.edu

We study the pricing of three-part tariffs (3PTs), where service providers charge a fixed fee with an allowance of free units, and a per-unit fee for additional units above the allowance. This is a pricing strategy that has been widely used in a variety of industries, including telecommunications and internet services. Many papers study the properties of the optimal solution of 3PTs. However, the existing solution approaches proposed in prior papers can only be used to solve 3PT problems under certain restricted conditions. This study expands the solution approach to more general cases.

Fairness in Real-world Systems

Community Committee Choice Session

Session Chair: Nikhil Garg, Cornell Tech, New York, NY

Session Chair: Zhi Liu, Cornell Tech, New York, NY

1 Online Fair Allocation of Perishable Resources

Sean Sinclair[1], Chamsi Hssaine[2], Sid Banerjee[3], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Amazon / Marshall School of Business, University of Southern California, Ithaca, NY, [3]Cornell University, Ithaca, NY

We consider a variant of the online fair allocation problem: a decision-maker has a budget of resources to allocate over a fixed number of rounds. Each round sees a random number of arrivals, and the decision-maker must commit to an allocation for these individuals before moving on to the next round. In contrast to prior work, we consider a setting in which resources are perishable and individuals' utilities are potentially non-linear (e.g., goods exhibit complementarities). The goal is to construct a sequence of allocations that is envy-free and efficient. We design an algorithm which takes as input a prediction of the perishing order, and a desired bound on envy. The algorithm uses forecasts of future demand and perishing to adaptively choose one of two carefully constructed guardrail quantities to achieve the optimal envy-efficiency Pareto frontier.

2 Redesigning Service Level Agreements: Equity and Efficiency in City Government Operations

Zhi Liu, Nikhil Garg, Cornell Tech, New York, NY, Contact: zl724@cornell.edu

We consider government service allocation -- how the government allocates resources over time. It is important to make these decisions efficiently, equitably, and transparently. In particular, we consider the design of Service Level Agreements (SLA). We model the problem of designing a set of SLAs as a tractable optimization problem with different equity and efficiency objectives under a queuing network framework, with two allocation levers for the city. We empirically apply our framework to calibrated simulations motivated by SLA design in New York City, and find that: (a) status quo budgets are highly inefficient and inequitable, and (b) in practice, the equity-efficiency tradeoff is not substantial: generally, budget and scheduling policies tend to be either both efficient and equitable, or neither efficient nor equitable.

3 Generative Social Choice

Paul Gölz, Simons Laufer Mathematical Sciences Institute, Berkeley, CA

Social choice theory offers group decision processes with mathematical fairness guarantees, but their applicability is limited to choices among few alternatives, not to richer outcome domains like selecting a text statement. We propose *generative social choice*, a framework that combines the mathematical rigor of social choice theory with large language models' capacities to generate text and extrapolate preferences. Our framework breaks down the design of AI-augmented democratic processes into two modules: (1) proving that the process satisfies representation guarantees when given access to oracle queries; and (2) empirically validating that these queries can be approximately implemented with a large language model. We demonstrate this framework for the task of aggregating representative statements in a real-world deliberation on AI governance.

4 Decision-Aware Learning for Global Health Supply Chains

Angel Tsai-Hsuan Chung[1], Vahid Rostami[2], Hamsa Sridhar Bastani[1], Osbert Bastani[3], [1]Wharton School, Philadelphia, PA, [2]Pendulum, Seattle, WA, [3]University of Pennsylvania, Shenzhen, China

Integrating ML and optimization is challenging due to the need to align the ML loss function with the decision loss of the downstream optimization. Current solutions show limits in flexibility and scalability. We present a decision-aware learning algorithm that uses a Taylor expansion of optimal decision loss for efficient learning and decision-making. It only requires re-weighting of training data and can be integrated into modern data science pipelines. We leverage random forests with meta-learning and apply our decision-aware approach to the distribution of essential medicines in Sierra Leone. Our approach significantly reduced unmet demand in over 1000 health facilities.

Flash Session

Session Chair: Jose Pius Nedumkallel, Clemson University, Clemson, SC

1 Improve Engagement in Multi-Tasking Social Referral Programs: The Framing Effect of Rewards

Xu Li[1], Kanliang Wang[2], Hongwei Wang[1], [1]Tongji University, Shanghai, China; [2]Renmin University of China, Beijing, China. Contact: xu.li.edu@hotmail.com

The goal of social referral reward programs is to incentivize existing customers to recommend a product to others. We divide social referrals into single-tasking and multi-tasking social referrals (SSR vs. MSR) based on the reward threshold (i.e., the number of respondents). This paper focuses on the task progress and time in MSR, and explores how to design an effective reward mechanism to improve referral intentions. Based on loss aversion theory, we first elucidate when downgrade- versus gain-framed rewards are most effective in influencing engagement by examining the moderating role of task completion progress. We propose that the above effects will be further moderated by the temporal distance (i.e., the remaining time). Two experiments are designed to test the three hypotheses. This study will provide important implications for designing reward mechanisms in MSR.

2 The Warranty Policy And The Contingent Consumable Products

Jiung Lee, Korea Advanced Institute of Science and Technology (KAIST), Seoul, Korea, Republic of. Contact: leejiung@kaist.ac.kr

The razor-blade pricing strategy involves selling equipment at a low price and charging high prices for related supplies. However, with the entry of low-cost compatible products in the market, firms are no longer able to benefit from deploying the razor-blade strategy. In response, some firms offer warranties that only apply to customers using their OEM supplies. This paper examines the impact of warranty-void policies on a firm's pricing strategy in a competitive environment. We find that implementing a warranty-void policy allows the firm set higher prices for both equipment and supplies, and furthermore, the firm can generate higher profits even after accounting for the cost of the warranty compared to the monopoly case.

3 App Developers' Complaint Response Strategies and Impacts

Jose Pius Nedumkallel, Zhihong Ke, William J. Kettinger, Clemson University, Clemson, SC, Contact: jpiusne@g.clemson.edu

Online reviews greatly influence consumer perceptions and decisions. Ineffective complaint responses can leave customers dissatisfied and negatively impact app adoption. We investigate the complaint response strategies employed by app developers and their impacts on app adoption. Analyzing 1.2 million apps on the Google Play Store from August 2022 to February 2023 using machine learning techniques, we identify two complaint categories: process and outcome failures. App developers use response types: initiation, promises, and resolution. Through fixed-effect panel data analysis, we demonstrate the significant impact of these response types on future app downloads. Our findings provide valuable insights for app developers to enhance their complaint response strategies, fostering positive user experiences and improving app adoption rates.

Stochastic Approaches to Healthcare Analytics

Community Committee Choice Session

Session Chair: Anil Aswani, UC Berkeley, Berkeley, CA
Session Chair: Ilgin Dogan, University of California, Berkeley, Berkeley, CA

1 Community/Committee'S Choice Submission

Alexander Ioannidis, Stanford University, CA

2 Detection of Early-stage Lung Cancer by DNA Methylation with Simple and Effective Machine Learning Techniques

Xin Guo, University of California-Berkeley, Piedmont, CA

The low abundance of circulating tumour DNA (ctDNA) in plasma samples makes the analysis of ctDNA biomarkers for the detection or monitoring of early-stage cancers (e.g., lung cancer) challenging. We show that deep methylation sequencing aided by a machine-learning classifier of methylation patterns enables the detection of tumour-derived signals at dilution factors as low as 1 in 10000. The low amounts of ctDNA permitted by machine-learning-aided deep methylation sequencing could provide advantages in cancer screening and the assessment of treatment efficacy.

Based on the work ``Ultrasensitive detection of circulating tumour DNA via deep methylation sequencing aided by machine learning'', Nature BME, 2021.

3 Miwaves: Rl Algorithm Design for Digital Health Interventions

Yongyi Guo, Harvard University, Cambridge, MA

MiWaves is a digital intervention aimed at reducing cannabis use among emerging adults using smartphone prompts. Given that excessive prompts can lead to user disengagement and habituation, we are developing an RL algorithm to personalize the timing of prompt delivery. The main theoretical challenge is to strike a balance between efficient learning and personalizing with respect to each user, while ensuring stability in an online low-data setting (with limited users). To achieve this goal, we propose a generalized Thompson-Sampling bandit algorithm with a mixed-effects-based reward model, which automatically adjusts the degree of personalization for each user based on previously available data. We also discuss the computational aspects of the algorithm and our simulation results.

4 Incentive, Lockdown and Testing

Thibaut Mastrolia, IEOR UC Berkeley, Berkeley, CA

In this work, we provide a general mathematical formalism to study the optimal control of an epidemic, such as the COVID-19 pandemic, via incentives to lockdown and testing. In particular, we model the interplay between the government and the population as a principal-agent problem with moral hazard, while an epidemic is spreading according to dynamics given by compartmental stochastic SIS or SIR models. Numerical results confirm that if a tax/incentive policy is implemented, the population is encouraged to significantly reduce its interactions. If the government also adjusts its testing policy, less effort is required on the population side, individuals can interact almost as usual, and the epidemic is largely contained by the targeted isolation of positively-tested individuals

Empirical Research in Healthcare

Community Committee Choice Session

Session Chair: Sriram Venkataraman, University of South Carolina, Columbia, SC

1 The Role of Surgical Consumable Standardization in Healthcare: An Empirical Study on Orthopedic Surgery

Ting Wang[1], Ding Xin[2], Kejia Hu[3], Yun Fong Lim[4], Vikram Tiwari[5], [1]University of Science and Technology of China, Hefei, China; [2]Rutgers Business School, New Jersey, NJ, [3]Vanderbilt University, Nashville, TN, [4]Singapore Management University, Singapore, Singapore; [5]Vanderbilt University Medical Center, Nashville, TN

We investigate how surgical consumable standardization (SCS) impacts the performance of healthcare service. To answer this question, we utilize point-of-usage data of over 17,000 orthopedic surgeries and focus on SCS's impact on three healthcare service outcomes: service quality, service efficiency, and service cost. We find that SCS promotes quality patient care at a cost-effective price. Our results provide important implications for (1) surgeons to reshape their understanding of SCS, (2) administrators to establish business cases for SCS initiatives at the hospital or system level, and (3) the healthcare industry to align SCS with ongoing supply chain operations (e.g., volume-based procurement programs) and financial reforms (e.g., from fee-for-service to bundled payments).

2 Impact of Clinical Focus on Patient Outcomes Through Ultra-Early Admissions

Aman Goswami[1], Xin Ding[2], David Dreyfus[3], [1]Rutgers Business School, Newark, NJ, [2]Rutgers University, Newark, NJ, [3]Rutgers University, Newark, NJ, Contact: ag77in@gmail.com

We present research examining the impact of clinical focus on patient outcomes through ultra-early procedures. A theoretical and empirical framework is developed to understand how and why clinical focus impacts patient outcomes. We generate and validate critical hypotheses linking patient outcomes to clinical focus and show how ultra-early procedures mediate this relationship. The results provide a new direction to the research of clinical focus and the applicability of speed, delivery of care, and ultra-early procedures in healthcare settings.

3 The Double-edged Sword Effect Of Corporate Venture Capital On Startup Innovation: Evidence From The Medical Device Industry

Moyan Li[1], George Ball[2], Haizhen Lin[1], [1]Indiana University, Bloomington, IN, [2]Operations and Decision Technologies, Kelley School of Business, Indiana University, Bloomington, IN, Contact: moyli@iu.edu

Venture capital is one of the most important external funding sources for startups. Unlike independent venture capital firms (IVC), corporate venture capital (CVC) not only brings funding but also specialized industry knowledge, comprehensive experience of product life cycle, and perhaps, negative established-industry practices that may lead to quality issues. Using difference-in-difference models and instrument variable strategy, we compare the causal effect of CVC versus IVC on innovation successes of U.S. medical device startup firms. CVCs foster innovation of startups more efficiently than IVCs. Moreover, CVC-backed innovations appear to suffer from more product quality failures than IVC-backed ones, indicating a potential double-edged sword to the innovation benefit of CVCs.

Incentive Design and Game Theory in Healthcare

Community Committee Choice Session

Session Chair: Saumya Sinha, University of Minnesota, Minneapolis, MN

1 Incentives and Decentralization for Enhancing Coordination in Consolidated Hospital Systems

Shima Mohebbi, George Mason University, Fairfax, VA

The integration of healthcare systems has been a solution to enhance the quality of care and reduce costs for more than a decade. This study investigates the collaboration of hospitals, consolidated for healthcare service delivery, in the patient's referral process. Cooperative game theory, coupled with optimization techniques, is utilized to model the interaction of main players (physicians, hospitals managers, and the central referral system) and devise an incentive scheme. The feasibility of the approach is examined via a case study. In this setting, a prototype decentralized patients assignment system will be presented which highlights the importance of interoperability and consensus among healthcare players in the decision-making process.

2 Optimal Integration of Screening Strategies and Incentive Mechanisms for the Effective Mitigation of Covid-19

Marie Jeanne Rabil[1], Sait Tunc[1], Douglas R. Bish[2], Ebru Korular Bish[2], [1]Virginia Tech, Blacksburg, VA, [2]University of Alabama, Tuscaloosa, AL, Contact: mariejeanne@vt.edu

Integrating protective and preventative interventions including screening and vaccination is essential for managing infectious disease outbreaks, as COVID-19 demonstrates. Although the vaccination resources became abundant in the later stages of the pandemic, not all universities (or other closed communities) can mandate vaccination, let alone require individuals to report their vaccination status, thus it is important to create mechanisms that will increase voluntary compliance. We propose a novel approach to infection control on university campuses, and study strategies that integrate routine screening and nudge mechanisms (e.g., monetary incentive, or exemption from routine screening, for all vaccinated individuals) under limited resources, considering behavioral issues of the campus population and an imperfect information on vaccination status.

3 Incentives to Improve Participant Retention in Clinical Studies

Xueze Song[1], Mili Mehrotra[2], Tharanga Kumudini Rajapakshe[3], [1]Universityof Illinois-Urbana-Champaign, Champaign, IL, [2]University Of Illinois Urbana Champaign, Champaign, IL, [3]University of Florida, Gainesville, FL, Contact: tharanga@ufl.edu

Participant retention is a significant issue in clinical studies. It is estimated that on average more than 40% of the participants of a clinical study drop out before the conclusion of the study. We analyze mechanisms to improve participant retention. Specifically, we focus on the characteristics of a clinical study, the clinical study team, and the participants, to design incentives and compensations, for the participants and providers, respectively, to achieve a targeted retention level.

4 Hybrid Telehealth Service with Heterogeneous Community Patients

Xiang Zhong[1], Yongpei Guan[2], Tan Yu[3], [1]Univ. of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, [3]University of Florida, Gainesville, FL, Contact: oliver040525@gmail.com

We consider a medical institution with one central care facility serving a broad catchment area including multiple communities. We follow the strategic queueing model conventions and conceptualize the care delivery system as an unobservable queue where the customers (patients) do not observe the queue prior to their actions. Two service options are provided, telehealth and in-person visits. Customers belonging to each community can have distinct service values and time costs, based on their proximity to the central care facility. We explore how the equilibrium patient flow looks like with two service options and what factors decide the market size of telehealth, and, how the revenue-maximizing stakeholder behaves differently from the social welfare-maximizing stakeholders with and without the telehealth option.

Data-driven Decision Making in Healthcare II

Community Committee Choice Session

Session Chair: Jin Qi, Hong Kong University of Science and Technology, Hong Kong, Hong Kong
Session Chair: Yi Chen, Hong Kong University of Science and Technology, Hong Kong, Hong Kong
Session Chair: Kai Sun, University of Texas-San Antonio, San Antonio, TX

1 Optimizing Early Discharge: Trade-Offs Between Capacity and Re-Admissions

Zhiyuan Lou[1], Gar Goei Loke[2], Jingui Xie[1], Taozeng Zhu[3], [1]Technical University of Munich, Heilbronn, Germany; [2]Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands; [3]Dongbei University of Finance and Economics, Dalian, China. Contact: louzy0803@gmail.com

In this work, we consider the ward capacity management problem where the decision-maker seeks to optimize elective schedule and an early discharge policy, so as to minimize the chance of bed shortages in the ward. In particular, the decision-maker needs to balance the trade-off between the immediate capacity freed up by early discharges and the increased chance of re-admissions. The presence of such re-entry makes it difficult to model this problem via traditional methods. We appeal to the Pipeline Queues (Bandi 2018) framework, and propose an optimization model where the early discharge policy is expressed as a linear state-dependent decision rule. The model has a reformulation, which can be solved as a sequence of convex program with asymptotically linear constraints. We numerically examine the conditions under which early discharge is favoured.

2 Model-Assisted Uniformly Honest Inference for Optimal Treatment Regimes in High Dimension

Yunan Wu, University of Texas at Dallas, Richardson, TX

We develop new tools to quantify uncertainty in optimal decision making and to gain insight into which variables one should collect information about given the potential cost of measuring a large number of variables. We investigate simultaneous inference to determine if a group of variables is relevant for estimating an optimal decision rule in a high-dimensional semiparametric framework. We first establish that a local restricted strong convexity condition holds with high probability and that any feasible local sparse solution of the estimation problem can achieve the near-oracle estimation error bound. We further rigorously verify that a wild bootstrap procedure based on a debiased version of the local solution can provide asymptotically honest uniform inference for the effect of a group of variables on optimal decision making.

3 Distributionally Robust Group Testing with Correlation Information

Daniel Zhuoyu Long[1], Jin Qi[2], Yu SUN[3], Aiqi Zhang[4], [1]The Chinese University of Hong Kong, Shatin, Hong Kong; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]The Chinese University of Hong Kong, Shatin, China; [4]Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: jinqi@ust.hk

In this work, we consider a group testing problem where the infection of subjects has a correlation. In such a setting, the joint distribution cannot be exactly characterized; hence, we use a distributionally robust framework. Given the marginal distribution and the correlation information, we evaluate the performance under the worst-case distribution and minimize the expected number of tests and misclassifications (false positive and false negative) to find an optimal partition. Specifically, we consider the pairwise and partial correlation: for the pairwise case, we show the optimality of common group size and derive the optimal partition in a few steps; for the partial case, we generalize the worst-case analysis and provide managerial insights. We also conduct numerical studies to show that the consideration of correlation information is significant.

4 Equitable Anesthesiologist Scheduling Under Demand Uncertainty Using Multiobjective Programming

Kai Sun[1], Minghe Sun[2], Deepak Agrawal[3], Ronald Dravenstott[4], Frank Rosinia[5], Arkajyoti Roy[6], [1]University of Texas at San Antonio, San Antonio, TX, [2]University of Texas-San Antonio, San Antonio, TX, [3]Meta, Fort Worth, TX, [4]UNT Health Science Center, Fort Worth, TX, [5]University of Texas Health Science Center at San Antonio, San Antonio, TX, [6]The University of Texas at San Antonio, San Antonio, TX, Contact: kai.sun@utsa.edu

This work addresses an anesthesiologist scheduling (AS) problem under uncertainty. The goal is to plan and deploy providers to meet clinical demand and institutional protocols. A data-driven two-step sequential AS framework is developed using a mixed-integer multi-objective program. Step 1 designs shifts to minimize excessive clinical time using conditional value-at-risk constraints to account for demand uncertainty. Step 2 assigns shifts to providers considering optimal and equitable workload distribution and the number of required providers. An ⍰-constraint solution method is applied for multi-objective optimization, and an iterative solution method is developed to improve workload equity in clinical applications. Two case studies, the budget and hiring planning and the monthly AS, are addressed in a large anesthesiology department via the AS framework.

The Pharma Industry

Flash Session

Session Chair: Nektarios Oraiopoulos, Cambridge University, Cambridge, United Kingdom

Session Chair: Lidia Betcheva, Cambridge Judge Business School, Cambridge, United Kingdom

1 Flash Paper Submission (5-Minute Presentation)

Feryal Erhun[1], Lidia Betcheva[2], Nektarios Oraiopoulos[3], [1]University of Cambridge, Cambridge, United Kingdom; [2]Cambridge Judge Business School, Cambridge, United Kingdom; [3]Cambridge University, Cambridge, United Kingdom. Contact: f.erhun@jbs.cam.ac.uk

This paper provides an overview of decentralized clinical trials (DCTs), emphasizing how they fit into and alter the current clinical development landscape. We propose a conceptual framework that employs systems thinking to evaluate the impact of trial decentralization on key stakeholders through a reiterative assessment of pain points.

2 Flash Paper Submission (5-Minute Presentation)

Hossein Nikpayam[1], Moritz Fleischmann[2], Jochen Schlapp[3], [1]ESMT, Berlin, Germany; [2]University of Mannheim, Mannheim, Germany; [3]Frankfurt School of Finance & Management gGmbH, Frankfurt Am Main, Germany. Contact: hossein.nikpayam@esmt.org

When composing their innovation portfolios, firms can rely on their internal R&D units and invest in projects that are promoted internally; or they can acquire projects that originated outside their boundaries. We ask: How should a firm allocate its scarce resources across the different sources? We investigate this decision by designing a stylized game-theoretic model, and we identify the firm's optimal resource allocation policy.

3 High-Impact Life Sciences Research from Fellows of Indiana Univ Kelley School Center for the Business of Life Sciences

Jonathan Eugene Helm[1], George P. Ball[2], Ozge Yapar[3], [1]Indiana University, Bloomington, IN, [2]Kelley School of Business, Indiana University, Bloomington, IN, [3]Indiana University, Kelley School of Business, Bloomington, IN

In this talk I will provide an overview of the exciting, problem driven research being done at Indiana University Kelley School of Business Center for the Business of Life Sciences (CBLS). CBLS consists of executives from life sciences companies (>15), faculty fellows (>20) who collaborate with these organizations on high-impact life sciences research, and students who learn and prepare for careers in the life sciences. The goal of the center is to match top researchers with innovative managers to engage in academia-industry collaborations, which this talk will highlight. I will also discuss an exciting new opportunity to meet our executives in a small conference setting to share research and generate new research ideas and collaborations jointly with major life sciences companies in April 2024.

4 Flash Paper Submission (5-Minute Presentation)

Carter Dredge, Stefan Scholtes, University of Cambridge, Cambridge, United Kingdom

This paper focuses on the generic drug supply chain's failure to supply essential medicines reliably at low cost. In a novel response, multiple US health systems founded a novel not-for-profit drug manufacturer, Civica Rx, to address the issue. Civica utilizes a new business model known as a *health care utility* that prioritizes access over profit. The company has scaled rapidly and now provides over 75 essential medications that are most at risk of shortages to over 55 health systems in the US. This paper provides first empirical evidence of Civica's effect on security and cost of supply for one of its member health systems, by utilizing internal supply chain, pharmacy, and external market data between 2016 and 2022. Results show that Civica was able to substantially improve essential access on a cohort of medicines plagued by shortages for years at a comparable cost structure.

5 Make It Personal: Standardization And Prosocial Behavior

Rob Glew[1], Claire Senot[2], [1]McGill University, Montreal, QC, Canada; [2]Tulane University, New Orleans, LA, Contact: rob.glew@mcgill.ca

We examined customisation in prosocial healthcare settings. Using a regression discontinuity in time identification method, we analysed a natural experiment in a healthcare programme, with over 300,000 observations of participation decisions. Participants were pseudo-randomly assigned to varying size groups for viral testing and provided with customised test kits. After nine weeks, test kits were made generic and lacked personal identifiers, resulting in a 20% decline in testing participation.We highlight the importance of customisation in fostering psychological ownership and enhancing prosocial behaviours in healthcare. The removal of customisation from test kits weakened psychological ownership, reducing commitment and motivation. However, this effect was moderated by group social influence, with smaller treatment effects in larger groups.

Empirical Research on Socially Responsible Operations

Community Committee Choice Session

Session Chair: Hailong Cui, University of Minnesota, Minneapolis, MN

Session Chair: Dwaipayan Roy, University of Virginia Darden School of Business, Albemarle, VA

1 Hiding Behind Complexity: Supply Chain, Oversight, Race, and the Opioid Crisis

Iman Attari, Jonathan Eugene Helm, Jorge Mejia, Indiana University, Bloomington, IN, Contact: iattari@iu.edu

In this study, we examine the opioid crisis from a supply chain perspective and provide evidence on how complexity of presecription opioid supply chains facilitated the flood of opioids into communites without detection by regulatory authorities. Further, we find new evidence on the greater impact of the complexity in non-White communitites that are typically overlooked in governtmental responses to the opioid crisis.

2 Compassion in Discretion: Leveraging Operations Managers' Guilty Conscience to Mitigate Suffering on the Shop Floor

Emily C. Dickey[1], Prisca Brosi[2], Jan C. Fransoo[3], [1]Kuehne Logistics University, Hamburg, Germany; [2]Kuehne Logistics University, Hamburg, Germany; [3]Tilburg University, Tilburg, Netherlands. Contact: emily.dickey@the-klu.org

Addressing suffering on the shop floor, we investigate the impact of emotions on managerial decision-making regarding the trade-off between decent working hours and traditional operational outcomes. Industry characteristics often force a trade-off between employee well-being and profit or productivity, but managers have discretion in this trade-off. We test whether managers' *emotional* responses to these trade-offs alters their decision-making. Across one survey of operations managers and two vignette experiments, we find that guilty managers who feel low autonomy actually de-prioritize worker well-being. In contrast, compassion fosters employee well-being but only when managers feel decision-making autonomy in the workplace. Thus, by encouraging managerial compassion and discretion, companies can mitigate suffering on the shop floor.

3 The Production Benefits of Personalized Agricultural Advice: A Case Study of Mkrishi

Campbell Clarkson, Necati Tereyagoglu, Sriram Venkataraman, University of South Carolina, Columbia, SC

We investigate the effects of introducing a mobile-based agricultural advisory service on crop production, utilizing the launch of one service in Buland Shahar district of India as a case study. We also examine whether such effects are explained by changes in three key agricultural inputs: cultivated area, chemical fertilizer usage, and irrigated area.

Emerging Topics in Empirical Operations

Community Committee Choice Session

Session Chair: Hailong Cui, University of Minnesota, Minneapolis, MN

Session Chair: Jiding Zhang, NYU, New York, NY

1 Rankings and Usage on Online B2b Platforms: Does Match Quality Matter?

Rakesh Allu, Vishal Gaur, Cornell University, Ithaca, NY, Contact: aa2688@cornell.edu

Large buyer volumes on online B2B platforms cause search friction, which lowers sellers' usage. To solve this problem, online B2B platforms actively invest in R&D to devise algorithms aimed at improving their match quality, that is, the ability to accurately display buyer requests in the decreasing order of their potential value to the sellers. This raises an important question of whether improving match quality is effective in increasing sellers' usage of the platform. We answer this question using page-rank data of 77 million transactions from an online B2B platform. We develop methods to compute match quality from page-rank data that address endogeneity and censorship in such data. Our results indicate that investments in improving match quality not only increase seller usage, they do so by reducing seller effort, measured as the number of positions viewed.

2 The Impact of the Opportunity Zone Program on Residential Real Estate

Xiaoyan Liu[1], Ron Bekkerman[2], Maxime Cohen[3], John Maiden[2], Dmitry Mitrofanov[4], [1]Santa Clara University, Santa Clara, CA, [2]Cherre Inc, New York, NY, [3]McGill University, Kirkland, QC, Canada; [4]Boston College, Chestnut Hill, MA, Contact: xliu10@scu.edu

Opportunity zones (OZs) are designated census tracts in which real estate investments can gain tax benefits. Introduced by the U.S. Tax Cuts and Jobs Act of 2017, the goal of the OZ program is to foster economic development in distressed neighborhoods. In this paper, we investigate and optimize the OZ selection process, and examine the impact of OZs by exploiting large-scale datasets. We find that the OZ program increased real estate prices by 4.03%-6.13% but do not observe a significant effect on the transaction volume. We also find that investors primarily targeted the high end real estate market, namely exhibiting a cherry-picking behavior. To better fulfill its intended societal and economic goals, we propose an optimization framework with fairness considerations for OZ assignment decisions.

3 Impact of Strategic Shifts and Policy Decisions on Global Supply Chains

Vidya Mani, University of Virginia, Charlottesville, VA

We leverage data from company transactions, trade and shipments, and multi-region input and output information to evaluate the impact of national-level policy decisions and company-level supply chain risk mitigation strategies on global supply chains in the apparel and electronics sectors. We identify how, why, and where these supply chains change, the spillover effects, and highlight the unintended consequences of these decisions.

Teaching Firm-Level Operations-Finance Interface Topics in the MBA Classroom

Community Committee Choice Session

Session Chair: Vishal Gaur, Cornell University, Ithaca, NY

1 Using Firm-Level to Study Operational Decisions

Danko Turcic, University of California, Riverside, 900 University Ave., CA

We present two research studies that use data to infer firm-level operational decision-making. The first study shows how data can be used to confirm our theoretical understanding of how a firm might optimally interact with its suppliers. The second study uses data to infer an optimal operational policy that is too complicated to describe with a tractable analytical model.

2 Teaching About Inventory Turnover and Its Relationship to Operations and Finance in the Mba Classroom

Vishal Gaur, Cornell University, Ithaca, NY

Inventory turnover is an important metric for the operational and financial performance of a firm. In this talk, I will summarize lessons from teaching about inventory turnover to MBA students and discuss the tools and resources that I utilize for this purpose. This talk is based on the extensive research done on inventory turnover in the Operations Management literature over the last two decades.

3 Supply Networks in Research and Mba Teaching

Nikolay Osadchiy, Emory University, Atlanta, GA

Supply networks provide a novel lens for studying important operational phenomena including demand risk, inventory productivity and the bullwhip effect. Main research findings and experiences from teaching them in a classroom will be discussed.

4 Global Sourcing Under External Shocks: Product-Level Network Dynamics

Maxi Udenio[1], Shaunak Dabadghao[2], James Zhang[3], [1]KU Leuven, Leuven, Belgium; [2]Eindhoven University of Technology, Eindhoven, Netherlands; [3]Technical University of Eindhoven, Eindhoven, Netherlands. Contact: maxi.udenio@kuleuven.be

We study global sourcing dynamics by analysing how firms responded to recent large-scale shocks, such as tariff regime changes. Based on the current literature in global sourcing strategies, we specifically examine the patterns of global sourcing by (1) investigating time-series of imports to the US aggregated at the firm level, and (2) by constructing a dynamic supply network at the product-level.
Our time series analysis enables us to understand tactical sourcing decisions taken by firms as a reaction to (and in anticipation of) structural changes in the network.Moreover, by analysing changes in the network topology at such a disaggregated level, we are able to distinguish previously unobservable dynamics in the supply network, such as changes in the (single/dual) sourcing strategy.

Session Chair: Xiaoyang Long, University of Wisconsin-Madison, Madison, WI

Session Chair: Dennis Zhang, Washington University in St Louis, St Louis, MO

1 Optimizing Solar-Powered Off-Grid Lights for the Bottom of the Pyramid: Evidence from Field Experiments in Ghana

Bhavani Shanker Uppari[1], Serguei Netessine[2], [1]Singapore Management University, Singapore, Singapore; [2]The Wharton School, Philadelphia, PA, Contact: bhavaniu@smu.edu.sg

A large part of Afrika's population does not have access to the electrical grid, and relies on non-sustainable energy sources. Solar lights have a potential of making impact but it remains unknown what configuration of bulbs/batteries/solar panels would enable fast and cost-effective transition to renewable energy. We conduct field experiments in Ghana to answer this question.

2 Self-Preference on E-Commerce Platforms: Evidence from Jd.Com

Zihan Zhao[1], Renyu Zhang[2], Dennis Zhang[3], [1]Washington University in St. Louis, St. Louis, MO, [2]The Chinese University of Hong Kong, Hong Kong, China; [3]Washington University in St Louis, ST LOUIS, MO, Contact: zihan.zhao@wustl.edu

Dual online e-commerce platforms provide the marketplace service and directly sell products as a retailer (e.g., Amazon and JD.COM). Such platforms may abuse their dominating market power to algorithmically discriminate against their third-party sellers by steering more consumer traffic to the platform-owned sellers even for the otherwise identical products. We develop an integrated modeling and empirical framework to identify the algorithmic discrimination against third-party sellers on an e-commerce platform and uncover the underlying mechanism of algorithmic discrimination.

3 Impact of Import Tariff on Lead Recycling in Bangladesh

Qiong Wang[1], Amrita Kundu[2], Erica Plambeck[3], [1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]McDonough School of Business, Georgetown University, Washington, DC, [3]Stanford University, Stanford, CA, Contact: qwang04@illinois.edu

Millions of electronic three-wheelers in Bangladesh are powered by lead acid batteries. Lead supply for producing new batteries comes from either import or recycling used lead acid batteries (ULABs). Informal recycling of ULABs is causing disastrous lead pollution, and government intervention is urgently needed to stimulate formal recycling that meets environmental standard. We show that to this end, deciding the import tariff on lead becomes a tricky choice. A low tariff makes importing lead more profitable than getting it from formal recycling. A high tariff provides the incentive to monopolize ULAB collection, which squeezes the profit margin of formal recycling. We discuss how relaxing export control of ULABs can help to resolve this dilemma.

Emerging Topics in Platform Operations

Community Committee Choice Session

Session Chair: Eryn He, University of Utah, Salt Lake City, UT

1 Machine Learning and Prediction Errors in Causal Inference

Daniel Chen[1], Gad Allon[1], Zhenling Jiang[1], Dennis Zhang[2], [1]University of Pennsylvania, Philadelphia, PA, [2]Washington University in St Louis, ST LOUIS, MO, Contact: zhenling@wharton.upenn.edu

Machine learning is a growing method for causal inference. In machine learning settings, prediction errors are a commonly overlooked problem that can bias results and lead to arbitrarily incorrect parameter estimates. We consider a two-stage model where (1) machine learning is used to predict variables of interest, and (2) these predictions are used in a regression model for causal inference. Even when the model specification is otherwise correct, traditional metrics such as p-values and first-stage model accuracy are not good signals of correct second-stage estimates when prediction error exists. We show that these problems are substantial and persist across simulations and an empirical dataset. We provide consistent corrections for the case where unbiased training data is available for the machine learning dataset.

2 Fostering Long-Tenured Seller Value-Creation: A Field Experiment

Grace Gu, University of Southern California, Los Angeles, CA

As e-commerce platforms mature, new seller entry slows down and platforms cannot take advantage of the cross-side network effect from new seller recruitments. Meanwhile, long-tenured sellers become a major part of the market but some of them lose motivation to actively create value. Therefore, it is important to understand how mature platforms can effectively incentivize long-tenured sellers value creation. We leverage a large-scale randomized control experiment in which the platform displays "long-tenured" tags on customer search results to emphasize sellers' tenure credit. The results show that tagging long-tenured sellers leads to significant increases in customer clicks and purchases, which benefits the platform. The mechanism analysis revealed a reputation spillover effect from the tagged sellers to their long-tail products.

3 Deep Learning in Choice Model

Zhi Wang, Rui Gao, University of Texas at Austin, Austin, TX, Contact: zhi.wang@mccombs.utexas.edu

One key principle in discrete choice model literature is the Random Utility Maximization (RUM), which can characterize many well-known parametric choice models like multinomial logit. Emerging literature demonstrates the powerfulness of neural networks (e.g., RUMnet) to represent RUM models. In this project, we design neural networks that represent a mapping of the choice probability distribution from the utilities by leveraging its convexity property. Such characteristics also inspire us to find the connection between the choice model and the optimal transport problem.

4 "uber" Your Cooking: The Sharing-Economy Operations of a Ghost-Kitchen Platform

Feihong Hu[1], junyu Cao[2], Wei Qi[3], [1]University of Texas at Austin, Austin, TX, [2]The University of Texas at Austin, Austin, TX, [3]Tsinghua University, Beijing, China. Contact: feihong.hu@mccombs.utexas.edu

We study a ghost kitchen platform with multiple home chefs, enabling customers to order from various kitchens. We find the optimal price and number of ghost kitchens on the platform to maximize profit. This is a new business model integrating adoption rate, waiting cost, queuing system, and delivery cost. We propose a queuing system that splits orders into sub-orders assigned to different chefs. Chefs proceed to the next dish after finishing the current sub-order, but the order remains incomplete until all sub-orders are fulfilled. We derive a closed-form solution for waiting time. We find that ghost kitchen platforms can be more profitable than traditional delivery platforms due to multi-dash capability, reduced fixed costs, productivity, and specialization. Multi-dash platforms outperform single-dash platforms with smaller service radius under the same conditions.

New Topics in Sustainable and Social Operations

Community Committee Choice Session

Session Chair: Amrita Kundu, McDonough School of Business, Georgetown University, Washington, DC

1 Are Firms Voluntarily Disclosing Emissions Greener

Yilin Shi[1], Christopher S. Tang[2], Jing Wu[3], [1]The Chinese University of Hong Kong, ShaTin, Hong Kong; [2]University of California-Los Angeles, Los Angeles, CA, [3]Chinese University of Hong Kong, Hong Kong, Hong Kong. Contact: ylshi@link.cuhk.edu.hk

Do firms voluntarily disclosing emissions generate less greenhouse gas in their in-house and outsourced operations? We examine this using Scope 1 and 3 emission data reported by firms or estimated by S\&P Trucost from 2002 to 2020. Our empirical results reveal that companies who make voluntary carbon disclosures generate less "internal emissions" (i.e., Scope 1 emissions but more "external emissions" from upstream suppliers (i.e., Scope 3 emissions). The net effect is that disclosing firms generate more emissions in the entire supply chain, implying they ``outsource" emissions to upstream suppliers. We also investigate the implications of mandatory environmental reporting regulations by different governments as encouragements for emission disclosure and find they effectively nudge disclosing firms to reduce total emissions.

2 The Effects of Diversity in Algorithmic Recommendations on Digital Content Consumption: A Field Experiment

Guangying Chen[1], Tat Y. Chan[1], Dennis J. Zhang[1], Senmao Liu[2], Yuxiang Wu[2], [1]Washington University in St. Louis, St. Louis, MO, [2]NetEase Cloud Music, Inc., Hangzhou, China. Contact: guangyingchen@wustl.edu

We conducted a large-scale field experiment on a music streaming platform to study the effects of content diversity in personalized recommendations. We randomly assigned users to receive video recommendations either from the platform's current recommender algorithm or our modified algorithm with 2.33% higher topic diversity. Overall, there is no clear evidence that our new algorithm increased the diversity of consumed content, but it decreased users' consumption level. However, for active users, a 1% increase in recommendation diversity boosted their consumption diversity by 0.55% without hurting consumption level. We show that the accuracy of predicting users' preferences is key for the new algorithm to increase the consumption diversity and, when users also highly value the platform, their consumption level will not be hurt.

3 End-Of-Life Product Collection Strategy and Remanufacturing Technology Portfolio Planning

Ying Cao[1], Guang Li[2], Xianghui Peng[1], [1]Penn State University - Erie, Erie, PA, [2]Queen's University, Kingston, ON, Canada. Contact: yxc673@psu.edu

End-of-Life (EOL) product collection rate is an important input in the closed-loop supply chain, which impacts the remanufacturing technology portfolio selection for a remanufacturer who is exposed to various technology alternatives. And, the remanufacturer's technology portfolio decision in return influences his preference for EOL product collection. In this research, we study remanufacturer's joint decision of EOL product collection pricing and remanufacturing technology portfolio planning in order to maximize the expected profit. We derive the properties of optimal pricing strategy and technology portfolio structure. In addition, we conduct numerical study and develop managerial insights for remanufacturing industry.

New Challenges for Retailers and Platforms

Community Committee Choice Session

Session Chair: Lai Wei, Boston College, Chestnut Hill, MA

1 Partnership Between Taxis and On-Demand Ride-Hailing Platforms: How Should It be Regulated?

Liling Lu[1], Guiyun Feng[2], Xin Fang[3], Sergei Savin[4], [1]singapore management university, singapore, Singapore; [2]Singapore Management University, singapore, Singapore; [3]Singapore Management University, Singapore, Singapore; [4]Wharton School, Philadelphia, PA

We consider an on-demand ride hailing platform who potentially collaborates with taxi companies to gain access to taxi drivers. We investigate the government regulation to such partnership and its implications. Taxi drivers and private car drivers differ in service quality. The platform sets ride fee for ride hailing riders and provides wage compensation for participating drivers. The government decides taxi drivers' access level to the platform to maximize social welfare. We find that the partnership may benefit all the parties, but advocating it is not always optimal for the government especially when street-hailing is important.

2 Anti-counterfeiting on E-commerce Platforms

Shuang Qiu[1], Man Yu[2], Ki Ling Cheung[3], [1]Hong Kong University of Science and Technology, Hong Kong, China; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]Hong Kong University of Science & Technology-HKUST, Kowloon, Hong Kong

As e-commerce platforms increasingly rely on third-party sales for profit, the problem of third-party counterfeiting is becoming a major threat to many online marketplaces. This paper explores various levers available to the e-platforms in combating counterfeits.

3 The Impact of Counterfeit Victims in the Victim Marketplace

Karl Aquino[1], Mingyuan Ban[2], Qiang Gong[2], Yi Qian[1], [1]University of British Columbia, Vancouver, BC, Canada; [2]Zhongnan University of Economics and Law, Wuhan, China. Contact: qgongpku@qq.com

The sources of inefficiency and unjust of charity are important to understand yet understudied. Our study aims to fill this void by modeling the victims' market in a collective reputation framework. By analyzing individuals who signal their victim status with different personalities, we derive the honest and dishonest equilibria as well as the mixed equilibrium. We reveal the mechanisms analogous to bank run and lemons market could take place in the victims' market. When charity resources are scarce, more strategic signalers could rush to emit false victim signals and drive the market to the dishonest equilibrium with lower social welfare. The need for screening signalers could drive up the psychological costs of honest victims to the extent that they voluntarily drop out of the market and suffer alone, resulting in misplaced charity funds and severe deadweight losses.

4 Coordinating Inventory Capacity Management for Third-Party Sellers on Online Selling Platforms

Rong Li[1], Weibin Mo[2], Lai Wei[3], [1]Syracuse University, Syracuse, NY, [2]Purdue University, West Lafayette, IN, [3]Boston College, Chestnut Hill, MA, Contact: harrymok@

purdue.edu

Online selling platforms (*e.g.* Amazon) have been offering fulfillment and inventory management services (*e.g.* "Fulfillment by Amazon") for third-party sellers. Sellers could leverage the well-established fulfillment networks of platforms to enhance their service and responsiveness while lowering operational costs. Meanwhile, platforms benefit from higher profitability of their investments in storage and fulfillment facilities as well as stronger customer loyalty to platforms. However, due to time-varying demand uncertainty, platforms have been experiencing increasing tension of their storage capacity, especially during holiday seasons. We develop a capacity management model to study coordination between the platform and one or several third-party sellers.

5 Design of Joint Replenishment and Order Fulfillment Processes for an Omni-Channel Retailer

Sinem Kinay Savaser[1], Opher Baron[2], Andre Augusto Cire[2], [1]Rotman School of Management, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada. Contact: sinem.savaser@rotman.utoronto.ca

We consider a strategic problem for an omni-channel retailer with a single fulfillment center (FC) and multiple stores. We consider walk-in demand at stores as well as online demand from originating from multiple regions. Given these demand streams, the omni-channel retailer simultaneously makes inventory replenishment decisions and fulfills online orders. We first work on a single-item problem and identify conditions under which the online orders can be shipped from stores instead of the FC. We then extend the analysis to multiple item orders and compare the solutions of models that allow or prevent split deliveries. We introduce an algorithm to solve the overall problem, which is NP-Hard, and provide upper bounds on its performance. We finally perform numerical analysis to observe the performance of the algorithm in practice.

Methods for Non-Convex Optimization

Contributed Session

Session Chair: Shangzhe Yang, Rutgers University, Piscataway, NJ

1 Adaptive Algorithms for Stochastic Sequential Quadratic Programming

Michael ONeill, University of North Carolina at Chapel Hill, Chapel Hill, NC

We develop a Sequential Quadratic Programming algorithm for minimizing a stochastic objective function subject to deterministic equality constraints. The method uses an adaptive stepsize rule that is not dependent on a pre-specified sequence and a complexity result is derived. In addition, new procedures are developed for estimating the merit parameter, which are more robust to the stochasticity than those proposed in prior work. Numerical validation of the proposed algorithms is also presented.

2 Novel Algorithms for Nonconvex Second-Order Optimization with Complexity Guarantees

Chuan He, Zhaosong Lu, University of Minnesota, Minneapolis, MN

This research introduces new algorithms with substantial theoretical improvements for seeking a second-order stationary point (SOSP) of two types of nonconvex constrained optimization problems. In our first work, we develop a novel augmented Lagrangian (AL) method for finding an SOSP of a nonconvex equality constrained optimization problem. The proposed AL method improves upon the best-known complexity guarantees. In our second work, we design efficient algorithms to find an SOSP of a general conic constrained nonconvex optimization problem. For the first time, we introduce a notion of an SOSP for general conic constrained optimization and propose efficient algorithms to find it. Numerical results also demonstrate the practical superiority of our proposed methods.

3 Confidence Regions in Stochastic Optimization and Systems of Nonlinear Equations

Yi Chu, Raghu Pasupathy, Purdue University, West Lafayette, IN, Contact: chu199@purdue.edu

We consider the question of constructing asymptotically exact confidence regions in two contexts: (i) stochastic optimization problems with a smooth convex objective f and observable first-order oracle; and (ii) stochastic nonlinear equations observable with a stochastic zeroth-order oracle. Relying on results from M-Estimation, we first show that the solutions to the sample-path problems associated with (i) and (ii) satisfy a strong Bahadur Representation (and hence also a functional CLT and a law of iterated logarithm) We then exploit such strong regularity to devise a simple but computationally intensive resampling technique called batching toward constructing exact confidence regions on the optimal value and solution to (i), and on the solution to (ii).

4 Methods for Nonconvex Conditional Stochastic Optimization

Shangzhe Yang[1], Andrzej Ruszczynski[2], [1]Rutgers University, Piscataway, NJ, [2]Rutgers University, Piscataway, NJ, Contact: shangzhe.yang@rutgers.edu

We propose a specialized single time-scale stochastic subgradient method for nonconvex constrained Conditional Stochastic Optimization problems with a Lipschitz smooth outer function and Norkin generalized differentiable inner function. We approximate the inner conditional expectation with a rich parametric model whose mean squared error satisfies a quadratic growth condition. The main feature of our approach is that unbiased stochastic estimates of the directions used by the method can be generated with one observation of the pair of random variables, which makes it applicable to online settings. We introduce a projected stochastic subgradient method and analyze its convergence, using the scheme of differential inclusions and a designed Lyapunov function. We further derive an $O(N^{-1/2})$ error bound for N iterations of the methods within a fixed stepsize.

Supply Chain Learning and Sourcing

Contributed Session

Session Chair: Mummad Zia Ul Haq, Ajman University, Ajman, United Arab Emirates

1 Autocorrelated Price-Sensitive Demand and the Dynamics of Supply Chains

Takamichi Hosoda[1], Stephen M. Disney[2], Gerard Gaalman[3], [1]Aoyama Gakuin University, Tokyo, Japan; [2]University of Exeter Business School, Exeter, United Kingdom; [3]University of Groningen, Groningen, Netherlands. Contact: hosoda@gsim.aoyama.ac.jp

We investigate the dynamics of a supply chain with an autocorrelated, price-sensitive, stochastic, and linear demand model. We assume the exogenous market price follows a first-order autoregressive process. The demand process is a weighted function of the current and previous market prices, the market potential, and the positive demand sensitivity coefficient. We assume that a manufacturer faces five different types of customers in the market: responsive, selective, naive, speculative, and slow customers. A weighting factor determines how customers react to period-to-period price changes. In addition to explaining the basic dynamics with this demand model, we propose new ideas for dual sourcing policies, assuming two suppliers, one offshore and one near shore.

2 Forecasting Capability Level and Consignment Contract Revenue Distribution: A Split Ratio Range Analysis

Seong-Hyun Nan, University of North Dakota, Grand Forks, ND, Contact: snam@business.und.edu

This study develops a model to illustrate the optimization and coordination of a revenue-sharing-based consignment contract in a decentralized supply chain. We investigate how the forecasting capability level set by the manufacturer can affect the revenue share allocations proposed by the retailer and measure whether and how both can achieve economic benefits from the given contractual parameter terms. Based on different combinations of the forecasting level and the split ratio, we determine the upper limit of the ratio range acceptable to the manufacturer and show how the ratio range should be adjusted to reduce risk and maximize the mutual profitability for both.

3 Optimizing Supplier Selection and Order Lot-Sizing Decisions in a TwoStage Supply Chain

Qingyuan Lu[1], Jose Antonio Ventura[2], Zijia Chen[3], [1]Penn State University, State college, PA, [2]Penn State University, University Park, PA, [3]Penn State University, state college, PA, Contact: qfl5079@psu.edu

This paper focuses on the analysis of different lot-sizing policies for the supplier selection and order allocation problem in a twostage supply chain. The supply chain consists of multiple suppliers and single buyer. Our goal is to evaluate two lot-sizing policies and select the one that optimizes the supply chain. A bi-objective mixed-integer nonlinear programming (MOMINLP) model is proposed. The first objective consists a coordination mechanism for supplier selection and order allocation , and the second objective comprises a data envelopment analysis (DEA) approach to evaluate the overall performance of suppliers. Then, the two lot-sizing policies are applied to the MOMINLP model separately to determine the set of selected suppliers well as orders allocated to each selected supplier per replenishment cycle. Numerical examples are provided.

Advacing Explanable Machine Learning

Contributed Session

Session Chair: Yifan Yang, The Ohio State University, Columbus, OH

1 Topological Learning for Imbalanced Time Series Analysis

Minh Nguyen, University of Hawaii, Honolulu, HI, Contact: duyminh@hawaii.edu

Topological data analysis (TDA) uses algebraic topological tools to analyze the shape of data. Sublevel set filtration is a widely used tool in TDA that captures homological features of data at multiple scales and summarizes the lifespan of these features in summary diagrams, namely persistence diagrams (PDs). By using sublevel set filtration approach and random persistence diagram generator (RPDG) method, we propose a general pipeline for analyzing the topological features of imbalanced time series data. We then investigate the efficacy of our pipeline using four main stock market indices in the US (Dow Jones, S&P 500, Nasdaq Composite, and Russell 2000) to distinguish between stock indices obtained with recessions and without recessions.

2 Development Of Explainable Anomaly Detection Algorithm For Multivariate Time Series Data Using Deep Learning

Sangyong Lee[1], DoHoon Kim[2], [1]Okestro, seoul, Korea, Republic of; [2]Yonsei University, seoul, Korea, Republic of. Contact: sy.lee@okestro.com

The surge in the Internet of Things (IoT) has amplified automated services potential, with anomaly detection being a key application. Traditional machine learning faces hurdles with intricate multivariate time series data, and while deep learning can navigate these, it frequently lacks decision transparency. This paper presents an Explainable Deep Learning-based Multivariate Anomaly Detection method, incorporating a Deep Embedded Clustering (DEC) algorithm for enhanced anomaly detection performance and explainability via eXplainable AI (XAI) techniques. Experimental results illustrate an improvement in performance compared to existing methods by augmenting the comprehensibility of decision-making via XAI. Furthermore, we evaluated multivariate time series benchmark data, validating its effectiveness in improving decision-making transparency.

3 Improving Knowledge Distillation for Regression Under Data Insufficiency

Myeonginn Kang, Seokho Kang, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: kmi0228@skku.edu

Knowledge distillation (KD) has been successful in compressing a large teacher network into a smaller student network. However, conventional KD methods can suffer from performance degradation when the original training dataset is not fully reusable. We propose a teacher-student matching method to improve KD under data insufficiency for regression. The proposed method enhances an existing KD method by introducing three additional learning objectives to make the student network better emulate the prediction capability of the teacher network: perturbation-based matching, adversarial belief matching, and gradient matching. Through experiments using benchmark regression datasets, we demonstrate that the proposed method can improve the predictive performance of the student network, especially when only a small part of the training dataset is usable.

4 Generalization Error Bounds for Learning Under Censored Feedback

Yifan Yang[1], Ali Payani[2], Parinaz Naghizadeh[3], [1]The Ohio State University, Columbus, OH, [2]Cisco, San Jose, CA, [3]Ohio State University, Columbus, OH, Contact: yang.5483@osu.edu

Generalization error bounds from learning theory provide statistical guarantees on how well an algorithm will perform on previously unseen data. In this paper, we characterize the impacts of training data non-IIDness due to censored feedback on generalization error guarantees in classification tasks. We propose to first split the non-IID training data into IID blocks on which the Dvoretzky-Kiefer-Wolfowitz (DKW) inequality can be used to provide error bounds. We then identify scaling and shifting factors that allow us to reassemble the error bounds on the IID blocks to obtain a full-domain error bound, extending the DKW bound to problems with censored feedback. We further analyze the effectiveness of exploration techniques, proposed in recent literature to alleviate censored feedback, on improving these error bounds.

First-order Methods for Constrained Optimization and Minimax Problems

Community Committee Choice Session

Session Chair: Afrooz Jalilzadeh, The University of Arizona, Tucson, AZ

Session Chair: Erfan Yazdandoost Hamedani, University of Arizona, Tucson, AZ

1 A Novel Catalyst Scheme for Stochastic Minimax Optimization

Guanghui Lan[1], Yan Li[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: george.lan@isye.gatech.edu

Existing accelerated proximal point (aka, catalyst) methods play an important role for minimax optimization to achieve fast rate of convergence. However, these schemes do not extend to the stochastic settings as they yield slower rate of convergence than those based on extragradient methods.We present a novel accelerated proximal point that can achieve optimal convergence for both deterministic and stochastic minimax optimization.

2 Scalable Algorithms for Robust Nonconvex Constrained Optimization

Tianjian Huang[1], Maher Nouiehed[2], Meisam Razaviyayn[1], [1]University of Southern California, Los Angeles, CA, [2]American University of Beirut, Beirut, Lebanon

In this study, we investigate the efficacy of different algorithms for solving (stochastic) constrained nonconvex optimization problems appearing in modern machine learning contexts. While the conventional method employed by the machine learning community is to solve the Lagrangian relaxation problem, we show that this approach may not always succeed in various scenarios. As a result, we turn to optimization literature to explore the effectiveness of a broad spectrum of algorithms, including penalty methods, min-max optimization procedures, and Alternating Direction Method of Multipliers, for addressing practical nonconvex constrained optimization issues. After observing the limitations of these algorithms, we propose novel modifications to them. Our experiments provide empirical evidence of the efficiency of our proposed techniques.

3 Projection-Free Methods for Solving Nonconvex-Concave Saddle Point Problems

Morteza Boroun[1], Erfan Yazdandoost Hamedani[1], Afrooz Jalilzadeh[2], [1]University of Arizona, Tucson, AZ, [2]The University of Arizona, Tucson, AZ, Contact: erfan.yzh@gmail.com

This talk addresses constrained saddle point optimization problems with nonconvex-concave and smooth objective functions, which have applications in machine learning. Existing methods rely on computationally expensive projection onto constraint sets. To fill this gap, we propose efficient single-loop projection-free methods using first-order information. We introduce a primal-dual conditional gradient method utilizing linear minimization oracles, achieving an □-stationary solution in O(□^(-6)) iterations when the maximization problem's constraint set is strongly convex. Additionally, we present a one-sided projection-free method with regularized projected gradient ascent, achieving an □-stationary solution in O(□^(-4)) iterations when the projection is easy to compute.

4 Stochastic Approximation for Estimating the Price of Stability in Stochastic Nash Games

Afrooz Jalilzadeh[1], Farzad Yousefian[2], Mohammadjavad Ebrahimi[2], [1]The University of Arizona, Tucson, AZ, [2]Rutgers University, Piscataway, NJ, Contact: me586@scarletmail.rutgers.edu

The goal in this talk is to approximate the Price of Stability (PoS) for stochastic Nash games using stochastic approximation schemes. Motivated by the absence of efficient methods for computing the PoS, first, we consider stochastic optimization problems with a nonsmooth and merely convex objective function and a merely monotone stochastic variational inequality (SVI) constraint. We develop a randomized block-coordinate stochastic extra-(sub) gradient method where we employ a novel iterative penalization scheme to account for the mapping of the SVI in each of the two gradient updates of the algorithm. Second, we develop an SA-based scheme for approximating the PoS and derive lower and upper bounds on the approximation error. To validate our theoretical findings, we provide some preliminary simulation results on a networked stochastic Nash Cournot competition.

5 Randomized Lagrangian Stochastic Approximation for Large-Scale Constrained Stochastic Nash Games

Zeinab Alizadeh[1], Afrooz Jalilzadeh[2], Farzad Yousefian[3], [1]University of Arizona, Tucson, AZ, [2]The University of Arizona, Tucson, AZ, [3]Rutgers University, Piscataway, NJ, Contact: zalizadeh@email.arizona.edu

In this paper, we consider stochastic monotone Nash games where each player's strategy set is characterized by possibly a large number of explicit convex constraint inequalities. The majority of the existing methods for solving such problems rely on employing projected stochastic approximation (SA) methods. However, the projected SA performs poorly when the constraint set is afflicted by the presence of a large number of possibly nonlinear functional inequalities. We develop a single timescale randomized Lagrangian multiplier stochastic approximation method where in the primal space, we employ an SA scheme, and in the dual space, we employ a randomized block-coordinate scheme where only a randomly selected Lagrangian multiplier is updated. We show convergence rate of O(log(k)/sqrt{k}) for suitably defined suboptimality and infeasibility metrics in a mean sense.

CC-North 222B

Efficient Algorithms for Non-convex Low-rank Matrix Optimization Problems

Community Committee Choice Session

Session Chair: Haixiang Zhang, UC Berkeley, Berkeley, CA

1 Understanding Incremental Learning of Gradient Descent: A Fine-Grained Analysis of Matrix Sensing

Jikai Jin[1], Zhiyuan Li[2], Kaifeng Lyu[3], Simon S. Du[4], Jason D. Lee[5], [1]Stanford University, Palo Alto, CA, [2]Toyota Technological Institute at Chicago, Chicago, IL, [3]Princeton University, Princeton, NJ, [4]University of Washington, Seattle, WA, [5]Princeton University, Princeton, NJ, Contact: jkjin@stanford.edu

It is believed that Gradient Descent (GD) induces an implicit bias towards good generalization in training machine learning models. We analyze the dynamics of GD for the matrix sensing problem, whose goal is to recover a low-rank matrix from near-isotropic linear measurements. We show that GD with small initialization follows an incremental learning procedure: GD sequentially learns solutions with increasing ranks until it recovers the ground truth. Compared to existing works which only analyze the rank-1 learning phase, our result provides characterizations for the whole learning process. Moreover, besides the over-parameterized regime that prior works focused on, our analysis of the incremental learning procedure also applies to the under-parameterized regime. Finally, we conduct numerical experiments to confirm our theoretical findings.

2 Alternating Minimization for Rank One Matrix Sensing: Sharp Predictions from a Random Initialization

Kabir Chandrasekher[1], Mengqi Lou[2], [1]Stanford University, Stanford, CA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: mlou30@gatech.edu

We consider the problem of estimating the factors of a rank-1 matrix with i.i.d. Gaussian, rank-1 measurements that are nonlinearly transformed and corrupted by noise. Considering two prototypical choices for the nonlinearity, we study the convergence properties of a natural alternating update rule for this nonconvex optimization problem starting from a random initialization. We show sharp convergence guarantees for a sample-split version of the algorithm by deriving a deterministic recursion that is accurate even in high-dimensional problems. Our sharp, non-asymptotic analysis also exposes several other fine-grained properties of this problem, including how the nonlinearity and noise level affect convergence behavior.

3 Convergence of the Momentum Method for Semi-Algebraic Functions with Locally Lipschitz Gradients

Cedric Josz[1], Lexiao Lai[2], Xiaopeng Li[2], [1]Columbia University, New York City, NY, [2]Columbia University, New York, NY, Contact: xl3040@columbia.edu

We propose a new length formula that governs the iterates of the momentum method when minimizing differentiable semi-algebraic functions with locally Lipschitz gradients. It enables us to establish local convergence, global convergence, and convergence to local minimizers without assuming global Lipschitz continuity of the gradient, coercivity, and a global growth condition, as is done in the literature. As a result, we provide the first convergence guarantee of the momentum method starting from arbitrary initial points when applied to principal component analysis, matrix sensing, and linear neural networks.

4 The Burer-Monteiro Sdp Method Can Fail Even Above the Barvinok-Pataki Bound

Vaidehi Srinivas, Northwestern University, Evanston, IL

The most widely used technique for solving large-scale semidefinite programs (SDPs) in practice is the non-convex Burer-Monteiro method, which explicitly maintains a low-rank SDP solution for memory efficiency. When the maximum allowed rank p of the SDP solution is above the Barvinok-Pataki bound ($p >= sqrt(2n)$, where a globally optimal solution of rank at most p is guaranteed to exist), a recent line of work established convergence to a global optimum for generic or smoothed instances of the problem. However, it was open whether there exists any instance in this regime where this method fails. We provide a family of instances on n vertices that have spurious local minima even when the rank $p = n/2$. This justifies the use of beyond worst-case paradigms like smoothed analysis to obtain guarantees for the Burer-Monteiro method.

5 Low-Rank Matrix Recovery from Unlabeled Data with Missing Entries

Liangzu Peng, University of Pennsylvania, Philadelphia, PA,

Contact: lpenn@seas.upenn.edu

As an important topic in data science, low-rank matrix recovery is concerned with estimating some ground truth low-rank matrix from certain types of data observations. As commonly seen, the observed data can be linear measurements, or sparsely perturbed, outlier-corrupted, or incomplete versions of the ground truth matrix. In this talk, I consider a recently proposed paradigm where the observed data matrix is a permuted (unlabeled) and incomplete version of the ground truth. After motivating this paradigm, I will present some algebraic-geometric theory that provides conditions under which the ground truth matrix can be recovered (uniquely or finitely). Then I proceed to non-convex optimization procedures to computationally recover the ground truth matrix. Experimental analysis will be given to illustrate the efficiency of the proposed method.

Advances in Mixed-Integer Optimization

Community Committee Choice Session

Session Chair: Peijing Liu, University of Southern California, Los Angeles, CA

1 An Adaptive Outer-Approximation Method for Solving Mixed-Integer Convex Programs with Indicators

Linchuan Wei, Northwestern University, Evanston, IL

The mixed-integer quadratic programs with indicator variables (MIQP)find various applications in financial economics, electricity powerproduction, transportation, statistical learning, and causal inference. In this paper, we propose to solve MIQPs using an adaptive outer approximation(OA) approach. Our main contributions are (1) a unifying scheme to derivethe OA formulations for the convex relaxations of MIQPs via decomposition, which also generalizes the OA formulation for the convex boolean relaxation, (2) a comprehensive computational study that showcases the performance of our adaptive OA method on the best subset selection and sparse portfolio selection problem.

2 On Relaxations of the Max K-Cut Problem Formulations

Ramin Fakhimi[1], Hamidreza Validi[2], Illya V. Hicks[3], Tamas Terlaky[1], Luis F. Zuluaga[1], [1]Lehigh University, Bethlehem, PA, [2]Texas Tech University, Lubbock, TX, [3]Rice University, Houston, TX, Contact: hvalidi@ttu.edu

The max k-cut problem is a fundamental combinatorial optimization problem with multiple notorious mixed integer optimization formulations. This talk explores four existing mixed integer optimization formulations of the max k-cut problem. We show that the continuous relaxation of a binary quadratic optimization formulation is: (i) stronger than that of two mixed integer linear optimization formulations and (ii) at least as strong as that of a mixed integer semidefinite optimization formulation. We also conduct a set of experiments on the state-of-the-art solvers to assess the theoretical results in practice. Due to the recent advancements of solvers in handling non-convex optimization formulations, we can run the binary quadratic optimization formulation by Gurobi solver. The computational results support our theoretical findings on multiple sets of instances.

3 Optimizing the Designs and Operations of Water Networks: A Decomposition Approach

Yijiang Li[1], Santanu Dey[2], Nikolaos Sahinidis[1], Naresh Susarla[3], Markus Gustav Drouven[4], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, [3]National Energy Technology Laboratory, Pittsburgh, PA, [4]U.S. Department of Energy, Pittsburgh, PA, Contact: yijiangli@gatech.edu

Water networks are used to transport water, a crucial resource for residential and industrial usages. The water network problems can be divided into the design and operational problem. The design problems can consider pipe sizing and placements of pump stations while the operation problems are generally multiple time period problems to account for temporal changes in supply and demand and can consider the scheduling of the pump stations and relief valves. In this talk, we focus on the network for the so-called produced water and propose two methods to obtain good primal (feasible) solutions. One method is based on decomposition framework while the other method is based on time decomposition. We conduct computational experiments on a network derived from The Produced Water Optimization Initiative (PARETO) case study.

4 A Feasible Direction Method for Convex Quadratic Optimization Problems with Indicators

Peijing Liu[1], Alper Atamturk[2], Andres Gomez[1], Simge Kucukyavuz[3], [1]University of Southern California, Los Angeles, CA, [2]Berkeley Analytics, Berkeley, CA, [3]Northwestern University, Evanston, IL, Contact: peijingl@usc.edu

We consider the convex quadratic optimization problem with indicator variables when the matrix Q defining the quadratic term is a Stieltjes matrix. According to previous research, a convex hull description of this problem in an extended space can be reduced to describing a polytope in the extended formulation. We propose a set of valid inequalities to approximate this polytope based on the submodularity of individual matrices of matrices, and show that separation can be done by computing a Cholesky decomposition. The resulting relaxation is SDP-representable and requires exponentially many linear constraints to describe. Thus, we propose a tailored algorithm to optimize the relaxation, inspired by feasible direction method. Our computational experiments demonstrate the effectiveness of the proposed method compared to state-of-the-art conic optimization solvers.

5 Inverse Optimization for Imputing Constraint Parameters in Quadratic Programs

Archis Ghate, Siva Ramani, University of Washington, Seattle, WA

The goal in (forward) optimization is to compute decision variables given the values of model parameters. In contrast, the goal in inverse optimization is to impute model parameters using given values of decision variables. We will discuss this problem in the context of quadratic programs wherein the left-hand-side constraint parameters are unknown. The resulting inverse problem is nonconvex. We will describe tailored computational methods designed to tackle this nonconvexity. These methods will be compared via numerical experiments.

Data-driven Optimization

Community Committee Choice Session

Session Chair: Juan Sebastian Borrero, Oklahoma State University, Stillwater, OK

1 Maximum Likelihood Probability Measures over Sets and Applications to Data-Driven Optimization

Juan S. Borrero[1], Denis Saure[2], [1]Oklahoma State University, Stillwater, OK, [2]Universidad de Chile, Santiago, Chile. Contact: juan.s.borrero@okstate.edu

Motivated by data-driven approaches to sequential decision-making under uncertainty, we study maximum likelihood estimation of a distribution over a general measurable space when realizations are not directly observable but instead are known to lie within observable sets. We show that maximum likelihood estimates concentrate on a collection of maximal intersections (CMI) sets, and can be found by solving a convex optimization problem whose size is linear in the size of the CMI. After studying the efficient computation of the CMI and the maximum likelihood estimate, we characterize convergence properties of the maximum likelihood estimate, and we apply our results to construct ambiguity sets and develop compact formulations in the context of Distributionally Robust, and Greedy and Optimistic Optimization

2 Optimal Sequential Stochastic Shortest Path Interdiction

Juan Sebastian Borrero[1], Denis Saure[2], Natalia Trigo[2], [1]Oklahoma State University, Stillwater, OK, [2]Universidad de Chile, Santiago, Chile

We consider a setting of sequential shortest-path interdiction, where a leader, unaware of the distribution of a sequence of iid cost vectors, must interdict a network periodically. On each period, a follower observes the interdicted network and responds traversing a shortest path. We assume that the leader only observes the path selected by the evader and the costs realizations associated with said path. We model the interaction between the leader and follower using bilevel programming, and the trade-off between exploration and exploitation through the bandit paradigm. We establish a fundamental limit on the performance of any admissible policy, and propose a series of policies inspired from the classic bandit setting.

3 Comparisons Between Bagging and Compromise Decisions

Shuotao Diao[1], Suvrajeet Sen[2], [1]Northwestern University, Evanston, IL, [2]University of Southern California, Los Angeles, CA, Contact: shuotao.diao@northwestern.edu

Bagging is a popular technique in Machine Learning, whereas Compromise Decisions come from using multiple replications in Stochastic Programming (SP). We will discuss the similarities and differences between the two in the context of SP.

4 Effective Scenarios in Distributionally Robust Optimization with Cressie-Read Power Divergence and Wasserstein Distance

Guzin Bayraksan[1], Chennan Zhou[2], [1]The Ohio State University, Columbus, OH, [2]The Ohio State University,

Columbus, OH, Contact: bayraksan.1@osu.edu
Effective scenarios are critical to data-driven Distributionally Robust Optimization (DRO) in the sense that, if removed, the optimal value will be changed. Earlier, effective scenarios were examined for convex DRO with Total Variation distance. In this work, we study them for a class of DRO formed with the Wasserstein distance and Cressie-Read power divergences. We present several properties, discuss how to identify effective scenarios, and illustrate our results numerically.

Wednesday, October 18, 8:00 AM - 9:15 AM

CC-North 224A

Semiconductur Industry and Batch Production

Contributed Session

Session Chair: Jorge Huertas, Georgia Institute of Technology, ATLANTA, GA

1 An Efficient Mixed-Integer Linear Programming Model of Batch Size and Production Frequency Constraints in Master Production Scheduling

Pei-Yu Lin, Sheng-I Chen, National Yang Ming Chiao Tung University, Hsinchu, Taiwan. Contact: jamie1110.mg11@nycu.edu.tw

Manufacturing firms consider the batch size and production frequency in the master production scheduling in order to aggregate production orders and average resource loading and WIP levels. In this study, we formulate various batch size constraints from real-world applications. Also, we apply compact formulations to reduce the model size of the mixed-integer linear programming. Computational experiments use actual problem instances to evaluate the effectiveness of proposed models. Results show that adding the compact batch-size constraints can fulfill decision-maker requirements and obtain well computational performance.

2 A Decentralized Approach for Rescheduling Semiconductor Assembly Systems with Re-Entrant Flows and Time Window Constraints

Yutong Su[1], Bala Krishnan[2], Husam Dauod[3], Nital Patel[3], Feng Ju[1], [1]Arizona State University, Tempe, AZ, [2]Intel Corporation, Bangalore, India; [3]Intel Corporation, Chandler, AZ, Contact: yutongs1@asu.edu

In semiconductor manufacturing, random disruptions, such as machine failures, may cause delays and time window violations, which make master schedule sub-optimal or even infeasible. Considering the re-entrant flows and time window constraints, the rescheduling problem in face of machine failures is formulated as a decentralized mixed integer programming model. To be able to solve the problem in close to real-time, a genetic algorithm (GA) is proposed based on the system decomposition. The computation results using real world case studies demonstrate the effectiveness of the method.

3 The Impact of Tool Allocation and Dedication on Cycle Time

Marino Arturo, Maryam Anvar, Chris Keith, Applied Materials, Santa Clara, CA, Contact: Marino_Arturo@amat.com

There are hundreds of steps that need to be followed to complete processing of wafers in a front-end wafer fab. Before a wafer runs a particular recipe on a tool, the tool must be qualified to run the recipe. In many situations the process of qualifying the recipe on the tool can be both time consuming and costly in terms of resources required. Therefore, there are many cases that some recipes are not supported by some tools in the fleet. This constraint is referred to as “dedication” which results in having fewer resources to support some process steps. Dedication along with other parameters such as tool allocation and uptime variability could impact the cycle time and responsiveness of the system. In this paper, we study the impact of these parameters on lot cycle time using discrete-event simulation software (AutoSched®).

4 Optimization Proxies in the Supply Chain for Semiconductor Manufacturing

Jorge Huertas[1,2], Ashish Nemani[2], Zhenying Zhao[2], Pascal Van Hentenryck[1], [1]ISyE Georgia Tech, Atlanta, GA, [2]Intel, Chandler, AZ, Contact: huertas.ja@gatech.edu

In the supply chain for semiconductor manufacturing, many processes at various stages and locations transform the silica wafers into multiple components to finally produce chips. To generate the production plan along this supply chain, a master production scheduler tool executes different optimization models sequentially. Hence, performing sensitivity analyses for planning purposes becomes a challenge, as it is necessary to execute the sequential optimization multiple times to quantify the impact of variations in the input parameters. To overcome this challenge, we combine optimization and machine learning to produce an optimization proxy of the sequential optimization, allowing quick sensitivity analyses for planning purposes.

Facility Logistics

Community Committee Choice Session

Session Chair: Mehdi Behroozi, Northeastern University, Boston, MA

1 Integrated Multi-Stakeholder Freight Transportation System with Uncertain Demand

Mojtaba Hosseini[1], Gita Taherkhani[2], Ali Hassanzadeh[3], [1]University of Iowa, Iowa City, IA, [2]Loyola University, Chicago, IL, [3]University of Manchester, Manchester, United Kingdom

This study focuses on investigating the tactical planning of an integrated multi-stakeholder system. The system receives time-dependent requests from carriers and shippers and optimizes in time and space the operations and transportation activities through the consolidation of loads of different shippers into the same vehicles. The demand values of shippers are taken under uncertainty. The aim of tactical planning in this system is to build an efficient service network and schedule to satisfy the demand and requirements of shippers by making use of the predicted services and their capacities offered by the carriers. A two-stage stochastic program is presented and an exact decomposition-based algorithm is developed. Extensive computational analysis is performed to evaluate the impact of uncertainty on the solution of the proposed model.

2 Health Care Facility Location Planning With Multi-type Facilities And Staff Sharing

Ozgur Unsal[1,2], Halit Uster[1], [1]Southern Methodist University (SMU), Dallas, TX, [2]Gebze Technical University, Kocaeli, Turkey. Contact: cunsal@smu.edu

Motivated by the design of a health care provider network which offers different combination of services in its branches, we study a variant of capacitated facility location problem in which patients seek for different health care services that are provided by facilities that can be built in candidate locations. In this variant, facilities can also share specialists to provide a specific service in more locations, albeit with a restricted operational capacity. The problem is modelled as a mixed-integer program and effective valid inequalities are provided. For larger instances, a Benders decomposition scheme is developed. Computational results show that the solution approaches that we propose for this formulation can tackle with real world sized instances.

3 Locating Electric Vehicles Charging Stations in a Convex Region

Mehdi Behroozi[1], Dinghao Ma[2], [1]Northeastern University, Boston, MA, [2]Northeastern University, Boston, MA, Contact: m.behroozi@neu.edu

The efforts to reduce greenhouse gas emissions to combat climate change has led to the development and increasing adoption of electric vehicles (EVs) that are considered competitive and in many aspects, better than their internal combustion engine counterparts (ICEVs). However, they still have a long way to go to replace ICEVs. One of the main aspects that EVs still have the lower hand is the accessibility of charging stations, which makes the optimal location of EV charging stations a significant factor in fast and successful adoption of EVs. In this paper, we take a robust partitioning and assignment approach for finding efficient locations for these charging stations.

Optimization in Transportation Applications

Community Committee Choice Session

Session Chair: Akhilesh Soni, University of Wisconsin-Madison, Madison, WI

1 Rideshare Routing with Flexible Meeting Points, Uncertain Travel Times and Passenger Cancellations

Zuhayer Mahtab, Maged M. Dessouky, University of Southern California, Los Angeles, CA, Contact: mahtab@usc.edu

Ridesharing has the potential to reduce congestion, pollution, and the need for personal vehicles. We propose a rideshare routing framework that has uncertain travel times and stochastic passenger cancellations. We incorporate flexible pickup/drop-off points, which we call meeting points, that can reduce driver detours and waiting times. We implement a Sample Average Approximation (SAA) and Branch and Price (BP) based solution approach that can solve small to medium-sized instances within reasonable computation time. By considering both sources of uncertainty together, we obtain superior results compared to when each source of uncertainty is considered individually.

2 A Progressive Hedging-Based Solution Approach for Multicommodity Network Design Problems Under Demand Uncertainty

Fatemeh Sarayloo[1], Teodor Gabriel Crainic[2], Walter Rei[3],

[1]University of Illinois at Chicago, Chicago, IL, [2]Université du Québec à Montréal, Montréal, QC, Canada; [3]University of Quebec-Montreal, Saint-Lambert, QC, Canada

In this paper, we propose a solution approach for stochastic network design problems with uncertain demand, which we formulate as a two-stage stochastic program. We rely on the progressive hedging (PH) algorithm of Rockafellar and Wets where the subproblems are defined using scenario groups. Our proposed method, referred to as "Integrated Learning and Progressive Hedging", takes advantage of a specialized learning-based matheuristic that is able to quickly produce high-quality solutions to multi-scenario subproblems. Furthermore, we propose a novel reference point definition, at each aggregation step of the PH algorithm, which leverages subproblem information regarding promising design variables. Extensive computational experiments illustrate the efficiency of the proposed matheuristic in obtaining high-quality solutions.

3 Network Design Using Lagrangian Decomposition

Akhilesh Soni[1], Semih Atakan[2], [1]University of Wisconsin-Madison, Madison, WI, [2]Amazon.com, Seattle, WA

We propose a Lagrangian relaxation-based regional decomposition approach for network design problems that leverages local fulfillment in the network. The parent network is decomposed into regional subnetworks while minimizing cross-regional commodities. The cross-regional variables are duplicated while imposing consistency constraints to ensure that the variables remain the same across subnetworks. The consistency constraints are then dualized, resulting in separable regional subproblems that can be solved in parallel. We employ a cutting-plane algorithm to iteratively solve the Lagrangian problem, using outer approximation on the Lagrangian dual and solving subproblems to improve the relaxed dual function's formulation.

4 Uv Mission Planning Under Uncertainty in Vehicles' Availability

Venkata Sirimuvva Chirala, Wayne State University, Detroit, MI, Contact: go1577@wayne.edu

Unmanned vehicles (UVs) are used in defense and civil applications. We present a two-stage stochastic model for a fuel-constrained UV mission planning problem with multiple refueling stations under uncertainty in availability of UVs. Given a set of points of interests (POI) and refueling stations, and a base station where the UVs are stationed and their availability is random, the objective is to determine route for each UV starting and terminating at the base station such that overall incentives collected by visiting POIs is maximized. We present an outer approximation based decomposition algorithm and the skewed variable neighborhood search heuristic to solve large instances, and perform extensive computational experiments. A data driven simulation study is performed using robot operating system framework to corroborate the use of the stochastic programming.

CC-North 225B

Machine Learning for Operations Problems

Contributed Session

Session Chair: Kiarash Ghasemzadeh, Arizona State University, Tempe, AZ

1 Diesel Engine Defect Prediction Framework Using Quantum Mechanics-Based Neural Network

Eunseo Oh[1], Hyunsoo Lee[2], [1]Kumoh National Institute of Technology, Gumi-si, Korea, Republic of; [2]Kumoh National Institute of Technology, Gumi, Korea, Republic of

Data is collected from sensors attached to process equipment through automation. Companies can improve economics and safety by predicting engine defects in advance using diesel engine defect data, one of the manufacturing process data. Diesel engine defects can be predicted through neural network analysis, which is a representative data analysis technique. However, the data collected from the sensor and the weights of the neural network model contain noise. This adversely affects the accuracy of neural network analysis. Therefore, in this study, a quantum mechanics-based neural network is modeled by considering the uncertainty of data and the weight of the neural network. In addition, the proposed framework proposes a new weight update methodology modeled by stochastic differential equations by reflecting the drift of weight and considering the uncertainty.

2 Solving the Paint Shop Problem Using Reinforcement Learning

Mirko Stappert, Bernhard Lutz, Dirk Neumann, University of Freiburg, Freiburg, Germany. Contact: dirk.neumann@is.uni-freiburg.de

In the paint shop problem, a sequence of cars has to be painted with the objective of minimizing the number of color changes. For this purpose, manufacturers employ a multi-lane buffer system with store and retrieval operations. Prior studies solely focused on retrieval operations and simple solution heuristics. In this study, we propose an integrated reinforcement learning approach that simultaneously learns to perform smart storage and retrieval operations. After proving that greedy retrieval is optimal, we incorporate this fact into the model using action masking. Our evaluation, based on problem instances with 2-8 buffer lanes and 5-15 colors, shows that our approach reduces color changes compared to existing methods by up to 59%.

3 Rl Vaccinator: Leveraging Reinforcement Learning for Optimal Immunization in Contact Networks

Ehsan Ardjmand[1], Alireza Fallahtafti[2], Ehsan Yazdani[3], Anwar Mahmoodi[3], [1]Ohio University, Athens, OH, [2]Case Western Reserve University, Cleveland, OH, [3]University of Kurdistan, Sanandaj, Iran, Islamic Republic of

The effective control of infectious diseases heavily relies on designing efficient vaccination policies. However, the complex nature of human contact networks poses significant challenges in determining the optimum allocation of vaccine resources. This research explores the utilization of reinforcement learning (RL) techniques to address this problem. Specifically, we investigate how RL algorithms can be employed to optimize vaccination policies by considering the dynamics of disease spread over human contact networks while targeting the individuals who are the best immunization candidates. For this purpose, a reinforcement learning approach based on graph neural networks is coupled with a pandemic simulator to estimate the future status of the disease spread. Through simulations and analyses, we demonstrate the efficacy of the proposed method.

4 Developing a Reinforcement Learning Based Water Quality Control System

Kiarash Ghasemzadeh[1], Pitu Mirchandani[1], Treavor Boyer[2], [1]Arizona State University, Tempe, AZ, [2]Arizona State University, Tempe, AZ, Contact: kghasemz@asu.edu

Managing water quality is a complex task, requiring the monitoring of interdependent contaminants and their control using measures such as flushing, filtration, chemical injection, and temperature adjustment. The challenge is amplified by the stagnation and lengthy transit times during the delivery process, along with the intricacies of the hydraulic system and the nonlinearity of water quality functions. This research introduces a reinforcement learning (RL) based system, a novel approach to maintaining optimal water quality in buildings. The RL-based system, adaptable to various structures and capable of handling stochastic demand can regulate these control mechanisms effectively and ensure consistent safe-for-drinking water for the end users, presenting a significant advancement in the field.

5 Data-Driven Portfolio Management for Motion Pictures Industry: A New Data-Driven Optimization Methodology Using Chat Gpt as an Expert

Mohammad Alipour-Vaezi, Kwok-Leung Tsui, Virginia Tech, Blacksburg, VA, Contact: alipourvaezi@vt.edu

Portfolio management is one of the unresponded problems of the Motion Pictures Industry (MPI). To design an optimal portfolio for an MPI investor, it is essential to predict the box office of each project. Moreover, for an accurate box office prediction, it is critical to consider the effect of the celebrities involved in each MPI project which was not possible with any precedent expert-base method. In this paper, firstly, the fame score of the celebrities is determined using Chat GPT. Then to tackle the unbalanced character of MPI's data, projects are classified. Furthermore, the box office prediction is taken place for the projects in each class. Finally, using a hybrid multi-attribute decision-making technique, the preferability of each project for the investor is calculated, and benefitting from a bi-objective optimization model, the optimal portfolio is designed.

Improving the Effectiveness of Human-AI Collaboration in Operations

Community Committee Choice Session

Session Chair: Stephanie Kelley, Ivey Business School, The University of Western Ontario, London, ON, Canada

1 Explanation Seeking and Recommendation Adherence in Human-to-Human Versus Human-to-AI Interactions

Tracy Jenkin[1], Stephanie Kelley[2], Anton Ovchinnikov[3], Cecilia Ying[4], [1]Queen's University, Kingston, ON, Canada; [2]Sobey School of Business, Saint Mary's University, Halifax, NS, Canada; [3]Smith School of Business, Queen's University, Kingston, ON, Canada; [4]Queen's University, Markham, ON, Canada

We conduct a lab experiment to examine when and why do explanation seeking and recommendation adherence behaviours differ in human-to-human versus human-to-AI settings, with variances in task abnormality, in the online rental market setting. We explore participant heterogeneity to determine how personality traits such as trust propensity, dispositional trust in automation, and perfect automation schema impact explanation-seeking and recommendation adherence between individuals with human and AI advisors. Our traditional experimental analysis is paired with machine learning topic modelling and emotion classification to further investigate participant heterogeneity.

2 Improving Human-Algorithm Collaboration in the Presence of Outliers

Matt DosSantos DiSorbo, Kris Johnson Ferreira, Harvard Business School, Boston, MA, Contact: mdisorbo@hbs.edu

Algorithms are imperfect. While models may perform well on data that are representative of the training set (inliers), they may exhibit sizable error when extrapolating on non-representative data (outliers). In a lab experiment, we demonstrate that participants are unable to sufficiently differentiate trust in an algorithm when faced with both inliers and outliers. We identify a simple intervention — alerting the participant when the feature values are inside or outside the range of the training set and referencing the potential impact on algorithm error — that significantly improves performance. Our work has implications across the many contexts of human-algorithm collaboration.

3 A Meta-Analysis of Algorithm Aversion

Shuba Srinivasan[1], Ya You[2], Amit Joshi[3], Carey Morewedge[1], Maude Lavanchy[3], [1]Boston University, Boston, MA, [2]Cal State, East Bay, CA, [3]IMD, Lausanne, Switzerland. Contact: ssrini@bu.edu

Algorithms have become ubiquitous, and the output of algorithms directly and indirectly affects users' decisions and actions. Despite the benefits of these systems, research has found that users sometimes exhibit negative attitudes and behavior toward algorithms versus humans delivering "equivalent" offerings, referred to algorithm aversion. This study conducts a meta-analysis of 302 effect sizes across 156 studies from 67 articles to identify key factors that may drive algorithm aversion. The results show that users have a significant overall algorithm aversion. Moreover, algorithm aversion is driven by algorithm characteristics, human characteristics, task characteristics and industry characteristics .

4 Multitask Prompt Learning for Hate Speech Detection

Kyuhan Lee[1], Ram Sudha[2], [1]Korea University Business School, Seoul, Korea, Republic of; [2]University of Arizona, Tucson, AZ, Contact: kyuhanlee@korea.ac.kr

The previous approaches for hate speech detection pose several issues including the inability to capture the nuanced variations within different subtypes of hate speech; the neglect of the findings from the psychology literature regarding personality and hate; and the lack of explanation to inform humans in making the final decision of content moderation. To this end, we propose a multi-task prompt-based few-shot learning architecture different from existing ones in the following aspects: applying the theory of questioning for our prompt generation; suggesting an information-theory-based method for computationally selecting prompts; (iii) proposing a multi-task personality-based fine-tuning architecture to incorporate personality information; and (iv) generating explanation more understandable to and acceptable by humans.

Simulation, Modeling, and Optimization for Air Transportation and Emerging Mobility

Community Committee Choice Session

Session Chair: Christopher Chin, Massachusetts Institute of Technology, Cambridge, MA

1 Route Network Planning for Urban Drone Delivery : Network Flow Theory or Graph Search Algorithms

Lishuai Li, Xinyu He, City University of Hong Kong, Kowloon, Hong Kong. Contact: lishuai.li@cityu.edu.hk

Unmanned Aerial Vehicles (UAVs)-based commercial services, exemplified by drone delivery, have captured widespread interest from technology companies. However, to scale up drone delivery in urban environments, air route network design and traffic management are essential, yet it is computationally challenging due to the scale, complexity, and density of the urban airspace. In this study, we compare two streams of methods for planning route networks, the Network Flow Models using mathematical programming and Graph Search Algorithms using heuristics. A set of experiments have been conducted and the results show that graph search will be more suitable for large real-world scenarios due to faster computational time, while the Network Flow Model generates routes with superior optimality but requires significantly more computational time.

2 Distributionally Robust Airport Ground Holding Problem Under Wasserstein Ambiguity Sets

Haochen Wu, University of Michigan, Ann Arbor, MI

The airport ground holding problem seeks to minimize flight delay costs due to reductions in the capacity of airports. However, the critical input of future airport capacities is often difficult to predict. To address the problem of designing airport ground holding policies under distributional uncertainty, we formulate and solve the airport ground holding problem using distributionally robust optimization (DRO). The experiment results show that the DRO model outperforms the stochastic models when there is a significant difference between the empirical airport capacity distribution and the realized airport capacity distribution.

3 On the Air Traffic Flow Management with Airspace Users' Preference

Guglielmo Lulli[1,2], Luigi De Giovanni[3], Carlo Lancia[2], Yuhan Jiang[1], [1]Lancaster University, Lancaster, United Kingdom; [2]Universita' di Milano-Bicocca, Milano, Italy; [3]University of Padua, Padova, Italy

In this talk, we present a novel data-driven optimization approach for trajectory-based air traffic flow management (ATFM). A key aspect of the proposed approach is the inclusion of airspace users' trajectory preferences, which are computed from traffic data using machine learning methods. The methodology has been tested on real instances of the problem. In this talk, we show an analysis of preference aware ATFM solutions, the trade-off between preferences and delays as well as the potential benefits. We expect that the proposed approach may facilitate to find a consensus between the network manager and airspace users.

4 Introducing a Novel Optimized Propulsion System for Enhanced Efficiency and Reduced Fuel Consumption in Aviation

Luis Cadarso, Jorge Saavedra García, Rey Juan Carlos University, Fuenlabrada, Spain. Contact: luis.cadarso@urjc.es

Engines in aviation are nearing maximum efficiency, while growing demand drives fuel consumption and emissions. To reduce them and comply with air traffic legislation which regulates emissions and resource use, a new, more efficient system is needed. Here, a novel optimized propulsion system is introduced, recovering heat from engine exhaust to enhance performance. The heated stream is combined with the bypass stream, while a pressure gain-based re-heater maximizes efficiency and power output. The system dynamics are captured by a nonlinear mathematical model that presents multiple decision variables and an objective function focused on minimizing fuel consumption. The optimized system achieves an 11% reduction in fuel consumption.

Wednesday, October 18, 8:00 AM - 9:15 AM

AI-Driven Cybersecurity

Community Committee Choice Session

Session Chair: Tung Cu, Northeastern Illinois University, Chicago, IL

1 Using Cognitive Agents to Collaborate with Cyber Defenders: Current Work and Major Challenges

Yinuo Du, Cleotilde Gonzalez, Carnegie Mellon University, Pittsburgh, PA, Contact: yinuod@andrew.cmu.edu

Cyber security is a team task but has mostly been studied from an individual defender perspective. Human-AI teaming presents an opportunity to improve Cyber Protection Teams but the coordination and collaboration of activities between humans and AI teammates need to be developed.
In the work, we will first propose a new Collaborative Team Defense Game, where one human defender can defend a network together with an autonomous agent. Then, we will introduce three types of autonomous agents to play the role of teammate. We contextualized a set of metrics to evaluate the collective intelligence of cyber teams of different composition. We conclude with future work on team task refinement and AI teammate design.

2 Digital Transformation of Moocs

Tung Cu, Northeastern Illinois University, Chicago, IL, Contact: tcu@neiu.edu

Massive Open Online Courses (MOOC) have caused disruption among higher education institutions by establishing new markets for learners who may not be served by the traditional university. This research aims to investigate whether the MOOCs growth and popularity amongst different countries may contribute to the country's digital transformation over time. To this end, data is collected and analyzed via multiple sources including MOOC enrollment and digital transformation. The use of predictive analytics is applied to estimate countries' transformation and digitalization over time. The study shows that MOOCs are evolving, and as their adoption continues to improve, new markets for new learners will be established, leading to digital growth and transformation among developing countries.

3 Case Studies of AI and Cybersecurity

Bonnie Holub, Infosys Consulting, Sunfish Lake, MN

This paper will consider several use cases where AI-driven cybersecurity solutions have been applied to real-world industrial problems. Use cases will span banking and financial services, manufacturing, technology, healthcare, and life science examples. Future challenges will be outlined as well as areas for future technology development. We will discuss AI-driven cybersecurity in light of cybersecurity risks, privacy, regulatory compliance, intellectual property, and ESG.

4 Ransomware Attack Preventions Based on Defense-In-Depth Algorithms

Arish Ali, Yi Yang, Tung Cu, Northeastern Illinois University, Chicago, IL

We propose several defense-in-depth algorithms against ransomware attacks, which combine two Moving Target Defense (MTD) approaches: an IP address shuffling algorithm and a file backup algorithm. The IP address shuffling algorithm changes the IP addresses of the network randomly to avoid being located by ransomware attackers. The files backup algorithm periodically creates copies of user files to the backup server to enable fast recovery in case of file encryption. We evaluate our algorithms against several well-known ransomware attack families, such as WannaCry, Cerber, Thanos, Tesla, and Bitlocker. Our experimental results are conducted under virtual machines, and they show that our proposed algorithms outperform existing methods in the literature, because they can effectively protect user files from ransomware attacks with only minimal performance overhead.

Machine Learning and Optimization Applications

Contributed Session

Session Chair: Joel Persson, ETH Zurich, Zurich, Switzerland

1 Interactive Optimization With Varying Refinement Actions For Supply Chain Design

Damsara Jayarathne[1], Michelle Zhang[2], Sandipan Mishra[1], John E. Mitchell[2], Jennifer Pazour[3], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Rensselaer Polytechnic Institute, Troy, NY, [3]Rensselaer Polytechnic Institute, Troy, NY, Contact: jayarj2@rpi.edu

We propose an interactive optimization framework that holistically interacts with a human user to recommend a supply chain design, the design's expected systematic performance and associated confidence intervals. Our framework asks the human user questions based on the math program's current solution, confidence intervals, and auxiliary information (e.g., dual variables) to gain access to more or better quality data, problem domain knowledge, or updated preference weights. The human user's responses are interpreted to make varying refinement actions that improve the solution quality, reduce the reality gap, or improve the confidence in the system performance estimates.

2 A Cost-Effective and Accuracy Sensitive Svm with Step Loss Function

Jing-Rung Yu, Chun-Yu Lin, National Chi-Nan University, Nantou, Taiwan. Contact: s110213512@mail1.ncnu.edu.tw

This study proposes a cost-effective and accuracy-sensitive $\ell 1$-norm support vector machine with step loss function (CEAS_SVM_SL) to handle feature selection cost under accuracy sensitivity. The objectives of the proposed model are to minimize misclassification and maximize the lower bounds of the true positive rate and true negative rate. From the empirical testing results, our model is insensitive to outliers. In addition, it shows that the CEAS_SVM_SL performs higher out-of-sample accuracy than other benchmark models while considering the feature cost. The proposed model can extend to handling individual feature and group structure cost-based feature selection even under feature cost uncertainty, saving more money.

3 Capacity Management and Modelling in the Agri-Food Supply Chain: A Systematic Literature Review

Chenqiang Yue, Dong Li, Dongping Song, University of Liverpool, Liverpool, United Kingdom. Contact: yuecq@liverpool.ac.uk

This paper conducts a systematic literature review of capacity management and modelling in the context of agri-food supply chains. Descriptive and theme-based analysis are presented to reveal how capacity management is modelled under uncertainty and risk preferences from perspectives of optimal decisions, influencing factors, and methodology. We highlight current research status and identify future research opportunities.

4 Off-Policy Learning of Content Promotions: Optimal Curation of Digital Distribution Channels

Joel Persson[1], Stefan Feuerriegel[2], Cristina Kadar[3], [1]ETH Zurich, Zurich, Switzerland; [2]LMU Munich, Munich, Germany; [3]Neue Zürcher Zeitung, Zurich, Switzerland. Contact: jpersson@ethz.ch

We present an off-policy learning framework for optimizing which content a digital publisher shall promote on its distribution channels. Our framework comprises a decision model, an identification and evaluation method, and a causal machine learning procedure. We show theoretically that the optimal policy selects the content with top-ranked conditional average treatment effect per time period, that the estimation procedure is sufficient, necessary and doubly robust, and that our estimation algorithm is computationally efficient. We partner with an international newspaper and, using large-scale internal data, demonstrate that the optimal policy improves upon the status quo and baseline methods by 8.5 percent in terms of the key business metric. Our work contributes to previous research by supporting content publishers in curating their distribution channels.

Decision-oriented Data Analytics for Modeling, Prediction, and Inference

Community Committee Choice Session

Session Chair: Minhee Kim, University of Florida, Gainesville, FL

1 Thermal History-Based Quantification and Prediction of Overheating in Laser Powder Bed Fusion

Samar Saleh[1], Yuebin Guo[2], Weihong Grace Guo[1], [1]Rutgers University, New Brunswick, NJ, [2]Rutgers University, New Brunswick, NJ, Contact: shs164@scarletmail.rutgers.edu

Despite its revolutionary influence on industries, metal 3D printing's broader adoption is hindered by challenges, most notably overheating, which endangers part quality, structural integrity, and accuracy. Factors like temperature tracking, material variability, complex geometries, and printing parameters complicate overheating quantification in LPBF, compounded by the absence of standards. We aim to create a method integrating pyrometry, image processing, and machine learning to extract representative features from thermal data for overheating quantification and prediction. By monitoring and minimizing overheating flaws, this method enhances 3D printing's dependability and performance, facilitating its wider adoption across diverse sectors.

2 Convolutional Non-Homogeneous Poisson Process with Application to Wildfire Risk Quantification for Power Delivery Networks

Guanzhou Wei[1], Xiao Liu[1], Feng Qiu[2], [1]University of Arkansas, Fayetteville, AR, [2]Argonne National Laboratory, Lemont, IL, Contact: gwei@uark.edu

This talk presents a new spatio-temporal point process model, Convolutional Non-homogeneous Poisson Process (cNHPP), to quantify wildfire risks for power delivery networks. The proposed model captures both the current short-term and cumulative long-term effects of covariates on wildfire risks, and the spatio-temporal dependency among different segments of the power delivery network.

3 Data Driven Sequential Learning Frameworks to Accelerate Multi-Objective Manufacturing Decisions

Hamed Khosravi[1], Taofeeq Olajire[1], Ahmed Shoyeb Raihan[2], Imtiaz Ahmed[2], [1]West Virginia University, Morgantown, WV, [2]West Virginia University, Morgantown, WV, Contact: hk00024@mix.wvu.edu

Optimizing the selection of data collection points is crucial in manufacturing experiments to minimize costs and time while obtaining a comprehensive understanding of the process. This paper introduces a novel data-driven Bayesian optimization framework for efficiently optimizing complex systems with multiple conflicting objectives. Also, it proposes an epsilon-greedy sequential prediction framework that addresses the exploration-exploitation trade-off by establishing a threshold. A novel metric for evaluating multi-objective data-driven optimization approaches is also presented. This metric considers both the quality of the Pareto front and the amount of data used to generate it. The methods and metric are evaluated on real-world manufacturing datasets, showing their superiority in achieving similar manufacturing decisions with reduced costs and time

Data Science in Healthcare, Medicine, and Public Health

Community Committee Choice Session

Session Chair: Bing Si, State University of New York at Binghamton, Binghamton, NY

Session Chair: Mingyang Li, University of South

Florida, Tampa, FL

1 Spatial Rank-Based Augmentation for Nonparametric Online Monitoring and Adaptive Sampling of Big Data Streams

Xin Zan[1], Di Wang[2], Xiaochen Xian[3], [1]University of Florida, GAINESVILLE, FL, [2]Shanghai Jiao Tong University, Shanghai, China; [3]University of Florida, Gainesville, FL, Contact: xin.zan@ufl.edu

The monitoring of big data streams remains a challenging task in various practical applications mainly due to their complexity in interrelationships, large volume, and high velocity, which places prohibitive demands on monitoring methodologies and resources. To tackle the challenges, we incorporate spatial rank-based statistics with effective data augmentation techniques to analytically inform the monitoring and sampling decisions for general big data streams with a practical partial observability constraint. Theoretical investigations and simulation studies are conducted to understand the proposed augmentation statistics, and also guarantee the superiority of the sampling performance over existing methods.

2 Stochastic Nursing Home Staffing and Scheduling Under Case-Mix Resident Need

Shujin Jiang[1], Mingyang Li[2], Nan Kong[1], [1]Purdue University, West Lafayette, IN, [2]University of South Florida, Tampa, FL, Contact: jiang557@purdue.edu

Staffing adequately in a cost-effective manner is vital to nursing home management in the United States. In this work, we propose SNHSS, short for stochastic nursing home staffing and scheduler—a staffing and scheduling approach tailored to address the unique challenges and uncertainties of nursing home service. Given probabilistic forecasts of nursing home service needs, SNHSS optimally schedules the caregiver's daily assignment based on nursing home resident acuity. SNHSS is formulated as a two-stage stochastic mixed-integer linear program, which we solve using a scenario-based rolling horizon. Tested on real-world data from the U.S. Indiana's nursing home, SNHSS enables nursing homes to provide appropriate and adequate service considering daily resident acuity and acuity-based care needs.

3 Federated Functional Regression for Telemedicine

Bing Si, State University of New York at Binghamton, Binghamton, NY

Federated Learning (FL) is an emerging computing paradigm that leverages multi-source data without data exchange to collaboratively train Machine Learning models with privacy preservation. Functional Regression (FR) aims at predicting a functional response from other functional variables and receives more and more attention in bio-signal-based telemedicine applications. However, no existing research has studied FL of the FR model to facilitate large-scale computing of high-dimensional functional data. This project contributes a novel federated Functional Regression model integrated with an efficient Gradient Boosting algorithm. Theoretical guarantee of the federated model's convergence is also discussed under certain statistical assumptions. The proposed model is tested in simulation studies and a real-world dataset for telemedicine.

4 A Deep Survival Analysis Approach to Improving Functional Outcomes Prediction of Nursing Home Residents

Yulun Xu[1], Hongdao Meng[2], Nan Kong[3], Kelly Smith[4], Mingyang Li[5], [1]University of South Florida, Tampa, FL, [2]University of South Florida, Tampa, FL, [3]Purdue University, West Lafayette, IN, [4]Q3 Healthcare Consulting LLC, Tampa, FL, [5]University of South Florida, Tampa, FL, Contact: yulun@usf.edu

Accurate prediction of discharge outcomes (i.e., time to community, time to re/hospitalization) of residents in a nursing home (NH) is crucial for maximizing restoration and maintenance of residents' functional status and returning them back to the community (e.g., private home or lower-level care settings). However, this task is challenging due to multiple discharge positions, varied individual characteristics, diseases, and treatment variations. We propose a new approach for individualized discharge outcomes prediction by integrating survival analysis and deep learning. The proposed work jointly considers multiple competing discharge dispositions and different censoring types. Using real-world NH data, we demonstrate the advantages of our proposed model over existing benchmarks, highlighting improved accuracy in discharge outcomes prediction.

Advanced Online Process Monitoring of Complex Data in Smart and Connected Systems

Community Committee Choice Session

Session Chair: Ziqian Zheng, University of Wisconsin-Madison, Madison, WI

Session Chair: Kaibo Liu, UW-Madison, Madison, WI

1 Self-Starting Monitoring for High-Dimensional Data Under Sampling Control

Jiahui Zhang[1], Jun Li[2], Kaibo Liu[1], [1]University of Wisconsin-Madison, Madison, WI, [2]University of California, Riverside, CA, Contact: jzhang2584@wisc.edu

Real-time process monitoring on high-dimensional data with limited observation resources is a critical challenge. Practitioners need to form a monitoring procedure based on partially observed data while deciding the sampling layout. Additionally, a lack of in-control reference data before production runs calls for self-starting schemes. In this paper, we propose a novel algorithm for monitoring such data under self-starting schemes with sampling control, based on a quantile-based nonparametric CUSUM procedure with likelihood ratio-based statistics, and the Thompson Sampling algorithm is tailored to handle partially observed data in the self-starting case. Our method is robust for detecting arbitrary deviations and compatible with arbitrary heterogeneous distributions. Advantages of the proposed method are shown in simulation experiments and a case study.

2 A Recurrent Variational Autoencoder for Predictive Monitoring of Continual Learning Processes

Adel Alaeddini, Julian Carvajal Rico, University of Texas at San Antonio, San Antonio, TX

Many intelligent algorithms and in particular deep learning models rely on continual learning to keep up with the dynamics of the environment. However, if not monitored appropriately, continual learning may lead to catastrophic forgetting. Several algorithms have been explored in the literature for incremental learning of classification and/or regression tasks to address problems with continual learning. However, less emphasis has been placed on predictive monitoring and control of the continuous learning processes. Here, we propose a recurrent variational autoencoder paired with an appropriate multivariate control charting scheme to dynamically monitor the latent features of the training data based on new samples, and predict possible changes to the performance of deep learning models. We validate the proposed method using extensive simulation studies.

3 Detecting Duplicated Comments from FCC Net Neutrality Rules Using Deep Learning Methods

Zhicheng Huang, The university of Oklahoma, Norman, OK

As part of the rulemaking process, the Federal Communications Commission (FCC) solicits comments from the American public to understand the impacts of proposed rules. However, duplicate comments, which are identical or similar to other comments already received by the FCC, make it challenging for agencies to identify unique content and learn publics' opinions. To address this challenge, we analyzed duplicate comments on the net neutrality docket and developed measures for their detection using a deep neural network. This study presents an experiment testing our approach and comparing its results to state-of-the-art deep learning models. Experimental results indicate that the proposed model outperformed the baseline Bert-based Bigbird classifier and standard Graph Convolutional Network with Long Short-Term Memory (GCN-LSTM) model.

4 Near-Real-Time Detection Objects from Videos via Spatial-Temporal Tensor Decomposition

Yinwei Zhang, Jian Liu, The University of Arizona, Tucson, AZ

Real-time detection of objects from videos is a challenging task. Existing methods based on supervised learning may fall short when the availability of the labeled data is limited. To overcome the limitation, an unsupervised learning method is proposed. Specifically, it considers a video as a three-dimensional tensor of individual pixel motions, which are estimated as optical flows. The tensor can be decomposed into three layers, i.e., a background layer, an object layer, and a noise layer, each of which is regularized mathematically by considering the corresponding motion patterns. An optimization algorithm is proposed to solve the regularization problem effectively and efficiently. A case study is conducted to validate the proposed method.

Prospects and Applications of Data Analytics in Human-Centered Manufacturing

Community Committee Choice Session

Session Chair: Shenghan Guo, Arizona State University, Gilbert, AZ

1 Workforce Efficiency and Safety on Human-Centric Manufacturing

Heejin Jeong, Arizona State University, Mesa, AZ

There is growing recognition in the Industry 5.0 paradigm that manufacturing should prioritize the well-being of human workers by adopting a human-centric approach rather than a system-centric approach driven solely by efficiency, quality improvement, and cost reduction. In this talk, Dr. Jeong will present his projects related to workplace safety and ergonomics within the paradigm. The aim is to promote efficiency in human-robot collaboration and ensure occupational workforce safety in the future of manufacturing. This talk will highlight human-technology interactions, focusing on extended reality, artificial intelligence, and wearable sensing, and discuss future directions pertaining to training and assessing the manufacturing workforce.

2 Interpretable and Reliable Machine Learning for Human-Centered Additive Manufacturing

Azadeh Haghighi, Suyog Ghungrad, Meysam Faegh, University of Illinois Chicago, Chicago, IL, Contact: ahaghi3@uic.edu

The manufacturing industry is undergoing a rapid transformation, and data analytics is playing a crucial role in this evolution, enabling and facilitating human-centered manufacturing. Consequently, innovations in interpretable and reliable artificial intelligence for human operators in advanced manufacturing scenarios are necessary. In this talk, we present a new methodology that fuses additive manufacturing-specific physics into the architecture of neural networks to achieve higher interpretability, reliability, and trustability. This fusion mechanism not only enhances performance but also addresses the challenge of learning with smaller sample sizes, which is particularly relevant for human-centered products and devices requiring a high level of customization.

3 Prediction of Optimal 3d Printing Conditions with Computer Vision

Shenghan Guo, Hasnaa Ouidadi, Boyang Xu, Arizona State University, Tempe, AZ

Artificial intelligence (AI) has been applied to a variety of fields and has proven to be an effective tool for many decision-making tasks like object detection, classification, *etc*. Nevertheless, training a machine learning (ML) model may require labelled data to ensure high performance. This data collection task may necessitate human knowledge. For instance, in 3D printing, decision-making for the printing conditions heavily relies on human expertise. This study leverages human knowledge to obtain the optimal printing parameters of Computer-Aided Design (CAD) models. These parameters along with multi-view images of the model will constitute the labelled data for training ML models and develop an automated computer vision tool for predicting the printing condition of new CAD models. This work fills in the gap for a lack of AI-aided design automation for 3D printing.

4 Computer-Vision-Enabled Worker Video Analysis for Motion Amount Quantification

Hari Iyer, Shenghan Guo, Heejin Jeong, Arizona State University, Mesa, AZ

Workers' motion amount is a highly influential factor in their performance. Monitoring and evaluating the motion amount has been challenging due to the difficulties in motion sensing, tracking, and quantitative evaluation. Recently, in-situ videos have been adopted for real-time sensing of worker behavior, providing vital resources for data-driven motion amount quantification. This study proposed a computer-vision-based worker video analysis framework to track workers' right arm, quantify their motion amount, and alarm situations when the motion amount reaches a warning level. AI object recognition tool is integrated with a Hotelling T2 monitoring statistic built upon the extracted information to quantify and monitor the motion amount. This study will shed light on AI-enabled worker behavioral analysis and future workforce training.

Advances in Multisectoral Model Data and Couplings for Complex Human-Earth Systems Analysis

Community Committee Choice Session

Session Chair: Stuart Cohen, National Renewable Energy Laboratory, Golden, CO

1 Calibrating Economy-Wide Energy, Matter, and Money Stocks and Flows in a Multi-Sector Macroeconomic Model of the United States

Carey King, Neeraj Hanumante, The University of Texas at Austin, Austin, TX

To coherently model a transition to a low-carbon economy, a macroeconomic model should be fully consistent in tracking stocks and flows of matter, energy, and money. The Human and Resources with MONEY (HARMONEY) model framework was created to do this via consistency with modern monetary principles (i.e., money issued as private debt by banks as well as spending by central governments) and biophysical principles (i.e., machines and capital are constructed of matter extracted from the environment and require energy input as fuel to operate). This presentation describes the effort to calibrate mass, energy, and monetary data to a multi-sector HARMONEY model of the United States (U.S.)

using databases standardized for many countries (e.g., EXIOBASE3, International Energy Agency) as well as literature and data sets specific to the U.S. (e.g., USGS material flows).

2 Equitably Improving Adaptive Capacity in Response to Health Risks from Air Pollution

Rebecca Saari, University of Waterloo, Waterloo, ON, Canada

We seek to inform policy to equitably improve adaptive capacity by modeling nature-society interactions. Air pollution and COVID-19 were both linked to millions of deaths over the recent pandemic. Current policy for adaptation to outdoor air quality relies on individuals moving to clean indoor environments, to which people experiencing socio-economic hardship and homelessness have limited access. The pandemic shifted where time indoors was spent, and introduced protective mask wearing that reduces air pollution exposure. Here, we assess different adaptation measures (avoidance, masks, improving buildings), and quantify the missed health opportunity by not improving indoor environments in equitably protecting health from air pollution.

3 Climate-Water-Electricity Interactions in the U.S. Under Alternative Decarbonized Futures

Stuart M. Cohen, National Renewable Energy Laboratory, Golden, CO, Contact: stuart.cohen@nrel.gov

The U.S. electric sector is rapidly evolving, with widespread renewable energy deployment, building and transport electrification, and nuanced decarbonization policies. Climate change influences the supply and demand for electricity by altering water resources for cooling and hydropower, thermal plant efficiencies, and heating and cooling demand. This research combines global climate model data, asset-level water and streamflow modeling, and electric sector capacity expansion modeling to study climate-water-electricity interactions across myriad future climate and electricity scenarios that consider electrification and decarbonization using renewable, hydrogen, carbon capture, and nuclear technologies. Multi-model integration leads to insights into power-water sector interactions and their impacts on grid economics and environmental outcomes.

4 A Multi-Model Integrated Workflow for Harmonized Energy System Transitions, Grid Operations, and Power Plant Siting

Kendall Mongird[1], Chris Vernon[1], Jennie Rice[1], Zarrar Khan[2], Kerem Akdemir[3], Konstantinos Oikonomou[1], Jordan Kern[3], [1]Pacific Northwest National Laboratory, Richland, WA, [2]Pacific Northwest National Laboratory, College Park, MD, [3]North Carolina State University, Durham, NC, Contact: kendall.mongird@pnnl.gov

Answering complex questions as to how the US electric grid will evolve under the compounding effects of climate change, energy system transitions, and changes in electricity demand requires the integration of electricity system models that operate at dissimilar temporal and spatial scales. We present a novel multi-model workflow to spatiotemporally link a geospatial power plant siting model (CERF) and a nodal grid operations model (GO) to achieve electricity price-informed power plant siting, and new infrastructure-informed grid operations for alternative energy system transitions developed by an integrated assessment model (GCAM-USA).

5 Pathways for Small Modular Reactor Deployment Serving Industrial Process Heat with Learning and Policy Impacts

Max Vanatta, University of Michigan, Ann Arbor, MI, Contact: mvanatta@umich.edu

Hard to decarbonize industrial emissions are a challenge which small modular nuclear reactors (SMRs) have the potential to satisfy. Current SMR designs are novel and expensive but due to their inherent manufacturability, they could benefit from learning curves. In this study, we evaluate deployment pathways for SMRs serving industrial process heat across the continental US. Defining these pathways are policy, supply chain, and learning rate variations which the nascent SMR industry will need to navigate. Initial results suggest that SMRs do have a significant potential to economically decarbonize, or partially decarbonize, large numbers of industrial facilities in the US though the extent of this is sensitive to policy and learning.

CC-North 229B

Integrating Non-Traditional Resources and Reducing Asset Delivery Risk in Power Systems

Community Committee Choice Session

Session Chair: Richard Paul O’Neill, ARPA-E, Silver Spring, MD

Session Chair: Jon Glass, ARPA-e, Washington, DC

1 Economic and Reliability Outcomes of a Risk-Adjusted Stochastic Day-Ahead Unit Commitment Model

Dalia Patino-Echeverri, Duke University, Durham, NC,

Contact: dalia.patino@duke.edu
This presentation will discuss the cost savings and reliability effects of using a risk-adjusted stochastic day-ahead unit commitment model in a vertically integrated utility and the impact of different methods to generate probabilistic forecasts.

2 Integrating Non-Traditional Resources and Reducing Asset Delivery Risk in Power Systems
Selin Yanikara, Tabors Caramanis Rudkevich, Newton, MA, Contact: syanikara@psopt.com
Extreme weather events, increasing electrification, and integration of weather-dependent resources pose significant risk for common mode failures in the power grid and increasingly threaten its reliable operation. We summarize the theoretical foundation for locational and temporal probabilistic assessment of resource adequacy and present novel adequacy metrics that establish spot pricing for scarcity and help value the contribution of each system asset - generation, transmission, or demand resource - to system adequacy. The Monte Carlo based probabilistic methodology is augmented with a computationally efficient stratified sampling approach to obtain statistical significance and accuracy. The presentation will illustrate the probabilistic methodology and metrics evaluation on a real size US market.

3 Stochastic Market Auction Redesigned Trading System (Smarts) Update: The Value of Virtual Power Plant and Global Market Intelligence
Hung-po Chao, Energy Trading Analytics (ETA), Palo Alto, CA, Contact: hungpo.chao@et-analytics.com
Our aim is to provide an update on the ARPA-E PERFORM project titled “Stochastic Market Auction: Redesigned Trading System (SMARTS).” We will focus on two key areas for risk management in electric power markets. First, we will discuss the game-changing potential of global market intelligence (GMI) by leveraging advanced data analytics and deep market insights to enhance price formation and investment incentives. Traders can improve their market performance, and market designers can test enhanced market features. Second, we will discuss the value of integrating demand flexibility and virtual power plants (VPP) into electric power markets under efficient revenue and energy yield management. In conclusion, the SMARTS project aims to leverage the power of GMI and harness demand flexibility in VPP to revolutionize risk management for future power grids.

4 Flexibility as Optionality: Methods to Value the Flexibility of Distributed Energy Resources
Helyette Geman, Johns Hopkins University, Baltimore, MD
Flexible loads, including smart thermostats, smart water heaters, and electric vehicles, can provide valuable flexibility services, but the capacity of these services is uncertain because it depends on the stochastic and time-varying nature of weather and occupant behavior. Properly valuing this flexibility can reduce the barriers of entry into existing markets and encourage adoption of these technologies. This talk will compare the ideas of energy flexibility and optionality and propose methods for flexible load valuation.

Wednesday, October 18, 8:00 AM - 9:15 AM

WA52

CC-North 230
Planning and Operating Hydropower
Community Committee Choice Session
Session Chair: Feng Pan, Pacific Northwest National Laboratory, Richland, WA

1 Optimization of Pumped Hydro Energy Storage: A Structural Analysis
Harun Avci[1], Ece Cigdem Karakoyun[2], Ayse Selin Kocaman[2], Emre Nadar[2], Parinaz Toufani[2], [1]Northwestern University, Evanston, IL, [2]Bilkent University, Ankara, Turkey. Contact: selin.kocaman@bilkent.edu.tr
We study the energy generation and storage problem for a pumped hydro energy storage facility that consists of two connected reservoirs fed by a natural inflow. The operator decides in real-time how much water to pump or release in order to determine how much energy to buy or sell. We model this problem as a Markov decision process that accounts for the uncertainty in streamflow rates and electricity prices. We establish the optimality of a state-dependent threshold policy when electricity prices are positive.

2 Probabilistic Seasonal Inflow Forecasts and Chance-Constrained Optimization for Cascading Hydro Power Systems
Lei Wu, Xianbang Chen, Stevens Institute of Technology, Hoboken, NJ, Contact: xchen130@stevens.edu
This presentation will discuss a probabilistic seasonal water inflow prediction model for cascading hydropower systems. The Bayesian neural network is used to deliver the water inflow prediction in the form of a Gaussian mixture model (GMM). A chance-constrained programming (CCP) based optimization framework is further developed to evaluate the probabilistic seasonal water inflow prediction framework. By accurately capturing the system’s physical characteristics,

the operation model determined the cascading hydropower systems operation decisions in enabling maximum hydropower generation over the long term. The CCP-based method leverages the uncertainty information provided by GMM-based predictions, to handle the inevitable errors in water inflow predictions.

3 Pumped Storage Hydro Units Optimization in Day-Ahead and Real-Time Market Under Uncertainty

Bing Huang[1], Arezou Ghesmati[1], Yonghong Chen[1], Ross Baldick[2], [1]Midcontinent Independent System Operator (MISO), Carmel, IN, [2]University of Texas at Austin, Austin, TX, Contact: bhuang@misoenergy.org

Pumped storage hydro units (PSHU) are great sources of flexibility which is especially valuable to the modern systems with increasing shares of intermittent renewable resources. However, the flexibility from PSHUs has not been fully explored and utilized in the current system. In this presentation, first, a strategic design of incorporating and fully optimizing PSHUs in the day-ahead (DA) market is presented. The DA computational impact is discussed. Second, to provide a practical solution to the daily operation of a PSHU in a single day look-ahead commitment (LAC) and real-time market, models that only use probabilistic price forecast to incorporate uncertainties and manage risks are presented. Numerical studies in Mid-continent Independent System Operator (MISO) show that market efficiency is improved with moderate impact on the LAC computational performance.

4 Hydropower Operational Strategies For Enhanced Wind Integration

Yiwen Wang[1], Todd Levin[2], Jonghwan Kwon[2], [1]University of Massachusetts - Amherst, Amherst, MA, [2]Argonne National Laboratory, Lemont, IL, Contact: yiwwang@umass.edu

The West Coast has vast hydropower and wind energy potential. Hydropower can be used to compensate for the intermittency of wind energy to provide cleaner and more reliable electricity. However, the operation of a hydro-wind hybrid system requires proper planning and optimization. This project uses the A-LEAF operation model to evaluate how operational strategies and market incentives for hydropower support or inhibit hydropower's ability to help integrate high penetrations of wind resources into the power system.

5 Enhance Day-Ahead Generation with Hydropower and Battery Storage

Feng Pan, Arun Veeramany, Slaven Kincic, Pacific Northwest National Laboratory, Richland, WA, Contact: feng.pan@pnnl.gov

Our objective is to assess the benefits of batteries in a power system with hydroelectric generators. We will introduce a day-ahead unit commitment model with enhanced hydropower representation to capture hydro related conditions on flow rate, hydro-power conversion, limits on flow fluctuation, reservoir operation, and river network. Additional constraints can be used to improve hydro operation by reducing the frequent ramping. Batteries are integrated into the system as co-optimized resource or as hybrids co-located with run-of-river generators. The simulation included several scenarios of battery locations, sizes, and hybridization in a utility-size system with different levels of clean energy penetration, and cost-reduction and clean energy utilization were compared in these settings.

Wednesday, October 18, 8:00 AM - 9:15 AM

WA53

CC-North 231A

Towards Net Zero: Efficient and Sustainable Operations

Community Committee Choice Session

Session Chair: Osman Alp, University of Calgary, Calgary, AB, Canada

1 Applying Energy Surcharges to Increase Supply Chain Energy Efficiency: A Cautionary Tale

Jason Nguyen[1], Karen L. Donohue[2], Mili Mehrotra[3], [1]Ivey Business School, Western University, London, ON, Canada; [2]University of Minnesota, Minneapolis, MN, [3]University Of Illinois Urbana Champaign, Champaign, IL, Contact: jnguyen@ivey.ca

Energy price surcharges are often recommended as an effective countermeasure to account for energy externalities and encourage more Energy Efficiency (EE) investments. However, the resulting higher energy price can cause loss of domestic manufacturing to external competitors. Extant research on the topic often overlooks details at an operational level, including supply chain interactions and the uncertainty in EE saving potential that may have important implications in practice. Our study analyzes how energy price surcharges and its supplemental policies, including surcharge reductions and EE investment subsidies, impact supply chain EE investments, domestic sourcing and overall social welfare while accounting for these factors.

2 Combatting Food Waste via Joint Pricing and Perishable Inventory Optimization

Zichun Liu[1], Sentao Miao[1], Wei Qi[2], [1]McGill University, Montreal, QC, Canada; [2]Tsinghua University, Beijing, China. Contact: zichun.liu@mail.mcgill.ca

We address the simultaneous determination of pricing and inventory control for perishable products to maximize profit. The optimal policy is computationally intractable due to the curse of dimensionality. We show our heuristic policy is asymptotically optimal under several parameter regimes. In addition, we prove the necessity to model perishibility nature, and how it reduces food waste compared with current operations.

3 Path to Energy Sovereignty: Clean and Affordable Solutions for Remote Communities

Serasu Duran[1], Feyza G. Sahinyazan[2], Jayashankar M. Swaminathan[3], [1]Haskayne School of Business, Calgary, AB, Canada; [2]Simon Fraser University, Burnaby, BC, Canada; [3]University of North Carolina Chapel Hill, Chapel Hill, NC, Contact: serasu.duran@haskayne.ucalgary.ca

Remote communities around the globe rely on off-grid installations of stand-alone diesel generators to cover their energy needs which can be cost-inefficient, harmful for the environment and subject to disruptions. Policy makers seek sustainable solutions for these communities to meet the Sustainable Development Goals regarding clean energy and reduced inequalities. Even with the best intentions, ignoring community perspectives can hamper the clean energy transition and energy accessibility goals of remote communities. Our objective in this research is to identify the optimal generation capacity investment decisions from a remote community's perspective and investigate how common policy mechanisms interact with these decisions.

4 Technological and Market Response to Environmental Tax by a Competitive Industry

Anton Ovchinnikov[1], Dmitry Krass[2], [1]Smith School of Business, Queen's University, Kingston, ON, Canada; [2]Rotman School of Management, University of Toronto, Toronto, ON, Canada. Contact: ao37@queensu.ca

We consider a response to environmental taxes by firms producing a commodity good with a polluting by-product. Firms are heterogeneous with respect to production efficiency and pollution control technology. Cournot competition is assumed, with two demand functions: iso-elastic and linear. In this setting, we consider a market response, where firms choose production quantities given their technology choices, and a technology response, where firms also choose among a discrete set of available technologies. We characterize the equilibria and examine using environmental taxes to incentivize "green" technology choices. We also show that results may qualitatively differ depending on the demand function assumed.

5 Optimal Rebate Level, Compensation Rate, and Capacity Investment for Fostering Solar Panel Adoption

Osman Alp[1], Serasu Duran[2], Saman TeymoorianMotlagh[1], [1]University of Calgary, Calgary, AB, Canada; [2]Haskayne School of Business, Calgary, AB, Canada. Contact: osman.alp@ucalgary.ca

Feed-in tariff policies and solar panel rebates incentivize roof-top solar adoption in the society. However, such policies can create stress on the electricity distribution system and non-solar households. By considering government, utility company, solar and non-solar households as four stakeholders, we develop optimal rebate level for solar installations and the feed-in tariff rates for solar generation so that none of the stakeholders are worse-off. Households determine how much to invest in solar energy based on the rebate level and the feed-in tariff rate set by the government as well as their solar intensity, roof top area and budget. Governments anticipate this action of the households and set a rebate level and a feed-in tariff rate so that the utility company's profit does not drop and the cost of electricity does not increase.

Use of Universal Quantum Computers and Quantum Annealers to Solve ORMS Problems

Community Committee Choice Session

Session Chair: Stefan Creemers, IESEG, Aarschot, Belgium

1 Discrete Optimization: A Quantum Revolution?

Stefan Creemers[1], Luis Fernando Perez Armas[2], [1]IESEG, Paris, France; [2]IESEG, lille, France

We use Grover's algorithm to build quantum algorithms that can be used to solve discrete optimization problems on a universal quantum computer. We use our quantum algorithms to solve the binary knapsack problem, and highlight a number of challenges that are faced when effectively using Grover's algorithm to solve discrete optimization problems.

2 Solving the Resource-Constrained Project Scheduling Problem (RCPSP) with Quantum Annealing

Luis Fernando Pérez Armas[1], Stefan Creemers[1], Samuel Deleplanque[2], [1]IESEG, Lille, France; [2]Junia Isen, Lille, France. Contact: l.perezarmas@ieseg.fr

Quantum annealing offers a promising approach for solving combinatorial optimization problems like the Resource-Constrained Project Scheduling Problem (RCPSP). We investigated its empirical performance by formulating the RCPSP as QUBO and ISING model. Experimental results are provided using a cutting-edge annealer (D-Wave Advantage) on RCPSP instances from the CV dataset. We conducted a thorough analysis of the solution energy landscape focusing on diversity and quality. Results are compared with classical solvers, shedding light on the potential advantages and limitations of using quantum annealing for RCPSP. Our findings suggest that quantum annealing delivers satisfying solutions for smaller to medium-sized problems. It also offers a high diversity of solutions making it a viable candidate for hybrid approaches to further enhance solution quality.

3 Solving Industry-Relevant Optimization Problems with Neutral Atoms-Based Quantum Computers

Wesley Coelho, PASQAL, Paris, France. Contact: wesley.coelho@pasqal.com

The emergence of quantum devices opens many exciting perspectives in the high-performance computing world. Among other quantum platforms, fully programmable neutral atom devices display unique characteristics and, by better controlling quantum entanglement and superposition, they represent a powerful tool to tackle complex problems and computing challenges. In this talk, Wesley Coelho will show how PASQAL Quantum Computers are used to address complex optimization problems while presenting the last achievements on industry-relevant use cases.

4 Neutral Atom Quantum Computers: The Platform and Applications

Hossein Sadeghi, PASQAL, Vancouver, BC, Canada. Contact: hossein.sadeghi@pasqal.com

PASQAL manufactures neutral atom quantum computers that use lasers to drive transition between atomic states and perform analog and digital operations on qubits.In addition, PASQAL is a full-stack company that provides access to quantum computers through cloud computing, a suite of SDKs that allows users to communicate with the quantum processor using a high-level language, and a suite of algorithms for a wide range of commercial applications.In this talk, I will walk you through an overview of the technology, its capabilities, and examples of real-world applications developed by PASQAL.

1 Price Pass-Through and Cost Burden Induced by Decarbonization Policies Considering Long-Term Capacity Expansion and Short-Term Grid Operation

Hongyang Zou[1], Huibin Du[1], Gang He[2], Kuishuang Feng[3], [1]Tianjin University, Tianjin, China; [2]Stony Brook University, New York, NY, [3]University of Maryland, Washington, MD

The impact of carbon cost on electricity supply and carbon pass-through requires a simulation that integrate CO_2 emission trading and electricity supply and dispatch into a continuous procedure. This study links agent-based model with SWITCH model that involves electricity supply, transmission and load centers, and estimates the carbon pass-through rates of different regions. The results show that a high carbon pass-through rates is closely related to local electricity supply and interregional power dispatch. The mix scenario that simultaneously considers CO_2 emission trading (CET) and renewable electricity target (RET) shows the synergistic effect of two policies on low-carbon electricity transition. Meanwhile, at low carbon cost, carbon market should be implemented combining with renewable electricity target to achieve the expected policy target.

2 A Data-Driven Model of the European Day-Ahead Electricity Market

Balazs Riskutia, Kenneth Bruninx, TU Delft, Delft, Netherlands. Contact: k.bruninx@tudelft.nl

In Europe’s day-ahead electricity market, flow-based market coupling facilitates electricity trade between market zones. Transmission system operators restrict commercial flows based on expected congestion on inter- and intra-zonal network elements. A lack of transparency on the strategies followed by transmission system operators and the bids/offers challenges studying the market’s performance. We leverage publicly available data sets to reconstruct supply curves and the flow-based domains through inverse optimization. The resulting interpretable model reproduces day-ahead electricity prices, cross-border flows, and flow-based domains with similar accuracy as state-of-the-art black-box tools. In addition, it allows studying the expected impact of structural changes, such as new transmission or generation assets.

3 Transcontinental Power Pools for Low-Carbon Electricity

Haozhe Yang[1], Ranjit Deshmukh[2], Sangwon Suh[1], [1]University of California, Santa Barbara, Santa Barbara, CA, [2]University of California Santa Barbara, Santa Barbara, CA, Contact: haozheyang@ucsb.edu

Transition to low-carbon electricity is crucial for meeting global climate goals. However, given the uneven spatial distribution and temporal variability of renewable resources, it is challenging to balance the supply and demand of electricity when relying heavily on renewables. Here, we use an electricity planning model to examine whether transcontinental power pools help meet global electricity demand by renewables. By utilizing only 10% available sites, renewables are economically infeasible to meet 12% of global demand in 2050 without international electricity trade. Introducing transcontinental power pools, however, renewables are feasible to meet 99% of electricity demand, while reducing the costs by 3-31% across power pools. Our results highlight the potential of expanding regional transmission networks in achieving decarbonization of electricity.

4 Modeling Ramping Constraints for the Statistical Unit Commitment Problem

Carlos Olivos[1,2], Jorge F. Valenzuela[1], [1]Auburn University, Auburn, AL, [2]Universidad Católica del Norte, Antofagasta, Chile. Contact: cro0010@auburn.edu

Over the past decade, stochastic models have gained relevance in the power systems operation field. Due to a growing integration of renewable energy sources, it is essential to incorporate the inherent variability of these sources into optimization models. In this work, we propose a variation of the Stochastic Unit Commitment problem that does not rely on scenario-based methods. Instead, an analytical formulation of the expected dispatch cost is derived from the net-load probability distribution function, considering technical constraints such as startup cost trajectories and ramping constraintsl. The model is tested in the California Independent System Operator (CAISO) power system. Results, algorithms, and conclusions will be presented.

5 The Role of Long Duration Energy Storage in Mitigating the Reliability Impacts of Climate-Driven Extreme Weather Events

Todd Levin, Argonne National Laboratory, Lemont, IL, Contact: tlevin@anl.gov

It is becoming clear that climate change will lead to changes in future weather patterns, including increasingly frequent and impactful periods of extreme operating conditions. We demonstrate the importance of considering future weather conditions in generation expansion planning through a case study analysis of the ERCOT power system, with a specific focus on establishing the role of long duration energy storage in mitigating the associated reliability impacts. We utilize data from three global climate models to generate a range of future scenarios for wind and solar availability and electricity demand, while also considering temperature-dependent generator and transmission infrastructure outage probabilities. We then illustrate how representing projected future weather conditions in a stochastic GEP framework impacts the optimal generation portfolio.

Managing Organizations to Boost Productivity

Contributed Session

Session Chair: Olivia Newton, University of Central Florida, Orlando, FL

1 Exploring Managerial Choice Making and Information Boundaries in Global Facility Location Decision Making Process

Debarshee Bhardwaj, Aseem Kinra, Universität Bremen, Bremen, Germany

Global facility location decision-making (GFLD) is a complex process that often prompts managers, particularly in small and medium-sized enterprises (SMEs) to adopt a satisficing approach. However, the optimal amount of information needed from site selection intermediaries regarding location attributes remains unclear, as managers may employ various decision-making and assessment strategies. To address this gap, our paper delves into the choice-making process of managers and investigates the information boundaries within the GFLD process specifically for SMEs. Using quasi-experiments based on verbal protocol analysis, involving 39 students and 50 SME managers, we found that medium information volume led to higher satisfaction, simplifying decision-making, improving outcomes, and generating relevant attributes, albeit with some trade-offs in accuracy.

2 Optimizing Healthcare Staff Efficiency Through Integration of Circadian Rhythms into Work Scheduling

Diana Lopez-Soto[1], Karen Niño[2], [1]North Dakota State University, Fargo, ND, [2]Universidad Militar Nueva Granada, Bogotá, D. C., Colombia. Contact: diana.lopez@ndsu.edu

Extended or rotating shifts in healthcare are practices commonly used to ensure patient care at all times; however, they can disrupt the body's natural circadian rhythm. Approximately 75% of workers face difficulties adapting to night shifts, which increases the risk of injuries, accidents, and chronic diseases, in addition, to impacting mental health. This research explores incorporating circadian rhythm variables into shift work scheduling to facilitate better adaptation for workers. A multi-objective model has been developed to address the problem, focusing on maximizing the allocation of personnel experience while considering the time needed for recovery before another shift and the desired level of performance and risk.

3 Maximizing Healthcare Worker Availability During Infectious Disease Outbreaks: A Novel Mdp Model and Validation Study

Mina Bahadori[1], Tugce Isik[2], [1]Clemson University, Central, SC, [2]Clemson University, Clemson, SC, Contact: mbahado@clemson.edu

Healthcare workers are at increased risk during infectious disease outbreaks, which can impact their ability to provide care. We develop an MDP model to optimize healthcare worker availability during an outbreak. Going beyond the SEIR framework, our model is prescriptive and provides implementable staffing policies. To validate the model, we first conduct a simulation study and demonstrate the alignment of model results with existing literature. We then present a case study using real-world Covid-19 infection and contact data collected on Clemson University campus. These analyses show the credibility of the proposed model and allow us to assess the model's ability to improve healthcare worker availability during an outbreak. We also discuss the potential use of our MDP model to devise optimal schedules for healthcare workers throughout different phases of an outbreak.

4 Modeling the Relationship Between Social Diversity and Organizational Decision Making on Open Collaborations in Information Systems

Olivia B. Newton, Stephen M. Fiore, University of Central Florida, Orlando, FL, Contact: olivia.newton@ucf.edu

Contemporary work is often based on the open collaboration model as observed in software development. Transparency of, and access to, information systems enables widespread participation in the development of software. At the same time, low social diversity in these ecosystems has implications for software and society. Combining data analytics with survey research for a mixed-methods approach, we use systems theory to study open source developers decision making. Our goal is to elucidate the relationship between individual, collective, and societal factors associated with social diversity in software projects maintained by organizations and online groups. We discuss how disparities drive the direction of technological innovations and explore the promises and pitfalls of organizational decisions on achieving social diversity in open information systems.

Multiple Criteria Decision Making and Decision Analysis

Community Committee Choice Session

Session Chair: K. Nadia Papamichail, The University of Manchester, Manchester, United Kingdom

1 Survey of Multiobjective Optimization Methods for Business Data Analytics

Pubudu Jayasekara[1], Dilhani Shalika Marasinghe[2], [1]The University of Tennessee at Chattanooga, Chattanooga, TN, [2]University of Tennessee Chattanooga, Chattanooga, TN, Contact: pubudu-jayasekara@utc.edu

We present a review of the use of data analytics in the context of multiobjective optimization. Research in multiobjective optimization aims to develop algorithms and techniques to solve problems having multiple, often conflicting, objectives efficiently, by identifying the Pareto set precisely or approximates as closely as possible. With the increasing availability of data and recent advancements in machine learning and optimization techniques, there has been a growing trend towards utilizing data analytics to address challenges in Management Science. This work provides a review of recent data analytics applications in three major areas of Management Science, namely revenue management, statistics, and supply chain management. Numerical results are included.

Creating Environments to Foster Diversity

Contributed Session

1 Uncovering The Network Power Gap:a Deep Learning Approach To Investigating Gender Disparities In The Boardrooms Of Canadian Public Firms

Yuhao (Jet) Zhou[1], Collins Ntim[2], María Óskarsdóttir[3], Matthew Davison[1], Cristian Bravo[4], [1]Western University, London, ON, Canada; [2]University of Southampton, Southampton, United Kingdom; [3]Reykjavík University, Reykjavik, Iceland; [4]University of Western Ontario, London, ON, Canada. Contact: yzho82@uwo.ca

Our study employs a multi-channel deep learning model to investigate factors influencing board appointments in Canadian public firms. We analyzed directors' social networks, career paths, and static features, including education and social engagement. The model demonstrated robust predictive power without gender stratification, providing insights into network channel decomposition. Applying the model separately for male and female directors, we identified significant differences in network power between genders. Our research offers a comprehensive understanding of mechanisms driving board appointments and provides evidence to inform policies aimed at addressing gender disparities, fostering a more inclusive corporate environment.

2 Founder Diversity: The Key to Unlocking a Diverse Tech Firm Workforce

Mi H. Tran, Johan Wiklund, Cristiano Bellavitis, Syracuse University, Syracuse, NY, Contact: mhtran@syr.edu

Our study investigates how founder gender and ethnicity impact high-tech firm hiring preferences regarding candidate gender and ethnicity. We analyzed a dataset of 73,520 job candidates and 1,170 firms from a high-tech networking platform across three stages of the recruitment process: initial contact, candidate response, and successful hire. The results show that firms are more likely to contact and receive responses from female and underrepresented minority (URM) candidates when the founding team has a higher proportion of female or URM founders. Our study highlights the imprinting influence of founder demographics on recruitment outcomes and suggests that creating a foundation for sustained diversity within the high-tech workforce requires providing resources and opportunities for female and URM entrepreneurs right from the onset of the business formation.

3 Remote Work Arrangement and Gender Inequality

Shuang Xia[1], Yuxiao Ye[1], Shenyang Jiang[2], Baofeng Huo[1], [1]College of Management and Economics, Tianjin University, Tianjin, China; [2]Advanced Institute of Business, Tongji University, Shanghai, China. Contact: xiashuang@tju.edu.cn

COVID-19 prompted widespread adoption of remote work arrangements (RWAs), now continued by many companies. This study investigates the impact of RWAs on workplace gender inequality and explores the moderating effects of government wage subsidies and female executives. By analyzing detailed firm-level data from 15,737 companies across 34 countries, our study reveals that RWAs exacerbate gender inequality, leading to a significant decline in the proportion of female employees and consequent reduction in firm performance. However, we find that government wage subsidies during the pandemic and the presence of female executives mitigate the impact on gender inequality. Our research highlights the cascading consequences of this operational decision for companies, while providing insights for businesses and policymakers on mitigating these negative impacts.

Humanitarian Operations and Disaster Management II

Community Committee Choice Session

Session Chair: Andrew N. Arnette, Virginia Tech, Blacksburg, VA

Session Chair: Christopher W. Zobel, Virginia Tech, Blacksburg, VA

1 Information Management For Disaster Response: The Role Of Operational Updates And Crew Experience

Alfonso J. Pedraza-Martinez[1], Sebastian Villa[2], Tricia Moravec[3], Eunae Yoo[3], Lu (Lucy) Yan[3], [1]University of Notre Dame, Notre Dame, IN, [2]University of New Mexico, Albuquerque, NM, [3]Indiana University, Bloomington, IN, Contact: apedraz2@nd.edu

We use text analysis, econometrics and online experiments to understand the effect of relief organizations' operational updates on public sentiment during wildfire response.

2 The Impact of Postponement and Stock Sharing Strategies on Prepositioned Relief Stocks

Lamia G. Kasap-Simsek[1], Burcu Balcik[1], Florent Chane[2], [1]Ozyegin University, Istanbul, Turkey; [2]Emergency Supply Pre-positioning Strategy (ESUPS), Bonn, Germany. Contact: lamia.kasap@ozu.edu.tr

We evaluate effects of postponement and stock-sharing practices among humanitarian agencies that preposition supplies in a depot. We develop a Monte Carlo simulation algorithm that involves inventory allocation models for sharing stock among agencies and mobilizing stock from agencies to countries. We test our approach using historical hurricane scenarios from the Caribbean region and data from agencies. We demonstrate significant savings in fill rate, response time, and inventory utilization.

3 Vulnerability-Based Prioritization in Disaster Relief Efforts

Feyza G. Sahinyazan[1], Halenur Sahin[2], Irfan Mahmutogullari[3], [1]Simon Fraser University, Vancouver, BC, Canada; [2]TOBB ETU, Ankara, Turkey; [3]KU Leuven, Leuven, Belgium

Equity, Efficiency and Effectiveness (3E) are commonly used objectives in disaster literature. In this paper, we introduce an alternative measure that prioritizes vulnerable populations during disaster response efforts, and we compared its performance against the 3E measure using Istanbul's population characteristics and earthquake data.

4 Optimizing Water Delivery in Post-Disaster Humanitarian Logistics with Social Costs

Azadeh Sadeghi[1], Felipe Aros-Vera[2], [1]University of Michigan- Flint, Flint, MI, [2]Ohio University, Athens, OH, Contact: sadeghia@umich.edu

This research focuses on the delivery of critical supplies, particularly water, in the aftermath of a disaster. The tradeoffs between using bottled water, which is easily distributed but costly, and bulk water, which is cheaper but requires containers, are explored. To address this, the Social Cost Vehicle Routing Problem is introduced as a mathematical optimization model that determines the best mix of water resources for transportation, routing, and delivery. The model is applied to a case study of post-disaster water distribution in Puerto Rico after Hurricanes Irma and Maria. The results indicate that a combination of bottled and bulk water is the most effective approach for aid delivery while minimizing social costs.

Contemporary Scheduling

Community Committee Choice Session

Session Chair: Yumei Huo, City University of New York, College of Staten Island & The Graduate Center, Staten Island, NY

1 A Self-Learning Multi-Population Evolutionary Algorithm for Flexible Job Shop Scheduling

Zhaohong Jia, Anhui University, Heifei, China

Due to the energy crisis and environmental downgrade, manufacturing companies face rising costs. The flexible job shop scheduling problem considering time-of-use pricing (FJSPTOUP) is studied to minimize the maximum completion time and total electricity cost. A new self-learning multi-population evolutionary algorithm (SLMPEA) is proposed to address the static scheduling problem. A self-learning module is designed to acquire knowledge from elite individuals in subpopulations. We present an elite retention and enhancement strategy. Two enhancement operators are developed to elevate the quality of elite individuals, and a selection strategy is designed for the enhancement operators. A time-of-use-based adjustment strategy is proposed to reduce the total electricity costs without increasing the maximum completion time.

2 The Circular Balancing Problem

Kangbok Lee[1], Myungho Lee[2], [1]Pohang University of Science and Technology, Pohang, Korea, Republic of; [2]POSTECH IME, Nam-gu, Pohang-si, Korea, Republic of. Contact: kblee@postech.ac.kr

We propose a balancing problem with a minmax objective in a circular layout. This balancing problem is to arrange an even number of items with weights on a circle to minimize the maximum total weight of the items arranged on a semicircle. Due to its generic structure, it may have applications in fair resource allocation. We show the NP-hardness of the problem and develop polynomial-time algorithms when the number of different weights is a fixed constant. We also propose a tight approximation algorithm that is better than existing ones. This worst-case performance ratio is derived by a linear combination of valid inequalities obtained from the problem definition, the properties of the proposed algorithm, and the optimal circular permutation structure.

3 Sublinear Time Algorithms For Scheduling Problems

Bin Fu, The University of Texas Rio Grande Valley

Sublinear Time Algorithms for Scheduling Problems We present a framework for sublinear time algorithms in the context of scheduling problems. Our focus lies in the classical scheduling problem involving parallel machines, where the precedence graph exhibits bounded depth. The objective entails minimizing the maximum completion time. Our contribution pioneers the development of sublinear time algorithms for this problem. We address scenarios where job processing times differ by no more than a constant factor 'c,' and the number of machines 'm' remains bounded. We introduce the novel concept of a 'scheduling sketch,' which furnishes a blueprint for efficiently scheduling all jobs. Our research demonstrates the feasibility of designing sublinear time algorithms for a substantial range of scheduling problems. This work is joint with Yumei Huo and Hairong Zhao.

4 Streaming Algorithms For Classical Scheduling Problems

Yumei Huo, City University of New York, College of Staten Island & The Graduate Center, Staten Island, NY

In this research, we study the streaming algorithms for the classical scheduling problems. Streaming algorithms are algorithms for processing the input where some or all of the data is not available for random access but rather arrives as a sequence of items and can be examined in only a few passes (typically just one). We consider both the case that the number of jobs and largest processing time are known as priori and the case that no information is given before stream input arrives. We introduce the concept of "sketch of schedule" for the applications where not only an approximate value, but also a schedule associated with the approximate value is needed.

Service Research in Supply Chain Management

Community Committee Choice Session

Session Chair: Bernie F. Quiroga, West Virginia University, Morgantown, WV

1 Logistics Service Quality in the Pharmaceutical Supply Chain

Molly Hughes, West Virginia University, Morgantown, WV

Policymakers assume that generic drugs are a substitute for brand name drugs. The FDA states, "You can take a generic medicine as an *equal substitute* for its brand-name counterpart." (FDA 2023). Something that is not taken into consideration is the logistics service quality (LSQ) behind these products. This research asks what risks come from the differentiation in LSQ and how LSQ compares brand and generic suppliers. Through comparison of logistics metrics from 283 brand drug suppliers and 199 generic drug suppliers it was found that brand suppliers outperformed generic suppliers in timeliness, order procedure, order discrepancy, and order quality, generic suppliers outperformed brand suppliers in order accuracy, information quality, and personal contact quality. This research has potential implications for policymakers, managers, and LSQ research.

2 Estimating Inventory Control Parameters for the Continuous Review Policy when Orders Crossover

John Patrick Saldanha[1], Bradley Price[1], Doug Thomas[2], Peter F. Swan[3], [1]West Virginia University, Morgantown, WV, [2]University of Virginia, Charlottesville, VA, [3]Penn State Harrisburg, Middletown, PA, Contact: jpsaldanha@mail.wvu.edu

The majority of the inventory management literature as well as inventory models implemented in ERP systems assume the probability of order crossover is negligible and therefore ignore this phenomenon. We empirically document the presence and effects of order crossover on setting inventory parameters to achieve a target cycle service level (CSL) for the continuous review policy. Employing a modified heuristic and bootstrap algorithm we demonstrate using data obtained from an industry partner that accounting for order crossover can significantly improve reorder point estimation accuracy.

3 Improving Parcel Delivery Operations by Using Autonomous Truck-Based Drones and Intermediate Points

Bo Lan[1], Yoshinori Suzuki[2], [1]West Virginia University, Morgantown, WV, [2]Iowa State University, Ames, IA, Contact: bo.lan@mail.wvu.edu

The current studies about parcel delivery with truck and drone are restricted the drones' launch and/or recovery sites to the customer locations. In practice, parcel carriers are considering the use of intermediate points (IPs) to operate drones. This study investigates if, when, and where the use of IPs can be beneficial for truck-and-drone parcel deliveries. We first theoretically analyze the merit of using IPs and show that IPs have both advantages and disadvantages so that their use does not always give positive cost savings. We then develop a set of hypotheses based on our theoretical findings along with existing theories, and test them empirically using a technique that combines computational experiments and regression analysis. The implications derived in this study may be used as a guideline for implementing the concept of IPs in the field.

4 Replenishing Personal Protective Equipment for Healthcare Systems in Rural America at the Onset of a Pandemic

Bradley Price[1], John Patrick Saldanha[2], Bernardo (Bernie) F. Quiroga[3], Sally L. Hodder[4], [1]West Virginia University, Morgantown, WV, [2]West Virginia University, Morgantown, WV, [3]West Virginia University, Morgantown, WV, [4]West Virginia University, Morgantown, WV, Contact: bernie.quiroga@mail.wvu.edu

In the face of a worldwide shortage of personal protection equipment (PPE) at the onset of the COVID-19 pandemic, we report on our team's challenge of meeting hard-to-forecast PPE demand with supply under challenging replenishment conditions in the state of West Virginia. We implement a novel agent-based epidemiological model for forecasting PPE demand of confirmed and suspected COVID-19 patients, extending popular epidemiological models. We developed nonparametric approaches to set inventory parameters needed by the combination of nonstandard lead-time distributions and autocorrelated demand. Our simulation studies, grounded in the practical need of replenishing PPE stocks for the entire state, demonstrate improvements in both a) forecast accuracy possible, and b) estimation improvement of our nonparametric inventory estimates over existing approaches.

Simulation Methods and Applications

Contributed Session

Session Chair: Jeroen Didden, Eindhoven University of Technology, Eindhoven, Netherlands

1 Calibration of Inexact Stochastic Simulation Models via Energy Score

Ziwei Su[1], Matthew Plumlee[2], [1]Northwestern University, Evanston, IL, [2]Northwestern University, Evanston, IL, Contact: ziwei.su@northwestern.edu

Stochastic simulation calibration is the act of using the output-level data from a process to align the stochastic simulation model with the target process by adjusting the parameters. Stochastic simulation calibration is difficult when the model is inexact, meaning there is always a discrepancy between the model and the process. To address this challenge, we propose using the score as the model discrepancy measure. Under the kernelized discrepancies such as the energy score, we introduce the simulated score and the expected simulated score as the loss functions of the simulation model based on the data. In this talk, we delineate different levels of approximation for estimating the optimal model parameter using optimization. We substantiate the estimation procedures with consistency results and numerical experiments.

2 Using Game Engines to Investigate the Cyber-Physical Security of Machines

Madison Evans, Gregory T. Purdy, Auburn University, Auburn, AL, Contact: mle0020@auburn.edu

Since the Stuxnet attack on the Iranian centrifuges, the cyber-physical security of systems has been an area of importance. For manufacturers, the Industry 4.0 revolution allows previously isolated systems to connect to other systems and the internet, creating a new security risk. Researching cyber-physical attacks on manufacturing equipment is a complicated process due to costs. To combat this issue, we have proposed the development of a Cyber-Physical Manufacturing Range, a controlled environment for security testing. One of the critical pieces of the range is the virtual component which acts as a realistic model of the physical system. The game engine platform will host a model driven by data collection. The game engine's platform has the necessary tools to generate an accurate replication.

3 Optimal Selection Of Financial Strategies For Tail Risk Mitigation

Taeho Kim[1], Dohyun Ahn[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]The Chinese University of Hong Kong, Shatin, Hong Kong. Contact: thk5594@gmail.com

This paper addresses the ranking and selection problem with a risk-sensitive objective. We aim to identify the least-likely system whose loss exceeds a given common threshold. If the threshold is sufficiently large, the naive Monte Carlo estimator to estimate the tail probability becomes highly unstable, leading to performance degradation in existing ranking and selection frameworks. To overcome this issue, we propose a new approach by reformulating the objective using a "tail indicator" that governs the tail behavior of the underlying distribution. Based on this quantity, we provide a framework to estimate the tail indicator and develop an efficient sampling scheme for comparing the tail indicators of each system.

4 Optimizing Tool-Path Distance in Drilling Operations

Mohamed Elnoor[1], Ebisa Wollega[2], [1]University of Maryland, College Park, MD, [2]Colorado State University Pueblo, Pueblo, CO, Contact: melnoor@umd.edu

In this paper, we present the use of a genetic algorithm to minimize tool path distance in multi-tool drilling NP-hard problem operations. Most of the research on hole-drilling path optimization focuses on drilling holes of the same diameter, primarily addressing single-tool path planning. However, optimizing drilling paths for multiple hole sizes in a workpiece involving multi-tool path planning has received relatively less attention. This paper presents an improved approach for minimizing the length of tool paths in multi-tool drilling using a genetic algorithm.

5 Design of Virtual Manufacturing Cells: An Approach Based on Aco and Negotiation-Based Mas

Jeroen Didden[1], Vinh Dang[2], Ivo Adan[2], [1]Eindhoven University of Technology, Eindhoven, Netherlands; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: j.b.h.c.didden@tue.nl

Customer profiles have rapidly changed toward high-mix, low-volume, high-complexity products. This research therefore presents a learning-based approach to design virtual manufacturing cells for reconfigurable manufacturing systems. Data from the shop floor is used to dynamically re-allocate machines, tools and fixtures among the cells, according to the current state of the shop floor.

Strategies and Insights on Workforce Training

Contributed Session

Session Chair: Emil Palikot, Stanford University, Stanford, CA

1 A Cross-Cultural Comparison of Information-Seeking and Uncertainty Reduction Among Newcomers During Organizational Entry

Michael J. Farzinpour, The University of Arizona, Tucson, AZ, Contact: michaelfarzinpour@gmail.com

National corporations have unique onboarding processes, during which newcomers experience uncertainty because they cannot predict veteran employees' behavior. Newcomers can reduce their uncertainty by engaging in information-seeking behaviors. This study investigates the effects of international and domestic newcomers' information-seeking behaviors in reducing their uncertainty during the entry phase of U.S. national corporations. A survey will be created to capture cross-sectional data addressing the theoretical constructs. 150 newcomers will be recruited, and respond to measures (of information-seeking behaviors, information accessibility, uncertainty reduction, familiarity of organizational culture, and intercultural communication competence) that will employ a Likert-type 5-point scale (1 = strongly disagree to 5 = strongly agree).

2 Understanding Tradeoffs Between Training and Readiness in U.S. Army Aviation

Austin Semmel, US Army, Raleigh, NC, Contact: adsemmel@ncsu.edu

The usage and maintenance of the US Army's AH-64 Apache helicopter are highly scrutinized, with monthly reports detailing flying hours and readiness rates prepared for Commanders on the 15th of every month. Since the publication of Army Regulation 700-138 in 1985, the Army has imposed a 75% readiness requirement on its units. First, an analysis of seven years of AH-64 maintenance data illustrates historical patterns surrounding the decision to fly/not fly an individual aircraft on a given day, the time until phase maintenance, and the unit readiness ratings over time. Analysis includes the presentation of an efficient frontier that captures tradeoffs between readiness and flight hours (training proficiency). Second, a mathematical model identifies relevant factors to provide the Army with decision support tools to maximize readiness subject to a readiness constraint.

3 Impact of Training on Faculty'S Motivation to Adopt the Simulation Pedagogy

Veena Pailwar, Institute of Management Technology, Nagpur, Nagpur, India. Contact: vpailwar@imtnag.ac.in

Simulations are considered to be very effective in teaching pedagogy. The adoption of simulation pedagogy is limited in online classes due to a lack of familiarity with online teaching platforms. This paper makes an assessment of the online training sessions on the faculty's motivation level to adopt the simulation pedagogy. The post-training session feedback from the faculty, which was analyzed using mixed methods, such as bar charts, sentiment analysis, and chi-square, indicated that most were motivated to adopt simulation pedagogy in their classes. The analysis also revealed that demographic characteristics, such as gender, designation, years of experience, and area of expertise, do not affect the sentiments.

4 Automation As Antidotes For Employee Overloaded? An Empirical Analysis In Digital Control Rooms

Changyu Men[1,2], Maud Van den Broeke[1], Marijn Verschelde[1,2], [1]IESEG School of Management, Lille, France; [2]KU Leuven, Leuven, Belgium. Contact: c.men@ieseg.fr

Workload and automation receive increasing attention in light of Industry 5.0. We examine how operators' performance is influenced by their objective workload and how this influence is moderated by their use of automation. Our empirical analysis builds upon a purposefully constructed operational data set in a digital control room setting.

5 Effective and Scalable Programs to Facilitate Labor Market Transitions for Women in Technology

Emil Palikot, Susan Athey, Stanford University, Stanford, CA, Contact: palikot@stanford.edu

We describe the design, implementation, and evaluation of a low-cost and scalable program that supports women in Poland in transitioning into jobs in the IT sector. This program, called "Challenges," helps participants develop portfolios that demonstrate capability for relevant jobs. We conduct two independent evaluations, one focusing on the Challenges program and another on a one-to-one mentoring program. We estimate that the mentoring program increases the probability of finding a job in technology by 13 percentage points (pp) and the Challenges program by 9 pp. Next, we show that treatment effects vary with individual characteristics, and we estimate gains from optimally assigning applicants across the two programs. We find that optimal assignment increases the average probability of finding a job in tech by approximately 13% compared to random assignment.

Advances in Data-driven Decision-Making in Operations Management

Community Committee Choice Session

Session Chair: Yonggab Kim, Purdue University, West Lafayette, IN

1 Learning-Based Operations of an Autonomous Mobile Robot System for Material Handling

Byeongmok Kim, Yonggab Kim, Seokcheon Lee, Purdue University, West Lafayette, IN

In a manufacturing environment, autonomous mobile robots (AMRs) operate autonomously and with greater operational flexibility than automated guided vehicles (AGVs), which are controlled by a central system. On the other hand, the inability to find an operationally optimal solution from a global perspective partially offsets the operational efficiency of AMRs. In our study, we propose a new learning framework to achieve both operational efficiency and flexibility of operations of AMRs by learning the operating policies of AMRs based on the optimal solution of a centralized system.

2 Computer Vision and Data Mining Toward the First Large-Scale Power Transmission Network Dataset

Minsoo Choi, Purdue University, West Lafayette, IN, Contact: choi502@purdue.edu

The electric power system infrastructure is a critical part of the reliable operation of modern society, and it has expanded rapidly in the past few decades. This growing infrastructure has also been increasingly exposed to natural and weather disasters due to climate change. It thus comes as no surprise that governments and researchers need to understand and build resilient power systems. However, there is no real or realistic power transmission tower network dataset available for the research community, which means only limited research, using proxy datasets, has been possible. In this study, we propose a method that can effectively and accurately build a country-wide transmission tower network dataset using optical satellite images and deep learning. Our results are the necessary first step for power infrastructure resilience studies to advance.

3 Towards Sustainable Electric Scooter Share System: A Deep Reinforcement Learning Based Model for Charging and Rebalancing

Zhuoli Yin[1], Hua Cai[2], [1]Purdue University, West Lafayette, IN, [2]Purdue University, West Lafayette, IN, Contact: zhuoliyin@purdue.edu

Electric scooter (e-scooter) share systems offer a potentially eco-friendly commuting solution, substituting private cars and mitigating traffic congestion, but their life cycle greenhouse gas (GHG) emissions are comparable to conventional private cars, challenging their sustainability in urban mobility. Existing operational studies primarily focus on profit maximization and customer retention through rebalancing the systems without considering sustainability. This study formulates a sustainability-oriented e-scooter rebalancing model to minimize the GHG emission while meeting customer demand. To solve this model, we propose a deep reinforcement learning based algorithm that learns the optimal strategy for sustainable rebalancing, emphasizing the sustainability consideration into operational practices for micro-mobility solutions.

4 An Explainable AI-Driven Algorithmic Framework for Decision-Making Evidence from Semiconductor Scheduling

Yonggab Kim, Purdue University, West Lafayette, IN

Semiconductor manufacturing is the most complex manufacturing process and requires substantial resources. However, the design of decision-making tools has become cumbersome and slow, making it difficult to apply them to the mega fabrication lines used today. Therefore, identifying the most critical factors that have the greatest impact on business goals and designing decision-making tools capable of handling those factors is essential. Additionally, every decision made in the manufacturing process requires a significant investment, and it is vital to have an explainable and reexamined decision-making process before investing. This study focuses on the design of an OHT dispatching rule that is explainable and scalable to the real world.

Large-scale Smooth Optimization

Community Committee Choice Session

Session Chair: Igor Molybog, University of California-Berkeley, Berkeley, CA

1 Personalized Dictionary Learning For Heterogeneous Datasets

Geyu Liang, Naichen Shi, Raed Al Kontar, Salar Fattahi, University of Michigan, Ann Arbor, MI

We introduce a relevant yet challenging problem named Personalized Dictionary Learning (PerDL), where the goal is to learn sparse linear representations from heterogeneous datasets that share some commonality. In PerDL, we model each dataset's shared and unique features as global and local dictionaries. Challenges for PerDL not only are inherited from classical Dictionary Learning (DL), but also arise due to the unknown nature of the shared and unique features. In this talk, we provide a meta-algorithm called Personalized Matching and Averaging (PerMA) that can recover both global and local dictionaries from heterogeneous datasets. PerMA is highly efficient; it converges to the ground truth at a linear rate under suitable conditions. Moreover, it automatically borrows strength from strong learners to improve the prediction of weak learners.

2 Optimizing Product Profile Selection for a Single-Product Firm: A Moment Method and Robust Optimization Approach

Hsin Lu, Northwestern University, Evanston, IL, Contact: hsin.lu@kellogg.northwestern.edu

This paper analyzes a firm's problem of selecting the optimal subset of product profiles to minimize mismatch costs while meeting customer demand. The production process involves uncertainty due to engineering errors, resulting in varying probabilities of product failures. The authors propose a moment method and robust optimization framework to handle high-dimensional correlations and apply it to an actual dataset. The model considers both engineering and operational factors and identifies profiles with lower engineering error probability as generally optimal. However, offering more product profiles may be preferable under certain operational strategies if managerial costs are low relative to mismatch costs. The model provides a framework for firms to make informed decisions based on customer preferences and tradeoffs between various factors.

Networks in Machine Learning and Data Science

Community Committee Choice Session

Session Chair: Yu Tian, University of Oxford, Oxford, United Kingdom

1 Curvature-Based Clustering in Mixed-Membership Graphs

Zachary Lubberts, Johns Hopkins University, Baltimore, MD

We study the problem of mixed-membership community detection using curvature-based algorithms, which utilize discrete notions of Ricci curvature to evolve the network edge weights, elucidating community structure. These curvature-based methods are especially effective at detecting edges that act as "bridges" between communities, but in the mixed-membership setting, networks may have nodes acting as bridges rather than edges, obscuring the community boundaries. In this context, the line graph arises as a natural tool, since it takes the edges of the base graph as its vertices and connects two edges whenever they are incident on the same vertex. This transforms the bridge-finding problem into one of identifying edges again. We also investigate the relationship of discrete curvature in the line graph to that of the original graph.

2 Learning Knowledge Networks with Dynamic Latent Space Models

Aaron Schecter, University of Georgia, Athens, GA

In knowledge based organizations, it is important to match tasks to individuals with the correct expertise. This matching often involves routing problems from one individual to another. To optimize routing, accurate knowledge networks - who knows who knows what - are critical. In this paper we model knowledge networks as a latent space model, and use repeated search behaviors to iteratively learn the network structure. We apply the model to an IT service company with over 70,000 routing actions. Implications for system design and performance are discussed.

3 Nonunifrom Sampling in Link Prediction on Real-World Networks

Xie He, Dartmouth College, West Lebanon, NH

Sampling is an important task in link predictions. A good sampling on the real-world networks will result in a better link prediction result and vice versa. However, most of the time, real world network's missing information are not uniformly at random, while the current state of the art link prediction almost always assume missing edges happen uniformly at random without even knowing the reason behind. This work aims to focus on the pattern of missing edges and how the different node, edge, graph based sampling process could affect the results of various types of link prediction algorithms.

4 Robustness to Embedding Dimensions via Classically Boosted Network Embeddings

Joel Nishimura[1], Yunpeng Zhao[2], [1]Arizona State University, Glendale, AZ, [2]Colorado State University, Fort Collins, CO, Contact: joel.nishimura@asu.edu

Network embeddings are a popular and effective preprocessing step for machine learning applied to network data. We demonstrate that standard boosting techniques, AdaBoost and Real AdaBoost can be applied to network embedding techniques to improve performance on link prediction. These approaches produce results competitive with other state-of-the-art embedding approaches when applied to a number of empirical networks. Additionally, we show on simulated data that Real AdaBoost can deaggregate some networks, wherein networks created by two independent latent features can have those separate latent features inferred by different boosted rounds. Further analysis of the performance of these boosted methods shows that they retain the characteristic robustness to over-fitting as boosting methods in classical settings.

AI, Text, Image and Video Analytics

Community Committee Choice Session

Session Chair: Hyunsang Son, The University of New Mexico, Albuquerque, NM

1 Predicting User Engagement Using Textual, Image, and Video Data in Instagram: A Transfer Learning Approach

Young Eun Park, Sookmyung Women's University

2 An Interpretable Sec2sec Co-Attention Transformer for Video Emotion Prediction

Mingwei Sun[1], Kunpeng Zhang[2], [1]University of Maryland, College Park, MD, [2]University of Maryland Robert H. Smith School of Business, College Park, MD

Emotion is associated with thoughts, feelings and a degree of pleasure, which can accordingly affect people's decision-making. Two major dimensions of emotion - valence and arousal have been widely studied in the literature. Video-based emotion detection is underexplored and has some challenges. For example, how to represent different modalities (visual and audio) in a video, how to capture their alignment, and how to model the temporal structure can significantly affect the model performance. In this study, we develop a novel LSTM-based network with a transformer co-attention mechanism to predict emotions. Results of experiments show that our proposed model outperforms state-of-the-art baselines. We also investigate the role of different parts of a video in emotion prediction, which has practical implications for video designers.

3 Ai-Enabled Material Tracking System for Extreme Environments in Open-Die Press Forging

Chiseong Kim, Taeju Bak, POSTECH, Pohang, Korea, Republic of. Contact: kimchistar@postech.ac.kr

Open-die press forging involves heating ingots in a furnace and pressing them into the desired product shape. The products are low volume and wide variety, and given the repeated cycles of heating and pressing, precise material flow tracking becomes an essential requirement. Conventional methods such as barcodes or sensors are not adaptable to extreme temperature environments, necessitating manual tracking. This study proposes an AI-enabled material tracking system for extreme environments that involves video data preprocessing using computer vision technology and material tracking utilizing a convolutional neural network based object detection model. The proposed system aims to mitigate the risk of wrong delivery by ensuring accurate and reliable material tracking.

4 Transfer Learning of Effects of ESG Posting on Consumer Engagement on Social Media and Firms' Abnormal Return

Hyunsang Son[1], Young Eun Park[2], [1]The University of New Mexico, Albuquerque, NM, [2]Sookmyung Women's University, Seoul, Korea, Republic of. Contact: hson@unm.edu

Timely and accurate predictions of factors affecting consumers' engagement in social media offer various benefits for managers and advertisers. Yet, modeling textual, image, and video data and their interaction systematically and simultaneously is challenging and complex because of the lack of modeling techniques and dynamics of various features. In this study, we first build a feature set that might influence users' engagement of Interbrand 100 companies' social media posts using Fortune 500 companies' ESG or CSR reports.

Empowerment of Data Science and Information Technology in eBusiness World

Community Committee Choice Session

Session Chair: Zihong Huang, University of Minnesota Twin Cities, Minneapolis, MN

1 Love-Hate Tango: The Intriguing Dance Between Long and Short Video Platforms

Yunxuan M. Yang[1], Xingchen Xu[2], Lijia Ma[2], Yong Tan[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Washington, Seattle, WA, Contact: YUY139@pitt.edu

Numerous creators on short video platforms often generate derivative works by utilizing content from long video platforms (e.g., producing summaries of television series). However, an ongoing debate exists concerning the potential infringement of copyrights associated with derivative works and the subsequent impact on long video platforms. Utilizing a natural experiment arising from a strategic collaboration between a long video platform and a short video platform in China, we examine how this partnership influences the exposure of long video content on short video platforms and, subsequently, the consumption patterns of long video platforms. Our research also includes an in-depth exploration of underlying mechanisms and heterogeneity analyses, offering valuable insights for platforms, content creators, and regulatory bodies.

2 A Comprehensive Study of Using ChatGPT for Seeking and Sharing Knowledge

Bahar Javadi Khasraghi, Eric Walden, Texas Tech University, Lubbock, TX, Contact: bahar.javadi@ttu.edu

Individuals adopt varying approaches to acquiring knowledge. With the advent of technology, people are now utilizing advanced techniques such as OpenAI's chatGPT to actively seek and contribute knowledge. ChatGPT is a chatbot powered by OpenAI that utilizes generative AI to respond to user queries using natural language processing (NLP) techniques. Individuals use ChatGPT to answer their questions even when they feel confident in answering questions on their own. They may seek knowledge to share and contribute to the knowledge of others. Our research suggests that users might have different emphasis on ChatGPT use cases when seeking knowledge for themselves, compared to when seeking knowledge for others to contribute to their knowledge and these differences are different enough that will be some difference in some aspects of the user's behavior.

3 The Value of Remote Work in the Post-Covid Era: An Empirical Assessment of Employee Turnover and Wage

Sojung Yoon[1], Jason Chan[1], Jinan Lin[2], Tingting Nian[2], [1]University of Minnesota, Minneapolis, MN, [2]Paul Merage School of Business, UC Irvine, Irvine, CA, Contact: yoon0180@umn.edu

The abrupt closure of offices during the COVID-19 has allowed millions of workers to discover these advantages of remote work. However, the question of whether remote work will become the new normal remains unresolved, as employers are reluctant to bear the costs that accompany remote work. For firms to provide remote work as a permanent working arrangement, it is essential to understand how workers perceive and value remote work. Adopting Herzberg's two-factor theory (1959), we provide empirical evidence of how remote work is valued and to what extent, by examining the causal relationship between firms' decision to offer remote work and workers' job-switching behaviors as well as changes in wages. Given that recruitment and retention are crucial to business success, understanding this relationship would provide valuable insights into the sustainability of remote work.

Statistical and Data Mining Approaches for Decision Making

Community Committee Choice Session

Session Chair: Sangahn Kim, Siena College, Loudonville, NY

Session Chair: Mehmet Turkoz, William Paterson University, New Brunswick, NJ

1 A New Data-Driven Multivariate Process Capability Index

Sangahn Kim[1], Mehmet Turkoz[2], [1]Siena College, Loudonville, NY, [2]William Paterson University, New Brunswick, NJ, Contact: skim@siena.edu

A process is typically monitored and controlled statistically to achieve high levels of production and quality performance. Along with the philosophy of six sigma, a process is measured by a single index to determine whether a process is capable of producing products and services within the specification, i.e., capable of a certain quality performance presented by producers or customers, so called process capability indices (PCIs). So far, several univariate PCIs and only a few multivariate PCIs have been introduced. Due to the complex nature of multivariate processes, the methods used to assume specific well-known distributions such as a multivariate normal distribution. This work develops a new data-driven multivariate PCI using a support vector data description (SVDD) without the assumption of normality or any known probability distribution for the process data.

2 Spatial Randomness Kullback-Leibler Divergence-Based Approach for Monitoring Local Variations in Multimode Surface Topography

Jaeseung Baek[1], Myong Kee Jeong[2], Elsayed A. Elsayed[3], [1]Northern Michigan University, Marquette, MI, [2]Rutgers University, Piscataway, NJ, [3]Rutgers University, East Brunswick, NJ, Contact: jbaek@nmu.edu

This study presents a novel approach for monitoring local topographic variations in the presence of multimode surface topography. We present a multimode surface binarization model to enhance the representation of the surface to distinguish the defective area where binarized patterns are spatially autocorrelated. To systematically evaluate the spatial randomness of binarized surfaces and utilize it for monitoring the surface, we introduce a new probabilistic distance measure (PDM) that quantifies the similarity between two binary patterns. The proposed PDM takes advantage of identifying local variations by utilizing the order neighbor statistics, which can capture the local property of binary patterns. Experimental results with numerical simulation data and real-life paper surface data are provided to show the effectiveness of the proposed approach.

1 Unleashing the Power of the 4P4C Model: A Novel Approach for Forging a Bridge Between Marketing Analysis and Strategic Business Decision in the Heavy Machinery Industry

Tian Tian, Kai Shu, Sai Zhang, Illinois Institute of

Technology, Chicago, IL, Contact: ttian4@hawk.iit.edu
This article presents a groundbreaking approach, the 4P4C model (Product, Place, Period, Prediction, Company, Chart, Comparison, and Clustering dimensions), to analyze sales data of heavy machinery products in the United States. By embracing a multidimensional perspective, this novel methodology enables a meticulous and all-encompassing examination of the market, unveiling crucial trends and patterns that may elude conventional approaches. Furthermore, through the detailed exploration of essential data collection and analysis aspects such as product, place, period, prediction, company, chart, comparison, and clustering, the model accurately sheds light on areas ripe for data collection and data-driven improvement. This innovative approach offers insights for businesses and organizations, empowering them to make well-informed decisions.

2 Optimizing Nuclear Power Plant'S Environmental Factors Through Functional Design of Experiments

Kangwon Seo, Benjamin Oguejiofor, University of Missouri, Columbia, MO, Contact: seoka@missouri.edu
Nuclear power plants rely on cooling systems to ensure the safe and reliable operation of the nuclear reactor. During operation, the reactor coolant pump (RCP) functions to circulate demineralized light water under pressure through the reactor vessel and loops. The RCP provides forced primary coolant flow to remove and transfer the amount of heat generated in the reactor core. In this study, a sample of continuous vibration signal data from an RCP of a nuclear power plant was analyzed. The continuous signal was acquired approximately every five seconds and visualized in real-time for trending and monitoring. Using wavelet functional analysis, we extract functional principal components (fPCs). Establishing a relationship between fPCs and environmental factors, the vibration signals will be controlled in an optimal shape.

3 Practical Implementations of the Multi-Period Model for a New Facility in a Horizontal Collaborative Network

Dilhani Shalika Marasinghe, Pubudu LW Jayasekara, University of Tennessee Chattanooga, Chattanooga, TN, Contact: dmarasi@g.clemson.edu
This study focuses on a facility type that has high throughput with a primary function of organizing and rerouting freight contained on pallets or pallet-like containers. The key difference with the existing similar facilities is that the freight does not have a predetermined path from origin to destination established before it begins its journey. Different policies have been introduced for enhancing the efficiency of operations in a unit load facility that is part of a horizontal collaborative network. The performance of the policies is evaluated by the total cost obtained by assigning pallets to locations under different conditions.

Supply Chain Methods in Practice

Contributed Session

Session Chair: Zuochun Tang, IBM, San Francisco, CA

1 A Strategic Decision-Making Tool for Last Mile Delivery Using Simulation

Raghavan Srinivasan[1], Joseph Gerard Szmerekovsky[2], [1]Ball State University, Muncie, IN, [2]North Dakota State University, Fargo, ND
To determine an aggregate delivery capacity plan for last mile delivery services, we conducted a simulation analysis. This simulation is done considering the use of permanent resources, seasonal resources and utilizing crowdsourcing capacity to meet the demand while aiming to achieve the lowest operational cost. In addition, we also consider the case of resource attrition and missed deliveries being fulfilled the next day. The results from the simulation runs lead to an overall understanding of the capacity needed to meet the desired service level. The use of crowdsourcing capacity can be influential in meeting the demand and lowering operational expenses.

2 Artificial Intelligence Frameworks for Supply Chain Digital Transformation in the Pc Industry

Suri Gurumurthi, Hong Kong University of Science and Technology, Kowloon, Hong Kong
The PC and consumer electronics industry has seen double digit declines in recent years with weakening demand and intensifying competition. This sector is of vital importance to the financial and economic health of several countries. The industry leaders are racing to cut costs and boost profitability in the face of the sharpening decline. We explore digital transformation frameworks that can potentially deliver greater efficiencies for this industry, while enhancing responsiveness. We identify the areas where Artificial Intelligence and Machine Learning tools have the greatest impact, and outline a recent case study based on the efforts of one of the

leading companies in the sector. We highlight some issues in implementation, and suggest some solutions that could accelerate the digital transformation efforts.

3 A Supplier Risk Scoring Framework for Strategic Alignment and Proactive Decision-Making

Zuochun Tang[1], Yihua Li[2], [1]IBM, san francisco, CA, [2]IBM, San Francisco, CA, Contact: ztang@us.ibm.com

Supplier risk scoring is critical for business success in complex supply chains. However, the absence of standardized scoring is a challenge due to diverse risk metrics, supplier diversity, and complex supply chain processes. Our proposed framework tackles these challenges by employing hierarchical categorization and rule-based guidelines. It effectively aligns supplier risk scoring with customer business strategies while utilizing machine learning techniques to address data quality and availability risks. By offering proactive risk warnings and aiding informed decision-making, the framework supports various industries. It considers diverse business data sources, including sustainability and financials, and caters to customer-specific interests.

Optimization for Advacing Machine Learning Methods

Contributed Session

Session Chair: Yinsong Wang, Northeastern University, Boston, MA

1 Path of Solutions for Non-Smooth Fused Lasso

Cheng Lu[1], Tor Nitayanont[2], Dorit Simona Hochbaum[2], [1]Apple, Cupertino, CA, [2]University of California-Berkeley, Berkeley, CA, Contact: torpong_nitayanont@berkeley.edu

In a fused lasso problem on a sequence data, the objective consists of two competing terms: the separation term and the deviation term. The two terms are balanced via a tradeoff parameter. Selecting a value for the tradeoff parameter is critical. However, we often do not know the quality of a certain tradeoff value until we obtain the solution. Here, we propose a minimum cut-based method that solves for all tradeoff values at once. This method eliminates the need to pre-specify tradeoff values since it solves the problem for all values that yield different solutions. Moreover, we prove that, for the L1 deviation, the number of solutions across all tradeoff values is at most 2n^3 for n variables. In fact, experimental results show a linear bound. For a general convex deviation function, the bound is 2n^3(U/⍰) where ⍰ is the solution accuracy and U is the range of variables.

2 A New Classification Method Based on Tuning of Hyper-Parameter and Decision Threshold for Imbalance Data

Tai-Jung Chen, Kwok-Leung Tsui, Virginia Tech, Blacksburg, VA, Contact: taijungchen@vt.edu

In many real world two-class classification problems, the data are imbalanced. This sometimes leads to naïve classifiers of predicting all the samples as the majority class and may result into misleading accuracy, poor precision, and confusing conclusions. One of the key reasons for the poor performance is related to the inappropriate decision threshold. Conventionally, the decision threshold of a two-class classification problem is set to 0.5, which may not be the best choice for imbalance data. In this paper, we propose a simultaneous tuning method that tunes the model hyper-parameter along with the decision threshold. We select Cohen's kappa as the tuning metric and re-interpret Cohen's kappa as measuring the improvement over a baseline classifier called p-naïve classifier. Finally, we extend the idea of kappa to other standard classification metrics such as f1 score.

3 Inverse Mixed-Integer Optimization for Learning Interpretable Decision Rules

Rishabh Gupta[1], John Wassick[2], Qi Zhang[1], [1]University of Minnesota, Twin Cities, Minneapolis, MN, [2]Carnegie Mellon University, Pittsburgh, PA

Humans rely on heuristics to simplify the complexity and ambiguity of real-world decision making. We propose a data-driven framework for learning these decision-making rules based on inverse optimization (IO). Our approach leverages the powerful modeling capability of mixed-integer optimization to incorporate domain knowledge and model complex logical relationships between decisions. IO is then used to learn the importance of each decision through its weight in the objective function, which provides interpretable insights into the decision policy of the decision maker. The effectiveness of the proposed framework is demonstrated through supply chain planning-based case studies.

4 Tap: The Attention Patch for Cross-Modal Knowledge Transfer from Unlabeled Modality

Yinsong Wang, Shahin Shahrampour, Northeastern University, Boston, MA, Contact: wang.yinso@northeastern.edu

This paper addresses a cross-modal learning framework, where the objective is to enhance the performance of supervised learning in the primary modality using an unlabeled, unpaired secondary modality. We show that the extra information contained in the secondary modality can be estimated via Nadaraya-Watson (NW) kernel regression, which can further be expressed as a kernelized cross-attention module (under linear transformation). Our results lay the foundations for introducing The Attention Patch (TAP), a simple neural network add-on that allows data-level knowledge transfer from the unlabeled modality. We provide extensive numerical simulations using four real-world datasets to show that TAP can provide statistically significant improvement in generalization across different domains and different neural network architectures.

Bin Packing: Algorithms and Applications

Contributed Session

Session Chair: Yanzhi Li, City University of Hong Kong, Hong Kong, Hong Kong

1 Three-Dimensional Container Loading Problem Solved by an Innovative-And-Iterative Algorithm

Yao-Huei Huang, Zi-Hsuan Lin, Fu Jen Catholic University, New Taipei City, Taiwan. Contact: ccc888880@gmail.com

This study addresses a novel method for the three-dimensional container loading problem (3DCLP), which is an NP-hard problem in management science and operations research. To reduce computational complexity and guarantee solution quality, this study designs a 3D relative-positions scheme so that the 3DCLP can be relaxed to a linear programming problem. Solving the relaxed 3DCLP can obtain a feasible solution. Subsequently, an innovative-and-iterative algorithm is designed to enhance the solution quality. Experimental results have shown that the proposed method has higher efficiency and accuracy in dealing with complex three-dimensional container loading problems.

2 Innovative and Iterative Algorithm with Relative-Positions Scheme for the Two-Dimensional Variable Sized Bin Packing Problem

Yao-Huei Huang, Hao-Jing Lin, Fu Jen Catholic University, New Taipei City, Taiwan. Contact: jinlin95040@gmail.com

The two-dimensional variable sized bin packing problem (2DVSBPP) is a classical problem in the field of management science and operations research. This study proposes a novel method that uses a relative-positions scheme to address the relaxed 2DVSBPP linear programming problem. Additionally, an innovative and iterative algorithm is adopted to improve the solution quality iteratively. The proposed algorithm not only obtains optimal solutions for small-scale problems, but also enhances the solution quality for large-scale problems. Numerical experiments also show that the proposed algorithm outperforms state-of-the-art algorithms.

3 Lower Bounds and Heuristics for the Multi-Class Constrained Bin Packing Problem

Baptiste Coutton[1], Dario Pacino[2], Klaus Holst[1], Stefan Guericke[3], Martin Kidd[4], [1]Maersk, Copenhagen, Denmark; [2]DTU, Kobenhavn, Denmark; [3]Hochschule Osnabrück, Osnabrück, Germany; [4]Vatenfall, Copenhagen, Denmark. Contact: bnco@dtu.dk

We study a variant of the Bin Packing Problem where, in addition to a size, items have a set of attributes (classes) for which they can take different values. Each bin has a limited capacity regarding the total size and the number of distinct values per attribute it can accommodate. The aim is to find the cheapest set of bins in which all items can fit. We propose two lower bounds as well as four greedy heuristics and an ALNS metaheuristic to solve the problem, the latter outperforming a commercial solver.

4 Integrated Multi-Level Multi-Item Capacitated Lot-Sizing and 2-Dimensional Packing Problem in Integrated Steel Production

Jeff Young[1,2], Defeng Sun[3], Lixin Tang[1], [1]National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China; [2]Key Laboratory of Data Analytics and Optimization for Smart Industry (Northeastern University), Ministry of Education, China, Shenyang, China; [3]Liaoning Engineering Laboratory of Data Analytics and Optimization for Smart Industry, Shenyang, China. Contact: yang_jie_fu2013@live.com

Integrated Steel Production (ISP) become the mainstream production in the steel industry. It incorporates multi-stage operations production (casting, rolling, etc.), which involves coupled multi-level multi-item capacitated lot-sizing and 2-dimensional packing problems. As a consequence, planning in ISP become increasingly challenging due to its large scale and interconnectedness. To address the problem, this paper formulates a mixed-integer programming model, which considers the widespread difficulties such as the batching production for orders with similar properties. And then the proposed model is solved by a Branch-Price-Cut algorithm. We apply Lagrangian relaxation and dynamic programming methods to improve the solving process of subproblems. Computational results on different sets of instances show the effectiveness of the new exact algorithm.

5 Anticipatory Packing

Tongwen Wu[1], Z. Max Shen[2], Yanzhi Li[1], [1]City University of Hong Kong, Hong Kong, China; [2]The University of Hong Kong, Hong Kong, China. Contact: yanzhili@cityu.edu.hk

In this paper, we study a novel practice termed anticipatory packing, which is to prepare some packages in non-peak periods to be used for fulfilling orders in the subsequent peak periods. Specifically, the preparation involves the operation of picking some items and putting them in the same customer bin but may not involve actual packaging. For effective anticipatory packing, we develop a sample-average approximation (SAA) model by using the order data of recent days and then design an effective approximation algorithm to solve it. We investigate the effectiveness of anticipatory packing and the SAA model with extensive experiments. On a real data set, we show that anticipatory packing can yield an significant operational cost reduction.

Emprical and Experimental Analysis of Online Retailers

Contributed Session

Session Chair: Yunhao Huang, UC Berkeley, Berkeley, CA

1 Do Consumers Return More when They Browse More Alternatives?

Ragip Gurlek[1], Diwas S. KC[2], Paolo Letizia[3], [1]Emory University, Atlanta, GA, [2]Emory University, Atlanta, GA, [3]University of Tennessee, Knoxville, TN, Contact: rgurlek@emory.edu

Although the existing literature establishes a relationship between product variety and purchase behavior, the impact on product returns has been overlooked. To address this gap, we conduct a study using clickstream and transaction data from 4 million unique visitors to a fashion accessories e-retailer. Our investigation utilizes a natural experiment setting, capitalizing on the exogenous variation caused by product model characteristics. The findings reveal that browsing one more SKU not only decreases the likelihood of a consumer visit being converted into an order but also increases the probability of a product return.

2 Ride the Wave or Not? the Spillover Effect of Online Shopping Festivals and Best Timing for Advertising

Yue Wang[1], Xiaobei Shen[2], Xiabing Zheng[2], [1]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]University of Science and Technology of China, Hefei, China. Contact: ywangmk@connect.ust.hk

This work explores the spillover effect of online shopping festivals on short-video advertising through a natural experiment. Online shopping festival has a spillover effect on short-video advertising and the effect changes over time. It is positive in the warm-up and general-promotion periods, and becomes negative in the peak-promotion and post-promotion periods of the festival. We propose three mechanisms to explain the positive effect (i.e., festival's environmental cues) and the negative effects (i.e., diminishing marginal utility and financial constraints of consumers). We conduct a field experiment, several surveys, and use some model-free evidence to verify the existence of these mechanisms. The results suggest firms may ride the wave of exogenous festivals, but shall carefully choose the best timing for their advertising.

3 How Does Offline Store Opening Affect Nearby Consumers' Online Market Baskets?

Youngsoo Kim, Texas Tech University, Lubbock, TX

We empirically examine how an offline store entry affects online consumer's purchase behavior. Our analyses show that online consumers' market baskets substantially change when an offline store opens. We find that different consumer segments respond differently to a store entry, and that the dominant store entry effects are determined by product types. Our results also show that (1) the final direction of store entry effects depends on consumer segments rather than product types; (2) when a pre-existing superstore exists, the number of items purchased online is not affected by a new store entry; (3) the decreased number of items purchased online decreases even after 6 months.

4 Unmasking the Deception: The Interplay Between Fake Reviews, Rating Dispersion, and Consumer Demand

Yunhao Huang, J. Miguel Villas-Boas, Mingduo Zhao, University of California, Berkeley, Berkeley, CA

This study explores the interplay between fake reviews, rating dispersion, and consumer demand. Using rating distribution rounding-induced dispersion changes as an identification strategy, we find that rating dispersion negatively affects sales. Then, we examine the connection between fake reviews and rating dispersion using an observational study. To investigate the underlying mechanism, we conduct an experiment and show that increased rating dispersion raises concerns about fake reviews, impacting consumer demand. We introduce an information treatment warning consumers about fake reviews, an instrumental variable (IV), to determine the impact of consumer suspicion of fake reviews on their demand. Crucially, the treatment has a greater impact on socially disadvantaged groups, indicating its potential to promote equity in the online marketplace.

Circular Economy and Sustainability Considerations

Contributed Session

Session Chair: Can Baris Cetin, HEC Montreal, Montreal, QC, Canada

1 Supply Chain Relationship Dependencies and Circular Economy Performance: The Contingency Role of Digitalization Capability

Mingjie Fang[1], Yanling Yu[2], Kwangtae Park[3], Feng Liu[2], Shufeng (Simon) Xiao[4], Yangyan Shi[5], [1]Korea University Business School (KUBS), Seoul, Korea, Republic of; [2]Shandong University, Weihai, China; [3]Korea University Business School (KUBS), Seoul, Korea, Republic of; [4]Sookmyung Women's University, Seoul, Korea, Republic of; [5]Macquarie University, Sydney, Australia. Contact: mj_fang@korea.ac.kr

Drawing on resource dependence theory, we investigated how the degree of dependence of focal firms on suppliers and customers affects their CE performance. Employing hierarchical linear modeling on a panel dataset of listed Chinese manufacturers during 2010-2020, we found that the more dependent a firm is on its major suppliers and customers (the higher the supplier and customer concentrations), the worse its CE performance. In addition, we utilized data mining techniques to capture manufacturers' digitalization capabilities. We examined how digitalization empowers manufacturers to alleviate power imbalances in supply chain dependencies. Our results suggest that the manufacturers' digitalization capability significantly weakens the negative impacts of supplier and customer concentrations on CE performance.

2 From Linear to Circular Economy: A Newsvendor's Perspective

Haokun Chen[1], Stanko Dimitrov[1], Xuan Zhao[2], [1]University of Waterloo, Waterloo, ON, Canada; [2]Wilfrid Laurier University, Waterloo, ON, Canada. Contact: h463chen@uwaterloo.ca

The circular economy promises to reduce waste and enable us to live in a sustainable manner. In this work, we examine the transition from the current linear economy to the circular economy through the lens of a newsvendor model. The insights we provide may be surprising but will inform regulators and firms on the impact of the transition from the linear to the circular economy.

3 Environmental Disclosure in Supply Chains

Jie Lian[1], Yan Dong[1], Sining Song[2], Natalie Ximin Huang[3], [1]University of South Carolina, Columbia, SC, [2]University of Tennessee Knoxville, Knoxville, TN, [3]University of Minnesota, Minneapolis, MN

Firms in supply chains have increasingly adopted environmental disclosure to improve environmental performance. This research studies the spillover effect of a firm in disclosing its environmental performance on its suppliers' decision to do the same. The firm's disclosure creates both a pressure to disclose and an opportunity to freeride. Using panel data and econometric analysis, we investigate the outcome of this tradeoff in supply chains.

4 Strategic Pricing and Investment in Environmental Quality by an Incumbent Facing a Greenwasher Entrant

Can Baris Cetin[1,2], Arka Mukherjee[3], Georges Zaccour[2,1], [1]HEC Montreal, Montreal, QC, Canada; [2]GERAD, Montreal, QC, Canada; [3]Concordia University, Montreal, QC, Canada. Contact: can-baris.cetin@hec.ca

We examine how greenwashing affects the strategies and outcomes of companies and consumers. We develop a two-stage game, where a monopolist sets price and invests in environmental quality in the first stage, and competes with a new entrant in the second stage. The incumbent company is genuinely environmentally friendly, while the new entrant may use deceptive green marketing. We assume that only inexperienced consumers can be influenced by greenwashing, and consider two important dynamic factors, i.e., a change in competitive structure and a learning effect in the market. We investigate the conditions under which greenwashing is profitable for the new entrant, the ways in which the incumbent company responds to it, and the impact of greenwashing on the environment and consumers.

On Online Retail Operations

Contributed Session

Session Chair: Pantelis Loupos, University of California, Davis, Davis, CA

1 Selling Format, Advertising Selling And Information Sharing In Online Retailing

Jianyue Wang, Albert Ha, Ki Ling Cheung, The Hong Kong University of Hong Kong, Hong Kong, China. Contact: jwangen@connect.ust.hk

We study the selling format (agency selling versus reselling) and the strategies of seller services (advertising and information sharing) in a supply chain with a supplier and an online retailer. For a game theoretic model with both seller services, we fully characterize its equilibrium and show how each firm's preference of the selling format depends on the model parameters. We also consider two other models with either advertising service only or no seller services. By comparing the models, we show how the offering of more seller services impacts the firms' profits as well as their preference of the selling format.

2 Anti-Counterfeit Strategies over E-Commerce Platforms

Ayesha Arora[1], Tarun Jain[2], [1]Indian Institute of Management Bangalore, Bangalore, India; [2]Indian Institute of Management Bangalore, Bangalore, India. Contact: ayesha.arora19@iimb.ac.in

Online sellers often sell counterfeit products over e-commerce platforms. We compare scenarios where different parties take actions to detect counterfeits and penalize the seller. Our research reveals some interesting managerial insights for the platforms and the regulators.

3 Dynamic Analysis of Language Style and Customer Attrition on Venmo

Pantelis Loupos, University of California, Davis, Davis, CA

We investigate the impact of language style and transactional topics on customer attrition on Venmo. Our study dynamically analyzes Venmo users and their interactions within their communities, and finds that changes in language style, particularly in description comments, can predict attrition. Additionally, the nature of transactions can also have an impact on attrition. Our findings highlight the importance of language style and transactional topics in predicting customer attrition, and suggest that targeted interventions based on these factors can help improve customer retention on Venmo.

Inventory Management: Algorithms and Applications

Contributed Session

Session Chair: Zhaoxuan Wei, 1</sup

1 Transportation Asset Acquisition Under a Newsvendor Model with Cutting Stock Restrictions: Approximation and Decomposition Algorithms

Joris Wagenaar, Tilburg University, Tilburg, Netherlands. Contact: j.c.wagenaar_1@uvt.nl

Logistics service providers use transportation assets to offer services to their customers. To cope with demand variability, they may require additional assets on a one-off (spot) basis. The planner's problem is to determine the optimal level of assets acquired upfront such that their cost is minimized. We introduce a two-stage newsvendor model where demand for spot assets is derived through optimal cutting stock patterns. Leveraging results from bin-packing, we propose polynomial algorithms that have worst-case guarantees for upper and lower bounds. Out method finds optimal solutions to instances intractable by commercial solvers.

2 Online Inventory Control with Partial Backorder

Zhaoxuan Wei[1], Andrew Lim[1], Hanqin Zhang[2], [1]National University of Singapore, Singapore, Singapore; [2]National University of Singapore, Singapore, Singapore. Contact: e0546201@u.nus.edu

We consider a single-product inventory model where the unmet demands may be either patient and choose to wait (backorder) or lose their patience and leave (lost sale), which can be taken as the hybrid of the canonical lost-sales and backorder model. With perfect information about the system primitives and perfect observation of the states of the system, we show that the base-stock policy is a uniformly asymptotically optimal policy. We then consider a more practical problem where the system primitives are unknown and only the sales are observed. Compared to the literature, our problem has unique challenges as (a) the state of the system is only partially observable and (b) the sales are mixed by the exogenous demand and the backorder. An UCB-type algorithm is then developed and we prove the regrets of the algorithm are (nearly) tight in the planning horizon T.

Managing Inventory in the Presence of Lead Time and Demand Correlation

Fouad H. Mirzaei[1], Andy A. Tsay[2], [1]University of North Texas, Denton, TX, [2]Santa Clara University, Leavey School of Business, Santa Clara, CA, Contact: fhmirzaei@unt.edu

Numerous studies commonly assume that lead time and daily demand are independent. In this study, we relax the assumption of independence between lead time and demand in a continuous review inventory system. By analyzing the optimal ordering policy, we compare the uncorrelated and correlated cases. Our findings demonstrate that considering the correlation between demand and lead time adds complexity, but it also leads to more generalized and robust recommendations.

Big Data Analytics for Higher Education

Community Committee Choice Session

Session Chair: Roger R. Gung, University of Phoenix, Phoenix, AZ

1 Behavior Risk Model and Interaction Optimization

Roger R. Gung, University of Phoenix, Phoenix, AZ

Classroom behavior is the early indicator of student learning outcomes. In online education, classroom behavior is stored in an Hadoop based big data system, that can be used to measure students' quality and risk to learning performance metrics. Using the quality and risk models output, in conjunction with interaction data, the model recommends the optimal interaction topic that would maximize the expected improvement of the quality and risk.

2 Short-term and Long-term Course Starts Forecasting

Jixiang Fang, University of Phoenix, Tempe, AZ

Course starts in adult on-line learning is the key performance indicator of student retention. In this research, we developed recursive survival model based forecasting method to predict each student's probability to take the course on a given course start date. For a given future course start date, all possible scenarios are analyized to measure the probability of starting the course. The method yields accurate forecast for the near future course start dates, as welll as the one-year out course start date.

New Models in Revenue Management

Community Committee Choice Session

Session Chair: Zhenyu Hu, Singapore, Singapore

1 learning Mixed Multinomial Logits with Provable Guarantees and Its Applications in Multi-Product Pricing

Yiqun Hu[1], Limeng Liu[2], David Simchi-Levi[3], Zhenzhen Yan[2], [1]Amazon, Chelsea, NY, [2]Nanyang Technological University, Singapore, Singapore; [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: yanzz@ntu.edu.sg

A mixture of multinomial logits (MMNL) is commonly used in modeling market demand to capture consumer heterogeneity. We propose a new algorithm built on the Frank-Wolfe (FW) method that learns both mixture weights and component-specific logit parameters with provable convergence guarantees for an arbitrary number of mixtures. Our algorithm utilizes historical choice data to generate a set of candidate choice probability vectors, each being close to the ground truth with a high probability. We further provide a sample complexity analysis to show that only a polynomial number of samples is required to secure the performance guarantee of our algorithm. Finally, we apply the learned MMNL to data-driven multi-product pricing problems. Numerical studies are conducted to evaluate the performance of the proposed algorithms.

2 Content Rotation in the Presence of Consumer Satiation

Xiao Lei[1], Shixin Wang[2], [1]University of Hong Kong, Hong Kong, Hong Kong; [2]The Chinese University of Hong Kong, Hong Kong, China

Content rotation is a common practice in the service industry to moderate operating costs and avoid customer satiation. However, designing an optimal rotation schedule remains a challenge. In this paper, we investigate how customers interact with rotation schedules, and how the correlation among service products affects the optimal rotation schedule. We also examine the impact of other factors, such as customer strategic behavior and sellers' competition. Our study aims to provide computational methods as well as managerial insights for service providers to make informed decisions about their rotation schedules.

3 Optimal Dynamic Mechanism Under Customer Search

Zhenyu Hu, Yangge Xiao, National University of Singapore, Singapore, Singapore

This paper investigates the seller's revenue-maximizing mechanism in the face of a customer who searches for outside alternatives over a finite horizon. Under a general recall function, we show that the optimal strategy for the seller is to offer a menu of American options consisting of deposits and strike prices. In the case where the customer can only recall a few recent outside alternatives, we further establish that customers with low valuation search for outside alternatives without engaging with the seller, while high-valuation customers exercise the option immediately, effectively turning the option into an exploding offer. Customers with intermediate valuation will only exercise the option, if ever, at the end of the search horizon. The seller's revenue decreases with more alternatives but it may first decrease and then increase as search cost increases.

Machine Learning and Analytics in Business Decision Making

Community Committee Choice Session

Session Chair: Heng Zhang, Arizona State University, Tempe, AZ

Session Chair: Dennis Zhang, Washington University in St Louis, ST LOUIS, MO

1 A Learning and Optimization Method for Personalized Product Design

Mengxin Wang[1], Meng Qi[2], Zuo-Jun Max Shen[3], [1]University of California, Berkeley, Berkeley, CA, [2]Cornell University, Ithaca, NY, [3]University of California Berkeley, Berkeley, CA, Contact: mengxin_wang@berkeley.edu

The product design problem aims to select a combination of features for a new product that maximizes the revenue of the releasing company. We developed an estimation and optimization framework that uses customer data to personalize product design. We present a learning method for estimating model parameters from choice-based conjoint data and provide finite sample performance guarantees for our estimation and optimization results. Our results, as far as we know, fill in the gap in the product design literature with the first finite sample performance guarantee. Our theoretical results reveal a missing angle in the literature that the assortment size in conjoint data can affect learning algorithm efficiency and provide insights for collecting conjoint data more efficiently. Numerical results validate our theoretical findings.

2 Estimating Effects of Long-Term Treatments

Shan Huang[1], Chen Wang[2], Yuan Yuan[3], Jinglong Zhao[4], Zhang Jingjing[5], [1]University of Hong Kong, Seattle, WA, [2]The University of Hong Kong, Hong Kong, Hong Kong; [3]Purdue University, West Lafayette, IN, [4]Boston University, Boston, MA, [5]Tencent Inc., Shenzhen, China

One lingering challenge of randomized controlled trials (or A/B tests) is to estimate the effects of long-term treatments. Learning such effects is crucial for management but conducting long-duration experiments is costly. In this paper, we propose a longitudinal surrogate model to estimate the effects of long-term treatments using data collected from short-term experiments and historical observations. We show that under standard assumptions, the effect of long-term treatments can be decomposed into a sequence of functions that depend on the user attributes, their short-term intermediate metrics, and the treatment assignments. We conduct two large-scale long-term experiments on WeChat, an instant messaging platform, and demonstrate the effectiveness of our methods.

Community Committee Choice Session

Session Chair: Xu Han, 1</sup

Session Chair: Lin Hao, Fordham University, New York City, NY

1 A Design Framework For Detecting And Understanding Ai-generated Texts: Fusing Transformers And Linguistic Features

Sen Yan, Zhiyi Wang, David Dobolyi, University of Colorado, Boulder - Leeds School of Business, Boulder, CO

AI-based large language models, represented by OpenAI's ChatGPT, have advanced rapidly, prompting the need for reliable detection methods and a systematic understanding of AI-generated content. In this study, we present a novel detector for AI-generated texts leveraging RoBERTa, a transformer-based model, and linguistic feature analysis for accurate and interpretable AI-text detection. The proposed detector exploits RoBERTa for its superior performance in capturing semantic relationships and uses linguistic features for recognizing AI-text patterns. Our study provides insights into AI-generated content detection and a better understanding in terms of the patterns of AI-generated texts. We inspire further research in AI text detection and responsible AI, and offer implications for digital platforms to better screen AI-generated content.

2 Examining the Effects of Firms' Dei Tweets with Deep Learning

Lingshu Hu[1], Weilu Zhang[2], [1]Washington and Lee University, Lexington, VA, [2]University of Kentucky, Lexington, KY, Contact: lhu@wlu.edu

Previous research has demonstrated that firm-generated content on social media plays a significant role in achieving marketing excellence. However, the question of what constitutes the "right content" remains unknown, especially with respect to the impact of Diversity, Equity, and Inclusion (DEI) related content. Therefore, this study uses tweets collected weekly from Fortune 1000 companies and users who mentioned these companies from May 2022 to May 2023 to develop a machine learning pipeline with pre-trained models that identifies various types of tweets discussing DEI topics. The study then analyzes the effects of these tweets on the firms' popularity and likability gains, implements NLP algorithms to investigate public perceptions of these firms on Twitter, and examines how the political orientation of the firms' followers moderates the effects of DEI tweets.

3 Algorithmic Recommendations Change Guys' Patience but Not Gals': Evidence from a Field Experiment

Guangrui(Kayla) Li[1], Zheng Gong[2], Xiaoquan(Michael) Zhang[3], [1]York University, Toronto, ON, Canada; [2]CUHK(SZ), Shenzhen, China; [3]Tsinghua University, Shenzhen, China. Contact: kaylali@schulich.yorku.ca

Algorithmic recommendations are widely used to predict user preferences and suggest relevant content or products. These recommendations can have a lasting impact on us by altering our preferences. One important preference algorithms can influence is patience - the marginal substitution rate between current and future consumption. While traditional video consumption involves active searching, algorithmic recommendations provide instant and continuous content, potentially decreasing users' patience. However, this constant content stream can also enhance happiness and positive moods, potentially increasing users' patience. To explore this, we conducted lab and field experiments. Interestingly, we observed that male users exhibited increased patience after disabling algorithmic recommendations, whereas no significant change was found among female users

4 Tensor Completion on Panel Data: Uncovering the Effect of Smart Vending Machine

Mingrui Zhang, University of Washington- Michael G. Foster School of Business, Seatttle, WA, Contact: mz74@uw.edu

Smart vending machines have revolutionized the retail industry by generating vast amounts of panel data encompassing sales, customer behavior, location of the machine, and operational performance. However, the presence of missing or incomplete data poses a challenge in accurately assessing the effects of these machines. To overcome this limitation, we apply tensor completion techniques to fill in data gaps and uncover the impact of smart vending machines on sales compared to traditional machines. Moreover, we combine the scenario and the region information to construct estimates of the vending machines' demands in different regions across different scenarios. This allows us to gain insights into the variations in demand patterns across other locations and circumstances, providing valuable information for optimizing the placements of vending machines.

Pricing and Inventory Estimation

Contributed Session

Session Chair: Fatemeh Nosrat, Rice University, Houston, TX

1 Probabilistic Inventory Estimation in Grocery with Inaccurate Records

Clement Micol, Aaron Stern, Afresh, San Francisco, CA, Contact: aaron.stern@afreshtechnologies.com

Inventory management is important in industries such as grocery and retail, but taking inventory can be tedious and time-consuming. Perpetual inventory methods are often used to estimate inventory, but these methods are sensitive to inventory record inaccuracy (IRI) and perishability. To improve inventory estimate accuracy, we present a probabilistic generative model (InvHMM) that explicitly models IRI and perishability. We use a particle filter to infer the posterior inventory, as well as a novel particle smoothing algorithm to estimate past inventory retrospectively. On a dataset from a major US grocery chain, InvHMM improves inventory estimate accuracy over a simply perpetual inventory by >40% and gives well-calibrated confidence bounds.

2 Willingness-to-Pay Estimation and Pricing Optimization for Airline Seat Assignment and Branded Fares

Sajad Aliakbari Sani[1], Adam Bockelie[1], Tianjiao Liu[1], Alan Regis[1], Yury Sambale[1], Cindy Yao[1], Alvarez Aldair[2], Dan Teodora[3], Carl Perreault-Lafleur[2], Emma Frejinger[4], Andrea Lodi[5], Guillaume Rabusseau[3], [1]Air Canada, Montreal, QC, Canada; [2]IVADO Labs, Montreal, QC, Canada; [3]IVADO LABS, Montreal, QC, Canada; [4]Université de Montreal, Montreal, QC, Canada; [5]IVADO labs, Montréal, QC, Canada

In response to different customer needs and preferences, airlines provide branded fares, a set of offers that bundle flights with other travel ancillaries and privileges like seat assignment, checked baggage, and flexibility for rescheduling or cancellation, etc. Decision makers are faced with the challenge of setting the markup price, the increment or decrement amount relative to a base fare brand, in such a way that maximizes total revenue. There are not many branded fare price optimization models presented in the literature that can be applied in practical settings. We present a machine learning willingness-to-pay estimation model and a price optimization model for branded fares that we designed and deployed at a major airline.

3 Risk-Averse Network Revenue Management

Christiane Barz[1], Martin Glanzer[2], [1]University of Zurich, Ermatingen, Switzerland; [2]University of Mannheim, Mannheim, Germany. Contact: christiane.barz@uzh.ch

We consider the network capacity control problem from the perspective of a risk-averse expected exponential utility maximizing revenue manager. To overcome the curse of dimensionality of the corresponding risk-sensitive Markov decision process, we build on a mathematical programming based ADP approach with a new multiplicative (monomial) value function approximation. Reformulating the resulting nonconvex approximate model as a signomial program and reducing the problem analytically, we present an algorithm that determines risk-averse acceptance policies. Policies generated by our algorithm resemble the popular structure of bid price controls and can decrease the revenue risk substantially in return for sacrificing only little expected revenue, as we illustrate with numerical examples.

4 Assortment Planning Problems with Network Effects Under Mixed Multinomial Logit Choice Models

Fatemeh Nosrat[1], William L. Cooper[2], [1]Rice University, Houston, TX, [2]University of Minnesota, Twin Cities, Minneapolis, MN, Contact: fn12@rice.edu

A product displays non-negative network effects if each customer's valuation for the product increases in its overall sales. In the case of multiple products, strategic firms must decide which subset of products to offer to customers to maximize their revenue. The problem of selecting the optimal assortment of products is known as assortment planning. We aim to identify the best assortment of products given network effects and multiple customer segments, using a mixed multinomial logit choice model as the base demand. Since the problem is NP-hard, we provide a method for constructing upper bounds on the optimal expected revenue. We demonstrate that well-known policies, such as revenue-ordered and quasi-revenue-ordered assortments, are not generally optimal. Instead, we introduce a new, tractable set of policies called k-quasi-revenue-ordered assortments.

Optimization over Probability Distributions: New Developments

Community Committee Choice Session

Session Chair: Daniel Alabi, Columbia University, New York, NY

1 Near-Optimal Fitting of Ellipsoids to Random Points

Prayaag Venkat, Harvard University

Given n independent standard Gaussian points in dimension d, for what values of (n, d) does there exist with high probability an origin-symmetric ellipsoid that simultaneously passes through all of the points? This basic problem of fitting an ellipsoid to random points has connections to low-rank matrix decompositions, independent component analysis, and principal component analysis. Based on strong numerical evidence, Saunderson, Parrilo, and Willsky (2011) conjectured that the ellipsoid fitting problem transitions from feasible to infeasible as the number of points n increases, with a sharp threshold at $n \sim d^2/4$. We resolve this conjecture up to logarithmic factors by constructing a fitting ellipsoid for some $n = d^2/\text{polylog}\}(d)$.

2 Leveraging Reviews: Learning to Price with Buyer and Seller Uncertainty

Wenshuo Guo[1], Nika Haghtalab[1], Kirthevasan Kandasamy[2], Ellen Vitercik[3], [1]University of California, Berkeley, Berkeley, CA, [2]University of Wisconsin, Madison, Madison, WA, [3]Stanford University, Stanford, CA, Contact: vitercik@stanford.edu

On online marketplaces, customers have access to hundreds of reviews for a single product. Buyers often use reviews from other customers that share their personal attributes—such as height for clothing or skin type for skincare products—to estimate their values, which they may not know a priori. Customers with few relevant reviews may hesitate to buy a product except at a low price, so for the seller, there is a tension between setting high prices and ensuring that there are enough reviews that buyers can confidently estimate their values. Simultaneously, sellers may use reviews to gauge the demand for items they wish to sell. In this talk, we formulate this pricing problem through the lens of online learning and provide a no-regret learning algorithm. Our matching regret upper and lower bounds show that our algorithm is minimax optimal up to lower order terms.

3 Out-Of-Distribution Generalization in Kernel Regression

Abdulkadir Canatar[1], Blake Bordelon[2], Cengiz Pehlevan[2], [1]Flatiron Institute, Simons Foundation, New York, NY, [2]Harvard University, Cambridge, MA, Contact: acanatar@flatironinstitute.org

Training distributions for machine learning models often differ from the test distribution. Under such distributional shifts, we study generalization in kernel regression using methods from statistical physics. We derive an analytical formula for the out-of-distribution generalization error applicable to any kernel and real datasets. The mismatch between distributions are quantified by an overlap matrix as a key determinant of generalization performance under distribution shift. We analyze and elucidate various generalization phenomena including possible improvement in generalization when there is a mismatch. We develop procedures for optimizing training and test distributions for a given data budget to find best and worst case generalizations under the shift. We present applications of our theory to real and synthetic datasets and for many kernels.

4 Crowdsourcing with Hard and Easy Tasks

Srikant Rayadurgam, UIUC

5 Degree Distribution Identifiability of Stochastic Kronecker Graphs

Daniel Alabi, Columbia University, New York, NY

Many network or graph generation algorithms rely on the Kronecker multiplication primitive. Seshadhri, Pinar, and Kolda (J. ACM, 2013) proved that stochastic Kronecker graph (SKG) models cannot generate graphs with degree distribution that follows a power-law or lognormal distribution. As a result, variants of the SKG model have been proposed to generate graphs which approximately follow degree distributions, without any significant oscillations. However, all existing solutions either require significant additional parameterization or have no provable guarantees on the degree distribution. In this work, we propose criteria, based on statistical and computational identifiability, that can be used to establish the usability and utility of SKG models.

Causal Inference in the Presence of Interference

Community Committee Choice Session

Session Chair: Shuangning Li, Harvard University, Cambridge, MA

1 Modeling Interference Using Experiment Roll-Out

Ariel Boyarsky[1], Hongseok Namkoong[1], Jean Pouget-Abadie[2], [1]Columbia University, New York, NY, [2]Google Research, New York, NY, Contact: a.boyarsky@columbia.edu

Experiments on online marketplaces and social networks suffer from interference, where the outcome of a unit is impacted by the treatment status of other units. We propose a framework for modeling interference using staggered roll-out designs, which slowly increase the fraction of units exposed to the treatment to mitigate any unanticipated adverse side effects. Our main idea leverages temporal variations in treatment assignments introduced by roll-outs to model the interference structure. We first present identification conditions under which the estimation of common estimands is possible and show how these conditions are aided by roll-out designs. Since there are often multiple competing models of interference in practice, we develop a model selection method that evaluates models based on their ability to explain outcome variation observed along the roll-out.

2 Low-Degree Outcomes and Clustered Designs: A Combined Approach for Causal Inference Under Interference

Matthew Eichhorn[1], Samir Khan[2], Johan Ugander[2], Christina Lee Yu[1], [1]Cornell University, Ithaca, NY, [2]Stanford University, Palo Alto, CA, Contact: cleeyu@cornell.edu

Existing literature on estimating causal effects under network interference falls under two primary approaches: leveraging assumptions on the interference to inform the experimental design or leveraging assumptions on the potential outcomes to inform the choice of estimator. These strategies have traditionally been considered in isolation; our work aims to understand and quantify their synergy. We present a general pseudoinverse estimator for causal effects under low-degree outcome models that works for arbitrary experimental designs. Next, we analyze the bias and variance of this estimator both for arbitrary designs and more specifically in the case of cluster randomized designs. Throughout, we see that the combination of cluster randomized designs and low-degree outcome models leads to more favorable properties than either strategy ensures on its own.

3 Optimal Individualized Treatment Rules Under Cluster Network Interference

Yi Zhang, Kosuke Imai, Harvard University, Cambridge, MA, Contact: yi_zhang@fas.harvard.edu

Most existing work on policy learning has assumed that the treatment assignment of one unit does not affect the outcome of another unit. We consider the problem of learning an optimal individualized treatment rule (ITR) under partial interference where clusters of units are sampled from a population and units may influence one another within each cluster. Unlike previous methods that impose restrictive interference structures, our method only assumes a semi-parametric model of interference, assuming that the cluster-level average outcome is an additive function of unit-level treatments within the cluster, where the proposed estimator for evaluating an ITR achieves better performance than the standard IPW estimator. We establish the regret bound for the learned ITR and illustrate its value in utilizing network information through simulation and empirical studies.

4 Model-Based Regression Adjustment with Model-Free Covariates for Network Interference

Kevin Han, Stanford University, Stanford, CA, Contact: kevinwh@stanford.edu

In this work, we introduce a sequential procedure to generate and select graph- and treatment-based covariates for GATE estimation under regression adjustment. We show that it is possible to simultaneously achieve low bias and considerably reduce variance with such a procedure. To tackle inferential complications caused by our feature generation and selection process, we introduce a way to construct confidence intervals based on a block bootstrap. We illustrate that our selection procedure and subsequent estimator can achieve good performance in terms of root mean squared error in several semi-synthetic experiments with Bernoulli designs. We apply our method to a real world experimental dataset with strong evidence of interference and demonstrate that it can estimate the GATE reasonably well without knowing the interference process a priori.

Inventory Management: Theory and Practice

Community Committee Choice Session

1 The Benefits of Delay to Online Decision-Making

Yaqi Xie[1], Will Ma[2], Linwei Xin[1], [1]University of Chicago, Chicago, IL, [2]Columbia University, New York, NY

Real-time decisions are usually irrevocable in many contexts of online decision-making. One common practice is delaying real-time decisions so that the decision-maker can gather more information to make better decisions. However, decisions cannot be delayed forever. In this paper, we study this fundamental trade-off and aim to theoretically characterize the benefits of delaying real-time decisions. We provide a theoretical foundation for a broad family of online decision-making problems by proving that the gap between the proposed online algorithm with delay and the offline optimal policy decays exponentially fast in the length of delay. We also conduct extensive numerical experiments on the benefits of delay, using both synthetic and real data. Both our theoretical and empirical results demonstrate an important managerial insight: a little delay is all we need.

2 Dynamic Commodities for Large Scale Fulfillment Optimization

Ioannis Spantidakis, Tolga Cezik, Amazon.com, Seattle, WA, Contact: spanioan@amazon.com

The fulfillment execution system of Amazon needs to optimize the fulfillment method for tens of millions of customer orders per day over hundreds of thousands of potential transportation paths. The goal is to evaluate all fulfillment methods per order and dynamically choose one that minimizes the fulfillment cost while reserving capacity for future demand. This requires frequent solving of an extremely large-scale problem, which does not scale at an individual order level. To reduce both the impact of demand forecast errors as well as the dimension of the problem, we cluster orders with similar characteristics into commodities. We give a formal definition of a commodity and study how different levels of granularity affect the tradeoff between optimization speed and fulfillment cost in the Amazon network.

Session Chair: Linwei Xin, University of Chicago, Chicago, IL

3 Multi-Period Multi-Secretary Problem

Zi Ling[1], Linwei Xin[2], Yuan Zhong[3], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago, IL, [3]University of Chicago / Booth School of Business, Chicago, IL, Contact: zling@chicagobooth.edu

Replenishment usually plays a crucial role in various online decision-making contexts (for example, replenishment after online order fulfillment in online retailing). In this paper, we mainly study the real-time decision problem with replenishment. To address this problem, we present a family of offline optimal hindsight policies, specifically when the offline optimal policy cannot be determined due to the complexities of replenishment. Subsequently, we propose a corresponding online policy tailored for real-time decision-making in such scenarios. To analyze the performance of the proposed algorithms, we provide a theoretical analysis that establishes performance bounds. This analysis serves as a foundation for understanding the effectiveness of the online policy in the absence of an optimal offline policy.

4 Sample Complexity of Policy Gradient Method and Applications in Inventory Models

Minda Zhao, Xin Chen, Georgia Institute of Technology, Atlanta, GA, Contact: mindazhao@gatech.edu

Policy gradient methods for Markov Decision Processes (MDPs) do not converge to global optimal solutions in general due to the non-convexity of the objectives. In this work, we show that for a class of MDPs in which the optimal policies described by a finite number of parameters and the cost-to-go functions are convex, the objectives of the policy gradient satisfy the gradient dominance conditions. Using this, we develop policy gradient-based algorithms and establish their sample complexities required to attain ϵ-global optimal solutions. Our results find applications in a host of inventory models including multi-period newsvendor model and multi-echelon inventory model. In particular, the policy gradient method achieves an $O(\epsilon^{-2})$ sample complexity for the capacitated inventory control models, matching the result of sample average approximation in the literature.

Learning, Experimental Design, and Societal Considerations

Community Committee Choice Session

Session Chair: Yunzong Xu, Massachusetts Institute of Technology, Cambridge, MA

1 On Differentially Private Federated Linear Contextual Bandits

Xingyu Zhou, Wayne State University, Detroit, MI

We consider differentially private cross-silo federated linear contextual bandit (LCB) problem. We identify three issues in the state-of-the-art: (i) failure of claimed privacy protection and (ii) incorrect regret bound due to noise miscalculation and (iii) ungrounded communication cost. We first design an algorithmic framework consisting of a generic federated LCB algorithm and flexible privacy protocols. Then, we establish privacy and regret guarantees under silo-level local differential privacy, which fix the issues present in state-of-the-art algorithm. To further improve the regret performance, we next consider shuffle model of differential privacy, under which we show that our algorithm can achieve nearly "optimal" regret without a trusted server.

2 Optimizer's Information Criterion: Dissecting and Correcting Bias in Data-Driven Optimization

Garud Iyengar, Henry Lam, Tianyu Wang, Columbia University, New York, NY, Contact: tw2837@columbia.edu

In data-driven optimization, the sample performance of the obtained decision typically incurs an optimistic bias known as the Optimizer's Curse. Common techniques to correct this bias, such as cross-validation, require repeatedly solving additional optimization problems and are computationally expensive. We develop a general bias correction approach, building on what we call *Optimizer's Information Criterion (OIC)*, that directly approximates the first-order bias and does *not* require solving any additional optimization problems. OIC evaluates the objective performance in data-driven optimization, which involves not only model fitting but also its interplay with the downstream optimization. We apply our approach to various formulations comprising empirical and parametric models, their regularized counterparts, and furthermore contextual optimization.

3 Switchback Experiments in a Reactive Environment

Hongyu Chen[1], David Simchi-Levi[2], [1]MIT, cambridge, MA, [2]Massachusetts Institute of Technology, Cambridge, MA, Contact: chenhy@mit.edu

In this paper, we consider the problem of estimating the treatment effect of a new policy by conducting switchback experiments in a reactive environment, where the system's response fully captures the potential temporal interference. We propose an estimator based on importance sampling and discuss an experimental design that has a near-optimal worst-case guarantee. For performing inferences, we develop the central limit theorem for the estimator and construct a corresponding conservative confidence interval. We show by numerical experiments that the proposed estimator along with the experimental design achieves smaller risk compared to the traditional inverse propensity score estimator.

4 Offline Reinforcement Learning: Fundamental Barriers for Value Function Approximation

Yunzong Xu, Massachusetts Institute of Technology, Cambridge, MA

We consider the offline reinforcement learning problem, where the aim is to learn a decision making policy from logged data. Offline RL -- particularly when coupled with (value) function approximation to allow for generalization in large or continuous state spaces -- is becoming increasingly relevant in practice, because it avoids costly and time-consuming online data collection and is well suited to safety-critical domains. We discuss some recent advances on the hardness of offline reinforcement learning and provide insights on algorithm design.

Data-driven Research with Social Impacts

Community Committee Choice Session

Session Chair: Masoud Kamalahmadi, University of Miami, Miami, FL

1 Admission Decisions Under Imperfect Classification: An Application to Criminal Justice

Zhiqiang Zhang[1], Pengyi Shi[2], Amy R. Ward[1], [1]The University of Chicago Booth School of Business, Chicago, IL, [2]Purdue University, West Lafayette, IN, Contact: zqzhang0@chicagobooth.edu

We study the decision of admitting individuals eligible for probation to incarceration diversion treatment programs, whose aim is to reduce the chance an individual re-offends. The admission decisions are made based on the outcome of a machine learning (ML) algorithm. We model the diversion program as a queueing loss model with reneging during service, and calibrate the model using data from Illinois. Using fluid optimization, we show that the optimal policy has a simple prioritization scheme when the ML algorithm's prediction is sufficiently accurate, but is suboptimal otherwise. We propose guidelines for when to follow the ML-based recommendation and when to involve human judgement. Finally, we investigate the fairness issues among different subpopulations and discuss the impact of various fairness criteria on the ML algorithm and admission decisions.

2 How Do Drug Shortages Affect Fda Inspections? an Empirical Study

Archie Zhuang[1], In Joon Noh[2], Hui Zhao[3], [1]Penn State University, State College, PA, [2]Penn State University, University Park, PA, [3]The Pennsylvania State University, University Park, PA, Contact: zpz5187@psu.edu

Drug shortages have been a significant and persistent challenge in the U.S. Some drug manufacturers blame FDA for the production delay and resultant shortages, claiming that FDA's inspections tend to be unnecessarily stringent. Given these anecdotes, we conduct a large-scale empirical study to investigate the impact of drug shortages on FDA inspections.

3 Communication Breakdown: A Study of Recall Effectiveness in the United States Automobile Industry

Ramin Sepehrirad[1], Kevin Mayo[2], George Ball[3], [1]Washington State University, Pullman, WA, [2]Washington State University, Pullman, WA, [3]Operations and Decision Technologies, Kelley School of Business, Indiana University,

Bloomington, IN, Contact: ramin.sepehrirad@wsu.edu
While significant research explores recall causes and effects, little is understood about recall effectiveness; how well the firm performs in repairing or replacing faulty products. Anecdotal reports indicate that firms are relatively ineffective in this endeavor, leading to millions of recalled products remaining in the market, unaddressed. We investigate communication strategies of recalling firms to raise customer awareness and encourage compliance with remedial procedures. Increasing recall effectiveness directly lowers the risk of harm to consumers, thereby meaningfully contributing to societal well-being. We leverage text analyses to explore the content and channels of manufacturer communications with dealers and affected customers in the United States automobile industry.

On the Fairness for Optimization and Learning

Contributed Session

Session Chair: Parian Haghighat, University of Illinois at Chicago, Chicago, IL
Session Chair: Hadis Anahideh, University of Illinois Chicago, Chicago, IL

1 Geometric Envy-Free Pricing of Seats in Planetariums: Maximizing Revenue and Welfare

Freija M. E. van Lent[1], Alexander Grigoriev[1], Julian A. P. Golak[2], [1]Maastricht University, Maastricht, Netherlands; [2]Hamburg University of Technology, Hamburg, Germany. Contact: f.vanlent@maastrichtuniversity.nl
We study a geometric envy-free pricing problem with a single item demand. The aim of the seller is to maximize the revenue by assigning prices to points in the plane and by allocating customers to these points in an envy-free manner, i.e., every allocated customer receives a point of her highest possible utility, and all non-allocated customers cannot afford any point. Next to this continuous problem, we consider a discrete version where customers purchase the tiles of a regular tessellation of the plane, e.g., grid squares or honeycomb hexagons. For a special case of the continuous version of the problem, where all customers have the same preferred point, we introduce a dynamic programming algorithm solving the problem in polynomial time. For the discrete version of the problem, we extend the dynamic programming algorithm to the quasi-polynomial time approximation scheme.

2 Existence and Computation of Epistemic EFX Allocations

Ioannis Caragiannis[1], Jugal Garg[2], Nidhi Rathi[1], Eklavya Sharma[2], Giovanna Varricchio[3], [1]Aarhus University, Aarhus, Denmark; [2]University of Illinois at Urbana-Champaign, Urbana, IL, [3]Goethe University Frankfurt, Frankfurt, Germany
For the problem of fairly dividing a set of indivisible items among agents, envy-freeness up to any item (EFX) and maximin fairness (MMS) are arguably the most compelling fairness concepts proposed till now. Unfortunately, despite significant efforts over the past few years, whether EFX allocations always exist is still an enigmatic open problem. Furthermore, we know that MMS allocations are not guaranteed to exist. These facts weaken the usefulness of both EFX and MMS despite their appealing conceptual characteristics. We propose an alternative fairness concept called epistemic EFX (EEFX) that is inspired by EFX and MMS. We explore its relationship to well-studied fairness notions and prove that for additive valuations, EEFX allocations always exist and can be computed efficiently. Our results justify that EEFX can be an excellent alternative to EFX and MMS.

3 Should I Stop or Should I Go: Early Stopping with Heterogeneous Populations

Hammaad Adam[1], Mary Hu[2], Fan Yin[3], Neil Tenenholtz[4], Lorin Crawford[4], Lester Mackey[4], Allison Koenecke[5], [1]Massachusetts Institute of Technology, Cambridge, MA, [2]Microsoft, Redmond, WA, [3]Amazon, Seattle, WA, [4]Microsoft Research, Cambridge, MA, [5]Cornell University, Ithaca, NY, Contact: hadam@mit.edu
Randomized experiments often need to be stopped prematurely due to the treatment having an unintended harmful effect. Existing methods that determine when to stop an experiment early are typically applied to the data in aggregate and do not account for treatment effect heterogeneity. In this paper, we study the early stopping of experiments for harm on heterogeneous populations. We first establish that current methods often fail to stop experiments when the treatment harms a minority group of participants. We then use causal machine learning to develop CLASH, the first broadly-applicable method for heterogeneous early stopping. We demonstrate CLASH’s performance on simulated and real data and show that it yields effective early stopping for both clinical trials and A/B tests.

4 Fairpilot: An Explorative System for Hyperparameter Tuning Through the Lens of Fairness

Francesco Di Carlo, Nazanin Nezami, Hadis Anahideh, Abolfazl Asudeh, University of Illinois Chicago, Chicago, IL, Contact: hadis@uic.edu

Despite the potential benefits of machine learning (ML) in high-risk decision-making domains, the deployment of ML is not accessible to practitioners, and there is a risk of discrimination. To establish trust and acceptance of ML in such domains, democratizing ML tools and fairness consideration are crucial. In this paper, we introduce FairPilot, an interactive system designed to promote the responsible development of ML models by exploring a combination of various models, different hyperparameters, and a wide range of fairness definitions. We emphasize the challenge of selecting the ``best" ML model and demonstrate how FairPilot allows users to select a set of evaluation criteria and then displays the Pareto frontier of models and hyperparameters. FairPilot offers a unique opportunity for users to responsibly choose their model.

5 Unleashing the Potential of Predictive Analytics with Fair Mars: A Statistical Model that Prioritizes Equity and Transparency

Parian Haghighat[1], Hadis Anahideh[1], Lulu Kang[2], [1]University of Illinois at Chicago, Chicago, IL, [2]Illinois Institute of Technology, Chicago, IL

This project aims to develop a fair Multivariate Adaptive Regression Splines (MARS) model that reduces bias towards sensitive attributes like race or gender across achieving more equitable outcomes. MARS is a non-parametric regression model with a built-in feature-selection step. Our fair MARS model prioritizes fairness as well as accuracy via pre-processing (decorrelating sensitive and non-sensitive attributes) and in-processing (incorporating fairness constraints during knot optimization). Adding the fairness component to the training process not only produces less biased predictions but also generates a fair set of decision rules based on the splitting criteria for the selected variables. By developing and sharing this model, we offer a more interpretable and accessible prediction model, enhancing the utility of predictive analytics in practice.

Data Informed Methodologies to Improve Patient Access to Healthcare Services

Community Committee Choice Session

Session Chair: Esma S. Gel, University of Nebraska-Lincoln, Lincoln, NE

Session Chair: Santiago Romero Brufau, Mayo Clinic, Rochester, MN

1 Improving the Compassionate Dialysis Process via Patient Routing and Prioritization Schemes

Olga Bountali[1], Farnaz Nourbakhsh[2], Sila Cetinkaya[3], [1]Rotman School Of Management, University of Toronto, Toronto, ON, Canada; [2]United Parcel Service, Elkridge, MD, [3]SMU, Dallas, TX, Contact: olga.bountali@utoronto.ca

Uninsured patients suffering from End Stage Renal Disease (ESRD) have access to treatment under EMTALA (a federal law) after being evaluated as in an 'life-threatening' condition. This practice, a.k.a. *compassionate dialysis,* routes these patients through the ER, blends them with non-ESRD patients, and assesses their condition factoring both medical 'emergency' criteria and existing available capacity. Compassionate dialysis has been proved to be inefficient for both hospital and patient outcomes. Informed by our analysis of real-life data from a hospital offering compassionate dialysis, we analyze alternative service protocols that rely on patient flow re-routing and prioritization schemes with the goal of informing medical personnel and government decision makers.

2 Community/Committee'S Choice Submission

Thomas Kingsley, Mayo Clinic, Rochester, MN

3 Statistical Characterization of Patient Response to Offered Access Delays Using Healthcare Transactional Data

Derya Kilinc[1], Esma S. Gel[2], Mustafa Y. Sir[3], Kalyan Pasupathy[4], [1]Socure Inc, Phoenix, AZ, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]Amazon, Redmond, WA, [4]University of Illinois at Chicago, Chicago, IL

We present a novel framework to characterize the probability that an appointment will be booked and attended by a patient. We refer to this probability as the probability of realization' and demonstrate how empirical characterization of this measure can be used to identify policies for managing patient demand and enabling the use of care resources. We consider the estimation problem in the context of new patients looking to establish care at a clinic, and offer a model of patient responses during appointment scheduling. We first demonstrate the accuracy of estimations using simulated data, and then highlight behavioral differences between different patient groups using real-life transactional data. Finally, we demonstrate a practical use case for the obtained probabilities by showing that they can be reliably used as input to a patient prioritization mechanism.

4 Ai Translation Advisory Board: Support the Process from Data to Clinical Impact

Lu Zheng, Mayo Clinic, Rochester, MN

In this session we will discuss the AI Translation Advisory Board, a Board within Mayo Clinic to accelerate the translation of AI projects into clinical practice at Mayo Clinic by providing comprehensive assessment and support for projects. We will describe the board's multi-background team and the streamlined process by going through an example of a project to implement ML-based models and process optimization to improve inadequate bowel preparation prior to colonoscopy.

OR Applications in Neuroscience

Community Committee Choice Session

Session Chair: Taghi Khaniyev, Bilkent University, Ankara, Turkey

1 Optimizing Concussion Assessment: A Mixed-Integer Optimization Approach with Time Constraints

Himadri S. Pandey, Gian-Gabriel P. Garcia, Georgia Institute of Technology, Atlanta, GA, Contact: hpandey30@gatech.edu

Concussion is a common type of brain injury in sports and recreation, with 1.6-4 million cases yearly, half of which go unreported or undetected. Prompt and precise diagnosis is vital to manage the injury and reduce the risk of severe short-term and long-term effects, such as cognitive impairment, depression, and neurodegenerative disorders. However, identifying appropriate concussion assessment tools in time-constrained settings like athletic competitions is still challenging. We are proposing a novel approach to optimize the accuracy of a concussion assessment battery under time constraints. Specifically, we formulate the problem as a mixed-integer optimization problem with chance constraints. Our findings demonstrate that we can create precise assessment batteries even for short timeframes, resulting in better outcomes in time-constrained settings.

2 Optimal State-Space Reconstruction of Complex Systems for Pattern Discovery of Brain Disorders

Chun-An Chou[1], Haidong Gu[1], Shaodi Qian[1], Huiyu Huang[2], [1]Northeastern University, Boston, MA, [2]Northeastern University, Brookline, MA, Contact: ch.chou@northeastern.edu

Human brain is considered as one of most complex systems. In theory, the dynamics of a complex system exists and follows an evolution rule. However, its behavior is not easily observed and analyzed. To this end, we formulate an optimization problem for identifying an intrinsic space of brain system, where the dynamics can be discovered in a reconstructed state space. Then, we present a complex measure to represent brain behaviors. We demonstrate the effectiveness of our proposed approach in neuroscience applications of seizure detection and schizophrenia classification using multi-variate EED signals.

3 Optimal Personalized Brain Parcellation

Taghi Khaniyev[1], Beyza Bakir[1], Sahin Hanalioglu[2], [1]Bilkent University, Ankara, Turkey; [2]Hacettepe University, Ankara, Turkey. Contact: taghi.khaniyev@bilkent.edu.tr

Recent advances in imaging technologies allowed researchers probe the human brain in high resolution. One of biggest challenges of analyzing the intricate nature of the human brain is to process the data emanating from high-resolution imaging. To tackle this challenge, neuroscientists typically conduct their analyses on brain area level rather than voxel level. Division of the brain cortex into distinct areas is called parcellation. Traditional parcellation approaches typically offer a universal atlas which ignores the large amount of inter-individual variability. We propose a novel mathematical optimization model for personalized parcellation. In this formulation, the objective is to assign each voxel to a brain region for each individual in such a way that the dissimilarity of the resulting connectivity network from an archetypical brain network is minimized.

Hospital's Surgical and Inpatient Operations

Community Committee Choice Session

Session Chair: Vikram Tiwari, Vanderbilt University Medical Center, Nashville, TN

1 Optimizing Intra-Hospital Patient Transport Services

Christopher Sun[1], Martin Copenhaver[2], A. Cecilia Zenteno[3], Retsef Levi[4], [1]University of Ottawa; University of Ottawa Heart Institute, Ottawa, ON, Canada; [2]Massachusetts General Hospital & Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Boston, MA, [4]MIT, Cambridge, MA, Contact: sun@telfer.uottawa.ca

Intra-hospital patient transportation services are an integral part of daily logistic activities in a hospital, facilitating patient flow between inpatient units on stretchers, wheelchairs, and beds. Delays stemming from suboptimal transport practices can significantly impact operations of procedural areas and test sites, potentially compromising quality of care. In this project, we identified the primary drivers of patient transport delays at Massachusetts General Hospital, and propose analytical frameworks to address these issues.

2 A Pareto Improvement Bumping-Rescheduling Policy for Operating Room Scheduling

Hung Do[1], David C. Novak[2], Mitchell H. Tsai[3], [1]University of Vermont, Burlington, VT, [2]University of Vermont, Burlington, VT, [3]University of Vermont Medical Center, South Burlington, VT, Contact: Hung.Do@uvm.edu

For hospitals using shared operating rooms for scheduled and emergent cases, a bumping policy is needed to facilitate emergent cases when they arrive, but it often operates with competing objectives. The current bumping policies do not offer efficient access to capacity (i.e., Operating Rooms) as well as any mechanism for collaboration. We introduce, model and analyze a bumping policy called First-In-First-Out (FIFO) Bump Policy in the context of Operating Room Scheduling that facilitates more efficient use of capacity with pooling effects and offers a collaborative mechanism with potential positive behavioral effects to speedup service rates.

3 Data-Driven Approach to the Surgical Block Auto-Release Decision

Sandeep Rath[1], Moe R. Lim[2], [1]University of North Carolina at Chapel Hill - Kenan Flagler, Chapel Hill, NC, [2]University of North Carolina at Chapel Hill, Chapel Hill, NC, Contact: sandeep_rath@kenan-flagler.unc.edu

Surgical block allocation involves reserving block time in operating rooms (OR) for surgeon scheduling. This gives the surgeons independence to manage their own schedules predictably and ensures fair distribution of OR capacity across departments. However, unused block time can result in idle time, leading to lower OR utilization. To improve utilization and total case volume, unused blocks are auto-released for open access several days before surgery. The decision on how far in advance to automatically release unfilled block time is a trade-off between predictable surgeon scheduling and OR utilization. We develop a data-driven approach for surgical block auto-release, using historical data of surgical case bookings from a large academic medical center. Our model improves OR utilization without compromising predictable surgeon scheduling.

4 A Multi-Treatment Forest Approach for Analyzing the Heterogeneous Effects of Team Familiarity

Minmin Zhang[1], Guihua Wang[2], Wallace J. Hopp[3], Michael Mathis[4], [1]The University of Texas at Dallas, Richardson, TX, [2]The University of Texas at Dallas, RICHARDSON, TX, [3]University of Michigan, Ann Arbor, MI, [4]University of Michigan Medical School, Ann Arbor, MI

Extensive research has revealed that prior collaborative experiences among team members (called “team familiarity”) enhance outcomes of group work in many different environments. In this study, we examine the effect of team familiarity on surgery duration and extend the literature on team dynamics by examining whether the effect of team familiarity is heterogeneous across patients. We find (1) an increase in team familiarity score, especially the anesthesiologist-nurse and surgeon-anesthesiologist familiarity scores, significantly reduces surgery duration, and (2) the effect of team familiarity is heterogeneous across patients with different features. Finally, we develop an optimization model to assess the value of leveraging the heterogeneous effects of team familiarity to better match surgical teams with patients.

Recent Development in Healthcare Analytics

Community Committee Choice Session

Session Chair: Susan F. Lu, Purdue University, West Lafayette, IN

Session Chair: Zhenzhen Yan, Nanyang Technological University, Singapore, Singapore

1 Got (Optimal) Milk? Pooling Donations in Human Milk Banks with Machine Learning and Optimization

Rachel K. Wong[1], Timothy C. Y. Chan[2], Rafid Mahmood[3], Ian Y. Zhu[2], Sharon Unger[4], Debbie Stone[4], Deborah O'Connor[5], [1]University of Toronto, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada; [3]Telfer School of Management, Ottawa, ON, Canada; [4]Sinai Health System, Toronto, ON, Canada; [5]University of Toronto, Toronto, ON, Canada. Contact: rache.wong@mail.utoronto.ca

Human donor milk provides critical nutrition for the millions of infants that are born preterm each year. While the macronutrients in donor milk are critical to infant development, they vary by donation. In collaboration with Rogers Hixon Ontario Human Milk Bank, we developed a data-driven framework to pool multiple donations using machine learning and optimization. Over a one-year trial, our implementation yielded significantly higher macronutrient content than current pooling practices, with the proportion of pools meeting clinical fat and protein targets increasing by approximately 31%, with a 60% decrease in recipe creation time.

2 Treatment Planning of Victims with Heterogeneous Time-Sensitivities in Mass Casualty Incidents

Yunting Shi[1], Nan Liu[2], Guohua Wan[1], [1]Shanghai Jiao Tong University, Shanghai, China; [2]Boston College, Chestnut Hill, MA, Contact: sherryshi@sjtu.edu.cn

Mass casualty incidents (MCIs) lead to a sudden jump in patient demand, making it inevitable to ration medical resources. Informed by a unique timestamps dataset collected during a large-scale earthquake, we develop data-driven approaches to aid treatment planning for MCIs . A distinguishing feature of our modeling framework is to simultaneously consider victim health deterioration and wait-dependent service times in making decisions. We identify conditions under which victims with a less critical initial condition have higher or lower priority than their counterparts in an optimal schedule—the priority order depends on victim deterioration trajectories and the resource (i.e., treatment time) availability.

3 Joint Prediction and Stopping in Treatment of Aortic Aneurysms

Huan Yu[1], Qingxia (Cynthia) Kong[2], Gar Goei Loke[2], Merieke Stevens[2], Merel Verhagen[3], Jan van Schaik[3], [1]University of Southampton, Southampton, United Kingdom; [2]Erasmus University, Rotterdam, Netherlands; [3]Leiden University Medical Center, Leiden, Netherlands. Contact: huan.yu@soton.ac.uk

In this paper, we consider the problem of finding the optimal treatment time for aortic aneurysm patients in a cardiac clinic. Treatment decisions depend on the trade-off between sudden mortality from aortic rupture and long-term chance and costs of complications. We propose a decision support tool that provides recommendations on the treatment time, that uses a survival model as inputs for estimating the risks of complications and mortality. We propose a novel robust optimization model to control for errors in the estimation of the hazard function, and to jointly form predictions and treatment time decisions. We illustrate our model on a data set of aortic patients in the Leiden University Medical Centre. Our model has the potential to open the door to preventive medicine as it forms individualized treatment decisions for patients based on their unique characteristics.

4 Test

Mabel Chou, National University of Singapore

5 Elective Surgery Sequencing and Scheduling Under Uncertainty

Xiaojin Fu[1], Jin Qi[2], Chen Yang[1], Han Ye[3], [1]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]Lehigh University, Bethlehem, PA, Contact: cyangap@connect.ust.hk

We consider a surgery sequencing and scheduling problem with uncertain surgical durations. Our goal is to balance the risk of delay and idle time, so the Punctuality Index is proposed. We derive exact solutions based on Benders Decomposition. The framework can also accommodate a robust optimization setting. For practical use, we propose two effective heuristics based on the variance and the forward-backward deviations. With comparison, we demonstrate that our framework is significantly good. The robust setting can effectively lessen the risk of large delay and idle time, and the heuristics are efficient with only little performance sacrificed.

Healthcare Products and Services Operations

Community Committee Choice Session

Session Chair: Jun Li, Ross School of Business, University of Michigan, Ann Arbor, MI

Session Chair: Xinyu Shirley Liang, 1</sup

1 The Impact of Workload on Racial Disparities in Healthcare

Alison Murphy[1], Rachna Shah[2], [1]University of Minnesota-Twin Cities, Minneapolis, MN, [2]University of Minnesota, Minneapolis, MN, Contact: murp1888@umn.edu

A growing stream of literature has shown how service rate and quality are impacted by workload. Increasing workload also increases cognitive load, which increases the likelihood that individuals will act on implicit biases. We explore how provider workload contributes to inequities in healthcare delivery and disparities in outcomes based on patient race in the context of maternal health. Overall, Black women are less likely to receive epidurals and are more likely to experience severe morbidities than White women. We show that the patterns of inequities and disparities vary with provider workload.

2 Generic Drug Effectiveness-An Empirical Study on Health Service Utilization and Clinical Outcomes

Xinyu Liang[1], Jun Li[2], Ravi Anupindi[1], [1]University of Michigan, Ann Arbor, MI, [2]Ross School of Business, University of Michigan, Ann Arbor, MI, Contact: xinyul@umich.edu

Close to 90% of drugs consumed in the US are generics, saving over 2.4 trillion dollars over the past decade. While the cost savings are evident, effectiveness of generic drugs have been the subject of debate. In this paper, we estimate the effect of generic drug usage on health outcomes and address the potential endogeneity using instrumental variables. We find that generic drug usage leads to significantly more hospital visits. Generics also appear to be less clinically effective in reducing low-density lipoprotein cholesterol levels and preventing hospitalizations. In particular, the effect of generic drug usage is more prominent among older patients and patients with high prior healthcare expenses. Furthermore, we find that the effectiveness varies across generics from different manufacturers, particularly between authorized generic manufacturers and others.

3 Optimizing Equitable Resource Allocation in Parallel Any-Scale Queues with Service Abandonment and Its Application to Liver Transplant

Shukai Li, Sanjay Mehrotra, Northwestern University, Evanston, IL

We study the problem of equitably and efficiently allocating resources, modeled as service rates, to multiple queues with abandonment. The problem is motivated by the national liver allocation system, which includes numerous small-scale patient waitlists in terms of arrival intensities, with the possibility of patients abandoning (death) until the required service is completed (matched donor livers arrive). We model each waitlist as a GI/MI/1+GI queue. To evaluate the queue performance, we develop a finite approximation method, which is further used within an optimization model. We find that increasing the proportion of livers allocated to waitlists with small scales or high abandonment (death) risks improves allocation equity. This suggests a proportionately greater allocation of organs to smaller transplant centers and those with more vulnerable populations.

4 Studying the Effect of Team Familiarity in Surgical Teams

Gulin Tuzcuoglu[1], Daniel Adelman[2], Cagla Keceli[1], Kiran Turaga[3], Hunter Witmer[1], Frederick Godley[1], Josh Morris-Levenson[1], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Booth School of Business, Chicago, IL, [3]Yale University, New Haven, CT, Contact: gulin@uchicago.edu

We study the effect of team familiarity in surgical teams to maximize team performance. Our approach takes the team members' individual and collaborative experiences into account, which we quantify using a novel metric. We report on results based on data from a high-volume academic medical center.

Decision making in sustainable supply chains

Community Committee Choice Session

Session Chair: Mirel Yavuz, University of California Los Angeles, Los Angeles, CA

Session Chair: Charles J. Corbett, University of California-Los Angeles, Los Angeles, CA

1 Interactive Optimization with Unknown Value Function: Illustrative Application to Sustainable Sourcing in the Apparel Industry

Mirel Yavuz, Charles J. Corbett, University of California Los Angeles, Los Angeles, CA, Contact: mirel.yavuz.phd@anderson.ucla.edu

Optimization in sustainability is inherently multi-criteria and the underlying value function used to indicate preferences is usually unknown and difficult to elicit. In this work, we consider the example of sustainable sourcing in the apparel industry and assume the economic and environmental preferences of a consistent and rational decision maker

(DM) are based on an unknown implicit value function. We propose a new interactive optimization approach that asks pairwise comparison questions to the DM to determine the sourcing mix that is most aligned with her preferences. Our interactive algorithm has a great potential in replacing/reducing the current ad-hoc approaches typically used in sustainable decision making.

2 The Impact of Extreme Weather Events on Firm Activity

Suvrat Dhanorkar[1], Suresh Muthulingam[2], [1]Pennsylvania State University, University Park, PA, [2]The Pennsylvania State University, University Park, PA, Contact: ssd14@psu.edu

Severe weather has been increasingly disrupting operations and supply chains. We examine the impact of extreme weather events on firm operations and outcomes.

3 Incentivizing Recycling to Improve Sustainability: Evidence from Field Experiments

Dayton T. Steele[1], Atalay Atasu[2], Saravanan Kesavan[3], [1]University of Minnesota, Carlson School, Minneapolis, MN, [2]INSEAD, Fontainebleau, France; [3]University of North Carolina-Chapel Hill, Chapel Hill, NC

The growing focus on sustainability initiatives for businesses has increased the need to understand how to encourage customers to participate. Through a partnership with a consumer electronics company, we conduct a set of field experiments to understand how its customers respond to incentives to return products to be recycled.

4 Promoting Circularity in Repair Operations with Incentives

Nail Tahirov[1], Tarkan Tan[2], Gizem Sagol Mullaoglu[3], [1]University of Zurich, Schaffhausen, Switzerland; [2]University of Zurich, Zurich, -, Switzerland; [3]ASML, Eindhoven, Netherlands

As sustainability becomes increasingly important, many manufacturers are switching their business model from the traditional "linear" approach to a "circular" paradigm. However, it is not easy for a company to realize it without the involvement of its suppliers. For a successful circular business model companies should induce their suppliers to invest in more circularity by producing durable materials and increasing reprocessing capabilities. We investigate a case presented by our industry partner, who seeks to enhance their circular economy by fostering collaboration with their suppliers in repairing spare parts. The willingness of suppliers to engage in joint initiatives with the manufacturer for circular economy improvement may vary depending on their preferences. Hence, this study addresses incentivization mechanisms aimed at benefiting both parties.

5 Remanufacturing of Consumer Returns by a Retailer: Implications for Supply Chains

Narendra Singh, Nazarbayev University, Astana, Kazakhstan. Contact: narendra.singh@nu.edu.kz

I analyze a supply chain where a manufacturer sells new products to consumers through a retailer and consumers return new products that are defective. I examine how strategic interactions among the manufacturer, the retailer, and consumers affect the supply chain profits in the presence of remanufacturing of consumer returns.

AI and decision making in operations management

Community Committee Choice Session

1 Scalable Optimal Multiway-Split Decision Trees

Shivaram Subramanian, Wei Sun, IBM T. J. Watson Research Center, Yorktown Heights, NY, Contact: subshiva@us.ibm.com

There has been a surge of interest in learning optimal decision trees using mixed-integer programs (MIP) as heuristic-based methods do not guarantee optimality and find it challenging to incorporate practical operational constraints. Existing MIP methods rely on an arc-based binary-tree formulations that are limited to datasets having a few thousand samples, sample-level constraints, and linear metrics. We propose a novel path-based MIP model that can be solved using a scalable column generation framework to produce a multiway-split tree that is more interpretable due to its shorter rules. Our method can optimize nonlinear metrics like F1 score and satisfy a broader class of constraints. We demonstrate its efficacy with extensive experiments including a million-sample dataset and report up to a 24X reduction in runtime compared to the state-of-art MIP-based methods.

2 Reducing Food Waste Through a Reservation System

Retsef Levi[1], Georgia Perakis[2], Emily Zhang[3], [1]MIT, Cambridge, MA, [2]Massachusetts Institute of Technology,

Cambridge, MA, [3]Massachusetts Institute of Technology, Cambridge, MA, Contact: eyzhang@mit.edu
With over one-third of all food produced going to waste, food waste is a critical issue that contributes to climate change and has adverse social and economic effects. We propose a grocery reservation system that aims to reduce food waste in grocery stores. Under this system, consumers can make advanced reservations for items at a reduced price or purchase them at the full price in-store. By providing the store with additional information about the customers' preferences, the reservation system can help to reduce demand variability, resulting in fewer unsold items going to waste. We identify conditions under which the reservation system can improve both profits and waste reduction, and our computational analysis shows that the reservation system can reduce expected waste by over 10% while increasing expected revenue by more than 5%.

3 Staffing Planning for Last Mile Delivery Drivers
Tolga Cezik[1], Tamar Cohen-Hillel[2], Liron Yedidsion[3], [1]Amazon.com, Seattle, WA, [2]UBC Sauder School of Business, Vancouver, BC, Canada; [3]Amazon, Redmond, WA
Staffing planning for last-mile delivery drivers is the process of planning the number of drivers required each week to deliver all the expected volume for a pre-determined time horizon, with the ability to adjust the decisions over time under guardrail restrictions. We formulate the problem as a multi-dimensional stochastic dynamic program with a newsvendor-based cost function. We propose an approximation algorithm to solve the problem near optimality in tractable time.
Session Chair: Pavithra Harsha, IBM Research, Pleasantville, NY

4 An Optimistic-Robust Approach for Omnichannel Inventory Management
Pavithra Harsha[1], Shivaram Subramanian[2], Ali Koc[1], Mahesh Ramakrishna[1], Brian Quanz[1], Dhruv Shah[1], Chandra Narayanaswami[1], [1]IBM Research, Yorktown Heights, NY, [2]IBM, Frisco, TX, Contact: pharsha@us.ibm.com
In this paper, we introduce a data-driven optimistic-robust bimodal inventory optimization (BIO) policy to allocate inventory across a retail chain to meet time-varying omnichannel demand. While prior Robust optimization (RO) methods emphasize the downside, i.e., worst-case adversarial demand, BIO also considers the upside to remain resilient like RO while also reaping the rewards of improved average-case performance. We provide structural insights about the BIO solution and how it can be tuned. Our experiments show significant benefits rethinking traditional approaches to inventory management that are siloed by channel and location, and additionally projects a 15% profitability gain for BIO over RO on real-world data from a mid-sized American retailer.

Pricing and Risk Management in New Business Practices
Community Committee Choice Session
Session Chair: Soudipta Chakraborty, University of Kansas, Lawrence

1 Insuring Autonomous Vehicles: Perspectives from Operations Management
Amin Abbasi Pooya, Nagarajan Sethuraman, Suman Mallik, University of Kansas, Lawrence, KS, Contact: a.abbasipooya@ku.edu
The objective of our study is to model issues related to the insurance of autonomous vehicles. We use optimization and game theory to generate insights about monopolistic and competitive markets. Our models allow us to characterize equilibrium, analyze its properties, and provide useful insights.

2 Retail Category Management with Slotting Fees
Yasin Alan[1], Mumin Kurtulus[2], Alper Nakkas[3], [1]Vanderbilt University - Owen Graduate School of Management, Nashville, TN, [2]Vanderbilt University, Nashville, TN, [3]University of Texas at Arlington, Arlington, TX, Contact: yasin.alan@vanderbilt.edu
Slotting fees are lump-sum payments manufacturers make to retailers to secure slots for their products in retailers' assortments. We study the role of slotting fees in a retailer's category management decisions and strategic interactions with national brand manufacturers.

3 Is Your Price Personalized? Alleviating Customer Concerns with Inventory Availability Information
Qian Kenneth Zhang[1], Arian Aflaki[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: qiz91@pitt.edu
Research has shown that personalized pricing(PP), i.e., the practice of customizing prices for individual customers, can benefit firm and some customers. However, customer concerns about being targeted by such practices, especially those who pay higher prices. Using a Bayesian persuasion

framework, we study whether and under what conditions price can signal such PP implementation to customers. We also investigate whether disclosing inventory availability information can alleviate customer concerns and benefit the firm and customers.

4 Persuading Skeptics and Fans in the Presence of Additional Information

Tamer Boyaci[1], Soudipta Chakraborty[2], Huseyin Gurkan[3], [1]ESMT Berlin GmbH, Berlin, Germany; [2]University of Kansas, Lawrence, KS, [3]ESMT GmbH, Berlin, Germany. Contact: soudipta.c@ku.edu

Motivated by the practice of firms selectively soliciting reviews from experts, we study the information design problem of a demand-maximizing firm launching a product of unknown quality to a polarized market consisting of customers who have heterogeneous prior beliefs about quality and can acquire additional information from outside sources.

Emerging topics in FinTech and novel financing schemes

Community Committee Choice Session

Session Chair: Jie Ning, Case Western Reserve University, Cleveland, OH

1 Quality Signaling Through Crowdfunding Pricing

Ehsan Bolandifar[1], Zhong Chen[2], Panos Kouvelis[3], Weihua Zhou[4], [1]HSBC Business School, Peking University, Shenzhen, China; [2]East China Normal University, Shanghai, China; [3]Washington University in St. Louis, St. Louis, MO, [4]Zhejiang University, Hangzhou, China. Contact: zchen@aebs.ecnu.edu.cn

This paper studies an entrepreneur's pricing strategy in a reward-based crowdfunding campaign under asymmetric product quality information. We develop a stylized game-theoretic signaling model with funding and regular selling periods, propose two signaling mechanisms and investigate how entrepreneurs can leverage their pricing strategy to signal a high-quality project. We show that the distinct feature of crowdfunding, that is, the probabilistic nature of crowdfunding, plays different roles in one- and two-price signaling. It is the driving force for the separating equilibrium in one-price signaling, and in two-price signaling, it affects how the entrepreneur should manipulate his funding and regular selling prices to reduce signaling cost.

2 Bargaining, Investment, and Trade Credit

Leon Chu[1], S. Alex Yang[2], Jin Yao[3], [1]Cheung Kong Graduate School of Business, Beijing, China; [2]London Business School, London, United Kingdom; [3]The University of Hong Kong, Hong Kong, Hong Kong

We propose a new theory that explains the prevalent usage of trade credit by even financially unconstrained firms. Using an alternative-offer bargaining model, we study the impact of trade credit on bilateral supply chain relationships and capacity investment. Under this bargaining framework, trade credit alters how the total payoff is shared between the two parties. This in turn alleviate holdup problem and boost supply chain capacity investment. Specifically, with trade credit, the market boost investment and profits of two parties in the supply chain are higher than those under the trade credit being not allowed.

3 Automating Supply Chain Contracts in the Presence of Demand Shifts and Contract Execution Lag

Xiaohang Yue, University of Wisconsin-Milwaukee, Milwaukee, WI

We develop an analytical model in which a supply chain can adopt either a conventional non-automated (long-term) contract or an automated contract in response to a potential demand shift. Under the automated contract, the wholesale prices are dynamically updated based on embedded Bayesian detection of the demand shift. A higher automation level means a smaller lag in executing the updated wholesale prices. A fully automated contract is known as a smart contract. We find that the magnitude and timing uncertainty of the demand shift are positive factors that favor the adoption of the automated contract in a supply chain. We also extend the model and explore the effect of supply chain competition on the adoption of automated contracts when two supply chains have Cournot competition.

Recent topics in inventory and supply chain management

Flash Session

1 Economic Policy Uncertainty and Inventory Holdings: Global Evidence

Rajeev A[1], Vishnu K Ramesh[2], Athira A[3], [1]IIM Raipur, Raipur, India; [2]IIM Rohtak, Rohtak, India; [3]IIM Bangalore, Bangalore, India

Using economic policy uncertainty (EPU) as a proxy to measure country-level policy uncertainty, we study how policy shocks impact inventory levels. We also investigate how the association between EPU and inventories varies with respect to leanness, industry type, and country-development status. We find that higher policy uncertainty leads to an overall reduction in inventory holding. In our subsequent analysis, we find that amid rising EPU, firms increase their proportion of raw materials and reduce work-in-progress inventory and finished goods. Further, we find that the negative effect of policy uncertainty on inventory is less pronounced for lean and non-manufacturing firms. We also document that the negative association between EPU and inventory is more severe amongst firms in emerging firms.

2 A Model for Planning the Production of Multi-Product Orders in Flexible Deadlines Settings

Cristian D. Palma, Universidad del Desarrollo, Concepcion, Chile. Contact: cristianpalma@udd.cl

Most of the time, customers place production orders that include different products. Current optimization models for production planning aggregate different orders and translate them into product demand constraints to be met in specific periods according to the order deadlines. We show a model that explicitly considers production orders instead of products, and provides the flexibility of completing orders before their deadlines, allowing a more flexible use of resources. The model is used to plan the production in a sawmill, and both the model formulation and its benefits are presented.

3 Supply Chain Resilience:The Intervening Roles of Autonomy and Heteronomy

Jiuh-Biing Sheu[1], Vivi Kuo[2], [1]National Taiwan University, Taipei, Taiwan; [2]National Chin-yi University of Technology, Taichung, Taiwan

This paper investigates the moderating effects of autonomy and heteronomy on strategic procurement planning and customers' panic buying to influence supply chain resilience amid the beginning of the Covid-19 pandemic. Meanwhile, resilience restoration will have reciprocal causality on the buyers and end customers. Drawing on hyperbolic discounting theory and supply chain risk management research, we create a conceptual model that autonomy and heteronomy(Name-based rationing system, NBRS) considered separately are treated as two critical moderators on the effect of strategic procurement planning and consumers' panic buying on supply chain resilience.

4 Assessing Supply Chain Disruption Severity and Occurrence with a Competing Risk Model Using Random Survival Forests

Amin Keramati, Afrooz Moatari-Kazerouni, Widener University, Chester, PA, Contact: akeramati@widener.edu

Supply chain disruptions can significantly impact business operations, leading to increased costs and revenue loss. Previous research focused on predicting disruption occurrence or severity, but this study introduces a competing risk model to assess both aspects simultaneously. The authors utilize Random Survival Forest, a machine learning algorithm effective in handling high-dimensional data. The findings offer businesses and decision-makers an improved understanding of the simultaneous effects of disruption causes on severity and occurrence likelihood, enabling better preparation and management of potential disruptions.

5 Building a Resilient Supply Chain to Face Disruption: An Empirical Study

Subarna Haque[1], Mehmet Bayram Yildirim[1], Mehmet Barut[2], [1]Wichita State University, Wichita, KS, [2]Wichita State University, Wichita, KS, Contact: sxhaque@shockers.wichita.edu

Most organizations were not prepared for the disruptions caused by the COVID-19 pandemic. As a result, this pandemic impacted every aspect of the supply chain. Therefore, in this empirical study we have focused on the effect of risk mitigation strategies and supply chain operational efficiency to build supply chain resiliency. The result of this empirical study indicates that the proactive risk mitigation strategies have a positive impact on the supply chain operational efficiency; supply chain operational efficiency has a positive impact on the supply chain resilience; there is no significant moderating impact of the post risk mitigation strategies on the relationship between supply chain operational efficiency and supply chain resiliency.

6 Online Marketplace Channel Introduction Strategies Of Logistics Service Supply Chain

Jing Xu[1], Nengmin Wang[2], [1]Xi'an Jiaotong University, Xi'an, China; [2]Xi'an Jiaotong university, Xi'an, China. Contact: xujing@stu.xjtu.edu.cn

This study investigates the online marketplace channel introduction and information transparency investment strategies in a logistics service supply chain (LSSC) comprising a service integrator (LSI) and a service provider (LSP). We compare three models in centralized and decentralized supply chains: the reselling model, the dual-channel model, and the marketplace model. We find that the competition in dual-channel presents a bright side on information transparency investment in some cases, and in a centralized supply chain, the dual-channel model is always a dominant strategy. However, the case in which the LSI and LSP reach a consensus is limited in a decentralized supply chain, and a sufficient low commission rate and high investment efficiency are not favorable for LSP and LSI, respectively.

Socially Responsible Supply Chains

Community Committee Choice Session

Session Chair: Leon Valdes, University of Pittsburgh, Pittsburgh, PA

1 Transparency into Sustainability Initiatives: A Field Experiment

Neslihan Ozlu[1], Basak Kalkanci[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: neslihan.ozlu@scheller.gatech.edu

As customers become more aware of the importance of sustainable supply chains, companies are being prompted to be transparent about their environmental and social responsibility initiatives and communicate them to customers. We collaborate with an apparel company that is active in both internal and external responsibility initiatives. Through our field experiments, we use audio and video displays to inform customers about these initiatives. By conducting these experiments in developing countries, we can analyze the effect of these initiatives on customers' purchasing behavior, and compare them with findings in the develop world.

2 Sustainability Implications of Supply Chain Responsiveness

Robert Swinney, Ali Kaan Tuna, Duke University, Durham, NC, Contact: alikaan.tuna@duke.edu

We study the environmental implications of a critical decision made by many firms: whether to adopt a responsive supply chain (prioritizing speed) or an efficient supply chain (prioritizing cost). We analyze a model wherein responsiveness increases marginal costs, decreases leadtimes, and changes the per-unit environmental impact of production and distribution. We consider three pathways to achieve responsiveness: offshoring uses expedited production and transportation methods; nearshoring reduces the physical distance between source and destination; and hybrid nearshoring is a mix of efficient production and nearshoring. We show that responsiveness is likely to both maximize firm profit and minimize environmental impact when demand variability is high and unsatisfied customers substitute with a product that generates high environmental impact.

3 Mitigating Shortages Of Generic Drug Supply: The Role Of Risk Certification

Robert Swinney, Xiaoyu Wu, Can Zhang, Duke University, Durham, NC, Contact: xiaoyu.wu@duke.edu

Generic drugs play a vital role in the U.S. healthcare system. However, generic drugs have experienced severe shortages due to supply disruptions, caused by a number of factors including low profit margins that lead manufacturers to underinvest in supply reliability. The U.S. Food and Drug Administration has recently proposed to implement a certification system that assesses the reliability of generic drug manufacturers. We propose a game-theoretic model that captures the effects of such a reliability certification. We characterize mandatory and voluntary certification schemes and discuss the impact of subsidizing reliable suppliers in the certification system. Interestingly, certification may motivate suppliers to invest more in reliability; however, this may increase the likelihood of a shortage once the buyer adjusts its sourcing strategy in response.

4 Behavioral Biases in Social Audits: An Experiment

Gabriel Pensamiento[1], Leon Valdes[2], [1]Katz Business School, University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, PA, Contact: gap75@pitt.edu

Companies often rely on third-party audits to assess the social and environmental practices of their suppliers. However, empirical evidence suggests that these audits may be too lenient and that poor practices can go undetected or unreported. We designed an incentivized lab experiment to investigate some of the causes and mechanisms behind this behavior. Specifically, we examine how the supplier choosing and/or paying the auditor affects the leniency of audit reports. In addition, we explore whether and to what extent these effects are impacted by what received information suggests is the supplier's true type, auditors' biased beliefs (stemming from motivated reasoning), and reciprocity towards the audited firm.

Behavioral Revenue Management

Community Committee Choice Session

Session Chair: Haokun Du, The University of Texas at Dallas, Richardson, TX

Session Chair: Na Zhang, Warrington College of Business, University of Florida, Gainesville, FL

1 Bargaining for Advance Purchase Discount

Haokun Du, Minmin Zhang, Elena Katok, The University of Texas at Dallas, Richardson, TX

Traditional newsvendor model concerns a highly structured one-shot game. In this paper, we consider two extensions to the traditional model: the supplier could produce more than what the retailer orders and the retailer could order additionally after demand realization, and (some of) the terms of transfer are negotiated in an unstructured manner. Our theory builds upon Nash bargaining framework and utilizes backward induction to derive normative predictions. We consider four different schemes and propose to test the theories with experiments. Preliminary results suggest that the theory fails to capture behavioral regularities and we discuss some of the implications.

2 Sharing Economy Platforms with Reference-Dependent Gig Workers

Na Zhang[1], Anand Paul[2], Liangfei Qiu[3], [1]Warrington College of Business, University of Florida, Gainesville, FL, [2]University of Florida, Gainesville, FL, [3]University of Florida Warrington College of Business Administration, Gainesville, FL

The sharing economy and gig workers have become a major feature in modern economies. The empirical literature shows that gig workers have reference-dependent, loss-averse preferences toward wage. To fill the gap between prior theoretical work, we initiate a theoretical study of gig worker's reference-dependent, loss-averse preferences in sharing economy platforms.

3 Community/Committee'S Choice Submission

Qiuxia Chen, The University of Texas at Dallas, Richardson, TX

4 Behavior-Based Personalization with Endogenous Consumer Preferences

Dawei Jian, University of Wisconsin - Milwaukee, Milwaukee, WI

Behavior-based personalization allows firms to improve product match, build long-term relationships, capitalize on CLV. We study a new class of personalization problems, where a consumer's past behavior reveals her current preference, and influences her future valuation. A challenge is how to simultaneously learn and shape the consumer's evolving preferences through service offerings. The optimal solution serves the purposes to prevent cannibalization, exploit consumer habituation, and extract surplus. The solution deploys a novel mechanism of homogenization to reduce future valuation heterogeneity. Our study helps explain the popularity of behavior-based personalization: it can help firms to leverage consumer uncertainty, relax self-selection constraints, and internalize surplus gain. As such, it can improve social welfare and produce Pareto outcomes.

Network Optimization Applications

Contributed Session

Session Chair: Dung Nguyen, Colorado State University, Fort Collins, CO

1 Boosting Efficiency in Power System State Estimation Leveraging Attention Mechanism

SangWoo Park, New Jersey Institute of Technology (NJIT), North Bergen, NJ, Contact: sangwoo.park@njit.edu

Ensuring stability in power systems requires accurate state estimation, which is challenging due to the presence of noise in measurements, nonlinearity of power flow equations and potential false data injections. We introduce the Graph Attention Estimation Network (GAEN) model for power system state estimation, which leverages the graph structure of power grids for efficient information exchange, distributed architecture, and resilience to cyber-attacks. Using Graph Convolutional Neural Networks (GCNNs) and attention mechanisms, we address the limitations of previous architectures. Empirical results show superior performance, scalability, and heightened efficacy compared to traditional techniques. This work advances the integration of learning architectures in power system state estimation, fostering reliable and secure power networks.

2 Production Networks Resilience: Cascading Failures, Power Laws and Optimal Interventions

Marios Papachristou[1], M. Amin Rahimian[2], [1]Cornell

University, Ithaca, NY, [2]University of Pittsburgh, Pittsburgh, PA, Contact: rahimian@pitt.edu

We propose a node percolation process on production networks that model product suppliers failing independently due to exogenous, systemic shocks and causing other products to fail when production requirements are unmet. We first show that the size of the cascading failures follows a power law in random directed acyclic graphs, whose topology encodes the natural ordering of products from simple raw materials to complex products. This motivates the need for a resilience metric, which we define as the maximum magnitude shock the production network can withstand with only a small fraction of products failing. We study the resilience of several architectures and classify them as resilient or fragile depending on their topological attributes. Finally we offer optimal interventions for improving resilience, empirically evaluate the resilience metrics and interventions.

3 A Benders-Decomposition Approach for Network Topology Optimization with Port Selection

Linxin Yang[1], Yuan Wang[2], Akang Wang[2], Xiaodong Luo[2], [1]The Chinese University of Hong Kong, Shenzhen, Shenzhen, China; [2]Shenzhen Research Institute of Big Data, Shenzhen, China. Contact: linxinyang@link.cuhk.edu.cn

The network topology optimization problem with port selection aims to identify routes for data streams and data-port assignments in wireless networks such that the total operational cost is minimized. We formulate this problem as a mixed-integer linear program and then tackle it via a Benders-decomposition approach. The master problem determines data flow routes while the subproblem assigns ports to each data stream. Since the subproblem entails discrete decision-making, we resort to scaled cuts for convexification. We conduct extensive computational experiments, and the results demonstrate that our proposed approach significantly outperforms off-the-shelf general-purpose optimization solvers.

4 Improved Airline Network Topologies for Building Resilient & Robust Aviation Infrastructures

Ashwini Ravindran, Sergiy Butenko, Texas A&M University, College Station, TX

We propose new mathematical models to generate network connectivity patterns for airline networks in order to provide cost-effective solutions for enhanced operational efficiency and airport connectivity with improved tolerance to node disruptions. The objective is to enable the creation of a modeling and optimization framework for the design and development of commercial airline networks and analyze them from a graph theoretic perspective. We compare these newly developed theoretically optimal network topologies with the existing airline networks to evaluate its performance with regard to connectivity, robustness, resilience and tolerance to targeted attacks.

5 A Scalable Optimization Model to Prioritize Landscape Fuel-Break Investment for Effective Wildfire Management

Dung Nguyen[1], Yu Wei[1], Erin Belval[2], Matthew Thompson[3], Benjamin Gannon[4], Jesse Young[5], David Calkin[5], [1]Colorado State University, Fort Collins, CO, [2]Rocky Mountain Research Station, USDA Forest Service, Fort Collins, CO, [3]USDA Forest Service, Rocky Mountain Research Station, Fort Collins, CO, [4]USDA Forest Service, National Office, Fire and Aviation Management, Fort Collins, CO, [5]USDA Forest Service, Rocky Mountain Research Station, Missoula, MT, Contact: dung.nguyen@colostate.edu

Optimization modeling for wildfire management has been a challenge due to the need for exact methods to handle vast datasets and large landscape scales. We introduce an exact optimization model based on mixed integer linear programming to prioritize investment in a landscape's fuel-break network and maximize protection against wildfires. We demonstrate the model's scalability through its implementation in a large Southern California landscape, with several hundred thousand simulated wildfires being used to find optimal fuel-break locations under different budget scenarios. Sensitivity analysis confirms the effectiveness and robustness of our model, making it a powerful tool to leverage data and improve decision-making in wildfire management.

1 A Beautiful Shock? Exploring the Impact of Pandemic Shocks on the Accuracy of Ai Forecasting in the Beauty Care Industry

Ilya Jackson, MIT, Cambridge, MA, Contact: ilyajack@mit.edu

This research focuses on the profound impact of the shocks caused by the COVID-19 pandemic on the accuracy of AI-based demand forecasting in the beauty care industry. It aims to understand the key factors that led to decreased forecasting accuracy during the pandemic and employs causal mediation analysis to systematically investigate this complex issue. The empirical analysis is conducted using extensive order data from a major beauty care product manufacturer and distributor, covering the pre-pandemic, pandemic, and post-pandemic periods. The findings reveal that it is primarily the increase in demand volatility, and not the surge in sales volume, that has led to an increase in forecasting errors. This research provides crucial insights into the nuanced effects of macroeconomic shocks and consumer behavior changes on AI-based forecasting within the beauty care industry. Furthermore, it highlights the importance of understanding the underlying mechanisms that drive forecasting errors, paving the way for more resilient and robust demand forecasting systems in the future.

2 Pickup and Delivery Problem with Time Window and Ride-Time Constraints

Xinbo Zhang, City University of Hong Kong, Hong Kong, Hong Kong. Contact: xinbzhang3-c@my.cityu.edu.hk

The PDPTW-RD is an important generalization of VRP and a basic distribution management problem that can be modeled for real-world problems and which consists of designing a set of minimum cost routes, originating and terminating at a central depot, for vehicles that service a set of customers with known demands. The customers must be assigned exactly once to vehicles such that the vehicle capacities are not exceeded. The service to a customer must begin within the time window when the customer permits the start of service. This paper proposes a path-based set-partitioned-liked formulation that derives the lower bounds. We propose the exact cut-and-column generation to find the optimal routes. Computational experiments show that our proposed algorithm can solve instances optimally up to around 50 requests.

3 Integrated Optimization of Train Path Selection and Rolling Stock Planning in Freight Transportation: A Column Generation Approach

Louis Fourcade[1,2], Stéphane Dauzère-Pérès[3], Juliette Pouzet[1], [1]SNCF SA, Saint-Denis, France; [2]Ecole Des Mines de Saint-Etienne, Gardanne, France; [3]Ecole Des Mines de Saint-Etienne, Gardanne, France

The optimal use of critical resources, in particular train paths, rolling stock and drivers, is crucial for railway companies to improve their operational efficiency and to reduce their costs. In this work, we explore the design and solutions through column generation of optimization models for the integrated planning of train paths and rolling stock for freight transport. We consider various constraints such as maximum load, maximum length, delivery time and rolling stock availability. Real-world data on the French railway network is used to validate the proposed approach, and good solutions are obtained in reasonable computational times. Our integrated approach is also compared with a sequential approach.

4 Capacity Pooling for Network Revenue Management

Asrar Ahmed[1], Milind Sohoni[2], Sumit Kunnumkal[3], Raja Gopalakrishnan[4], [1]ISB Hyderabad, Hyderabad, India; [2]Indian School of Business, Hyderabad, India; [3]ISB, India, India; [4]Indian Railways, New Delhi, India. Contact: asrar_ahmed@isb.edu

Motivated by the resource allocation rule used by a large passenger rail operator, we consider a novel variant of the classical network revenue management. In our setting, the firm, along with carrying dedicated capacities for its products, sets aside some of its capacity that is common for all products. The firm's decision problem is to determine the optimal partitioned and common pooled capacities. We model the above problem as a dynamic program and provide insights into simple conditions under which only-pooling or only-pooling is optimal. To address the large state space of the dynamic program, we develop a Lagrange relaxation-based solution, benchmark it against the deterministic linear program and find the Lagrange relaxation provides tighter upper bounds. Finally, we evaluate our solution on synthetic and real-world data sets.

5 Using Machine Learning/Regression Analysis to Solve the Equilibrium Network Design Problem

Lingyun (Iris) He, Terry Lee Friesz, Pennsylvania State University, State College, PA, Contact: lbh5479@psu.edu

For applications of realistic size, the continuous equilibrium network design problem is often too computationally intensive to be solved. To fill this gap, we developed machine learning models to predict the relationship between the equilibrium traffic flow and capacity improvement. We created a data set by fixing capacity improvements and solving for the corresponding equilibrium traffic flow using standard methods. These data were used to derive relationships between arc flows and capacity using a variety of regression schemes. Such relationships are used to reduce the problem to a conventional mathematical program whose solution is relatively easy and produces new local optima superior to those discovered historically using an MPEC formulation.

Optimization for Deep Learning: Modern Perspectives

Community Committee Choice Session

Session Chair: Kayhan Behdin, Massachusetts Institute of Technology, Cambridge, MA

1 A Theory for Overparameterization

Jianhao Ma, University of Michigan, Ann Arbor, MI

Overparameterization plays an extremely important role in modern machine learning. However, it is still unclear whether overparameterization affects underlining optimization. In this work, we identify some sufficient and necessary conditions under which overparameterization can benefit the optimization.

2 How Does Sharpness-Aware Minimization Minimize Sharpness?

Zhiyuan Li, Toyota Technological Institute at Chicago, Chicago, IL

Sharpness-Aware Minimization (SAM) is a highly effective regularization technique for improving the generalization of neural networks. However, the underlying working of SAM remains elusive. SAM intends to penalize a notion of sharpness of the model but implements a computationally efficient variant; moreover, a third notion of sharpness was used for proving generalization guarantees. his paper rigorously nails down the exact sharpness notion that SAM regularizes and clarifies the underlying mechanism. We also show that the two steps of approximations in the original motivation of SAM individually lead to inaccurate local conclusions, but their combination accidentally reveals the correct effect, when full-batch gradients are applied. Furthermore, we also prove that the stochastic version of SAM in fact regularizes the third notion of sharpness mentioned above.

3 On First-Order Meta-Reinforcement Learning with Moreau Envelopes

Mohammad Taha Toghani[1], Sebastian Perez-Salazar[2], Cesar A. Uribe[3], [1]Rice University, HOUSTON, TX, [2]Rice University, HOUSTON, TX, [3]Rice University, Houston, TX, Contact: mttoghani@rice.edu

We study the Meta-Reinforcement Learning (MRL) problem under the policy gradient formulation, where we propose a novel algorithm that uses Moreau Envelope surrogate regularizers to jointly learn a meta-policy that is adjustable to the environment of each individual task. Our algorithm, Moreau Envelope Meta-Reinforcement Learning (MEMRL), learns a meta-policy that can adapt to a distribution of tasks by efficiently updating the policy parameters using a combination of gradient-based optimization and Moreau Envelope regularization. We provide a detailed analysis of the MEMRL algorithm, where we show a sublinear convergence rate to a first-order stationary point for non-convex policy gradient optimization. We finally show the effectiveness of MEMRL on a multi-task 2D-navigation problem.

4 The Dynamics of Neural Network Training: Edge of Stability

Jeremy Cohen, Carnegie Mellon University, Pittsburgh, PA, Contact: jeremycohen@cmu.edu

According to classical optimization theory, gradient descent converges because its step size is set small relative to the curvature of the objective function. Yet recent studies have demonstrated that this is not how deep learning works. Instead, in deep learning, gradient descent *automatically* remains in low-curvature regions via an in-built negative feedback mechanism that was only discovered recently. The mechanism is: if the curvature is high, gradient descent oscillates, yet these oscillations implicitly trigger a movement into lower-curvature regions - an effect revealed by a cubic Taylor approximation (rather than the usual quadratic one). Rigorous mathematical analysis of this behavior is needed, and could even conceivably lead to improved algorithms for training neural networks.

First-Order Methods for Challenging Constrained Optimization Problems

Community Committee Choice Session

Session Chair: Paul Grigas, UC Berkeley, Berkeley, CA

1 Nonconvex Functional Constrained Optimization with Applications in Risk Aversion and Sparsity Control

Yi Cheng, Amazon LLC, Bellevue, WA

Risk and sparsity are essential in many applications, e.g., portfolio optimization, assortment planning, and healthcare treatment planning. Effectively balancing these requirements involves nonconvex functional constrained formulation and the creation of projection-free methods. In this talk, we introduce Level Inexact Proximal Point (LIPP) and Direct Nonconvex Conditional Gradient (DNCG) for solving challenging nonconvex functional constrained problems by generating sparse solution trajectory with risk aversion. LIPP leverages a convex oracle to solve a series of subproblems while DNCG is a single-loop algorithm directly accessing the conditional gradient step. Effectiveness of LIPP and DNCG is demonstrated by two risk averse sparse applications: (1) cardinality-constrained portfolio selection, (2) radiation therapy treatment planning.

2 Some Primal-Dual Theory for Subgradient Methods for Strongly Convex Optimization

Benjamin Grimmer, Danlin Li, Johns Hopkins University, Baltimore, MD, Contact: grimmer@jhu.edu

We consider (stochastic) subgradient methods for strongly convex but potentially nonsmooth non-Lipschitz optimization. We provide new equivalent dual descriptions (in the style of dual averaging) for the classic subgradient method, the proximal subgradient method, and the switching subgradient method. These equivalences enable optimal convergence guarantees for both a classic primal gap and a not previously analyzed dual gap. Consequently, our theory provides these classic methods with simple, optimal stopping criteria and optimality certificates at no added computational cost. Our results apply under nearly any stepsize selection and for a range of non-Lipschitz ill-conditioned problems where the early iterations of the subgradient method may diverge exponentially quickly (a phenomenon which, to the best of our knowledge, no prior works address).

3 Splitting Conditional Gradient Algorithms

Zev Woodstock, Zuse Institute Berlin (ZIB), Berlin, Germany

Classical Conditional Gradient minimization algorithms enforce a single closed convex constraint using its linear minimization oracle (LMO). We develop and analyze a method for minimization over an intersection of multiple sets without computing the LMO of their intersection (which is often computationally expensive) - instead, we use LMOs for the individual sets.

4 Stochastic First-Order Algorithms for Constrained Distributionally Robust Optimization

Hyungki Im[1], Paul Grigas[2], [1]UC, Berkeley, Berkeley, CA, [2]UC Berkeley, Berkeley, CA

We consider distributionally robust optimization (DRO) problems with multiple expectation constraints. We propose a generic stochastic first-order meta-algorithm, wherein the decision variables and uncertain distribution parameters are each updated separately by applying stochastic first-order methods. We then specialize our results when using particular versions of stochastic mirror descent to update both sets of variables. In this case, we demonstrate that the per iteration cost to update the decision variables is almost independent of the dimension of the distribution parameters. When the ambiguity sets are □^{2}-divergence sets, we additionally show that the update cost of the distribution parameters is almost independent of the dimension of the distribution parameters.

Geometry and Optimization Methods

Community Committee Choice Session

Session Chair: Dogyoon Song, 1</sup

Session Chair: Diego Cifuentes, Georgia Institute of Technology, Atlanta, GA

1 Geometry of Regularizing Norms and Structured M-Estimation

Dogyoon Song[1], Venkat Chandrasekaran[2], [1]University of Michigan, Ann Arbor, MI, [2]California Institute of Technology Division of Engineering and Applied Science, Pasadena, CA, Contact: dogyoons@umich.edu

Regularization is a fundamental technique in optimization with numerous applications. In this talk, we discuss the geometric properties of the solution of regularized optimization problems --- particularly the minimizer of the objective function consisting of a loss and a regularizing norm. We introduce a novel concept of "structure" induced by the regularizer in terms of geometric properties of the associated convex body. Further, we identify the class of regularizers that induce such a structure. Additionally, we examine the geometry of regularized M-estimators, presenting a condition for successful structure-consistent estimation. Our findings offer advancements in the analysis of graphical Lasso and low-rank matrix estimation, among others. Overall, these results provided enhanced insights into the role of regularization and its potential applications.

2 A Superlinearly Convergent Subgradient Method for Sharp Semismooth Problems

Vasileios Charisopoulos, Cornell University, Ithaca, NY
Standard first-order methods for nonsmooth optimization can be slow for "poorly conditioned" problems. In this talk, I will present a locally accelerated first-order method that is less sensitive to conditioning and achieves superlinear convergence near solutions for a broad class of sharp semismooth problems and discuss its stochastic extensions. The algorithm is inspired by Newton's method for solving nonlinear equations.
Joint work with Damek Davis.

3 Outlier-Robust Second-Order Nonconvex Optimization and Its Application to Low-Rank Matrix Sensing
Shuyao Li[1], Yu Cheng[2], Ilias Diakonikolas[1], Jelena Diakonikolas[1], Rong Ge[3], Stephen Wright[1], [1]University of Wisconsin-Madison, Madison, WI, [2]Brown University, Providence, RI, [3]Duke University, Durham, NC, Contact: shuyao.li@wisc.edu
Finding an approximate second-order stationary point (SOSP) is a fundamental problem in stochastic nonconvex optimization. However, this problem is poorly understood in the presence of outliers. In this paper, we study the problem of finding SOSPs where a constant fraction of the datapoints are arbitrarily corrupted. As our main application, low-rank matrix sensing can be robustly solved in our framework, which allows for corruptions in both the sensing matrices and the measurements. We further take advantage of the geometry of low-rank matrix sensing to show that if measurements are taken with no additive noise, we can achieve exact recovery with gradient descent. On the lower bound side, we establish a Statistical Query lower bound showing that the quadratic dependence on the dimension in the sample complexity is necessary for computationally efficient algorithms.

CC-North 222C
New advances in global optimization -- theory and applications
Community Committee Choice Session
Session Chair: Andy Sun, 1</sup

1 Advances in Constructing Tight Quadratic Underestimators for Global Optimization
William Strahl[1], Arvind Raghunathan[2], Nikolaos Sahinidis[3], Chrysanthos E. Gounaris[1], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Mitsubishi Electric Research Laboratories, Cambridge, MA, [3]Georgia Institute of Technology, Atlanta, GA
Global optimization algorithms typically rely on polyhedral outer approximations to determine lower bounds. We explore the potential of using quadratic outer approximations to expedite these algorithms by tightening bounds and increasing fathoming. Our approach is implemented in a cutting-plane algorithm that generates quadratic underestimators for C^2 convex and non-convex difference of convex functions by scaling the 2^{nd} order term of a Taylor series expansion. We will present methodological advances and computational results for these underestimators, including their hierarchical tightening through non-uniform Hessian matrix scaling and their impact in accelerating the convergence of outer approximation algorithms for MINLPs.

2 Facility Planning For EV Battery Recycling Via Adaptive Piecewise Linearization
Matthew Brun[1], Andy Sun[2], [1]Operations Research Center, MIT, Cambridge, MA, [2]MIT, Cambridge, MA, Contact: brunm@mit.edu
Recycling of spent electric vehicle (EV) batteries has the potential to address issues surrounding both disposal of retired batteries and sourcing of critical minerals required for new battery manufacture. We construct a long-term facility planning model to determine an optimal investment strategy in EV battery recycling plants. The model is a linearly constrained concave minimization problem, which we solve by a new global optimization algorithm that adaptively constructs piecewise linear approximations of the objective functions and solves them as a sequence of mixed-integer linear programs. This method converges to a global optimal solution in a finite number of iterations and allows for considerable speedup relative to spatial branch and bound algorithms by leveraging the power of MILP solvers to approach a continuous nonconvex problem.

3 Convexification Techniques for Fractional Programs
Mohit Tawarmalani[1], Taotao He[2], Siyue Liu[3], [1]Purdue University, West Lafayette, IN, [2]Shanghai Jiaotong University, Shanghai, China; [3]Carnegie Mellon University, Pittsburgh, PA, Contact: mtawarma@purdue.edu
We convexify various sets involving fractional functions using a projective transformation that allows us to clear denominators. This result recovers the SDP formulation for the convex hull of ratio of two nonconvex quadratics over an ellipsoid, yields new formulations to minimize quasiconvex functions defined as a ratio of a convex and a concave

function, and new results that relate convex hulls of certain functions that appear in distillation problems with the convex hull of moment curve.

4 Community/Committee'S Choice Submission

Multi-Stage Stochastic and Robust Programs

Community Committee Choice Session

Session Chair: Beste Basciftci, University of Iowa

1 Distributionally Robust Optimization with Decision-Dependent Information Discovery

Qing Jin[1], Angelos Georghiou[2], Phebe Vayanos[3], Grani Adiwena Hanasusanto[4], [1]University of Southern California, LA, CA, [2]University of Cyprus, Nicosia, Cyprus; [3]University of Southern California, Los Angeles, CA, [4]University of Illinois Urbana-Champaign, Urbana, IL, Contact: qingjin@usc.edu

We study two-stage distributionally robust optimization problems with decision-dependent information discovery (DRO-DDID) wherein (a portion of) the uncertain parameters are revealed only if an (often costly) investment is made in the first stage. We formulate the problem as a min-max-min-max problem and adopt the popular K-adaptability approximation scheme. We then present a decomposition algorithm that solves the K-adaptable formulation exactly. In particular, we devise a cutting plane algorithm which iteratively solves a relaxed version of the problem, evaluates the true objective value of the corresponding solution by a branch-and-cut algorithm, generate valid cuts and imposes them in the master problem. We showcase the effectiveness of our framework on the R&D project portfolio optimization problem and the best box problem.

2 Multi-Stage Stochastic Programming for Integrated Hurricane Evacuation and Logistics Planning

Sudhan Bhattarai, Yongjia Song, Clemson University, Clemson, SC, Contact: sudhanb@g.clemson.edu

We study an integrated hurricane relief logistics and evacuation planning (HRLEP) problem. We propose stochastic optimization models and methods that integrate the hurricane relief item pre-positioning problem and the hurricane evacuation planning problem, which are often treated as separate problems in the literature, by incorporating the forecast information as well as the forecast errors (FE). Specifically, we fit historical FE data into an auto-regressive model of order one (AR-1), from which we generate FE realizations to create evacuation demand scenarios. We propose a fully adaptive multi-stage stochastic programming method to solve HRLEP. We conduct a preliminary numerical experiment based on real-world data to validate the value of stochastic optimization.`

3 Adaptive Multistage Stochastic Programming

Sezen Ece Kayacik[1], Beste Basciftci[2], Albert Schrotenboer[3], Evrim Ursavas[4], [1]University of Groningen, Groningen, Netherlands; [2]University of Iowa, Iowa City, IA, [3]Eindhoven University of Technology, Eindhoven, -, Netherlands; [4]University of Groningen, Groningen, Netherlands

Multistage stochastic programming is a powerful tool that allows decision-makers to adapt decisions at each stage based on the realized uncertainty. However, fully adaptive approaches may not be applicable due to the need for consistency in decision-making. To strike a balance between adaptability and stability, we propose an adaptive multistage stochastic programming approach which revises the decisions at stages determined optimally providing a partial flexibility. We introduce a novel model with theoretical properties to reduce the model size. We develop a solution algorithm based on the Integer L-shaped method and Benders decomposition. Computational experiments on lot-sizing and generation expansion planning show the importance of partial flexibility, as our approach converges to optimal multistage stochastic programming even with limited revisions.

4 Markov Chain-Based Policies for Multi-Stage Stochastic Integer Linear Programming

Margarita Castro[1], Merve Bodur[2], Yongjia Song[3], [1]Pontificia Universidad Católica de Chile, Santiago, Chile; [2]University of Toronto, Toronto, ON, Canada; [3]Clemson University, Clemson, SC, Contact: bodur@mie.utoronto.ca

We introduce a novel aggregation framework to address multi-stage stochastic programs with mixed-integer state variables and continuous local variables (MSILPs). Our aggregation imposes additional structure to the integer state variables by leveraging the information of the underlying stochastic process, which is modeled as a Markov chain (MC). We demonstrate that the aggregated MSILP can be solved exactly via a branch-and-cut algorithm integrated with a variant of stochastic dual dynamic programming. To improve tractability, we propose to use this approach to obtain dual bounds. We apply two-stage linear decision rule approximations and propose MC-based variants to obtain high-quality decision policies with significantly reduced computational effort. We test the proposed methodologies in a novel MSILP model for hurricane disaster relief logistics planning.

Exploring Equilibrium in Games

Contributed Session

Session Chair: Bill W. Corley, University of Texas at Arlington, Arlington, TX

1 Energy Function Based Approach for Generalized Nash Equilibrium Problems

Nabiha Nasir Orpa, Lichun Li, FAMU-FSU College of Engineering, Tallahassee, FL, Contact: no18k@fsu.edu

Generalized Nash Equilibrium (GNE) is an extended version of the traditional Nash Equilibrium, where players' objectives and strategy sets depend not only on their own actions but also on their opponents'. It has many practical applications in non-cooperative multi-agent problems, but its computational difficulties limit its application in practical scenarios. Our proposed algorithm uses an energy function-based approach to efficiently compute Nash Equilibrium of GNE problems, which include equality and inequality constraints. The energy function's unique structure produces a zero value when the players reach the equilibrium point. To address the constraint component of the problem, we have introduced a set of dual players with special objective functions, which act as opponents of the primal players when they go out of bounds.

2 Perfect Bayesian Equilibrium with Common-Action-Independent Consistency and Its Square-Root-Barrier Selection

Yiyin Cao[1], Chuangyin Dang[2], [1]City University of Hong Kong, Hong Kong, Hong Kong; [2]City University of Hong Kong, Kowloon, China. Contact: yiyincao2-c@my.cityu.edu.hk

The concept of perfect Bayesian equilibrium was established through a slight relaxation to the requirements of sequential equilibrium while sustaining the subgame perfection. However, this establishment lacks a practicable and effective formulation for computationally finding such an equilibrium. To resolve this deficiency, this paper introduces common-action-independent consistency on beliefs and develops a mathematical characterization of perfect Bayesian equilibrium with this consistency through local sequential rationality. As a result of this characterization, the perfect Bayesian equilibrium can be explicitly specified by a polynomial system, which leads to a differentiable path-following method for computing such an equilibrium. Numerical results further confirm the effectiveness and efficiency of the method.

3 Meta Heuristic Optimization of Mechanism Design

Zheyong Bian[1], Bijun Wang[2,2], [1]University of Houston, Houston, TX, [2]Florida Polytechnic University, Lakeland, FL, Contact: zbian2@central.uh.edu

This research innovates the optimization of mechanism design problems, in which multiple rational agents are coordinating a Nash Equilibrium state in complex systems. Different from conventional optimization, given a set of decision variables, an objective function, and a set of constraints for these decisions, mechanism optimization aims to selects the optimal mechanism from a set of feasible mechanisms with an objective function given a set of Nash Equilibrium states and a set of constraints for mechanism results. Instead of developing analytical solutions to mechanism optimization problems that can be formulated as stochastic bi-level optimization models, this research develops a novel concept of mechanism optimization meta-heuristics that iterate to search in a mechanism space by changing possible mechanism parameters and mechanism results.

4 Quasi-Sequential Equilibrium and Its Smooth-Path Selection

Yiyin Cao, Chuangyin Dang, City University of Hong Kong, Kowloon, Hong Kong

By slightly relaxing the requirements of sequential rationality and consistency on beliefs in a sequential equilibrium while retaining subgame perfection, we establish the concept of quasi-sequential equilibrium through the introduction of common-action-and-belief-independent consistency. This relaxation allows an explicit mathematical characterization through local sequential rationality, which directly yields a polynomial system as a necessary and sufficient condition for a quasi-sequential equilibrium. For many well-known games, a quasi-sequential equilibrium is identical to a sequential equilibrium. To compute such an equilibrium, we develop a differentiable path-following method by constituting a square-root-barrier agent extensive-form game. Numerical results further confirm the effectiveness and efficiency of the method.

5 Pure Scalar Equilibria for Normal Form Games

Bill Corley, University of Texas at Arlington, Arlington, TX, Contact: corley@uta.edu

A scalar equilibrium (SE) is an alternative type of equilibrium in pure strategies for an n-person normal-form game G. It yields a pure strategy for each player of G by maximizing an appropriate utility function chosen by the players or an arbitrator over the acceptable joint actions. An SE is an equilibrium since no players of G can increase the value of this utility function by changing their strategies. Examples include a greedy SE in which the players' action give them the largest individual payoffs jointly possible, as well as a satisficing SE in which each player achieves a personal target payoff value. The vector payoff associated with each of these SEs is shown to be Pareto optimal and computationally tractable.

Security and Privacy of Intelligent Transportation Systems (ITS)

Community Committee Choice Session

Session Chair: Mohamadhossein Noruzoliaee, University of Texas Rio Grande Valley, Edinburg, TX

1 Anomaly Detection Against Gps Spoofing Attacks on Connected and Autonomous Vehicles Using Learning from Demonstration

Yiheng Feng, Purdue University, West Lafayette, IN, Contact: feng333@purdue.edu

GPS spoofing attacks pose great challenges to connected vehicle (CVs) safety applications and localization of autonomous vehicles (AVs). In this study, we a novel anomaly detection method using learning from demonstration is developed, which can be implemented in both vehicles and at the transportation infrastructure. A computational-efficient driving model, which can be learned from historical trajectories of the vehicles, is constructed to predict normal driving behaviors. Then a statistical method is developed to measure the dissimilarities between the observed trajectory and the predicted normal trajectory for anomaly detection. We validate the proposed method using two threat models on two real-world datasets. Results show that the proposed model is able to detect almost all of the attacks in time with low false positive and false negative rates.

2 Informational Cyber Resilience in Intelligent Transportation Systems

Quanyan Zhu, New York University, New York, NY, Contact: qz494@nyu.edu

Transportation systems rely heavily on information systems, creating vulnerabilities to data poisoning, manipulation, and misinformation across inter-vehicle, intra-vehicle, system, and human domains in intelligent transportation systems (ITS). Cyber resilience is critical for dependable and safe transportation infrastructure. Our framework enables quantification of tradeoffs and facilitates proactive mitigation through feedback and learning-based mechanisms. We will discuss zero-trust and proactive defense mechanisms to mitigate Advanced Persistent Threats (APTs) on 5G-enabled vehicle-to-vehicle communication systems, data poisoning attacks on GPS navigation systems, and misinformation attacks on route recommendation systems.

3 Anomaly Detection and String Stability Analysis in Connected Automated Vehicular Platoons

Yiyang Wang[1], Ruixuan Zhang[2], Neda Masoud[1], Henry Liu[1], [1]University of Michigan, Ann Arbor, MI, [2]New York University, New York, NY, Contact: ruixuan.zhang@nyu.edu

In this study, we develop a comprehensive framework for modeling the impact of cyberattacks on the safety, security, and head-to-tail stability of connected and automated vehicular platoons. We propose a platoon dynamics model with heterogeneous time delays from communication channels and/or sensors. Utilizing this model, we create an augmented state extended Kalman filter (ASEKF) for sensor data smoothing and anomaly detection. We introduce pseudo string stability, a novel concept for assessing platoon stability under cyberattacks and platoon model uncertainties. We demonstrate the relationship between a platoon's pseudo string stability and its detection rate, identifying the critical detection sensitivity/recall needed for maintaining pseudo string stability.

4 Toward Certified Cybersecurity of Learning-Based Traffic Signal Control

Mohamadhossein Noruzoliaee, University of Texas Rio Grande Valley, Edinburg, TX, Contact: h.noruzoliaee@utrgv.edu

Reinforcement learning (RL) has gained traction in traffic control applications, such as traffic signal control, due to its computational capability to deal with real-time changes in traffic flow dynamics. Despite growing popularity, RL has been recently found to be vulnerable to adversarial attacks, precluding its reliable application unless vulnerabilities are mitigated. This research aims to certify the security of an RL-based traffic signal controller (victim) against adversarial attack on the victim's state observations. We explore an optimal (strategic) adversary and an optimal (robust) victim, which can adapt to each other's actions. The adversary-victim interaction is characterized as a new state-adversarial Markov decision process (SAMDP), which is solved by decomposing it into two novel MDPs with redefined environment dynamics and reward functions.

Wednesday, October 18, 9:30 AM - 10:45 AM

Machine Learning Approaches to Vehicle Routing

Community Committee Choice Session

Session Chair: Gustavo Hurovich, Erasmus University, Rotterdam, Netherlands

1 Machine Learning Approaches to Estimate Routing Costs in Home Delivery Time Slot Management

Gustavo M. Hurovich, Luuk P. Veelenturf, Niels Agatz, Rotterdam School of Management, Erasmus University, Rotterdam, Netherlands. Contact: hurovich@rsm.nl

In the context of online attended home delivery services, customers are usually presented with a selection of available timeslots to choose from. When a customer shows up, the seller must quickly decide which timeslots to offer and whether to incentivize them to pick one that allows for efficient routes. To determine the extra cost and distance associated with accepting that customer in each available timeslot, a Vehicle Routing Problem with Time Windows (VRPTW) must be solved, which is a difficult problem. In practice, routing heuristics are in place to estimate these costs. We explored a different approach, based on Machine Learning, to get quick and reliable estimations of the marginal routing costs for each timeslot.

2 Application of Reinforcement Learning in Optimal Truck-Drone Fleet Sizing and Routing

Mohammadhosein Pourgholamali[1], Mohammad Miralinaghi[2], Samuel Labi[1], [1]Purdue University, West Lafayette, IN, [2]Illinois Institute of Technology, Chicago, IL

Recent advances in unmanned aerial vehicle (UAV) technology have encouraged logistics firms to adopt UAVs as a viable transport alternative. However, route optimization for delivery trucks and UAVs is challenging due to the special UAV operations (such as battery and loading limitations). This study leverages reinforcement learning (RL) to solve this problem and optimize the total delivery service cost. The control variables are the truck and UAV fleet sizes and their optimal routes, and the constraints include UAV range limitations and available fleet size. Trucks are assumed to provide battery swapping for the UAVs during the delivery service. The performance of the RL algorithm is evaluated by comparing the solutions generated by the RL algorithm with those generated by a metaheuristic using numerical experiments.

3 Combinatorial Optimization Enriched Machine Learning for the Dynamic and Stochastic Inventory Routing Problem

Toni Greif[1], Louis Bouvier[2], Christoph M. Flath[1], Sonja Rohmer[3], Axel Parmentier[2], Thibaut Vidal[4], [1]University of Wuerzburg, Wuerzburg, Germany; [2]CERMICS, Ecole des Ponts, Marne-la-Vallée, France; [3]HEC Montréal, Montréal, QC, Canada; [4]CIRRELT & SCALE-AI Chair in Data-Driven Supply Chains, Polytechnique Montréal, Montréal, QC, Canada. Contact: toni.greif@uni-wuerzburg.de

In this research, we introduce a novel combinatorial optimization-enriched imitation learning pipeline to solve inventory routing problems with stochastic demand and dynamic inventory updates. After each inventory update, our approach reduces replenishment and routing decisions to an optimal solution of a prize-collecting traveling salesman problem for which well-established algorithms exist. Discovering good prize parametrizations is non-trivial, and thus we use machine learning. We evaluate the performance of our pipelines in settings with steady-state and more complex demand patterns. Compared to previous works, we find good-quality decisions very quickly and can leverage contextual information.

4 An Optimal Order Consolidation Policy for Last-Mile Delivery: A Deep Q-Learning Approach to Vehicle Routing Plans

Yooneun Lee[1], Seokgi Lee[2], Hyeong Suk Na[3], Sang Jin Kweon[4], Yuncheol Kang[5], [1]University of Dayton, Dayton, OH, [2]Youngstown State University, Youngstown, OH, [3]University of Missouri-Columbia, Columbia, MO, [4]Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of; [5]Ewha Womans University, Seoul, Korea, Republic of. Contact: ylee03@udayton.edu

In this study, we focus on developing an algorithm for order consolidation policies and vehicle routing problems with time windows for retailers. The proposed system consists of interactive modules to manage customer orders for a planning horizon. A gateway module handles real-time delivery requests. The simulator creates vehicle routing plans and makes decisions on shipment and order consolidation for various operating scenarios based on how customers place orders and how these orders are fulfilled by multiple warehouses. To learn optimal polices for the current system state, resulting expected rewards are fed back to the learning module, which updates and learns optimal using a double deep Q-learning algorithm. The efficiency of the proposed algorithm is demonstrated through numerical experiments of medium-size problems for a month-long period.

New Methods for Inventory Policies

Contributed Session

Session Chair: Nayan Chakrabarty, University of Arkansas, Fayetteville, AR

1 Adapting the Inventory Routing Problem to Improve Water Access and Quality in Water Insecure Areas

Emerald Dudzinski, Virginia Tech, Blacksburg, VA, Contact: emerald@vt.edu

Access to clean drinking water can be a luxury in impoverished communities in the United States. Nationally, more than 2 million people lack access to safe drinking water and indoor plumbing, and this figure does not include homes with a working tap of unsafe drinking water. Therefore, a far larger number of Americans face water insecurity. A recent examination of US Census and Safe Drinking Water Act violation data reveals that rural low-income and minority communities are significantly more likely to be burdened with unavailable or unsafe in-home drinking water. This research explores an alternative to traditional water infrastructure: how to optimally deliver drinking water to households without access to reliable, clean water sources by adapting the inventory routing problem and creating heuristic algorithms to schedule efficient water delivery.

2 Integrating Neural Network And Genetic Algorithms For Location-inventory-routing Problem

Guoqing Zhang, Behrang Bootaki, University of Windsor, Windsor, ON, Canada. Contact: gzhang@uwindsor.ca

We consider a new type of Location-Inventory-Routing (LIR) model, which can be leveraged to configure production and delivery systems. Considering the complexity of the LIR problems, a new solution strategy is presented by integrating the genetic algorithm (GA) and the neural network regression models. In our solution method, the problem is decomposed into two parts: (1) the location-allocation decision, and (2) lot-sizing and routing sub-decisions. The neural network regression models help GA evaluate the total fitness of each chromosome by giving the cost feedback for lot-sizing and routing subproblems. The numerical results are presented. We also applied the method to a real-world problem.

3 Improved Iterated Greedy Constraint Programming for Scheduling Steelmaking Continuous Casting

Dongyun Kim, Yeonjun Choi, Kyungduk Moon, Myungho Lee, Kangbok Lee, POSTECH, Pohang, Korea, Republic of. Contact: choichoi@postech.ac.kr

We study a steelmaking-continuous casting (SCC) scheduling problem, which is a variant of the hybrid flow shop scheduling problem. We improve the existing method called Iterated Greedy Constraint Programming (IGC) which contains a greedy heuristic constructing an initial solution and a large neighborhood search (LNS) while iteratively solving constraint programming models. Various neighborhood designs were introduced for the LNS of our algorithm and the influence of each neighborhood on the performance was measured across different scenarios. Computational experiments show that our improved algorithm gives a superior solution for the given instances, and we discover it can also be successfully applied to other SCC scheduling problems.

4 A Partial Survival Signature Method to Identify Time-Based Policies for Redeploying Nodes into a Wireless Sensor Network

Nayan Chakrabarty, Kelly Sullivan, University of Arkansas, Fayetteville, AR, Contact: nchakrab@uark.edu

We consider the problem of redeploying nodes into a wireless sensor network (WSN), where the network is inspected after a fixed time interval, and new sensor nodes are deployed to maintain reliable area coverage. Whereas previous research assumes *i.i.d.* failure for all nodes, we use multiple classes of sensor nodes to present a situation where positioning within the network affects failure rate of sensor nodes. We propose a partial survival signature (PSS) approach for estimating coverage reliability under a given time-based redeployment policy, where the PSS is estimated by Monte Carlo simulation. This PSS representation enables efficient re-evaluation of coverage reliability under different redeployment policies; so, we show that the method can be applied to identify time-based redeployment policies that are efficient with respect to cost and coverage reliability.

AI/ML in Surface Mining and Processing

Community Committee Choice Session

Session Chair: Bart Maciszewski, Imperial Oil, Calgary, AB, Canada

Session Chair: Andrew Milne, 1</sup

1 Primary Separation Vessel Control Using Rl

Jansen Fajar Soesanto[1], Bart Maciszewski[2], Leyli Mirmontazeri[2], Sabrina Romero[2], Mike Michonski[2], Andrew Milne[2], Biao Huang[1], [1]University of Alberta, Edmonton, AB, Canada; [2]Imperial Oil, Calgary, AB, Canada. Contact: soesanto@ualberta.ca

The primary separation vessel is critical for bitumen extraction from oil sands. However, controlling its operation is complicated due to complex separation mechanisms, upstream mining uncertainties, and process constraints. While Reinforcement Learning (RL) is mostly unexplored in industrial processes, our study applies the state-of-the-art RL strategy to hierarchical decision-making in the primary separation vessel operation. By leveraging RL, we optimize primary separation vessel operation, thus improving bitumen extraction efficiency. Our presentation showcases the potential of RL in industrial process control and the steps toward achieving autonomous operation and decision-making.

2 Integrated Machine Learning and Optimization for the Simultaneous Stochastic Optimization of Mining Complexes

Yassine Yaakoubi, Roussos Dimitrakopoulos, McGill University, Montreal, QC, Canada. Contact: yassine.yaakoubi@mcgill.ca

Addressing large-scale, nonlinear, and stochastic optimization challenges in industrial mining complexes (mineral supply/value chains) necessitates innovative solutions. To produce robust mine plans and production schedules under both supply and demand uncertainties, optimization and machine learning are combined. The proposed approach comprises a hyper-heuristic optimizing supply/value chain dynamics, a neural diving policy for primal heuristic selection trees, and a neural (soft) branching policy mapping variable features to their impact on the objective function value, all in one-shot learning. Results on large-scale mining complexes demonstrate a 40% increase in net present value and three-orders of magnitude reduction in execution time, underscoring the potential of this self-learning task-informed solution to optimize supply/value chains.

3 Production Planning in Mining Complexes: A Stochastic Programming and Reinforcement Learning Approach for Connecting Short- and Long-Term Production Schedules

Zachary Levinson, Roussos Dimitrakopoulos, McGill University, Montreal, QC, Canada. Contact: zachary.levinson@mail.mcgill.ca

Short- and long-term production schedules in mining complexes are highly dependent. Typically, schedules of different timescales are optimized separately ignoring key considerations related to schedules of different timescales. Connecting short- and long-term production schedules and optimizing across timescales increases value, mitigates risk, and considers key operational aspects that improve production plans. A stochastic programming and actor-critic reinforcement framework that connects short- and long-term production scheduling is developed. An actor-critic reinforcement learning agent learns a discrete-continuous neural network policy for production scheduling decisions that is embedded within a stochastic programming framework. The method is applied at a large-scale mining complex improving compliance between schedules by 21%.

4 Predicting Extraction Excursions Using Explainable Ai

Bart Maciszewski[1], Andrew Milne[1], Bhanuday Sharma[2], Stefano Scaini[1], Leyli Mirmontazeri[1], Charles Cook[1], Andrew Bonnell[1], Farah El Mallah[1], Anastasia Startseva[1], Jamie Neil[1], Ian Macisaac[1], Patrick Mccrady[1], [1]Imperial Oil, Calgary, AB, Canada; [2]ExxonMobil Services & Technology Private Limited, Bangalore, India. Contact: andrew.c.milne@esso.ca

Kearl oil sands is a large open pit mine in Northern Alberta leveraging a fleet of shovels and autonomous haul trucks feeding two processing facilities. Water based gravity separation is used as a primary method of oil extraction. The ore varies in geologic properties and has different processibility characteristics. In this work we build a model to predict likelihood of elevated extraction excursions based on the ore characteristics and plant processing variables. We employ SHAP analysis to identify shovels or process variables that are likely causes for the excursions. We evaluate the model for ability to reduce excursions and their durations.

Data-driven approaches in reliability analysis

Contributed Session

Session Chair: Jamie R. Wieland, Illinois State University, Normal, IL

1 Quantile Degradation Modeling and Lifetime Estimation for Accelerated Destructive Degradation Test

Munwon Lim[1], Suk Joo Bae[2], [1]Hanyang University, Seoul, Korea, Republic of; [2]Hanyang University, Seoul, Korea, Republic of. Contact: moonmunwon@psm.hanyang.ac.kr

As product development period has been shortened, manufacturing industry conducts accelerated destructive degradation tests (ADDT) to predict the lifetime of the products within a short period of time. In general ADDT, lifetime estimation based on mean degradation path is conducted, but if the failure or deterioration pattern has non-normal distribution, the modeling result can lead to the biased estimation results. To resolve this problem, we propose an ADDT model based on quantile regression (QR), considering the asymmetry of lifetime distribution. According to the application to the test data for real automobile components, the proposed method effectively describes the imbalanced lifetime distribution and provides more precise prediction results compared to the general ADDT model.

2 Quality And Reliability Monitoring In Multi-stage Processes

Emmanuel Yashchin, IBM TJ Watson Research Center, Yorktown Heights, NY, Contact: yashchi@us.ibm.com

In multi-stage processes, downstream variables are influenced by events in upstream stages. One example is the assembly process of a computing system, which relies on components produced at various locations over wide timeframes. The quality and reliability (Q&R) assurance process involves models and data pertaining to the components, assembly process itself, and product experience in the field. In this paper, we focus on the process of monitoring Q&R, diagnostics and root cause analysis based on the so-called timeslides: data orderings corresponding to passage of components, sub-assemblies and the product itself through various stages. Given that the product and component Q&R can be impacted by numerous stages, the problem acquires a combinatorial character and complexity. We discuss the design of search engines for selecting timeslides that merit investigation.

3 A Retesting Model For Binary Classification With Random Error

Jamie R. Wieland, Illinois State University, Normal, IL

We consider a binary classification problem, where given a sample of interest, a test is used to classify the sample as either a 0 or 1. The test is assumed to be a stochastic oracle, in which the binary outcome is noisy due to random error. Our objective is to determine the impact of retesting on the probability of correct sample classification, as compared to conducting only a single test. Retesting is common practice in numerous applications of importance, including quality control, identification of forensic evidence, and medical diagnostics. We develop a probability model for retesting, and two decision polices for retesting are analyzed. Conditions under which retesting policies improve the probability of correct sample classification are identified and discussed, along with the effects of dependence.

Transforming business via reinforcement learning

Community Committee Choice Session

Session Chair: Linda Zhao, University of Pennsylvania, Philadelphia, PA

1 Personalized Reinforcement Learning with Application to Business

Junhui Cai[1], Ran Chen[2], Martin Wainwright[2], Linda Zhao[3], [1]University of Notre Dame, Notre Dame, IN, [2]MIT, Cambridge, MA, [3]University of Pennsylvania, Philadelphia, PA, Contact: jcai2@nd.edu

Reinforcement learning, while has gained great success in low-stake fields (e.g., game, ChatGPT), has involved a great sacrifice of interpretability, reliability and fundamental understanding. However, the price of incorrect actions, non-interpretable procedures and model fragility is high in files like e-commerce, start-up fund-raising and healthcare. In particular, the crucial personalized information is not accounted for in the model in the hope that high-complexity and high-expressive model can somehow learn it out from the relatively scarce data. We propose a personalized reinforcement learning model encoding personalized information into the transition mechanism and reward-generating mechanism and develop an algorithm to address it. We study its performance both numerically and theoretically.

2 Reinforcement Learning with Heterogeneous Data

Elynn Chen[1], Rui Song[2], Michael Jordan[3], [1]New York University, New York, NY, [2]Amazon Inc, Seattle, WA, [3]University of California, Berkeley, Berkeley, CA, Contact: elynn.chen@stern.nyu.edu

RL has the promise of providing data-driven supports to decision-making in a wide range of social settings such as healthcare, education, and business. Classical methods focus on the mean of the total return and, thus, may provide misleading results for heterogeneous populations that commonly underlie large-scale datasets. We introduce K-Hetero Markov Decision Process to address sequential decision problems with population heterogeneity. We propose Auto-Clustered Policy Evaluation for estimating the value of a given policy, and Auto-Clustered Policy Iteration for estimating the optimal policy in a parametric policy class. Our auto-clustered algorithms can automatically detect and identify homogeneous subpopulations while estimating the action value function and the optimal policy for each subpopulation.

3 Doubly High-Dimensional Contextual Bandits: An Interpretable Model for Joint Assortment and Pricing

Junhui Cai[1], Ran Chen[2], Martin J. Wainwright[2], Linda Zhao[3], [1]University of Notre Dame, Notre Dame, IN, [2]MIT, Cambridge, MA, [3]University of Pennsylvania, Philadelphia, PA, Contact: ran1chen@mit.edu

Both assortment and pricing are important problems in revenue management that usually appear together. But current literature addresses them separately due to technical difficulties. We formulate the joint assortment and pricing problem as contextual bandits that are doubly high-dimensional in the sense that both covariates and actions are allowed to take continuous values in high-dimensional spaces. Our formulation is expressive, structure-rich, and interpretable. We propose an efficient bandit algorithm for our new model with theoretical justification. We demonstrate the effectiveness of our algorithm on joint assortment and pricing for two giant online retailers. In addition, the generality of our model makes several bandit problems and dynamic pricing models its special cases and allows wider applications in business and healthcare.

4 A More Realistic Mnl Model for Assortment

Wu Zhu[1], Ran Chen[2], Junhui Cai[3], Qitao Huang[4], Linda Zhao[5], [1]Tsinghua University, Beijing, China; [2]Massachusetts Institute of Technology, Cambridge, MA, [3]University of Notre Dame, Notre Dame, IN, [4]Tsinghua University, Beijing, China; [5]University of Pennsylvania, Philadelphia, PA

Joint assortment and pricing optimization is critical in maximizing revenue in the retail sector. Traditional models, such as the Multinomial Logit (MNL) model, effectively address this problem but miss the dynamic arrivals of customers. To bridge this gap, we extend the MNL model with a Poisson arrival that depends on the current assortment and pricing. The challenge lies in balancing the \emph{popularity} in the Poisson model to attract more customers and the \emph{profitability} in the MNL to increase conversion and revenue for each visit. We propose an efficient algorithm to jointly solve the Poisson and MNL model and provide a non-asymptotic bound for regret. We finally demonstrate the effectiveness of our approach for one of the largest instant noodles producers on an e-commerce platform.

Machine Learning Applications in Disaster Management

Contributed Session

Session Chair: Samiul Hasan, University of Central Florida, Orlando, FL

1 A Data-Driven Strategy to Predict Incident Hotspots

Hiruni Niwunhella, Asya Atik, Leila Hajibabai, North Carolina State University, Raleigh, NC, Contact: dhniwunh@ncsu.edu

This study predicts incident hotspot locations using deep learning techniques including neural networks and long short-term memory (LSTM) network methods. The proposed study validates the models using real-world incident data in North Carolina and incorporating additional variables such as weather information, holidays, unusual events, and annual average daily traffic (AADT) index that affect the likelihood of a crash. The error estimates are compared against those of other machine learning techniques. Numerical experiments indicate that the proposed approach provides better predictions with higher accuracy compared to benchmarks.

2 Surge Level Responses in Emergency Medical Services

Qixuan Zhao[1], Peter Vanberkel[2], [1]Dalhousie University, Halifax, NS, Canada; [2]Dahousie University, Halifax, NS,

Canada. Contact: peter.vanberkel@dal.ca
This study proposes a machine learning and simulation-based approach for categorizing surge levels in Emergency Medical Services. Instead of using traditional performance metrics, this study will use simulation to evaluate the machine learning-based categorization models. Particularly, simulation's responses to different interventions based on different surge levels categorization are used to evaluate the machine learning models.

3 Integrating Ml-Based Reverse Engineering of Cge Models with Optimization for Enhancing Resilience

Nushra Zannat, University of Oklahoma, Norman, OK, Contact: nzannat@ou.edu
This study presents a novel approach that utilizes machine learning techniques to reverse engineer CGE models. The outputs obtained from the model are then connected to optimization models used to enhance hazard mitigation and improve community resilience. The integration of ML and optimization holds the potential to improve policy analysis and decision-making in disaster risk management.

4 Monitoring the Mental Health of Individuals Post Earthquake Through Space Time Textual Analysis

Edwin Y. Wang[1], Adeela Gulzari[2], Victor R. Prybutok[2], [1]Kean University, Union, NJ, [2]University of North Texas, Denton, TX
This study analyzes geo-referenced social media data to explore emotional responses of users after a significant natural disaster. It focuses on the 2023 Turkey-Syria earthquake and investigates mental health effects using data mining and machine learning techniques. Twitter data is collected and preprocessed, followed by sentiment analysis using a clustering ensemble model. The study introduces a categorical distribution for Monte Carlo simulation to enhance reliability. By assessing the assigned sentiment score generated by this research in every tweet from affected areas and worldwide (the ratings can then be aggregated to give an overall sentiment for each cluster, which reveals the public's perceptions of the earthquakes.), the research aims to identify mental health conditions, understand exposure impact, and propose post-disaster interventions.

5 A Deep Learning Approach for Predicting Traffic During Evacuation Using Social and Infrastructure Sensors Data: A Case Study from Hurricane Ian

Samiul Hasan, Md Mobasshir Rashid, University of Central florida, Orlando, FL, Contact: samiul.hasan@ucf.edu
A network-wide traffic prediction model is developed which exploits traffic flow data available from detectors and population movement data available from social media (e.g., Facebook) during a hurricane. The model uses a deep learning based approach that is trained on regular period data to learn typical traffic movement patterns. The model achieves an R-square of 0.96 during regular period traffic prediction, but it performs poorly during an evacuation period. To better predict evacuation period traffic, a transfer learning approach is developed utilizing evacuation related features. The model is trained and tested over real-world evacuation data available from Hurricane Ian (2022). Transportation agencies can use the developed model to predict traffic congestions in advance and take protective measures to reduce delays during evacuation.

Functional data in manufacturing

Community Committee Choice Session

Session Chair: Shilan Jin, 1</sup

Session Chair: Yu Ding, Texas A&M University, College Station, TX

1 A Sensor-Based Monitoring Approach for Real-Time Characterizations of Nanomachining Using Ensemble Kriging Model

Xinchen Wang, Zimo Wang, SUNY Binghamton, Binghamton, NY, Contact: xwang295@binghamton.edu
We present a sensor-based modeling approach incorporating ensemble kriging for autonomously recognizing temporal-spectral features of the acoustic emission (AE) sensor signals to predict the surface profile during nanomachining. The experimental case study suggests that the presented approach allows accurate prediction (R-squared value around 92%) for the surface morphology under the nanoscale. This presented framework opens up an opportunity to realize real-time characterization, quality inspection, and autonomous control for nanofabrication.

2 Inverse Process Parameter Design for Additive Manufacturing with Bayesian-Pinn

Raghav Gnanasambandam, Zhenyu James Kong, Virginia Tech, Blacksburg, VA, Contact: raghavg@vt.edu

Designing process parameters in metal Additive Manufacturing is challenging due to complexity of process and restriction on data collection due to cost of operation. "Black-box" approaches like Bayesian Optimization are not that accurate whereas using solely physics-based simulations do not conform with real process data. In this work, we propose a Bayesian framework based on Bayesian Physics Informed Neural Networks (B-PINNs) for sequential design of process parameters to optimize the desired quality. B-PINNs solve Partial Differential Equations (PDEs) to provide uncertainty estimates of the process signatures like thermal history. The proposed method relates process signatures with quality to quantify uncertainty, and in turn utilize the uncertainty estimates for sequential design.

3 Optimized Block Maxima For Extreme Statistics In Predicting Surface Roughness Of Additive Manufacturing

Jia Liu, Shehzaib Irfan, Auburn University, Auburn, AL, Contact: lzj0040@auburn.edu

The fatigue performance of additively manufactured parts is largely impacted by local extreme surface roughness features, such as deep valleys with high stress concentration. Extreme statistics can be used to infer the deepest valley with the highest stress concentration and predict the fatigue life accordingly based on the sampled surface profiles from the block maxima method. This work aims to use multi-objective Bayesian optimization and extreme value statistics to build a framework for optimizing the block number and the size for surface roughness characterization in terms of goodness of fit, prediction accuracy, and quality of estimates of extreme value distribution parameters. This framework could be extended beyond the AM to areas for which accurate modeling of extreme events is paramount, including hydrology, climatology, and finance.

4 Vibration Signal-Assisted Endpoint Detection for Long-Stretch, Ultraprecision Polishing Processes

Shilan Jin, Yu Ding, Texas A&M University, College Station, TX, Contact: jin0541@tamu.edu

The research reported in this article concerns the question of detecting and subsequently determining the endpoint in a long-stretch, ultraprecision surface polishing process. We develop an offline method that utilizes a functional regression to relate the vibration signals to the surface roughness. The method shows that the polishing process progresses in three states, including a saturation phase, over which the polishing action could be substantially shortened. The three states revealed are consistent with the polishing literature studies. Our work is the first work that quantifies these polishing phases. When appropriately implemented, our method could lead to substantial savings in polishing time and energy and significantly improve the throughput of such polishing processes without inadvertently affecting the quality of the final polish.

Deep Learning for Quality Assurance in Manufacturing Systems

Community Committee Choice Session

Session Chair: Wenbo Sun, University of Michigan Transportation Research Institute, Ann Arbor, MI

1 Out-Of-Distribution (Ood) Learning with Few Ood Samples

Xiaoyang Song[1], Wenbo Sun[2], Jionghua Jin[3], Raed Al Kontar[3], Maher Nouiehed[4], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Transportation Research Institute, Ann Arbor, MI, [3]University of Michigan, Ann Arbor, MI, [4]American University of Beirut, Burbank, CA, Contact: xysong@umich.edu

Deep Neural Networks (DNNs) have shown promising capabilities in many benchmark tasks yet are known to be not robust to Out-of-Distribution (OOD) data that fall outside the distribution of the training data (In-Distribution (InD) data). OOD detection thus becomes an important task to be tackled before reliably deploying DNNs to real-world applications. In this work, we introduce a model that separates InD and OoD data in a Wasserstein-distance-based space and exploits the advantages of a few observed OOD samples using Generate Adversarial Network (GAN). The proposed model is compared with the state-of-the-art methods on various datasets and achieves better OOD detection performance, especially when fewer OOD samples are observed. Through data augmentation, the proposed model shows better generalizability, robustness, and interpretability.

2 Continual Learning for In-Situ Quality Prediction in Dynamic Manufacturing Processes

Mengfei Chen[1], Rajiv Malhotra[2], Weihong (Grace) Guo[1], [1]Rutgers, The State University of New Jersey, Piscataway, NJ, [2]Rutgers, The State University of New Jersey, Piscataway, NJ

Manufacturing processes undergo continuous changes in order to meet various requirements, such as process changes and variations in tool conditions. Thus, a quality prediction model trained from previous data may not perform well when new tasks emerge. This study proposes a deep learning method with continual learning for in-situ quality prediction capable of learning from new tasks without forgetting previous ones. A deep CNN is designed to analyze acoustic emission data from the laser-induced plasma micro-machining process. To be applicable in both old and new tasks, the deep CNN consists of shared layers to capture common underlying features across all tasks, and task-specific layers that capture characteristics of each individual task. When new data come in, the model first identifies the task, followed by predicting quality of the current part under its own task.

3 Interpretable Thermal Physics-Informed Machine Learning Methodology for Weld Bead Distortion in Wire Arc Additive Manufacturing

Christian Zamiela[1], Ryan Stokes[2], Linkan Bian[1], Wenmeng Tian[1], [1]Mississippi State University, Mississippi State University, MS, [2]Mississippi State University, Mississippi State University, MS

The objective is to develop an interpretable physics-informed machine learning (PIML) model for in-situ weld bead distortion detection in Wire-Arc Additive Manufacturing (WAAM). A core problem with WAAM is that the rapid deposition of metal wire to join successive layers results in distortion and residual stresses from thermal expansion and heat transfer. There is a lack of interpretability of PIML model's prediction logic from real-time thermal spatial-temporal data features that lead to detecting anomalies. This work aims to enhance the interpretability of valuable input features by decoding predictions using physics-informed gradient mapping. Furthermore, it addresses the need for rapid processing of thermal data-driven knowledge within a neural network, guided by physical constraints, to improve model detection accuracy and ensure real-time quality.

4 A Novel Data Augmentation Method Using Machine Learning for Wafer Defect Detection with Imbalanced Wafer Bin Map Data

Jihoon Chung[1], Bo Shen[2], Zhenyu James Kong[1], [1]Virginia Tech, Blacksburg, VA, [2]New Jersey Institute of Technology, Newark, NJ, Contact: jihoon7@vt.edu

Since hundreds of processes are involved in wafer manufacturing, errors in different processes can lead to various wafer defects. The different defects which occur along the processes cause the highly imbalanced wafer bin map (WBM) data between defects used to identify the defective patterns of each wafer. Consequently, this leads to low classification results in wafer pattern recognition, hindering the process adjustment to mitigate each defect. The failure to mitigate the defects timely causes the low reliability and yields of integrated circuits in the semiconductor manufacturing process. To overcome the limitation, we propose a novel machine learning-based data augmentation method to address the imbalanced WBM data.

Adaptive sampling strategies for real-time anomaly detection

Community Committee Choice Session

Session Chair: Ana Maria Estrada Gomez, Purdue University, West Lafayette, IN

1 Adaptive Sampling Strategy for Real-Time Anomaly Detection with Unmanned Sensing Vehicles

Yue Jiang, Ana Maria Estrada Gomez, Purdue University, West Lafayette, IN, Contact: jiang905@purdue.edu

Unmanned sensing vehicles (USVs) have been widely used for real-time anomaly detection. The collected data only provide partial information about the space. Thus, it is critical to decide the locations of USVs at each time to maximize the change detection capability while considering deployment costs. This paper proposes an adaptive sampling strategy for real-time anomaly detection with USVs. First, a novel Spatio-Temporal Sequential Tensor Decomposition algorithm is developed to decompose the high-dimensional data into a spatial-temporal structure and a sparse component that captures suspicious locations. The spatial-temporal structure is used for prediction. The strategy is designed to balance exploration and exploitation by designing a sampling function to decide the locations of USVs. The movement of the USVs is controlled by using Voronoi tessellations.

2 Implicit Regularization Based Quickest Detection in High-Dimensional Linear Regression Models

Qunzhi Xu[1], Yajun Mei[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]ISyE Georgia Tech, Atlanta, GA, Contact: xuqunzhi@gatech.edu

In this work, we present a method for detection of change-point in a linear regression model, where the high-dimensional coefficient vector may change at an unknown time and only the projection matrix and low-dimensional projection can be observed in a sequential manner. We propose to estimate the unknown coefficient based on the data within a sliding window, and raise an alarm if the L_∞- norm of the estimator is extremely large. We also investigate the theoretical properties on the average run length (ARL) to false alarm and expected detection delay. Numerical studies are conducted to validate our theoretical results.

3 A Deep Learning Framework for Adaptive Sampling Strategy in Monitoring High-Dimensional Processes

Ziqian Zheng[1], Haoqian Li[1], Kaibo Liu[2], [1]University of Wisconsin-Madison, Madison, WI, [2]UW-Madison, Madison, WI, Contact: zzheng92@wisc.edu

The advancements in sensing technology have created data-rich environments that offer unprecedented opportunities for enhancing system monitoring. However, the limited transmission bandwidth presents a challenge as only a subset of data streams can be accessed. Existing methods for adaptively sampling informative data streams rely on heuristic approaches, lacking a systematic framework. In this study, we address this issue by proposing a deep learning framework. We utilize a monotonic deep neural network to learn a function that quantifies the urgency of collecting new observations from the current data stream. The training process of the network is based on simulations and incorporates a carefully designed loss function. Through simulations and a case study, we evaluate the performance of our approach and demonstrate its superiority over existing methods.

4 Thompson Sampling Based Partially Observable Online Monitoring Approach for Large Dynamic Networks

Jie Guo, Chen Zhang, Tsinghua University, Beijing, China

The monitoring of high-dimensional dynamic network data has gained significant attention in various applications. However, it is difficult to acquire complete relations in a network each time due to the limited sensing resources. We propose an adaptive sampling strategy for prompt change detection in the networks. Our approach utilizes a latent space model to represent the underlying mechanism of edge formation in networks, where latent states evolve with time according to a bi-transit state space model. Besides, we employ a variational Bayesian method to infer abnormal variables on each node. Then, we employ a likelihood ratio test to detect changes on the edges. By further formulating the test statistic as the reward function of combinatorial multi-armed bandit, Thompson sampling is proposed to select changed edges with the balance of exploration and exploitation.

Innovations in Data-Driven Approaches for Process Optimization and Quality Enhancement

Community Committee Choice Session

Session Chair: Jinming Wan, State University of New York at Binghamton, Vestal, NY

Session Chair: Changqing Cheng, Binghamton University, Binghamton, NY

1 Design and Analysis of Experiments to Support Facility Location Applied to Sanitizer Dispensers

Abedallah Al Kader[1], Theodore T. Allen[2], James Arbogast[3], Stephen Wagner[3], Nanshan Chen[4], Cathy Honghui Xia[4], Susan O'Hara[4], [1]The Ohio State University, Columbus, OH, [2]Ohio State University, Columbus, OH, [3]Gojo Industries, Inc, Akron, OH, [4]The Ohio State University, Columbus, OH, Contact: alkader.1@osu.edu

The subject of optimal facility location has received considerable attention. Recent research has addressed highly random and spatial-temporal demand. The complications of large numbers of facilities and demand dependent on location and varying over time have been considered. We present the first experimental exploration of the implication of facility location on demand. Using an optimal split-plot design with augmentation, we show that, at least in the case of PURREL dispensers generate new demand, and location factors influence demand exponentially. The implications for optimal location problems are explored.

2 Exploratory Image Data Analysis for Quality Improvement Hypothesis Generation

Yifei Zhang, Theodore T. Allen, Ramiro Rodriguez Buno, Ohio State University, Columbus, OH, Contact: rodriguezbuno.1@osu.edu

This work proposes Exploratory Image Data Analysis (EIDA) as a special case of EDA (Exploratory Data Analysis) for quality improvement problems with image data. The proposed four steps of EIDA are: (1) image processing, (2) quantitative image data analysis and display, (3) salient feature identification, and (4) salient feature interpretation.

4 Optimal Path Mining Of Small Steel Bar Manufacturing Process

KwangHo Jeong, Sungkyunkwan University, Suwon, Korea, Republic of. Contact: jebiri98@g.skku.edu

Surface defects in small steel bars (SSBs) are a significant quality concern. Existing studies about SSB surface quality overlook two common issues: "merged measurement" and "variation over operational dates." This study proposes a method to find the faulty process path that cause surface defects of small steel bars manufacturing process, while considering the issues. The method divides factor value in several groups, see continuous combination of factor groups as process path and finds faulty process path using data mining. A case study using operational data demonstrates the effectiveness of the proposed method in finding faulty process path of SSB causing surface defects.

The Hydrogen Economy: Challenges and Opportunities in Production, Transportation, and Use

Community Committee Choice Session

Session Chair: Tyler Ruggles, Carnegie Science, Stanford, CA

Session Chair: Jacqueline Dowling, California Institute of Technology, Pasadena, CA

1 Grid-Powered Hydrogen Production: Emission Metrics and Carbon Intensity Criteria

Tyler H. Ruggles, Carnegie Science, Stanford, CA

The US Inflation Reduction Act (IRA) incentivizes H_2 production based on the carbon intensity (CI) of production instead of the production mechanism. In this study, we analyze three methods for quantifying the CI of grid power: average grid CI, and short- and long-run marginal emission rates. We use a least-cost model constrained by these grid CI metrics to model equipment sizing and operations of electrolysis facilities producing H_2 and suppling offtakers. Hourly power prices and grid emissions rates are taken from NREL's Cambium dataset representing possible future electricity systems. This work shows the cost of producing low-CI H_2 from the grid could vary substantially depending on how grid CI is defined and shows how the CI of the H_2 could vary when a system is planned and operated under one interpretation, then evaluated using a different CI metric.

2 Decarbonizing the European Ammonia Industry via Low-Carbon Hydrogen Production

Paolo Gabrielli, ETH Zurich, Zurich, Switzerland

The European ammonia industry is responsible for 36 Mt of CO_2 per year, primarily due to hydrogen production from steam methane reforming. These emissions can be mitigated via electrolytic hydrogen, namely hydrogen produced via water electrolysis powered by dedicated renewable energy sources. We investigate the conditions under which electrolytic hydrogen is cost-competitive against steam methane reforming, and we focus on the impact of emissions targets on the economic viability and technical feasibility of on-site production of electrolytic hydrogen in European ammonia plants. Results show that an emission cap of 1 kg CO_2/kg H_2 might lead to an emissions reduction of 95% while maintaining cost-competitiveness with steam methane reforming.

3 Hydrogen Production from Biogenic Sources Coupled with Ccs

Cristina Antonini, OST University of Applied Sciences of Eastern Switzerland, Rapperswil, Switzerland

Hydrogen will play a crucial role to decarbonize the world energy system. However, the current benchmark hydrogen production pathway is fossil-based (i.e., via methane reforming). While H2 production by means of water electrolysis is expected to become the benchmark by 2050, in the next decades the existing infrastructure will still be used. An effective way to defossilize the current hydrogen production plants and reach net zero is to couple existing methane reformers with CCS and blend biogenic fuels (i.e., biomethane or the product gas from biomass gasification) to compensate for the residual emissions that are not captured. This work focuses on the techno- and economic aspects of blending biogenic sources coupled with CCS to make the existing H2 production plants net zero. Different regions allover the world, such as Asia, US and Europe, will be considered as case studies

4 Modelling Use-Dependent Degradation of Electrolyzers in Capacity Expansion Models

Ruaridh Macdonald, Landon Schofield, Dharik Sanchan Mallapragada, MIT Energy Initiative, Massachusetts Institute of Technology, Cambridge, MA, Contact: rmacd@mit.edu

Water electrolysis is predicted to be the primary source of hydrogen by models of future low-emission hydrogen economies because of its potential to produce hydrogen with zero emissions. To keep the cost of hydrogen as low as possible, these electrolyzers will operate dynamically, over-producing and storing hydrogen during periods of low electricity prices. Existing capacity expansion models limit electrolyzers to their rated output. However, it is possible for electrolyzers to raise their output further at the cost of increased wear and tear and more frequent replacement. We present a method to incorporate this tradeoff between higher capital costs and lower operating costs into capacity expansion models. We show the impact it has in example energy systems, particularly for high temperature electrolyzers which have rated outputs much lower than their maximums.

5 Exploring the Broad Range of Energy Technologies Available to Firm up Wind and Solar Generation in Least-Cost Decarbonized Electricity Systems

Alicia Wongel, Ken Caldeira, Carnegie Institution of Science, Stanford, CA, Contact: awongel@carnegiescience.edu

Additional technologies are needed if variable wind and solar generation is to reliably meet demand. Options that could participate in this firming role include dispatchable energy generators, electricity storage technologies, atmospheric carbon dioxide removal, and demand management. Firming technologies are typically studied individually or in small groups. In this study, we allow for a large variety of firm technologies to participate in the system. By examining a series of least-cost systems, in which the dominant firming technologies are sequentially removed resulting in other technologies playing a firming role, we demonstrate that a wide range of technologies and approaches could potentially contribute to system reliability.

Wednesday, October 18, 9:30 AM - 10:45 AM

New Approaches to Risk Management in Power Markets

Community Committee Choice Session

Session Chair: Jon Glass, arpa-e, DC

Session Chair: Richard Paul O'Neill, ARPA-E, Silver Spring, MD

1 System Risk of Renewable Technologies and Its Impact on Clearing Power Markets

Alexander Wasilkoff[1], Panagiotis Andrianesis[2], Michael C, Caramanis[1], [1]Boston University, Boston, MA, [2]Boston University, Boston, MA, Contact: wasilkof@bu.edu

Day Ahead Market bidding Renewable Generation Farms (RGFs) are scheduled and dispatched subject to their bids and transmission congestion. Since RGF available capacity in real time may fall short of RGF economic dispatch, reserve requirements exceeding the conventional generating technologies N-1 contingency must be additionally secured. We add a reasonably likely worse-case endogenous reserve requirement constraint to ensure robust system reliability. Our contribution is the use of system wide correlations to assign RGF-Specific contributions to these additional reserve requirements and to reflect their impact on (i) optimal LMC and RGF Specific clearing prices and (ii) RGF Security Constrained Economic Dispatch.

2 Abscores, Managing Risk and Uncertainty in Electricity Systems Using Banking Scoring and Rating Methodologies

Alberto Lamadrid, Lehigh University, Philadelphia, PA

We present a multi-layered framework that facilitates the implementation of data-enabled recourse actions, instead of worst-case risk management, and manages prospective decisions about the system dispatch and planningThe ABSCORES platform establishes an Electric Assets Risk Bureau, with different scores customized according to the application required. We leverage scoring and ratings methodologies from banking and financial institutions alongside current optimization methods in dispatching power systems to help system operators and electricity markets schedule resources.

3 Performance Risk Scoring of Risk-Free Renewable Generation Bids

Aparna Gupta[1], Denis Osipov[2], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Rensselaer Polytechnic Institute, Troy, NY, Contact: guptaa@rpi.edu

Renewable generators can bid a conservative segment of the forecasted power generated into the day-ahead market with the aim of generating greater risk-adjusted profitability. However, these bids and their underlying risks may vary across renewable generators, which must be calibrated for a reliable clearing of the day-ahead market. A rigorous third-party performance risk scoring of these risk-free bids is a valuable input and validation in support of a robust day-ahead market clearing framework. In this paper, we develop an ensemble machine learning approach for performance risk scoring of risk-free renewable generation bids and evaluate the performance of these bids made by different renewable resources and in different geographies.

4 Enhancing Decision Support for Electricity Markets with Machine Learning
Yury Dvorkin, Johns Hopkins University, Baltimore, MD
This presentation describes how machine learning can be leveraged to enhance computational speed of day-ahead and real-time unit commitment and optimal power flow routines, which are at the core of market-clearing procedures in US ISOs. Our machine learning architecture embeds both power flow physics and market design properties (e.g., cost recovery and revenue adequacy) into the training stage, which increases accuracy of computations and preserves a relationship between primal (dispatch) and dual (prices) variables. The accuracy and scalability of the proposed method is tested on a realistic 1814-bus NYISO system with current and future renewable energy penetration levels. We also demonstrate ~100x gain in computations relative to traditional optimization approaches.

Electric Reliability and Resilience
Community Committee Choice Session
Session Chair: Benjamin D. Leibowicz, The University of Texas at Austin, Austin, TX

1 Optimal Restoration of Power Infrastructure Following a Disaster with Environmental Hazards
Rachel Moglen[1], Benjamin D. Leibowicz[1], Alexis Kwasinski[2], Grant Cruse[2], [1]The University of Texas at Austin, Austin, TX, [2]The University of Pittsburgh, Pittsburgh, PA, Contact: rmoglen@utexas.edu
After a disaster, the power grid helps support infrastructure systems that are essential to the recovery effort in addition to the critical services it provides every day. While many studies discuss optimal power grid restoration, they ignore coincident environmental hazards like debris, chemical hazards, or abnormal radioactivity that may constrain the restoration process. We formulate an optimal restoration planning framework with constraints imposed by acute and cumulative environmental hazards. In our analysis, we compare the performance of an optimal restoration strategy to a heuristic based on best practice restoration in the field. We apply our formulation to a case study of a nuclear event causing abnormal radioactivity.

2 Optimal Resource Placement for Electric Grid Resilience via Network Topology
Balasubramanian Sambasivam, Connor Colombe, John Hasenbein, Benjamin D. Leibowicz, The University of Texas at Austin, Austin, TX
In this paper, we investigate the resilience of alternative electric grid configurations (binary trees and rectangular lattices) by adopting a stylized approach based on graph theory, probabilistic analysis, and simulation. For each configuration, we derive the probabilities that customers located at various nodes in the network will continue to have power following a disaster, depending on the locations of resources (e.g., generators, storage units) in the network. Then, these probabilities are incorporated into the problem of optimally placing resources throughout the network. This is a cost-benefit problem that weighs the benefits of placing resources closer to customers - that is, pursuing a distributed resilience strategy - against the higher total cost of deploying a greater number of smaller resource units.

3 Enhancing Climate Resilience of Electric Vehicles by Coordinated Charging and Heating in Extreme Cold
Guangchun Ruan, Massachusetts Institute of Technology, Boston, MA, Contact: gruan@mit.edu
The performance and service life of electric vehicle (EV) batteries degrade deadly in extreme cold temperatures, and heating is a common-but-expensive option to survive EVs in this case. Coordinating the heating and charging demand at scale has great potential to enhance the climate resilience of EVs. In this talk, we propose a novel station-level decision system to simultaneously manage the EV heating and charging demand. With a thermal dynamic model and a temperature-aware EV charging model, we conduct a rigorous assessment of extreme cold impacts on the EV charging performance and lifespan. The key findings of this talk are informative to enhance the climate resilience of EVs and contribute to the construction of green charging stations.

4 Estimating the Economic Impacts of Widespread, Long Duration Power Interruptions
Peter Larsen, Lawrence Berkeley National Laboratory, Berkeley, CA
Estimates of the economic impact of widespread, long duration (WLD) power interruptions can be used to prioritize and justify significant investments in power system resilience. This project involved surveying Commonwealth

Edison (ComEd) customers to understand how they might respond when confronted with a WLD power interruption. The research team used the survey responses to calibrate a state-of-the-art regional economic model ("POET") to estimate economic impacts to households and 38 industry sectors across 17 impacted micro-regions (individual counties or aggregations of counties) within ComEd's service territory and beyond. We ran one day, three day, and 14 day interruption duration scenarios and various geographic extents as well as estimated the benefits of deploying additional backup generation across the service territory.

Emerging research on electric vehicles operations

Community Committee Choice Session

Session Chair: Ali Fattahi, Johns Hopkins University, Baltimore, MD

Session Chair: Hang Ren, George Mason University, Fairfax, VA

1 The Role of Dealer Demonstration in the Adoption of Electric Vehicles

Vishal Agrawal[1], Ioannis Bellos[2], Hang Ren[2], [1]Georgetown University, Washington, [2]George Mason University, Fairfax, VA, Contact: hren5@gmu.edu

Drivers' uncertainty around the extent to which they will be able to meet their mobility needs with an electric vehicle (EV) is often cited as one of the barriers to EV adoption. It has been suggested that one way to alleviate this issue is by offering demonstration services such as extended test drives. However, it has been noted that not all dealers adopt such practices. Empirical evidence also suggest that some dealers exhibit a lackluster attitude toward familiarizing customers with the electric vehicle technology. In this work we consider a monopolist dealer offering conventional and/or electric vehicles to customers who differ in their mobility needs. In addition to vehicle prices, the dealer determines whether to offer demonstration services. We explore the economic and environmental implications of this decision.

2 Circular Economy of Ev Batteries: Economic and Environmental Impacts of Repurposing

Lingling Shi[1], Metin Cakanyildirim[2], Sila Cetinkaya[3], [1]The University of Texas-Dallas, Richardson, TX, [2]The University of Texas at Dallas, Richardson, TX, [3]SMU, Dallas, TX, Contact: lingling.shi@utdallas.edu

The fast growth of electric vehicle (EV) market and the increased energy storage market stimulate the demand for batteries and in turn the critical minerals, which face high supply uncertainty. We investigate the economic and environmental impacts of repurposing spent EV batteries for energy storage in addition to recycling.

3 Optimal Vehicle Charging In Bilevel Power-traffic Networks Via Charging Demand Function

Yufan Zhang[1], Sujit Dey[1], Long He[2], Yuanyuan Shi[1], [1]University of California San Diego, San Diego, CA, [2]George Washington University, Washington, Contact: yuz254@ucsd.edu

We model EV charging management by a bilevel program, with the power network at the upper-level settling the price and the traffic network at the lower-level optimizing the charging power given the price. Solving it is nontrivial, as the two networks are managed by separate entities and the charging expense term, calculated as the product of charging price and charging demand, is nonlinear. To overcome these challenges, we derive the charging demand function. This function establishes a piecewise linear relationship between the charging price and the optimal charging power, enabling the power network operator to manage EV charging power independently while accounting for the coupling between the two networks. With the derived function, we can replace the nonlinear charging expense term with a piecewise quadratic one, thus guaranteeing solution optimality.

4 Utilities' Managed Home-Charging Programs for Electric Vehicles

Ali Fattahi, Johns Hopkins University, Baltimore, MD

Experts estimate 20 million electric vehicles (EVs) will be on U.S. roads by 2030, and around 80% of EV drivers will perform home charging. Many utilities are designing managed home-charging (MH) programs to centrally manage EV drivers' home charging to reduce cost, avoid new and aggravated peaks and blackouts, and ensure grid stability. We present a program-design model and a load-management model for jointly designing and executing various forms of MH programs. We present an effective approximation method, conduct thorough theoretical and numerical analyses of our approximation, and provide worst-case error bounds. We present managerial insights on jointly designing MH programs, effects of high participation in MH programs, trade-off between cost and demand variability, importance of customizing MH programs, and effects of charging frequency.

Machine Learning for Modeling, Optimization, and Applications

Community Committee Choice Session

Session Chair: Qingyang Xiao, 1</sup

1 A Machine Learning-Based L-Shaped Method for Large Scale Two-Stage Stochastic Programming

Qingyang Xiao[1], Haowei Yang[2], Zhijie "Sasha" Dong[1], [1]University of Houston, Missouri City, TX, [2]University of Houston, Houston, TX, Contact: qxiao2@uh.edu

In this work, we focus on developing a machine learning (ML) framework to enhance the L-shaped method to improve the computational efficiency for large scale two-stage stochastic programming (SP). The proposed supervised learning is designed for the decomposition-based SP second stage upper bound prediction. The performance analysis of ML based L-shaped method is conducted per classical SP problems comparing to benchmarks. The targeted achievement of this research is to generate a new class of theoretical optimization methods for various real-world applications.

2 Spidarman: System Physics-informed Detection Of Anomalies In Reactors Considering Human Errors

Ezgi Gursel[1], Jamie Coble[1], Mahboubeh Madadi[2], Vivek Agarwal[3], Ronald Boring[3], Vaibhav Yadav[3], Anahita Khojandi[1], [1]University of Tennessee, Knoxville, TN, [2]San Jose State University, San Jose, CA, [3]Idaho National Laboratory, Idaho Falls, ID

In nuclear power plants (NPPs), anomalies arising from sensors or human errors (HEs) can undermine the performance and reliability of plant operations. Anomaly detection models can be employed to detect sensor errors and human errors. Additionally, physics-informed machine learning (PIML) models can utilize the known physics of the system, as described by mathematical equations, to ensure sensor values are consistent with physical laws. Hence, we propose SPIDARman: System Physics-Informed Detection of Anomalies in Reactors Considering Human Errors, a holistic physics-informed anomaly detection approach based on generative adversarial networks to detect anomalies in both automatically collected sensor data and manually collected surveillance data. We test our approach on data collected from a flow loop testbed, showcasing its potential to detect anomalies.

3 Extending Conformal Prediction to Hidden Markov Models with Exact Validity via De Finetti'S Theorem for Markov Chains

Buddhika Nettasinghe[1], Samrat Chatterjee[2], Ramakrishna Tipireddy[3], Mahantesh Halappanavar[2], [1]University of Iowa, Iowa City, IA, [2]Pacific Northwest National Laboratory, Richland, WA, [3]Palo Alto Networks, Santa Clara, CA

Conformal prediction is a widely used method to quantify the uncertainty of a classifier under the assumption of exchangeability (e.g., IID data). We generalize conformal prediction to the Hidden Markov Model (HMM) framework where the assumption of exchangeability is not valid. The key idea of the proposed method is to partition the non-exchangeable Markovian data from the HMM into exchangeable blocks by exploiting the de Finetti's Theorem for Markov Chains discovered by Diaconis and Freedman (1980). The permutations of the exchangeable blocks are viewed as randomizations of the observed Markovian data from the HMM. The proposed method provably retains all desirable theoretical guarantees offered by the classical conformal prediction framework in both exchangeable and Markovian settings.

Energy Consumption and Decarbonization

Contributed Session

Session Chair: Esra Agca Aktunc, Rensselaer Polytechnic Institute, Troy, NY

1 The Impact of Macroeconomic Indicators on Oil Prices: Evidence from Emerging Economies

Muhammad Suleman, Xi'an Jiaotong University, xian, China. Contact: suleman@stu.xjtu.edu.cn

The research endeavours to understand the concept of macroeconomic indicators and assessment of variations in oil prices in any country, the impact of macroeconomic indicators on oil prices and to provide recommendations in this regard. The data from the years 1999-2019 was adopted where the variables used for assessment were inflation, interest, exchange rate, GDP and oil prices of the global market. It was concluded that the variables are interrelated with each other as it explains the association between the variables as having an impact on the oil prices in the country. Based on results from the current research it is recommended to provide the balance regarding four macroeconomic factors, taken in this research such as interest rate, inflation rate, exchange rate and real GDP of a country that could influence the development of the economy.

2 Frequency Regulation and Storage: On Losses and Profits

Dirk Lauinger[1], Francois Vuille[2], Daniel Kuhn[3], [1]MIT, Cambridge, MA, [2]Etat de Vaud, Lausanne, Switzerland; [3]Ecole Polytechnique Federale de Lausanne (EPFL), Lausanne, Switzerland

We derive an analytical solution to the decision-making problem of storage operators who sell frequency regulation power to grid operators and trade electricity on day-ahead markets. Thanks to a constraint on the expected terminal state-of-charge, the amount of electricity traded on day-ahead markets becomes an implicit function of the regulation power sold to grid operators. The implicit function quantifies the amount of power that needs to be purchased to cover the expected energy loss that results from providing frequency regulation. We show how the associated marginal cost of frequency regulation decreases with roundtrip efficiency and increases with frequency deviation dispersion. We find that the profits over the lifetime of energy-constrained storage devices are inversely proportional to the length of time for which regulation power must be committed.

3 An Overview of Electricity Consumption in Europe Using Classification, Segregation, and Prediction Models

Esra Agca Aktunc[1], Ergun Yukseltan[2], Ayse Bilge[2], Ahmet Yucekaya[2], [1]Rensselaer Polytechnic Institute, Troy, NY, [2]Kadir Has University, Istanbul, Turkey. Contact: agcaae@rpi.edu

Although aggregate electricity consumption provides valuable information for market analysis, demand composition of industrial, residential, illumination, and other uses, and special days, such as holidays and industrial shutdowns, differ for each country. We analyze the hourly electricity consumption of countries in the European Transmission System Operation for Electricity (ENTSO-E) grid from 2006 to 2018. We propose an outlier detection method to identify special days using the hourly time series and a modulated Fourier Series Expansion model to determine the breakdown of industrial-household and heating-cooling consumption. The proposed demand prediction model has a 3% average error when heating use is not dominant. It also allows country classification by consumption patterns to efficiently manage regional or country-based electricity markets.

Stochastic Analysis of Energy Power Systems

Contributed Session

Session Chair: Sam Chakrabarti, Princeton University, Princeton, NJ

1 Impacts of Regional Allowance Allocation Difference on Capacity Portfolios and Facility Location Under Cap-And-Trade

Xiangzhou Cao, Tsinghua University, Beijing, China. Contact: 2038118374@qq.com

This study presents a two-stage modeling approach to investigate the effect of environmental regulation in the form of carbon allowance allocation under Cap-and-Trade system on capacity portfolio and facility location decisions of a firm. In this context, carbon allowance for a facility has a regional difference and is allocated based some rule (grandfathering, benchmark). Carbon emission of a facility includes its production emission and transportation emission from production location to market. As a response, the firm decides facility locations and corresponding capacity portfolios, which include capacity size and the type of technology (dirty or green). Uncertainties like carbon price and consumer demand are considered. L-shaped method is implemented to get sight into the firm's optimal decisions under different allocation rules.

2 A Binary Expansion Approach for the Optimal Demand Response in Large and High Altitude Water Distribution Networks

Denise Carolina Cariaga Sandoval, University of Edinburgh, Edinburgh, United Kingdom. Contact: D.C.Cariaga-Sandoval@sms.ed.ac.uk

Demand response for water networks is an optimisation model that determines which water pumps will be turned on or off every time according to a dynamic electrical tariff. The problem is relevant in mining due to the high power usage of water pumps and the power prices uncertainty. The problem faces difficulties: i) nonlinearities of the frictional losses along the pipes and pumps; ii) many possible combinations of pressure head and flow rate, which leads to high computational costs. These limitations prevent the problem from being solved in a reasonable computational time in water networks with more than two pumps and reservoirs. Therefore, we develop new models for this problem that use a binary expansion approach to account for the nonlinearities and minimise the systemic cost; and it reduces the computational time compared to the current nonlinear Gurobi solver.

3 Resilient Planning of Power Systems - Fundamental Value Analysis

Farhad Billimoria[1], Sam Chakrabarti[2], [1]University of Oxford, Oxford, United Kingdom; [2]Princeton University, Princeton, NJ, Contact: sc87@princeton.edu

This paper addresses the increasing vulnerability of power systems to extreme weather and climate events resulting from climate change. Resilience of the power system is critical, and optimal planning requires a granular representation of risk relating to extremes. We examine the trade-offs between the variability of new sources of supply and demand and the codependence of existing fossil generation infrastructure and supply chains. To understand fundamental exposures of the system to extremes and the resilient system mix for future power systems, we develop a risk-averse stochastic electricity planning model adapted from the state of the art GenX power system planning model. Our results provide insights for policymakers and power system planners to design more resilient power systems.

Understanding customer behavior to inform decision making

Contributed Session

Session Chair: Shan Li, City University of New York, New York, NY

1 Mobile Advertisement Campaigns for Boosting In-Store Visits: A Design Framework and Case Study

Kimia Keshanian[1], Narayan Ramasubbu[2], Kaushik Dutta[3], [1]University of Tampa, Tampa, FL, [2]University of Pittsburgh, Pittsburgh, PA, [3]University of South Florida, Tampa, FL, Contact: kkeshanian@ut.edu

Brick-and-mortar retailers aim to increase foot traffic in their stores for better sales opportunities. Mobile location-based advertising has become a crucial marketing tool for reaching potential customers. However, designing effective campaigns requires complex analysis of data to target the right customers at the right time and place. We present a campaign design framework that considers data acquisition costs, data utilization, and the varying effects of data on campaign performance. Using a real-world case study, we demonstrate that the optimal attributes for targeting customers depend on their proximity to the store. Campaigns that use all or a naïve subset of data attributes yield lower returns compared to our proposed approach. Our findings have implications for mobile advertising campaign design, deployment, and further research in targeted advertising.

2 Selection And Moral Hazard In Gig And Traditional Agents: Evidence From A Field Experiment In E-commerce Call Center

Qiaowen Guo, Olin business school at Washington University in St. Louis, Saint Louis, MO, Contact: qiaowenguo@wustl.edu

We conduct a field experiment in the call center of Alibaba to compare the performance of gig agents and traditional agents. We investigate whether gig agents perform better than traditional agents in the context of e-commerce call centers when incentivized by sharing platforms through earnings, ratings, and penalties. We also examine if gig agents still outperform traditional agents when all features that could influence performance are controlled. Finally, we seek to identify the driving incentives that lead to the results.

3 Product Design and Branding Decision in the Presence of Brand Spillovers

Katsunari Tajima, Nobuo Matsubayashi, Keio University, Yokohama, Japan

When consumers evaluate the quality of a branded firm's new product, their perception of that firm's existing products can influence their evaluation with some bias. Considering such a brand spillover effect, we analytically examine a branded firm's quality choice and brand strategy for its new product. Our results show that the firm's optimal strategy depends on the quality level of its existing product and the ratio of two types of consumers who differ in their attitudes to the quality change with the new product offering. Unlike the results in the related literature, it can be optimal to set the strength of spillover at an intermediate level through a use of sub-brand.

4 How to Make You Trust Me All the Time? Guidance Strategies in a Cost-Loss Game

Bochen Zhu[1,2], Lijia Tan[2], Rob Basten[2], Lijia Wei[1],

[1]Wuhan University, Wuhan, China; [2]Eindhoven University of Technology, Eindhoven, Netherlands. Contact: b.zhu1@tue.nl

The expert possesses knowledge regarding the possibility of a state's realization that the decision maker lacks and offers an unequivocal advice to the decision maker, who then determines whether to follow the advice. The decision maker's action impacts the welfare of both players. How can the expert persuade the nonexpert decision maker to follow his advice, even when their benefits are not completely aligned? We test two strategies to convey this advice: Bayesian Persuasion and Third Threshold. We consider a cost-loss game with heterogeneous payoffs between players, in which decision makers decide whether to take a risk of a loss or pay a cost to avoid the risk. We find that the Third Threshold strategy is superior for the expert.

1 Bpm Methodology for Implementing Ai in Business Processes

Vinayaka Gude, Texas A&M University - Commerce, Commerce, TX, Contact: vinayaka.gude@tamuc.edu

AI has already begun to automate specific tasks and roles, leading to changes in the job market. Therefore, it is crucial to establish a framework for implementing changes in the business process that involve completing or partially replacing tasks with AI. This research aims to present a BPM-based methodology that enables the identification of criteria and the extent to which tasks within a process can be either replaced or complemented by AI. The simulation results for a loan approval process comparing the pre-and post-implementation phases indicate substantial long-term cost savings and reduced processing time. Furthermore, this paper delves into the challenges of implementing AI technologies in a business process, encompassing accuracy, effective information transfer, and ethical and security considerations.

2 Large Language Models and Knowledge Graphs to Optimize Commercial Real Estate Portfolio

Fearghal O'Donncha[1], John Sheehan[1], Fabio Lorenzi[1], Alexander Timms[1], Malgorzata J. Zimon[2], Joern Ploennigs[1], [1]IBM Research Europe - Ireland, Mulhuddart, Ireland; [2]IBM Research Europe, Warrington, United Kingdom. Contact: feardonn@ie.ibm.com

Commercial real estate decision making is a complex process influenced by various factors. Factors such as supply and demand, economic conditions, sustainability objectives, government regulations, infrastructure, socioeconomic and demographic trends, and market sentiment all play a role in shaping the dynamics of the market. To optimize real estate portfolios, companies need cost-effective and efficient space utilization through data-informed decision frameworks supported by AI-backed intelligence. Extracting insights from diverse data with complex causal dynamics requires contextual knowledge. Additionally, as economic and market conditions evolve, synoptic evaluations may lose value. In this talk, we explore the potential of combining knowledge graphs and insights from large language models to enhance real estate decision making.

3 Enhancing Interpretability and Prediction Reliability in Regression Tasks Through Constrained Mixture of Experts

Francis Kim[1], Minseok Han[2], Jong-Seok Lee[2], [1]Sungkyunkwan University, Suwon, Korea, Republic of; [2]Sungkyunkwan University, Suwon, Korea, Republic of. Contact: kimfrancis.cg@gmail.com

In this paper, we introduce a new method leveraging Mixture of Experts (MOE) models for reliability prediction in regression tasks, with a focus on interpretability. Traditional MOE models can capture complex relationships but lack in interpretability. We mitigate this by constraining MOEs into simple, localized linear models. The MOE gating network weights, usually employed to weigh the contribution of each expert, are repurposed in our work. They are used to measure prediction confidence, offering an insightful reliability evaluation. Our model was trained on both synthetic and real data and consistently showed accurate reliability measures in different scenarios, demonstraing the robustness of our approach.

4 Learning Human-Interpretable Models Using Machine Learning and a Smooth Information Criterion

Benjamin Cohen, Nazia Aslam, Burcu Beykal, George M. Bollas, University of Connecticut, Storrs, CT, Contact: benjamin.2.cohen@uconn.edu

We propose a method that harnesses scarce data and domain-expert knowledge to discover human-interpretable models. Our approach combines a smooth information criterion within a physics-informed machine learning loss function, allowing for simultaneous identification of a human-interpretable model and its parameter estimates. Our method can discover physics from data, without the biases inherent in sequential threshold regression techniques. We demonstrate our approach through a study of various nonlinear dynamic systems, comparing it to symbolic regression and physics-informed neural networks. Our results emphasize the significance of smooth information criterion loss functions on data-driven model discovery and parameter identification.

1 Physics-enhanced Neural Ordinary Differential Equations: A Hybrid Framework for Chemical Reaction Systems

You Peng[1], Farshud Sorourifar[2], Ivan Castillo[3], Linh Bui[4], Juan Venegas[5], Joel A. Paulson[2], [1]The Dow Chemical Company, Columbus, OH, [2]The Ohio State University, Columbus, OH, [3]The Dow Chemical Company, Lake Jackson, TX, [4]The Dow Chemical Company, Lake Jackson, TX, [5]The Dow Chemical Company, Midland, MI

Ordinary differential equations (ODEs) are of critical importance to science and engineering. Fields of research are dedicated to the task of building such models through domain expertise. A data-driven framework for constructing dynamic models has the potential to accelerate the lab-to-market pipeline by removing some of the need for domain expertise. In this work we investigate the applicability of neural ODEs (NODEs) for building models of reaction kinetics from experimental data, and how available domain knowledge may be used to accelerate learning. Using a simulation case-study we show that utilizing information of the system's dynamics can aid in training models; however, extreme care should be taken when attempting to use additional information. Our findings on two industrial reaction data sets suggest that even weak assumptions can impair NODE training.

2 Design Variable Selection in Personalized System Design Through Bayesian Optimization

Jiacheng Liu[1], Wenbo Sun[2], Judy Jin[1], Jingwen Hu[2], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan Transportation Research Institute, Ann Arbor, MI, Contact: liujc@umich.edu

Achieving an effective personalized design policy through Bayesian Optimization (BO) remains a computational challenge with high-dimensional design variables. Constructing a reliable surrogate model involves conducting computationally intensive simulations and costly predictions. Moreover, policy parameters optimization is time-consuming. Conventional BO tackles the first task by taking a lower-dimensional subspace with the important variables. However, in personalized system design, the design variable selection must account not only for their importance in surrogate model but also for their variance in design policy. We propose a BO algorithm that develops a new importance score to assess the relevance of each design variable in GP and design policy. Both the results on the synthetic data and case study demonstrate the effectiveness and robustness.

3 A Parametric Perspective on Benders' Decomposition

Benjamin J. Hamlin, Margaret M. Wiecek, Clemson University, Clemson, SC, Contact: bjhamli@clemson.edu

We consider a linear program suitable for Benders' decomposition with a parameter in the objective function. Applying parametric linear programming duality and following on the original results by Benders on the feasible region of the relaxed master problem to yield an optimal solution of the original problem, we develop a theory for a parametric master problem and parametric sub-problem in support of analogous conditions. Examples are included.

Evidence-based Interventions using Causal Inference

Community Committee Choice Session

Session Chair: Nur Kaynar, Cornell University, Ithaca, NY

1 Staggered Rollout Designs for Estimating the Total Treatment Effect Under Network Interference

Mayleen Cortez-Rodriguez, Cornell University, Ithaca, NY, Contact: mec383@cornell.edu
Interference, where the treatment of an individual influences the outcomes of others, arises in many causal inference settings. We present methods for estimating the total treatment effect (TTE), or the average difference between the outcomes when the population is treated versus when the population is untreated, when interference is constrained to low-order interactions among neighbors of an individual. We leverage a staggered rollout design, in which treatment is incrementally given to random subsets of individuals, to construct estimators for the TTE. We also consider a bias-variance trade-off when we introduce cluster-correlated designs, highlighting regimes where utilizing staggered rollout designs, information about the network, and estimators exploiting low-order interactions in the potential outcomes leads to useful estimation methods.

2 Causal Discovery in Retailing Choice Estimation
Vishal Gaur, Nur Kaynar, Ziwei Zhu, Cornell University, Ithaca, NY, Contact: zz575@cornell.edu
Causal discovery is widely used to uncover causal relationships from observational data. In our study, we utilize this approach to construct directed acyclic graphs (DAGs) that represent causal links between product purchases in basket shopping data in retailing. Using the estimated DAGs, we estimate choice and substitution behavior between products. This method is useful for verifying established assumptions in category choice models, such as symmetric substitution effects across categories. To validate these classical assumptions, we apply the PC algorithm, which is a widely used algorithm in causal discovery, to Walmart retail data. Additionally, we demonstrate how the causal discovery approach can enhance the accuracy of predicting customer choice.

3 Causal Discovery for Instrument Validity
Nur Kaynar[1], Auyon Siddiq[2], Frederick Eberhardt[3], [1]Cornell University, Ithaca, NY, [2]University of California-Los Angrles, Los Angeles, CA, [3]Caltech, Pasadena, CA
We propose a new optimization-based method for learning causal structures from observational data, a process known as causal discovery. We consider a highly general search space that accommodates latent confounders and feedback cycles, which few extant methods do. We formulate the discovery problem as an integer program, and propose a solution technique that identifies promising edges for inclusion in the output graph. We leverage our method to develop a graphical test for the validity of an instrumental variable and demonstrate it on the influential instruments for estimating the returns to education from Angrist and Krueger (1991) and Card (1993). In particular, our test complements existing instrument tests by revealing the precise causal pathways that undermine instrument validity, highlighting the unique merits of the graphical perspective on causality.

4 Evaluating Instrument Validity Using the Principle of Independent Mechanisms
Patrick Burauel, California Institute of Technology, Pasadena, CA, Contact: pburauel@caltech.edu
The validity of instrumental variables to estimate causal effects is typically justified narratively and often remains controversial. Critical assumptions are difficult to evaluate since they involve unobserved variables. Building on Janzing and Schölkopf's (2018) method to quantify a degree of confounding in multivariate linear models, we develop a test that evaluates IV validity without relying on Balke and Pearl's (1997) inequality constraints. Instead, our approach is based on the Principle of Independent Mechanisms (causal models have a modular structure). Monte Carlo studies show a high accuracy of the procedure. We apply our method to two empirical studies: e.g., we can corroborate the narrative justification given by Card (1995) for the validity of college proximity as an instrument for educational attainment to estimate financial returns to education.

1 Mission vs. Profit: The Interplay Between Social Service Agencies and Private Service Providers
Gulten Busra Karkili, Senay Solak, University of Massachusetts Amherst, Amherst, MA
In this paper, we consider subsidy welfare programs that involve mission-oriented service agencies cooperating with profit-oriented service providers. We identify funding-based mechanisms for service agencies to incentivize program participation and capacity allocation by private service providers. A provider's decision process is impacted by funds received from the service agency, demand uncertainty, and participation decisions of competitors. We characterize

optimal fund allocation policies for service agencies to providers such that total social impact of the subsidy welfare programs is maximized.

2 Improving Foster Care Visitation Scheduling: Maximizing Visitation Appointments via Time-Space Networks

Shima Azizi[1], Caroline Johnston[2], Erhun Kundakcioglu[3], Rizk Makroum[4], Andrew C. Trapp[5], [1]St. John's University, New York, NY, [2]University of Southern California, Los Angeles, CA, [3]Ozyegin University, Istanbul, Turkey; [4]Aubay, Lisbonne, Portugal; [5]Worcester Polytechnic Institute, Worcester, MA, Contact: azizis@stjohns.edu

Child welfare agencies charged with ensuring foster children regularly visit biological parents can be challenged due to fixed workforce levels and fluctuating caseloads. We introduce the Foster Care Visitation Scheduling Problem to assign, schedule, and route workers to foster children. We develop a two-phased network-based optimization approach that 1) preprocesses and pre-computes a time-space network structure, and 2) solves a novel large-scale integer optimization problem over this network. We incorporate our approach into an interface, assists foster care organizations to better operationalize their resources, and improves the consistency of visits and so quality of life for foster children. We discuss computational experiments on a variety of instances inspired by real data from New York State that reveal encouraging computational performance.

3 Performance Evaluation Of Child Welfare Departments Using Data Envelopment Analysis: A Comparative Study Across Us States

Sepideh Sedghi[1], Shima Azizi[2], Charles Vincent[3], Andrew C. Trapp[1], [1]Worcester Polytechnic Institute, Worcester, MA, [2]St. John's University, Queens, NY, [3]University of Bradford, Bradford, United Kingdom

The performance of departments of children and families is of critical importance to the future of our society. However, limited previous research appears to exist in performance analysis in the context of child welfare. We use Data Envelopment Analysis (DEA) to evaluate the performance of departments of children and families across different US states. Key inputs and outputs include child welfare spending and the re-entry rate of children, respectively. We conduct multiple analyses toward identifying high-performing states and explore additional methodological directions concerning the factors that contribute to disparities in DEA scores. The findings from this study provide valuable insights into the performance of foster care agencies and offer guidance for improving the quality of care provided to children in need.

4 Lessons Learned: New Perspectives on Cognitive Engineering in Child Welfare

Connor Wurst, University at Buffalo, Buffalo, NY

The child welfare system functions under high stakes, tight constraints, and a wide range of different stakeholder perspectives. There has been a number of calls for technological interventions to improve practitioner decision making and outcomes for youth in care, and our multidisciplinary team set out nearly four years ago to attempt to answer these calls. Through a number of different studies and approaches we have shifted our perspectives on this complex domain and the best path forward. This presentation broadly outlines the work that we have conducted, our shifts in perspective, and our hopes for future work, focusing particularly on our application of cognitive engineering to the domain.

Advances in Project Management

Contributed Session

Session Chair: Yihong Liu, The University of Texas at Dallas, Richardson, TX

1 An Improved Simulated Annealing Algorithm for Centralised Resource-Constrained Multiproject Scheduling to Minimise the Maximal Cash Flow Gap

Yukang He, Xi'an Jiaotong University, Xi'an, China

This paper involves a centralised resource-constrained multiproject scheduling problem, where renewable resources can be shared by all the individual projects and the task is to arrange activities' start times to minimise the contractor's maximal cash flow gap. First, we construct an optimisation model and propose some properties for the problem. Then, we develop a simulated annealing algorithm and design an improvement measure to enhance its searching efficiency. Finally, we conduct an computational experiment on an existing dataset, and the obtained results indicate that the developed algorithm is the most promising algorithm for the studied problem and some key parameters may exert important effects on the objective function value.

2 Research On Bi-level Project Network Control Method Based On Schedule Risk Analysis

Shuting Wang, Xiaobing Liu, Zhaoyang Bai, Dalian University of Technology, Dalian, China

Schedule Risk Analysis (SRA) has been shown to identify highly sensitive activities that significantly impact project duration, highlighting project control management priorities. The bi-level project planning model is strongly motivated by real-world applications. Since SRA focuses solely on single-level networks, traditional SRA metrics do not accurately reflect activity sensitivity in bi-level networks. This paper extends the traditional SRA metrics, introduces the sensitivity metrics (B-SRA) applicable to bi-level activity networks, and integrates them into buffer management. Five different B-SRA metrics are proposed to allocate project buffers and set tolerance limits. We conducted computational experiments on a set of large projects with different characteristics. Results show that the proposed project control method is effective and reliable.

3 A Dynamic Programming Approach to Multi Skilled Decentralized Multi Projects Scheduling with Uncertain Resource Availabilities

Xinyu Lin[1], Min Wang[2], [1]Renmin University of China, Beijing, China; [2]Fujian Jiangxia University, Fujian, China. Contact: lxylinxinyu@163.com

The paper studied the effect of multi-skilled resources in mitigating resource conflicts and coping with resource disruption in decentralized multi-project scheduling. Due to the geographical or organizational decentralization of multiple projects, global resource conflicts can easily occur while unexpected resource disruption brings new challenges. How to reduce the adverse effects of resource scarcity has become a widely concerned issue. Multi-skilled resources play a vital role in resolving resource conflicts and reducing project delays. Idle resources can replenish excess or missing resources, whose skills can be dynamically switched. The paper designed a bi-level model, proposed two new priority rules for multi-skilled resource scheduling, and designed a stochastic scheduling policy. The effectiveness of the algorithm was verified by experiment.

4 An Incremental Approach to Team Formation: A Markov Decision Process Framework

Yihong Liu, Sumit Sarkar, Syam Menon, The University of Texas at Dallas, Richardson, TX

Finding good team members for complex tasks in online platforms can be difficult when many candidates with diverse skills are available. We propose a novel recommendation framework that forms teams incrementally using a Markov decision process. The framework suggests potential collaborators to a focal participant (requester) based on the current team state and the expected contribution of potential candidates. Our approach aims to optimize team performance while accounting for the uncertainty associated with candidates' willingness to join the team.

Advances in Simulation Methodologies

Contributed Session

Session Chair: Eunji Lim, Adelphi University, Mineola, NY

1 Mining Simulation Log Data

Farhad Moeeni, Arkansas State University, Jonesboro, AR, Contact: moeeni@astate.edu

Discrete-event simulation (DES) is a powerful tool to model systems' behavior and to measure performance under various values of decision or input variables. Analysis of output is typically performed through the traditional statistical sampling methods, for example, the method of batch means and replication deletion. Each simulation run produces massive volume of "log data" including those corresponding to state variables as the simulation clock advances. Traditionally, the log data has been used for validation and verification of the simulation model. This exploratory study investigates the usefulness of data mining techniques to analyze log data to potentially extract insights not possible through the conventional output analysis.

2 Resolving Pert Ambiguity: A Unified Framework for Classifying Pert-Beta Rng Models

Byung-Cheol Kim, Penn State Behrend, Erie, PA, Contact: buk70@psu.edu

This study explores the ambiguity errors in ostensibly interchangeable PERT(program evaluation and review technique)-beta reparameterization models for project risk simulations, challenging the implicit assumption of their functional equivalency. Through empirical and theoretical assessments, we demonstrate the presence of ambiguity errors and identify three distinct PERT-beta distribution variants. We present empirical evidence by applying seven PERT RNG (random number generation) models to anecdotal cases in the literature. Moreover, our research introduces a unified visual classification framework to resolve the PERT ambiguity problem, contributing to the theory and practice of PERT-based risk simulation in project management.

3 Efficient Influence Function Estimation via Nonparametric Regression Method to Quantify Simulation Input Uncertainty

Jaime Gonzalez[1], Eunhye Song[2], [1]Georgia Institute of Technology, Atlanta, GA, [2]Georgia Institute of Technology, Atlanta, GA, Contact: jhodar3@gatech.edu

In this talk, we discuss efficient input uncertainty (IU) quantification when nonparametric input models estimated from data are adopted to run simulations. IU refers to the variance in the simulation output due to the estimation error of the input models. To construct the asymptotically correct confidence interval (CI) for the true performance measure of the system, the nonparametric delta method can be applied, which requires influence function (IF) estimation for the simulation output mean. However, estimating the IF is computationally expensive. We present a method to reduce the cost of estimation via nonparametric regression. We numerically demonstrate its computational efficiency using some discrete-event simulation examples for which it significantly reduces the estimation error in IF and empirical coverage of the CI.

4 Integrated Robust Simulation-Optimization

Pengxiang Zhou[1], Wai Kin (Victor) Chan[1], Zuo-Jun Max Shen[2], [1]Tsinghua University, Tsinghua Shenzhen International Graduate School, Shenzhen, China; [2]University of California Berkeley, Berkeley, CA, Contact: zpx20@mails.tsinghua.edu.cn

Simulation-optimization involves generating candidate system configurations and evaluating their performance through simulation. The integrated robust simulation-optimization models efficiently integrate optimization and evaluation using closed-form robust performance measure in a two-stage formulation, where the first-stage objective is to minimize system costs, and the second stage involves costs associated with worst scenarios. Integrating optimization models with simulation enables the generation of the worst-case scenarios which are unavailable in simulation, and facilitates optimal robust simulation-optimization strategies. Numerical experiments show that the integrated models balance cost and system reliability, and demonstrate the efficacy of decomposition methods along with simulation module for fast performance evaluation.

5 Simulation-Based Prediction

Eunji Lim[1], Peter W. Glynn[2], [1]Adelphi University, Garden City, NY, [2]Stanford University, Stanford, CA, Contact: elim@adelphi.edu

We are concerned with the use of simulation in computing predictors in settings in which real-world observations are collected. A major challenge is that the state description underlying the simulation will typically include information that is not observed in the real system. This makes it challenging to initialize simulations that are aligned with the most recent observation collected in the real-world system, especially when the simulation does not visit the most recently observed value frequently. Our estimation methodology involves "splitting," so that multiple simulations are launched from states that are aligned with the most recently collected observation. We provide estimators both in the setting that the observed real-world values are discrete and are continuous, with kernel smoothing methods being systematically exploited in the continuous setting.

Innovations for Product Development and Adoption

Contributed Session

Session Chair: Yixuan Zhang, University of Science and Technology Beijing, Beijing, China

1 Characterizing Dis/Misinformation Spreading Patterns in Online Social Media

Ensheng Ensheng[1], Andreas Nearchou[1], Lauren Gardner[1,2], [1]Johns Hopkins University, Baltimore, MD, [2]Bloomberg School of Public Health, Baltimore, MD, Contact: edong1@jhu.edu

Online social media platforms play a critical role in the sharing of information, ranging from scientific facts to harmful dis/misinformation. While misinformation spread is well-studied, the mechanisms that characterize information sharing are still unclear, in particular, how information flow differs by content type. In this study we utilize 40M+ COVID-19 and vaccine-related tweets (Jan-May 2021), and categorize these tweets into left, right, center and misinformation subgroupings. We characterize the information flow patterns by generating directed, weighted retweet networks, and evaluate the difference in content-specific information spread using a suite of network analysis tools. The study reveals differences in structural flow patterns, top influencers, and other content-specific behaviors that shed new light on information spread and impact.

2 Optimal Mixed Subsidy Policy for Innovation

Myeonghun Lee, KAIST, Seoul, Korea, Republic of. Contact: mhlee96@kaist.ac.kr

Government intervention plays a pivotal role in fostering the development and adoption of socially beneficial technology. In this study, we explore the optimal mix of two distinct subsidy types utilized by the government: a technology push that incentivizes manufacturers' R&D efforts, and a demand pull that directly rewards consumers. We formulate a multi-period model incorporating multiple firms that initiate R&D investments early on and subsequently engage in market competition. Interestingly, while a more beneficial technology corresponds to an increased overall subsidy budget, the distribution between push and pull subsidies exhibits non-monotonic shifts contingent on the equilibrium regime. We further show that contrary to the convention that spillover dissuades firms from R&D investment, spillover may indeed stimulate R&D investment.

3 The Distance Between Ideal and Reality: How Do Firms Embracing Artificial Intelligence Respond to Innovation Activities?

Yixuan Zhang, Xiangbin Yan, University of Science and Technology Beijing, Beijing, China. Contact: d202210500@xs.ustb.edu.cn

We aim to explore how artificial intelligence (AI) application practices create valuables for corporate innovation activities in the global data revolution context. Using large datasets from firms, we develop econometric models that consider moderating factors of managers' ecological concerns and corporate privacy-protecting to provide clearer support for our research. We have some interesting findings that AI applications can change innovation activities from multiple perspectives, such as substituting labor, introducing new tasks, strengthening user co-create abilities, and facilitating the development of green energy products. This study provides valuable insights for firms to achieve technology-driven innovation activities.

Predictive Analysis in Medical Care

Community Committee Choice Session

Session Chair: Syed Hasib Akhter Faruqui, Northwestern University, Chicago, IL

1 Probabilistic Ensemble Learning for Prediction of Stroke Thrombectomy Outcomes from the Neurovascular Quality Initiative - Quality Outcomes Database (Nvqi-Qod) Registry

Chaochao Zhou, Syed Hasib Akhter Faruqui, Abhinav Patel, Ramez Abdalla, Ali Shaibani, Matthew Potts, Babak Jahromi, Sameer Ansari, Donald Cantrell, Northwestern University, Chicago, IL, Contact: chaochao.zhou@northwestern.edu

Mechanical Thrombectomy is the standard-of-care in the interventional management of Acute Ischemic Stroke. We identified feature variables from the NVQI-QOD registry. We introduced a Probabilistic Neural Network (PNN) that predicts the expected distribution of NIH Stroke Scale (NIHSS) changes and 90-day modified Rankin Scale (mRS). The predictions of the PNN were compared to those of XGBoost, with both PNN and XGBoost trained using bagging ensemble learning. For both regression and classification, there were almost no differences in the prediction performance between the PNN and XGBoost ensembles. However, PNN can accurately describe the distributions of NIHSS changes represented by predicted means and SDs. This study demonstrates the utility of probabilistic ensemble learning in providing robust predictions while simultaneously quantifying uncertainty.

2 Application of Cnn to Detect and Compare the Dyslexia Level

Niamat Hossain, Jonathan Stubblefield, Arkansas State University, Jonesboro, AR

Dyslexia is a common neurodevelopmental disorder affecting individuals' reading and writing abilities. In recent years, the use of artificial intelligence, particularly Convolutional Neural Networks (CNNs), has shown promising results in dyslexia detection. While several CNN types of research have been conducted to detect dyslexia, there is a lack of research that examines the dyslexia proneness of the alphabet. To void this gap, this study uses a CNN classifier to identify alphabets with higher dyslexia by running CNN models to classify dyslexia-prone letters and comparing the F1 scores to see which alphabet is most deviated from the norm. The dataset in hand on Dyslexia contains handwritten normal alphabets and alphabets written for dyslexia patients. Finally, the paper discusses future directions and challenges in the field of dyslexia detection using CNN.

3 A Systematic Review and Tutorial of Machine Learning Approaches in Predicting Cardiovascular Diseases

Rakib Hasan[1], Syed Hasib Akhter Faruqui[2], [1]University of Texas at San Antonio, San Antonio, TX, [2]Northwestern University, Chicago, IL

Cardiovascular diseases (CVDs) pose a significant health burden for patients with multimorbidity. Post-COVID, this has become more concerning as several case studies have shown that the long-COVID involves CVD manifestations such as chest pain, palpitations, and persistent myocardial inflammation, which may contribute to long-term CVD consequences. Machine Learning (ML) techniques can support and facilitate medical practitioners in swift decision-making and adopt a patient-centered approach. This work systematically reviews ML techniques in predicting CVDs and their contributing factors. Additionally, we provide a comprehensive list of datasets, code tutorials, and guidelines for best practices in developing such ML models.

Data-driven vs. Rule-based: The Capability of Data-Driven Solutions for Real-World Applications

Community Committee Choice Session

Session Chair: Jiajing Huang, Arizona State University, Tempe, AZ

1 Doing Well By Doing Good: Interest Rate Determination For Unsecured Personal Loans

Ram Gopal[1], Xiao Qiao[2], Moris Simon Strub[1], Zonghao Yang[2], [1]University of Warwick, Coventry, United Kingdom; [2]City University of Hong Kong, Kowloon, China. Contact: zonghao.y@my.cityu.edu.hk

Perhaps the most important aspect of an unsecured personal loan is its interest rate. In practice, interest rates often fail to accurately reflect loan risk, which can lead to biases of borrowers and sub-optimal credit allocation. We propose a novel method to determine interest rates based on the economic rationale that interest rates should provide the same risk-return trade-off across loans. We evaluate the pricing framework using loan samples from LendingClub. Compared with LendingClub, our method effectively narrow the gap in interest rates between prime and super-prime borrowers by 42.5% and remove the existing bias against African Americans. Our results show that by setting interest rates that reflect the inherent risk of loans, online lending platforms can effectively improve social welfare and promote fair lending practices - doing well by doing good.

2 Optimal Integration of Supervised Tensor Decomposition and Ensemble Learning for in Situ Quality Evaluation in Friction Stir Blind Riveting

Zhe Gao[1], Weihong Guo[2], Xiaowei Yue[3], [1]Shanghai Normal University, Shanghai, China; [2]Rutgers, The State University of New Jersey, Piscataway, NJ, [3]Virginia Tech, Blacksburg, VA

We develops an in situ nondestructive quality evaluation for friction stir blind riveting in joining lightweight materials. This method is able to solve the small sample size problem that is commonly occurred in manufacturing experiments. Our method achieves an optimal integration of the tensor decomposition and ensemble learning by utilizing the mutual benefits. Diversified feature matrices are extracted via tensor decomposition to maximize the ensemble learning performance. Regularized tensor decomposition results deviate with different regularization parameter values and ensemble learning is able to determine the optimal parameter value via a heuristic algorithm, which stabilizes the tensor decomposition results. Numerical and case studies are performed to demonstrate the effectiveness of our method as well as its superiority over the existing methods.

3 Eigen Entropy Based Time Series Signatures to Support Multivariate Time Series Classification

Abhidnya Patharkar[1], Jiajing Huang[2], Teresa Wu[2], [1]ARIZONA STATE UNIVERSITY, Tempe, AZ, [2]Arizona State University, Tempe, AZ

Current multivariate time series classification algorithms typically do not consider the correlations between time series of different variables, leading to inaccurate predictions. To address this issue, we propose a new framework called Eigen Entropy based Time Series Signatures. This incorporates Eigen Entropy, which captures correlations between different time series, and utilizes a cumulative moving window to generate time series signatures. Additionally, we employ Dense Multi Scale Entropy to preprocess the data to accommodate its dynamic nature. This approach preserves both temporal and dynamic aspects of the dataset, thus has potential to improve multivariate time series classification accuracy. Our algorithm outperforms the baseline algorithm for datasets under consideration in terms of recall, with an average value of 22% across all datasets.

4 Cardiovascular Disease Management via Rule-Based Personalized Lifestyle Recommendation

Thamer S. Alnazzal[1], Ying Lin[2], [1]University of Houston, Houston, TX, [2]University of Houston, Houston, TX, Contact: t.alnazzal@hotmail.com

Modifying lifestyle behaviors can prevent cardiovascular disease (CVD). Personalized lifestyle recommendation which was enabled by the machine learning (ML)-based CVD risk prediction and optimization algorithms recommends lifestyle changes tailored to individuals. But their utility in clinical practice is limited due to the lack of interpretability and patient adherence. To solve this, we develop a Rule-based personalized lifestyle recommendation method to discover decision-support rules from data and integrate discovered rules with optimization techniques to recommend feasible lifestyle change criteria to individuals. This method effectively predicts CVD risk and suggests better lifestyle behavior to prevent CVD in a real-world population. This method holds promise for advancing CVD knowledge and developing new lifestyle modification guidelines.

5 Estimating Treatment Effects over Time with Causal Forests: An Application to the Acic 2022 Data Challenge

Shu Wan[1], Guanghui Zhang[2], [1]Arizona State University, Tempe, AZ, [2]Didi Global, Beijing, China. Contact: swan@asu.edu

We present DiConfounder, our winning approach for ACIC 2022 Data Science challenge, ranking 1st in RMSE and 5th in coverage among 58 submissions. It's a transformed outcome estimator combining difference-in-difference and conditional average treatment effect estimation. Our multistage pipeline includes feature engineering, missing value imputation, outcome and propensity score modeling, treatment effects modeling, and SATT and uncertainty estimations. Our model achieves an RMSE of 11 and 84.5% coverage. We discuss confidence intervals, limitations, and highlight the importance of clustered data structure. Source code is available on GitHub.

Advancing Interpretable Machine Learning: Novel Approaches and Applications

Community Committee Choice Session

Session Chair: Chudi Zhong, Morrisville, NC
Session Chair: Jiachang Liu, Duke University, Durham, NC

1 Fast Interpretable Matching for Observational Causal Inference

Cynthia Rudin, Duke University, Durham, NC

Our goal is to produce methods for observational causal inference that are auditable, easy to troubleshoot, yield accurate treatment effect estimates, and scalable to high-dimensional data. We describe an almost-exact matching approach that achieves these goals by (i) learning a distance metric via outcome modeling, (ii) creating matched groups using the distance metric, and (iii) using the matched groups to estimate treatment effects. Our proposed method uses variable importance measurements to construct a distance metric, making it a flexible method that can be adapted to various applications. Joint work with Quinn Lanners, Harsh Parikh, Alexander Volfovsky and David Page

2 Misuse of Post-Hoc Explainers in Business Applications

Ronilo Ragodos[1], Tong Wang[2], Feng Lu[3], Yu Jeffrey Hu[4], [1]University Of Iowa, Iowa City, IA, [2]University of Iowa, Iowa City, IA, [3]University of Electronic Science and Technology of China, Chengdu, China; [4]Georgia Institute of Technologuy, Atlanta, GA, Contact: ronilo-ragodos@uiowa.edu

Attributive post hoc explanation methods, and counterfactual explainers to a lesser extent, have become very popular in machine learning. A unique problem arises when they are used in business contexts since stakeholders may want to make decisions on post hoc explanations or draw managerial insights from feature importance measures. This is a problem because post hoc explainers have been shown to have intrinsic issues that may make their results untrustworthy. In this work, we investigate how and why post hoc explanations can be misused or misunderstood in business contexts. We also identify two crucial choices users make that affect the quality of post hoc explanations: the choice of explainer and the choice of hyperparameters. We summarize theoretical and practical reasons for the importance of these choices and demonstrate their consequences on managerial decisions.

3 Optimal Linear Classification Without Optimization

Berk Ustun, 1</sup

We introduce an enumerative paradigm for Boolean classification. Our approach enumerates a set of all possible labellings that can be realized by a model class (e.g., linear classifiers). Given this set, we can learn using map and filter operations. To learn the most accurate model, we compute the accuracy of each labelling and return the best ones. To learn a model that obeys constraints, we filter the set. We show how the labellings from these operations can be cast to a representative model without compromising performance or feasibility (e.g., a linear classifier with integer weights). We present procedures to enumerate major classes of interpretable classifiers, and an algorithm to fit certifiably optimal sparse models from these classes without an optimization solver.

Advances in Machine Learning for Economics and Finance

Community Committee Choice Session

Session Chair: Artem Prokhorov, University of Sydney Business School, CEBA, CIREQ, Woodcroft, Australia

1 Copula and Optimal Transport in Finance

Jessica Leung[1], Robert James[2], Artem Prokhorov[3], [1]Monash University, Melbourne, Australia; [2]University of Sydney, Sydney, Australia; [3]University of Sydney Business School, Sydney, Australia. Contact: jessica.leung@monash.edu

The optimal mass transport problem seeks the most cost-efficient way to transform one distribution of mass into another. This problem has been studied extensively in countless applications such as economics, transportation modelling, and natural language processing. We study a copula-based approach to the optimal transport problem and consider its application in dependence modelling in financial markets.

2 Bi-Objective Cost-Sensitive Machine Learning: Predicting Stock Return Direction Using Option Prices

Robert James, Artem Prokhorov, University Of Sydney, Sydney, Australia. Contact: r.james@sydney.edu.au

This paper design a bi-objective loss function for training binary classification machine learning models that predict the direction of future equity market index returns. Our bi-objective loss function combines the log-loss with a second objective which asymmetrically penalizes individual false-positive and false-negative miss-classification errors. We discuss how put and call option prices are natural measures of the miss-classification costs. Using 21 years of data and a comprehensive suite of classification performance metrics we demonstrate that both a linear logistic regression model and a non-linear gradient boosting model trained using our bi-objective outperform their traditional counterparts. A long/short investment strategy that uses predictions from our bi-objective models generates superior risk-adjusted returns net of transaction costs.

3 On Robust Causal Inference in Models of Firm Productivity and Efficiency in the Presence of Many Environmental Variables

Artem Prokhorov[1], Valentin Zelenyuk[2], Christopher Parmeter[3], [1]University of Sydney Business School, PEMA, CEBA, CIREQ, Woodcroft, Australia; [2]University of Queensland, Brisbane, Australia; [3]University of Miami, Miami, FL

The paper provides a moment-based framework for consistent estimation and normal inference for a firm's production function and inefficiency scores, when relevant confounding factors are selected from a large set of variables using various machine learning tools such as lasso or deep neural networks. We discussed connections between the estimator and the concept of moment and parameter redundancy and we work out the specific case of a debiased lasso estimator.

4 Dependence Maps: Graphical Analysis of Multivariate Dependence

Ivan Medovikov, Brock University, St Catharines, ON, Canada. Contact: imedovikov@brocku.ca

We propose a new graphical tool for the discovery of multivariate dependence that we term "dependence map". The map enables quick identification of feature clusters and can be applied to the discovery multivariate predictive features. We illustrate the applicability of dependence maps by searching for non-obvious predictive signals of the daily energy demand in New England.

Wednesday, October 18, 9:30 AM - 10:45 AM

WB70

CC-West 105B

(TBD)

Community Committee Choice Session

Session Chair: Mohammed Alyakoob, New York

1 Consumer Privacy Concerns, Multihoming, and Platform Competition in Two-Sided Markets

Xin Zhang[1], Hong Xu[2], Wei Thoo Yue[3], Yugang Yu[1], [1]University of Science and Technology of China, Hefei, China; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]City University of Hong Kong, Hong Kong, Hong Kong

Many online platforms adopt the ad-sponsored business model, which involves offering free services to consumers while collecting their data and selling targeted advertising space to advertisers. However, collecting consumer data has raised growing privacy concerns, which may affect consumers' homing behavior, i.e., using one platform (i.e., singlehoming) or multiple platforms (multihoming). This study develops a game-theoretic model to examine how consumer privacy concerns affect platform competition. Our model allows both consumers and advertisers to choose singlehoming or multihoming endogenously. Our results show that growing privacy concerns may be more likely to benefit the disadvantaged platforms, thereby promoting platform competition. We discuss relevant managerial and theoretical implications.

2 standardized Tools and Worker Mobility

Milan Miric[1], Hakan Ozalp[2], [1]USC Marshall, Los Angeles, CA, [2]University of Amsterdam, Amsterdam, Netherlands. Contact: mmiric@marshall.usc.edu

As new technologies emerge, they impact the value of worker skills. We study the diffusion and de-facto standardization of technologies (middleware tools) that made human capital more general and industry specific (rather than firm-specific), which in turn, increases the ability of individuals to move between companies. We contrast the impact on individuals with skills that are complementary to these technologies in comparison to those being substituted by these technologies. We exploit the uneven diffusion of tools and find that the diffusion of these tools lead to an increase in labor mobility on average but was associated with higher mobility for individuals with skills that complemented those tools, in comparison to those that were partly substituted by these tools. These effects were compounded by worker experiences.

Digital Economy and Platforms

Community Committee Choice Session

Session Chair: Siliang Tong, Nanyang Technological University, Singapore, Singapore

1 Location Divide in Digital Platforms: Evidence from a Natural Experiment

Lanfei Shi[1], Raveesh K. Mayya[2], Shun Ye[3], [1]University of Virginia, Charlottesville, VA, [2]NYU Stern School of Business, New York, NY, [3]George Mason University, Fairfax, VA, Contact: ls4tj@comm.virginia.edu

This study examines a less investigated information signal—*the seller's location*—in digital platforms. We ask whether and how the disclosure of seller location affects sellers' product sales and pricing strategies. Our findings show that the seller location disclosure policy may create a competitive disadvantage for international sellers, leading to a location divide on global e-commerce platforms. These findings highlight the unintended consequences of information disclosure and provide valuable implications for managing global e-commerce platforms.

2 Skill-Biased Technical Change Again? Online Gig Platforms and Local Employment

Aaron Cheng[1], Xue Guo[2], Paul A. Pavlou[3], [1]London School of Economics, London, United Kingdom; [2]University of North Carolina at Charlotte, Charlotte, NC, [3]University of Houston, Houston, TX

Online gig platforms are on the rise, but their roles in labor markets have been little understood. We study the impact of TaskRabbit and find a significant decrease in traditional housekeeping employment after the platform entry. This is driven by a decline in middle-skilled workers (i.e., first-line managers) whose labor tasks could easily be automated by the matching algorithms of TaskRabbit, rather than low-skilled manual workers (i.e., janitors). Interestingly, online gig platforms do not lay middle-skilled housekeeping workers off or shift them to other occupations, but rather they facilitate local entrepreneurial activities in the same industry. Our findings have profound implications: gig platforms could not simply be viewed as skill-biased; instead, they exert a labor redistribution that reconciles the tension between automation with labor augmentation.

3 The Value of External Data for Digital Platforms: Evidence from a Field Experiment on Search Suggestions

Ananya Sen[1], Xiaoxia Lei[2], [1]Carnegie Mellon University, Pittsburgh, PA, [2]Shanghai Jiao Tong University, Shanghai, China

Firms increasingly leverage external data with an aim to unlock improvements in products and services. Collaborating with a large Chinese technology company, we analyze a field experiment where we manipulate access to the market leader's application programming interface (API) to measure the causal impact of depersonalized external data on CTR for the focal company's nascent search product. We report three main findings: First, compared to the baseline with access to the market leader's API, API removal leads to a

4.6% decrease in CTR for search suggestions. Second, the negative effect due to API removal is more prevalent among heavy users, when users' search intent is implicit, and for mainstream (popular) content. Third, the magnitude of this negative effect in the long run is half as much as what we would have obtained with a short-term experiment.

4 Payout Frequency and Gig Workers' Performance: Evidence from a Multination Quasi-Natural Experiment

Jack Tong[1], Shiyi Wang[2], Nan Jia[3], [1]Nanyang Technological University, Singapore, Singapore; [2]Nanyang Technological University, Singapore, Singapore; [3]University of Southern California, Los Angeles, CA, Contact: jack.tong@ntu.edu.sg

In this study, we investigate how the design of payout frequency schemes motivates gig workers' commitment to work and improves the quality of work on the platform. In collaboration with an online social streaming platform, we explore a quasi-natural experiment in which the platform's payout cycle for gig workers (streamers) in the South Asia region is changed from 30 days to 10 days because of the system upgrade of a local financial vendor. Our analyses provide the first empirical evidence showing that a shorter payout cycle induces gig workers to expend more effort at work (produce more streaming sessions with longer streaming duration). Moreover, a shorter payout cycle motivates gig workers to deliver higher quality of work (more audiences engaged with the streamer for a longer viewing duration and higher gifting value).

Advancements in Complex Systems and Digital Health Technologies

Community Committee Choice Session

Session Chair: Quoc Nguyen, University of South Florida, Tampa, FL

Session Chair: Trung Le, University of South Florida, Tampa, FL

1 The Impact of Exercise and Nutrition on Mental Distress in Men and Women During Different Stages of Covid-19

Zeynep Ertem, State University of New York- Binghamton, Vesta;l, NY

2 Multiplex Network Analysis of ***F. Covae*** Genomes

Harun Pirim[1], Zaidur Rahman[1], Yusuf Akbulut[1], Hasan C. Tekedar[2], Larry Hanson[2], Matt Griffin[2], [1]North Dakota State University, Fargo, ND, [2]Mississippi State University, Starkville, MS, Contact: harun.pirim@ndsu.edu

Multiplex network analysis (MNA) provides a framework to analyze multiple relationships of the same nodes represented as different layers. MNA can help better understand the resilience and robustness of complex systems such as protein interactions that can be defined based on different criteria. We are interested in eliciting diverse relationships between proteins including hypothetical ones. Hence, we focused on unique proteins (singletons) of four distinct genomes of F. *covae* downloaded from NCBI database. PANNZER annotation server is used to filter proteins with the highest annotation scores and PPV values higher than 0.5. Sequence, physicochemical features, and cellular localization information are used to construct three layers of the multiplex network for the retained 192 proteins. R multinet and muxViz libraries are used for the analysis and visualization.

3 Label Conditioning Diffusion Model With Application To Brain Tumor Mri Synthesis

Quoc Nguyen[1], Thang Nguyen[1], Minh Nguyen[2], Trung Le[1], [1]University of South Florida, Tampa, FL, [2]Digital Science and Technology Institute, The University of Danang—Vietnam-Korea University of Information and Communication Technology, Da Nang, Viet Nam. Contact: nguyenq29@usf.edu

Medical image synthesis is an important area of research that has seen significant advancements in recent years, particularly with the advent of deep learning-based approaches. In this article, we proposes a conditional diffusion model-based framework for generating synthetic medical images for MRI brain tumor classification tasks. The proposed framework was also found to be able to handle the similarity of non-tumor areas in brain tumor images and differences in tumor location, surpassing the performance of other generative models like GANs. Overall, the results highlight the potential of conditional diffusion models for medical image synthesis and their ability to address challenges associated with imbalanced data in medical image classification tasks.

Applications of Data Mining II

Community Committee Choice Session

Session Chair: Yanjing Wang, University of Miami, Miami, FL

1 Typology-Enhanced Origin-Destination-Transfer Inference from Noisy Mobile Boarding Observations

Mohammed A. A. Mohammed[1], Jimi Oke[2], [1]University of Massachusetts Amherst, Amherst, MA, [2]University of Massachusetts Amherst, Amherst, MA

Addressing data limitations is crucial in cost-effective transit planning. In this study, we present a computational method that transforms sparse mobile automatic fare collection (AFC) and automatic passenger count data into a precise origin-destination-transfer model for the Pioneer Valley Transit Authority, our case study network. We begin with the identification of spatiotemporal trip pattern typologies, revealing the distinct character of passenger behaviors and informing a seasonal trip chaining framework. These patterns enable the development of a transfer model that accounts for route interactions, ultimately leading to a data-driven transit planning dashboard that visualizes passenger demand and transfer dynamics. In the end, our cost-effective and adaptable method emerges as a valuable tool for transit planning in resource-constrained systems.

2 Unveiling the Intricacies of Physiological Signals: A Novel Network-Based Approach for Complex Dynamic System Quantification and Characterization

Yujie Wang[1], Cheng-Bang Chen[1], Diane Lim[2], [1]University of Miami, Miami, FL, [2]Miami VA Healthcare System, Miami, FL, Contact: yxw509@miami.edu

This research presents a novel weighted-network-based approach to measure and profile intricate dynamic systems in physiological signals. Many existing methods often overlook the nonlinear and nonstationary properties, hindering comprehensive characterization. By leveraging sophisticated network topology structures to model the recurrence patterns, our approach proficiently captures the nonstationary dynamic properties, offering significant insights into complex physiological phenomena. The experimental results illustrate its potential of physiological signal processing in the fields of healthcare and biomedicine, indicating a promising direction comprehending intricate physiological systems.

3 Prediction Models for Inter-Stop Travel Time of Urban Buses Using Automatic Vehicle Location Data

Fateme Hafizi[1], Seyedehsan Seyedabrishami[2], Mohammad Miralinaghi[3], [1]Illinois Institute of Technology, chicago, IL, [2]Tarbiat Modares University, Tehran, Iran, Islamic Republic of; [3]Illinois Institute of Technology, Chicago, IL, Contact: fhafizi@hawk.iit.edu

To optimally use the existing transportation infrastructure, urban authorities and travelers need reliable travel time forecasts for the public transportation systems. Emerging technologies, such as automatic vehicle location (AVL) systems, are able to improve public transit data forecasting. Using AVL data collected in Tehran, Iran, this study evaluates the efficacy of both statistical and deep learning methods for predicting inter-stop travel time, which can be beneficial for both transit users and agencies. The results indicate that deep learning is superior to the statistical method. It is also found that the static features of the public transit routes have the greatest impact on predicted travel times.

4 AI Trend in the Exploration of Public Opinion Analysis About ChatGPT

Yanjing Wang, Yihan Wang, Ziru Wang, Clark University, Worcester, MA, Contact: yanjwang222@outlook.com

ChatGPT is considered a revolutionary innovation in human civilization, yet what exactly is the public factual perception of ChatGPT? This study aims to measure the public's use of ChatGPT and its outlook. We decided to use Twitter to monitor and analyze real-time events, using a programming language for sentiment analysis, first using API integration to collect the latest tweets about ChatGPT, immediately followed by machine learning algorithms that can be used to classify tweets as positive, negative or neutral sentiment. By analyzing these results, valuable insights can be gained, and then the model can be enhanced to ultimately provide a comprehensive understanding of the overall sentiment of the public towards it.

Improving Inventory and Supply Chain Management

Contributed Session

Session Chair: Xiaotong Liu, Tsinghua University,

Shenzhen, China

1 Forecast-Driven Dual-Sourcing Inventory Management Using Simulation-Optimization

Ashwin Pothen, Benoit Montreuil, Georgia Institute of Technology, Atlanta, GA, Contact: ashwinpothen@gatech.edu

Dynamic supplier management is an effective strategy for a supply chain operating in a volatile and disruptive environment. We study a dual-mode forecast-driven inventory management problem for a real-world furniture manufacturer. The manufacturer faces a non-stationary stochastic demand and enforces a chance stock-out constraint for consistent product availability. We consider two suppliers, regular who has stochastic lead time, and an emergency supplier with a constant lead time but highly vulnerable to disruptions. With daily update of demand forecasts, we employ a simulation-optimization approach to estimate inventory policy parameters. We compare the performance of three relevant policies namely single-index, dual-index and tailored base-surge, and investigate the sensitivity of the policy parameters to supplier characteristics and constraints.

2 Optimizing Air Cargo Operations: An Integrated Model for Flight Scheduling, Aircraft Routing, and Cargo Assignment to Ulds

Matias Alvo[1], Alessandro Bombelli[2], Felipe Delgado[3], Gustavo Angulo[1], Bruno Santos[4], [1]Pontificia Universidad Católica de Chile, Santiago, Chile; [2]Delft University of Technology, Delft, Netherlands; [3]Pontificia U Catolica-Chile, Santiago, Chile; [4]TU Delft, Delft, Netherlands. Contact: a.bombelli@tudelft.nl

Planning air cargo operations entails aircraft routing, cargo routing, and cargo assignment to available Unit Load Devices (ULDs), among other decisions. These decisions are often made in sequence due to the complexity of the operations. This work proposes an integrated model to solve the flight schedule, aircraft routing, ULD routing, and cargo assignment to ULDs of a full freighter fleet of aircraft. We propose two different formulations, a fully arc-based and a hybrid one. We tested our models on a set of synthetic instances inspired by a major European airline's full freighter operations. Our results showed that the integrated approach consistently outperforms solving the problem sequentially with profits that are 10-15% higher, particularly for instances with many incompatibilities and special handling requirements.

3 Who Should Donate? a Socially Responsible Supply Chain with Prosocial Customers

Xiuyi Zhang, Yongbo Xiao, School of Economics and Management, Tsinghua University, Beijing, China. Contact: xy-zhang21@mails.tsinghua.edu.cn

In a society that advocates corporate social responsibility, it has been common for firms to make donations to the "bottom of the pyramid". Besides improving consumer welfare, donation helps firms expand their demand base because customers are prosocial. In this paper, we consider a socially responsible supply chain that consists of a manufacturer and a retailer. We study the interactive donation and inventory decisions between the supply chain members and show that, under equilibrium, only one firm donates and the other firm acts as a free-rider. To improve the supply chain performance, we suggest the firms to make a joint donation; that is, each firm shares a portion of the other party's donation cost. Furthermore, we examine two intervention policies, i.e., donation subsidy and tax deduction, from the perspective of the government, who seeks to optimize the social welfare.

4 Improving Resilience in a Multi-Tier Supply Chain Network: Roles of Delegation and Deferred Payment

Xiaotong Liu[1], Lijian Lu[2], Zuo-Jun Max Shen[3], Li Xiao[4], [1]Tsinghua University, Shenzhen, China; [2]The Hong Kong University of Science and Technology, Hong Kong, China; [3]University of California Berkeley, Berkeley, CA, [4]Tsinghua University, shenzhen, China. Contact: xiaotong18@mails.tsinghua.edu.cn

Deferred payment allows suppliers to secure financing for resilience improvement by deferring payment based on their reliability. However, implementing this scheme in a complex supply network is challenging. Our game-theoretic model analyzes the interactions among a buyer, a tier 1 supplier, and a tier 2 sub-supplier who can improve delivery reliability through costly effort. We find that the deferred payment under control mechanism is preferred when the retail price is low, especially when the supply chain network has multiple competing tier 2 suppliers or when the retail price is endogenous. Finally, we conduct an empirical analysis to verify the main results we derive.

Optimization on Graphical Models

Contributed Session

Session Chair: Shabnam Mahmoudzadeh Vaziri, Concordia University, Montreal, QC, Canada

1 Dc Algorithm For Estimation Of Sparse Gaussian Graphical Models

Tomokaze Shiratori, Yuichi Takano, University of Tsukuba, Tsukuba-Shi, Japan. Contact: s2230119@u.tsukuba.ac.jp

Graphical lasso is widely used as a method for estimation of sparse Gaussian graphical models, where the L1 norm of elements in the precision matrix is used as a regularization term for sparse estimation. However, since the L1 norm is a convex approximation of the L0 pseudo-norm (i.e., total number of nonzero elements), it is more desirable to use the L0 pseudo-norm as a regularization term to obtain high-quality solutions. We propose a method that leverages the DC algorithm based on the L0 pseudo-norm to achieve estimation of sparse Gaussian graphical models. To demonstrate the effectiveness of the proposed method, we conduct computational experiments for comparing the performance of the proposed method with the graphical lasso for various experimental settings with different sample sizes and numbers of features.

2 A Biased Random-Key Genetic Algorithm for the Minimum Quasi-Clique Partitioning Problem

Celso C. Ribeiro[1], Rafael Melo[2], Jose Angel Riveaux[3], [1]Universidade Federal Fluminense, Niterói, Brazil; [2]Universidade Federal da Bahia, Salvador, Brazil; [3]Universidade de São Paulo, São Paulo, Brazil. Contact: celso.ribeiro@gmail.com

Let G=(V, E) be a graph with vertex set V and edge set E, and ⍰ in [0,1) a constant. A quasi-clique is a subset V' of V inducing a subgraph of G with edge density at least ⍰. The minimum quasi-clique partitioning problem (MQCPP) consists of obtaining a minimum cardinality partition of V into quasi-cliques. We propose a biased random-key genetic algorithm (BRKGA) for MQCPP that relies on an efficient partitioning decoder. The BRKGA is very effective in obtaining high-quality solutions for MQCPP in low computational times. It matches all best solutions available in the literature, improving over them for 20.3% of the benchmark instances. The approach is robust as it obtains small deviations from the best-achieved solutions when executing multiple independent runs. We also consider the performance of the BRKGA on a set of new, larger challenging instances with up to 2851 vertices.

3 Approximation Algorithms for Generalizations of Strong Connectivity Augmentation Problem

Ryoma Norose, Yutaro Yamaguchi, Osaka University, Osaka, Japan. Contact: ryoma.norose@ist.osaka-u.ac.jp

Strong connectivity augmentation (SCA) problem is one of the fundamental problems on graphs. In SCA we are required to make a given directed graph strongly connected by adding an edge set of minimum weight. SCA is NP-hard and the best known approximation factor is 2. We consider several generalizations of SCA and try to design approximation algorithms for them.

4 A Graph Neural Network for Optimum Communication Spanning Tree Fortification Problem

Shabnam Mahmoudzadeh Vaziri, Onur Kuzgunkaya, Navneet Vidyarthi, Concordia University, Montreal, QC, Canada

We present a tri-level mathematical model for the fortification decisions of optimum communication spanning tree problem (OCST) against worst-case disruptions, using a game theoretic framework between the defender and the interdictor. We consider uncertainty in the number of disruptions since the defender may not have complete information about the interdictor's capabilities. To solve the stochastic tri-level model, we use backward sampling framework where OCST is solved using branch-and-Benders-cut algorithm (BBC). BBC is not able to solve large-size instances; therefore, we use graph neural network (GNN) to solve OCST. Through extensive numerical experiments, we compare the computational performance of BBC algorithm and GNN method and demonstrate the advantages of the proposed stochastic model.

New Methods for Combinatorial Problems

Contributed Session

Session Chair: Avinash Bhardwaj, Indian Institute of Technology Bombay, Mumbai, India

1 A Learning-Based Exact Algorithm for the Quadratic Multiple Knapsack Problem

Qingyang Wang, Ying Meng, Lixin Tang, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, 110819, China, Shenyang, China. Contact: 2407242535@qq.com

The quadratic multiple knapsack problem (QMKP) is a classic combinatorial optimization problem that finds wide applications in various scenarios. Despite a plethora of heuristics, only a few exact algorithms for QMKP have been developed. This paper proposes a new exact branch-and-price algorithm to solve QMKP, in which we reformulate the master problem model using the identity of pricing subproblems. In addition, a learning-based method is used to generate the near-optimal solution quickly for the pricing subproblems, thus enhancing the efficiency of column generation. The experiments show that our method exhibits excellent performance in solving large-scale quadratic multiple knapsack problems compared to existing exact algorithms.

2 An Efficient Linearization Technique for Project Portfolio Selection Problem

Yao-Huei Huang[1], Chiayi Wang[2], Hao-Chun Lu[2], [1]Fu Jen Catholic University, New Taipei City, Taiwan; [2]National Yang Ming Chiao Tung University, Hsinchu, Taiwan. Contact: erica880430@gmail.com

This study addresses the problem of project portfolio selection (PPS), which is a classical problem in management science and operational research. By solving the problem efficiently and effectively, the decision maker can not only choose the right projects conveniently but also obtain good benefits. In conventional PPS, each project is considered selected or not using binary variables. This study proposes a reformulation of PPS where projects can be selected multiple times using integer variables. An efficient linearization technique is proposed for the reformed PPS to allow the decision maker to conveniently find the optimal solution. Numerical experimental results show that the proposed linearization technique not only outperforms state-of-the-art methods but also solves large-scale problems efficiently and effectively.

3 Bipartite Graph for Boolean Pattern Recognition

Yoonsik Jung, Hong Seo Ryoo, Korea University, Seoul, Korea, Republic of. Contact: ys_jung@korea.ac.kr

Boolean pattern recognition can be formulated as an IP with min cover inequalities. To address this problem, we utilize a bipartite graph to represent the Boolean literals as nodes on one side and the inequalities as the other. Next, we introduce an edge between a literal and a constraint if the literal appears in the corresponding cover inequality. For solution, we design scores based on local optimality and feasibility criteria and integrate them to yield a combinatorial algorithm that strives to identify solutions that are optimal in a 'large' neighborhood. Through preliminary experiments on public data mining datasets, we test robustness and efficiency of the proposed algorithm.

4 A Few More Lonely Runners

Avinash Bhardwaj[1], Vishnu Narayanan[1], Hrishikesh Venkataraman[2], [1]Indian Institute of Technology Bombay, Mumbai, India; [2]Indian Institute of Science Education and Research, Pune, Pune, India. Contact: abhardwaj@iitb.ac.in

Lonely Runner Conjecture, proposed by Jörg M. Wills and so nomenclatured by Luis Goddyn, has been an object of interest since it was first conceived in 1967 : Given positive integers k and n1, n2,...,nk there exists a positive real number t such that the distance of t nj to the nearest integer is at least 1⁄k+1, for all 1 ≤ j ≤ k. In a recent article Beck, Hosten and Schymura described the Lonely Runner polyhedron and provided a polyhedral approach to identifying families of lonely runner instances. We revisit the Lonely Runner polyhedron and highlight some new families of instances satisfying the conjecture.

5 Continuous And Integer Formulations For Spacecraft With Water-based Propulsion

Emily Pitts[1], Matthew Harris[2], [1]Utah State University, Logan, UT, [2]Utah State University, Logan, UT

The work considers spacecraft equipped with water-based propulsion systems. These systems provide impulsive thrust and require a minimal recharge, or rest, time between thrust events. The impulsive nature and recharge constraint render the spacecraft trajectory design problem an integer program. Continuous-time and discrete-time formulations are developed. In the context of learning to branch, numerical solve times are studied statistically across multiple solver settings to identify settings suitable for onboard implementation.

Emerging Topics in eBusiness

Contributed Session

Session Chair: Sunil Erevelles, University of North Carolina, Charlotte, Charlotte, NC

1 Metaverse and User Engagement: The Role of Psychological Ownership and the Benefits of Virtual Assets

Minyoung Lee, Sanghyun Kim, Kyungpook national university, Daege, Korea, Republic of. Contact: bibianna0910@naver.com

This study studied the engagement of metaverse users in the context of virtual communities and psychological ownership. To this end, the factors affecting psychological ownership of virtual space were identified, and the structural relationship between individual psychological ownership and collective psychological ownership was examined. Studies have shown that the interaction between individual psychological ownership and social identity affects collective psychological ownership of metaverse community, and the relationship between psychological ownership and engagement intention is moderated by the perceived benefits of virtual assets. This study is expected to expand research on metaverse communities by verifying how psychological ownership, social identity, and the virtual assets affect the engagement behavior of metaverse platform users.

2 Brand Exploration in Metaverse: Effects of User-Avatar Resemblance on Engagement and Brand Attitude

Jaehyun Lee, MinChung Kim, Yeolib Kim, Ulsan National Institute of Science and Technology (UNIST), Ulsan, Korea, Republic of. Contact: jhyunlee@unist.ac.kr

Brand metaverse, which refers to the brand in a virtual world, has become an important medium for brands to communicate with customers. In this study, we investigate the influence of user-avatar resemblance on brand metaverse engagement and brand attitude. Specifically, we propose that user-avatar resemblance affects brand attitude by virtue of the engagement with the brand metaverse. Furthermore, we posit that copresence, the simultaneous presence of multiple avatars in the brand metaverse, acts as a moderator that strengthens the mediation. We conducted an experiment using a fashion brand's virtual world in a popular metaverse platform. Our hypotheses were supported for the main and interaction effects. The findings provide meaningful implications for marketing practitioners who have intentions to implement 'metaverse marketing.'

3 Consumer Privacy Concerns, Multihoming, and Platform Competition in Two-Sided Markets

Xin Zhang[1], Hong Xu[2], Wei Thoo Yue[3], Yugang Yu[1], [1]University of Science and Technology of China, Hefei, China; [2]Hong Kong University of Science and Technology, Hong Kong, Hong Kong; [3]City University of Hong Kong, Hong Kong, Hong Kong

Many online platforms adopt the ad-sponsored business model, which involves offering free services to consumers while collecting their data and selling targeted advertising space to advertisers. However, collecting consumer data has raised growing privacy concerns, which may affect consumers' homing behavior, i.e., using one platform (i.e., singlehoming) or multiple platforms (multihoming). This study develops a game-theoretic model to examine how consumer privacy concerns affect platform competition. Our model allows both consumers and advertisers to choose singlehoming or multihoming endogenously. Our results show that growing privacy concerns may be more likely to benefit the disadvantaged platforms, thereby promoting platform competition. We discuss relevant managerial and theoretical implications.

4 standardized Tools and Worker Mobility

Milan Miric[1], Hakan Ozalp[2], [1]USC Marshall, Los Angeles, CA, [2]University of Amsterdam, Amsterdam, Netherlands. Contact: mmiric@marshall.usc.edu

As new technologies emerge, they impact the value of worker skills. We study the diffusion and de-facto standardization of technologies (middleware tools) that made human capital more general and industry specific (rather than firm-specific), which in turn, increases the ability of individuals to move between companies. We contrast the impact on individuals with skills that are complementary to these technologies in comparison to those being substituted by these technologies. We exploit the uneven diffusion of tools and find that the diffusion of these tools lead to an increase in labor mobility on average but was associated with higher mobility for individuals with skills that complemented those tools, in comparison to those that were partly substituted by these tools. These effects were compounded by worker experiences.

5 Market Genomics: Genomics Big Data on the Blockchain

Sunil Erevelles[1], Anthony Erevelles[2], Erin Erevelles[2], [1]University of North Carolina, Charlotte, NC, [2]GeneBlock, Charlotte, NC, Contact: sunil.erevelles@uncc.edu

The Genomic Data Revolution represents a monumental paradigm shift in research on markets and consumer behavior. Approximately 50% of human behavioral traits are driven by genomics, and can potentially be predicted at birth. However, approximately 120 years of market research has mostly focused on the other 50%. Additionally, the effects of genomics increase, not decrease, over a person's lifetime. In this paper, the authors introduce a new field that they term, "Market Genomics," that delineates how Genomic Big Data can be used to predict market behavior at birth. Genomic Big Data cannot, however, be ethically or practically used without the blockchain. The authors thus present a theoretical framework and model for Genomic Big Data on the Blockchain. The framework may serve as a seminal foundation for future research, and may stimulate a new field of research on markets.

Sustainable Sourcing, Packing, and Service

Contributed Session

Session Chair: Nima Safaei, University of Illinois Urbana-Champaign, , IL, Champaign, IL

1 Direct Trade Sourcing Strategies for Specialty Coffee

Scott Webster[1], Burak Kazaz[2], Shahryar Gheibi[3], [1]Arizona State University, Tempe, AZ, [2]Syracuse University, Syracuse, NY, [3]Siena College, Loudonville, NY, Contact: scott.webster@asu.edu

Leading specialty coffee roasters rely on direct trade to source premium coffee beans. We study how characteristics of the operating and market environment affect the optimal sourcing strategy and incentives for a closer relationship with a grower.

2 The Impact of Different Contracting Mechanisms on the Performance of Reusable Packaging Systems

Sandra Transchel, Kuehne Logistics University, Hamburg, Germany. Contact: sandra.transchel@the-klu.org

Implementing functioning reusable packaging systems that guarantee a smooth circulation of the reusables requires the collaboration and coordination of various stakeholders in a supply chain. We investigate the impact of different contractual agreements in a two-stage supply chain consisting of two producers with different products and a wholesaler, who has to invest in sorting capacity to manage these return rates. We develop a game-theoretical model and study different types of contracts and their impact on the performance of the reuse system along different dimensions (cost and return rates).

3 Risk Management for Second-Hand Clothing Imports in the Least-Developed-Countries: The Design of Sterilization Legislation Schemes

Shu Guo, University of Liverpool, Liverpool, United Kingdom

The second-hand clothing imports are very popular in the Least-Developed-Countries (LDCs). The social health risk associated with second-hand clothing products and the lack of relevant legislations in LDCs, however, bring substantial challenges. This research is therefore developed to explore the sterilization legislation design for second-hand clothing supply chains in LDCs. Both the Extended Exporter Responsibility legislation scheme and the Extended Importer Responsibility legislation scheme are considered. We compare the performance of sterilization legislation schemes under different sterilization legislation structures. Our findings complement the extant knowledge on risk management of second-hand clothing in LDCs, and provide an important guidance regarding the design of sterilization legislations on second-hand clothing imports.

4 No News About Climate Action is Good News for the Firm

Nima Safaei[1], Gautam Pant[2], [1]University of Illinois Urbana-Champaign, Champaign, IL, [2]University of Illinois Urbana-Champaign, Champaign, IL, Contact: nimaasafaei@gmail.com

Heightened societal focus on corporate environmental responsibility encourages firms to publicize climate actions via media. Yet, media spotlight can also unveil negative environmental activities. Despite extensive study on media influence on corporate finance, the impact of media spotlight on firms' climate action on their financial performance remains unexplored. Our study fills this void, revealing that increased media spotlight negatively impacts financial performance due to higher costs incurred by the firm. Interestingly, this negative effect is less for high-pollution industries and firms with poor environmental performance. This research informs corporate leaders on the financial implications of media exposure of environmental initiatives, guiding informed decision-making about media engagement and strategic responses.

Scheduling Problems in Health Operations

Contributed Session

Session Chair: Muhammad Adnan Zahid Chudhery, School of Management, University of Science and Technology of China, Hefei, China

1 Outpatient Appointment Scheduling: Developing New Scheduling Systems to Improve a Psychiatric Clinic Scheduling Efficiency

Alireza Kasaie[1], Suchithra Rajendran[2], [1]University of Missouri-Columbia, Columbia, MO, [2]University of Missouri, Columbia, MO, Contact: skdx2@umsystem.edu

This study examines new scheduling rules to minimize physician idle time, overtime, patient waiting time, number of unscheduled patients, and total cost in psychiatric clinics. Results show that VBVI rules are most effective in reducing

idle time, overtime, waiting time, and total cost, while VBFI rules have the lowest number of unscheduled patients. VBVI rules are also more robust and less sensitive to patient unpunctuality rates. The study highlights the negative impact of lower punctuality on productivity and patient waiting time. Overall, VBVI rules are recommended for improved patient outcomes and cost reduction.

2 A Novel Mobile-Based Outpatient Healthcare Service Delivery Model: Investigating Acceptance and Its Impact on Physicians' Performance

Muhammad Adnan Zahid Chudhery[1], Sarah Safdar[2], [1]School of Management, University of Science and Technology of China, Hefei, China; [2]School of Management, Hefei University of Technology, Hefei, China. Contact: adnanzahidpk@yahoo.com

China's tertiary hospitals are overcrowded despite increased emergency department capacity, while primary healthcare centers are well-equipped to treat outpatients but underutilized and could help address the issue. Therefore, we first suggest a mobile-based healthcare service delivery model to streamline outpatient flow and optimize resource utilization between emergency departments of tertiary hospitals and primary healthcare centers. Secondly, the technology and public-private sharing economy-based nature of the suggested healthcare service delivery model provoked us to employ task technology fit and channel expansion theories in this study to investigate its acceptance and impact on physicians' performance. This study has implications for researchers, government healthcare authorities, policymakers, and online healthcare service companies.

3 Anesthesiologist Scheduling of Cases in Geographically Dispersed Locations

Elizabeth Loggia, Pelin Damci Kurt, Perfectserve, Knoxville, TN, Contact: eloggia@perfectserve.com

The scheduling of cases for anesthesia groups often follow a daily tiered system. Each day, anesthesiologists are ranked according to their previous day's case load, assigning the most complex and time-consuming cases to the highest-ranked provider and continuing down to the lowest. The manual scheduling process typically takes about an hour each day. Using mixed integer programming, we formulated this problem and found that a commercial solver can find a schedule in less than a second.

Wednesday, October 18, 9:30 AM - 10:45 AM

WB84

Session.Location:CC-West 213B

Online Retail Platforms

Contributed Session

Session Chair: Ji Soo Park, Georgia Institute of Technology, Atlanta, GA

1 Secondary Marketplace of Online Retail Platforms

Yuanyuan Yang[1], Yunjie Wang[1], Guoming Lai[2], [1]Renmin University of China, Beijing, China; [2]The University of Texas at Austin, Austin, TX, Contact: 2021102688@ruc.edu.cn

We examine the incentive and the impact of an online retail platform introducing a secondary market in addition to the existing new-product market. We consider a supply chain with a manufacturer selling a new product through the platform under reselling or agency channel. Given each channel structure, the platform determines whether or not to open a secondary market where consumers can resell or purchase used products. If so, he further decides whether to operate the secondary market under a consumer-to-consumer strategy or a buy-back strategy. We develop a multi-stage game-theoretic model, fully characterize these equilibrium decisions, and show how they depend on key factors such as product durability and service commission rate. We also examine the impact of the existence of the secondary market on the manufacturer, the consumer surplus and the environment.

2 Freemium Versus Free Trial : The Art of Attracting Customers and Winning in the Business World

Sangyoon Cha, Seoul National University, Seoul, Korea, Republic of. Contact: 97chadol@snu.ac.kr

A stylized model is developed in order to quantitatively analyze and compare two major business models which is applicable to a variety of products and services; Freemium model and Free Trial model. While Freemium model offers a limited portion of the maximum providable product or service for unlimited time length, Free Trial model gives a potential customer an opportunity to experience the complete version of the same product or service but with a fairly limited time frame. Taking various factors(the learning rate of customers upon the utility of a given product or service, cost to provide a product or service for a unit length of time, etc.) into consideration, the study aims to characterize which business model is more favorable under what circumstances. Thereby the result of this study may contribute to the never-ending debate on 'Freemium vs Free Trial'.

3 Optimal Fulfillment and Transshipment Strategies in Omnichannel Retailing with Cross-Channel Returns

Yuchi Guo[1], Armagan Bayram[2], [1]University of Michigan - Dearborn, Dearborn, MI, [2]University of Michigan Dearborn, Dearborn, MI, Contact: yuchig@umich.edu

To satisfy customer demand and maintain their competitiveness, retailers are exploring ways to exploit rising online sales, such as by investing in cross-channel strategies. Addressing the challenges in operating both the online and offline channels efficiently, in this study, we build a dynamic programming model and investigate optimal fulfillment and transshipment strategies in omnichannel retailing with cross-channel returns. With the objective of maximizing the total profit of the retailer, we investigate (i) from where to fulfill a home delivery order when it occurs, (ii) when and how to transship returns to balance inventory. In order to develop the optimal omnichannel fulfillment and transshipment policy, we accommodate the uncertainty in the customer demand, returns, and the product per unit cost of shipping and transshipping.

4 Dynamic Effects of Store Promotions on Conversion Fraction: Expanding Technology Applications with Innovative Analytics

Ignacio E. Inostroza-Quezada[1], Leonardo D. Epstein[2], Ronald C. Goodstein[3], S. Chan Choi[4], [1]University of the Andes, Santiago, Chile; [2]Universidad de Los Andes, Santiago, Chile; [3]Georgetown University, Washington DC, WA, [4]Rutgers University, Newark, NJ

In retail settings conversion fractions (CFs) matter to managers because they measure the stores' effectiveness to convert visitors into buyers. Despite CFs importance, available methods to evaluate effects of marketing action (MA) on CF are scarce and provide limited evaluations of these effects. We present an approach that (i) builds a model for conversion probabilities with data outside the MA period, (ii) uses this model to predict a baseline for conversion probabilities during the promotional period conditional on the counterfactual hypothesis that the MA had not occurred, and (iii) evaluates MA effects on CF by comparing this baseline to observed data during the MA period. We illustrate our approach with data from an actual MA consisting of a two-day promotion. The analysis combines arrival data from video images and conversion data from cash registers.

5 Substitution-Based Portfolio Optimization

Ji Soo Park, Ashwin Pothen, Benoit Montreuil, Georgia Institute of Technology, Atlanta, GA, Contact: jisoopark@gatech.edu

With limited capacity, budgetary, and operational constraints, retailers are often unable to produce and offer all items in the portfolio and thus need to decide on the subset that best meets the customers' expectations and maximizes profit. One approach is to focus on the most popular items based on historical or forecasted demands, but doing so fails to adequately model customer behavior especially in regard to substitution. In this work, we study optimization of a product portfolio to maximize the expected profit over the planning horizon. We provide empirical results for a case study with our industry partner to compare the resulting product portfolio and expected profit with and without considering the substitution behavior.

Closing Plenary: Reinventing Operations Management's Research and Practice with Data Science

Plenary Session

1 Reinventing Operations Management's Research and Practice with Data Science

David Simchi-Levi, Massachusetts Institute of Technology, Cambridge, MA

Machine learning is playing increasingly important roles in decision making, with key applications ranging from dynamic pricing and recommendation systems to personalized medicine and clinical trials. While supervised machine learning traditionally excels at making predictions based on i.i.d. offline data, many modern decision-making tasks, in particular in operations management, require making sequential decisions based on data collected online. Such discrepancy gives rise to important challenges of bridging offline supervised learning and online interactive learning to unlock the full potential of data - driven decision making. The presentation will focus on the integration of online and offline learning to improve decision making in operations management. We highlight three examples. In the first, we consider the challenges of reducing difficult online decision-making problems to well-understood offline supervised learning problems. In the second, we show the impact of offline data on online decision making. Finally, in clinical trials, we show how to convert offline randomized control trials into adaptive, online, experimental design.
