We study a two-stage stochastic multi-objective linear program (TSSMOLP) under risk neutral formulation, which is a natural generalization of the well-studied two-stage stochastic linear program (TSSLP). The proposed TSSMOLP formulation allows modelers to specify multiple objectives in each stage. The second-stage recourse decision is modeled by a random multi-objective linear program (MOLP) whose solution maps to a random second-stage nondominated set. The TSSMOLP then comprises the objective, which is the Minkowski sum of a linear term plus the expected value of the second-stage nondominated set, and the constraints, which are linear. We prove properties of TSSMOLPs, which are stochastic set optimization problems, and the multifunctions that arise therein. To aid theoretical analysis, we propose nondominance-equivalent reformulations to the original problem and show that (i) the global Pareto set of a TSSMOLP is cone-convex, (ii) solving a parameterized TSSLP produces a weakly efficient point for the TSSMOLP, and (iii) a TSSMOLP in which the uncertainty is governed by an atomic probability measure with finite support can be reformulated as an MOLP. Leveraging the above properties we demonstrate that solving a TSSMOLP under a sample average approximation framework is equivalent to solving a large scale MOLP, and validate our results through a numerical example.

1 - Reducing Contextual Stochastic Bilevel Optimization via Structured Function Approximation

Maxime Bouscary, MIT, Cambridge, MA, United States, Jiawei Zhang, Saurabh Amin

Contextual Stochastic Bilevel Optimization (CSBO) extends standard stochastic bilevel optimization (SBO) by incorporating context-dependent lower-level problems, as in hyperparameter tuning and inverse optimization. This added structure introduces significant computational challenges: solving CSBO requires solving an infinite number of lower-level problems - one for each context realization - and existing approaches either suffer from high sample complexity or rely on impractical conditional sampling oracles. We propose a reduction framework that approximates the lower-level solutions using expressive basis functions, thereby decoupling the lower-level dependence on context and transforming CSBO into a standard SBO problem solvable using only joint samples from the context and noise distribution. Under mild assumptions, we show this reduction preserves hypergradient accuracy and yields an ϵ -stationary solution to CSBO. We relate the sample complexity of the reduced problem to simple metrics of the basis and show that using Chebyshev polynomials leads to a near-optimal complexity of $\tilde{O}(\epsilon^{-3})$, matching the best-known rates for standard SBO. Empirical results on hyperparameter and inverse optimization tasks demonstrate that our approach outperforms CSBO baselines in convergence, sample efficiency, and memory usage, especially in settings without conditional sampling access.

2 - Admission Control for A Single Server Waiting Time Process in Heavy Traffic

Bowen Xie, The University of Akron, Akron, OH, United States, Haoyu Yin

We investigate a single-server queue control problem (QCP) in a heavy-traffic regime, extending the framework from Lee and Weerasinghe (2011). The state process represents the offered waiting time, the customer arrival has a state-dependent intensity, and the customers' service and patience times are i.i.d generally distributed. We introduce an infinite-horizon discounted cost functional consisting of a control cost and a penalty for idleness cost. Our primary goal is to tackle the QCP, taking into account a non-trivial polynomial decaying cost function resulting from the control mechanisms in the waiting time. Under mild assumptions, the heavy traffic limit of the QCP yields a control problem described by a diffusion process, referred to as a diffusion control problem (DCP). We find the optimal control of the associated DCP by incorporating the Legendre-Fenchel transform and a formal Hamilton-Jacobi-Bellman (HJB) equation. Then, we "translate" this optimal strategy to the QCP, of which we obtain the asymptotic optimality. Beyond theoretical analysis, we explore the application of the REINFORCE algorithm, a reinforcement learning (RL) approach, to solve stochastic control problems, motivated by recent advances in the field. We compare theoretical insights with data-driven algorithmic solutions, highlighting the advantages and limitations of both simulation-based and analytical approaches.

3 - Ten Years of CVXPY

William Zhang, Polytechnique Montreal, Montreal, QC, Canada, Steven Diamond

The CVXPY project has been under development for over ten years. The initial motivation was to reproduce in Python the functionality of the CVX MATLAB package. However, early CVXPY design decisions diverged from CVX, with a greater emphasis on modular problem construction, expression trees, and parameterized problems. We explore how these initial design decisions led to later research on object oriented optimization, matrix-free optimization, and differentiable optimization. We conclude with an overview of upcoming CVXPY features.

4 - Advances on Multi-Parametric Dynamic Optimization Problems

Lida Lamakani, Artie McFerrin Department of Chemical Engineering, Texas A&M University, College Station, TX, United States, Efstratios Pistikopoulos

The increasing complexity of engineering systems demands advanced control strategies. Model Predictive Control (MPC) has emerged as an advanced optimization-based control that uses system models to predict future behavior and manage constraints. Traditional MPC solves the optimization problem at each sampling step, which can be

computationally demanding. Multiparametric programming offers a more efficient alternative by solving the optimization problem offline and partitioning the state space into regions, each with an explicit control law, enabling fast, real-time decisions without online computation.

Most multiparametric MPC approaches are in discrete time, which may cause inaccuracies in systems with fast dynamics or long sampling intervals. Continuous-time formulations preserve the system's natural behavior and ensure constraints are satisfied throughout the horizon. In this work, both linear and nonlinear dynamic MPC problems are solved by combining the Hamiltonian function and Pontryagin's Maximum Principle with the multiparametric framework instead of the KKT conditions, resulting in fewer critical regions and the identification of switching points, when system behavior changes due to constraint activity, which can additionally accelerate online implementation.

For nonlinear systems, several strategies are explored to solve nonlinear ODEs that result from the above optimality conditions. First, the Koopman operator lifts nonlinear space into linear space but may struggle with small powers. Second, a regression-based method uses the structure of linear ODEs to approximate expressions for solutions obtained from numerically solved nonlinear systems, though sensitivity to time and nonlinearity remains a limitation. Finally, neural networks are used to capture nonlinear behavior while enabling interpolation and extrapolation.

5 - Solving Latency Location-Routing Problem Using Dynamic Programming Method

Peng Ren, George Mason University, Fairfax, VA, United States, Rajesh Ganesan

The Latency Location-Routing Problem (LLRP) seeks to minimize cumulative customer waiting time by determining both which depots to open and how vehicles should be routed to minimize total latency while fulfilling demand. This problem is especially critical in situations such as post-disaster logistics, where timely delivery and responsiveness are essential. Yet the existing literature remains limited: most models ignore real-world uncertainty in travel times and demand, and few approaches scale well or support adaptive decision-making. Challenges arise in simultaneously accounting for evolving system state including depot configurations, vehicle positions, remaining vehicle capacities, and dynamically changing demand over time.

This work introduces a dynamic programming (DP) formulation of LLRP that addresses these challenges. The model captures the system state as a combination of depot status, vehicle locations, residual capacities, and stochastic demand, and models their evolution through probabilistic transitions. Dynamic programming is well suited for such problems due to its ability to handle cumulative cost objectives, sequential routing and allocation decisions, and adaptation as uncertainty unfolds. While exact DP may be computationally intensive, this framework enables the development of scalable approximate dynamic programming or learning-based strategies tailored for time-sensitive, uncertainty-rich environments.

A small case study demonstrates how the model structure accommodates evolving network conditions and demand realization. This work contributes a new formulation perspective for LLRP, enabling more adaptive and interpretable decision-making and addressing key modeling gaps in the literature.

1 - Cognitive and Motivational Components of Normalcy Bias: a Signal Detection Approach

Richard John, University of Southern California, Los Angeles, CA, United States, Robin Dillon, Kevin Kapadia, Nicholas Scurich

Officers at the United States Coast Guard (USCG) Search and Rescue (SAR) make a variety of high-stakes decisions under conditions of uncertainty and imperfect information. A voluminous body of psychological research has documented that many decisions in these situations are subject to various biases that can lead to poor outcomes. For the USCG, these can be catastrophic outcomes, such as when the USCG fails to initiate a search and rescue or when a search and rescue mission is unnecessarily initiated, putting officers' well-being at risk and incurring significant financial expenses. This project seeks to identify potential cognitive and motivational biases that might impact USCG decision making and determine how these biases affect decisions that result in normalcy bias, wherein warning signals and threats are disbelieved. We utilize a normative Signal Detection Theory (SDT) framework, which partitions decision accuracy into (1) the ability to discriminate signals from noise and (2) the selection of a decision threshold. This framework illustrates how cognitive and motivational biases can affect both components in SAR decisions made by the USCG. We report empirical behavioral research to understand deviations from the normative SDT model, including Normalcy Bias.

2 - Gain-Loss Bias Within Multi-Attribute Value Theory

Geqie Sun, Delft University of Technology, Delft, Netherlands

Human judgments are essential inputs in decision analysis methods, yet behavioral decision research has shown that such judgments are susceptible to various cognitive biases. When these biases affect the inputs, they can undermine the quality of the methods and their results. This study investigates gain-loss bias, a well-documented cognitive bias, within the context of Multi-Attribute Value Theory (MAVT). We focus on two sources of potential bias: (i) attribute framing: We examine whether framing the same attribute as a gain versus as a loss influences the elicited attribute-specific value functions and weights (scaling constants). (ii) tradeoff framing: In MAVT's tradeoff procedure for weight elicitation, decision-makers are asked how much of one attribute they are willing to give up or gain in exchange for some change in another attribute. Though the alternatives being compared are logically equivalent, framing the tradeoff as a gain (adjusting from the worst level) or a loss (adjusting from the best level) can influence the perceived value of the attributes due to gain-loss bias and distort the attribute-specific value functions and weights. To test these hypotheses, we designed a questionnaire based on the MAVT methodology and conducted an experiment involving 283 participants in a decision problem. The results show that gain-loss bias significantly affects both the attribute-specific value functions and weights, and consequently, the decision results.

3 - Time Preference in Multi-Attribute Decision Making: An Experimental Study

Pelin Gülüm Taş, Delft University of Technology, Delft, Netherlands

Research on time preference has predominantly employed descriptive approaches, focusing on intertemporal trade-offs within single-objective decision-making frameworks. However, real-world problems are often multi-objective, requiring trade-offs not only over time but also between conflicting objectives. This complexity calls for prescriptive approaches that move beyond description and support decision-making in the face of intertwined trade-offs. Addressing this gap, the present study investigates time preferences within a multi-attribute decision-making (MADM) context using the Multi-Attribute Value Theory (MAVT) framework. First, we theorize the potential impact of time discounting on attribute-specific value functions (AVF) and scaling constants (weights) (two main components of MAVT), formulating four hypotheses. Then, three controlled experiments are conducted around an intertemporal MADM problem involving two attributes. A total of 279 participants took part in the experiments, each completing two scenarios in which the timing (present vs. future) of outcomes varied in relation to specific attributes. The results indicate that both the scaling constants and the perceived AVFs vary significantly with delays. Furthermore, the underlying drivers of these changes depend on the specific trade-off relationships involved. While delaying a single outcome typically leads to discounting, our findings indicate that postponing multiple outcomes in multi-objective contexts does not necessarily result in the same behavior. The presence of multiple objectives challenges conventional assumptions about delay discounting. These insights are particularly relevant for researchers and practitioners in economics, psychology, health, and public policy who deal with complex, multi-dimensional intertemporal decisions.

4 - Fairness Concerns in 3-Tier Contests

HUA CHEN, University of Georgia, Athens, GA, United States, Kevin Chung

Consider a contest conducted in a **3-tier** organization where the owner provides a winning prize for branches to compete and the manager of each branch offers a reward to motivate his agents. The standard economic theory predicts that the information on total winning prize or the reward offered to the opponent agents would have no impact on the effort decisions by the focal agent. Using an incentive-aligned lab experiment, contrary to the predictions, the authors find that: 1) the agents adjust their effort based on their knowledge about the total winning prize or the reward offered to the opponent agents; 2) the managers modify their reward upward (downward) when either (both) of the information is revealed to the agents. These behavioral regularities are explained by a model that incorporates the fairness concerns (vertical and horizontal) and the relative saliency of the two into the agent's utility function.

Novel Applications in Empirical Research

Invited Session

MSOM: Technology, Innovation, and Entrepreneurship

Chair: Serguei Netessine, The Wharton School, Philadelphia, PA, United States

1 - Adaptive Sampling for Learning Rankings from Few Evaluators

Motti Goldberger, Yale School of Management, New Haven, CT, United States, Nils Rudi

Organizations that must choose among multiple alternatives—whether hiring job candidates, prioritizing R&D projects, or deciding which athletes to draft—often rely on input from evaluators. The set of evaluators may be small, either due to limited availability of domain experts or confidentiality constraints. Furthermore, each evaluator's capacity to provide input may be limited: their time is costly, and their accuracy may degrade as the scope or complexity of the evaluation increases. In such settings, the choice of whom to query and what input to collect becomes important.

We consider a setting where an organization aims to learn a complete ranking of a set of alternatives. Although collecting full rankings from evaluators would be ideal, asking them to rank many items can be cognitively demanding and reduce the reliability of their input. Instead, we focus on simpler elicitation formats—pairwise comparisons and ordinal ratings—which are easier for evaluators to provide while still informative for learning the overall ranking. We allow for the possibility that evaluators' beliefs may be biased and their responses may be noisy.

To model this, we adopt a hierarchical Bayesian framework in which both the true ranking and each evaluator's belief are treated as random. The aim is to sequentially collect inputs that minimize posterior uncertainty about the true ranking. To that end, we develop an adaptive sampling algorithm that, at each step, chooses both which evaluator to query and which comparison to elicit, making the most efficient use of limited evaluation opportunities.

2 - Dynamic Staffing for Harvesting Under Climate and Labor Pool Uncertainties

Sanchita Das, University of Washington, Seattle, WA, United States, Masha Shunko, Leonard Boussieux

Eastern Washington's tree fruit industry is grappling with the dual challenges of accelerating climate change, leading to more frequent heatwaves than ever, and evolving labor regulations that are reshaping the workforce. This research addresses the critical problem of optimizing harvest labor management strategies for this vulnerable sector by collaborating extensively with the regional agricultural community. The study develops a robust model using a combination of stochastic dynamic programming and distributionally robust optimization to account for uncertainties in ripe fruit forecasts and seasonal weather patterns. Key drivers of profitability, such as picking timeliness and adaptive hiring policies, are utilized to develop the model. Results indicate that the proposed methodology significantly increases profitability compared to baseline staffing models, generating a positive net present value over a multi-year planning horizon while enhancing resilience to these growing uncertainties. The findings underscore the urgent need for a coordinated response from government, farmers, labor platforms, and other stakeholders to mitigate the economic threats posed by global warming and changing labor landscapes. This research provides a fundamental model to quantify and optimize the impact of various initiatives on harvest labor management, offering heuristics to guide farmers in maximizing profits amidst climate and labor-related uncertainties.

3 - More Money, More Motivation? a Field Experiment on the Impact of Bonus on Service Performance in a Multitasking Setting

Tom Tan, Southern Methodist University, Dallas, TX, United States, Jia Li

In service settings, workers often handle multiple tasks of varying difficulty. While financial incentives are commonly used to motivate performance on challenging tasks, they may unintentionally distort behavior by diverting effort from other tasks. We study this issue through a six-week field experiment with the after-sales department of a Fortune Global 100 online retailer. Gig agents on a live-chat platform were randomly assigned to a treatment group, which received real-time notifications for difficult cases (flagged by an AI model) indicating a bonus opportunity, or to a control group without such notifications.

We analyze customer satisfaction scores and redial rates as performance measures across four case difficulty levels. On average, financial incentives improved satisfaction scores. However, we find heterogeneity by task difficulty: for Level 1 (most difficult) cases, customer satisfaction declined in the treatment group, while satisfaction improved for easier, non-incentivized cases. These patterns suggest that agents strategically reallocate effort based on perceived attainability of rewards. When the likelihood of earning a bonus on very difficult cases appears low, agents redirect effort toward easier cases with more achievable outcomes.

Our study highlights how incentives may trigger unintended motivational spillovers in multitasking environments. Workers may reduce effort on the very tasks the incentives were meant to improve. We contribute to the literature by showing that in such settings, bonus design must consider strategic effort allocation. We also suggest that combining monetary and non-monetary interventions—like real-time AI support—may better address effort challenges on the most difficult tasks.

4 - From Information Aggregators to Transaction Facilitators: An Empirical Investigation of the Impact of the Platform Payment Integration

Serguei Netessine, The Wharton School, Philadelphia, PA, United States, Shi Zhenming, Vivek Choudhary

Over the last decade, digital platforms have grown significantly, broadly operating under two distinct models from the perspective of where the final transactions occur. Some platforms function as “information aggregators”, solely matching buyers with sellers, while transactions occur outside the platform. Others serve as “transaction facilitators”, integrating payment systems that enable users to complete transactions directly within the platform. What is the impact of payment integration on various stakeholders when a platform transitions from an information aggregator to a transaction facilitator? We examine this evolution in the novel context of trucking platforms. Using a quasi-experimental study of a major Chinese freight logistics platform that introduced transaction capabilities, we analyze over 2.6 million transportation records through a Difference-in-Differences (DID) approach to understand how this transition affects platform stakeholders. Our results show that integrating a transaction system improved operational efficiency by reducing order acceptance times and delivery costs. Weekly driver earnings increased by ~15%, primarily because the platform's transaction system likely builds trust between drivers and unfamiliar shippers, leading to higher order acceptance rates and better resource utilization. However, earnings per kilometer per ton decreased by ~3.4%, suggesting drivers needed to handle larger workloads to maintain their income levels.

Causal Inference and Machine Learning in Operations Management

Invited Session

MSOM: Service Operations

Chair: Ruomeng Cui, Emory University, Amazon, Decatur, GA, United States

Co-Chair: Zhikun Lu, NYU Shanghai, Shanghai, China, People's Republic of

1 - Synthesizing Evidence: Data-Pooling for Treatment Selection in Online Experiments

Renyu Zhang, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Zhenkang Peng, Chengzhang Li, Ying Rong

Randomized experiments are the gold standard for causal inference but face significant challenges in business applications, including limited traffic allocation, the need for heterogeneous treatment effect estimation, and the complexity of managing overlapping experiments. These factors lead to high variability in treatment effect estimates, making data-driven policy roll-out difficult. To address these issues, we introduce the data-pooling treatment roll-out (DTR) framework, which enhances policy roll-out by pooling data across experiments rather than focusing narrowly on individual ones. DTR can effectively accommodate both overlapping and non-overlapping traffic scenarios, regardless of linear or nonlinear model specifications. We demonstrate the framework's robustness through a three-pronged validation: (a) theoretical analysis shows that DTR surpasses the traditional difference-in-mean method under non-overlapping experiments, particularly when the number of experiments is large; (b) synthetic simulations confirm its adaptability in complex scenarios with overlapping traffic, rich features and nonlinear specifications; and (c) empirical applications to experimental data from online platforms showcase its strength in group-based policy roll-out. By reducing estimation variability to improve decision-making accuracy and efficiency, DTR provides a scalable, practical solution for online platforms to better leverage their experimental data in today's increasingly complex business environments.

2 - Incentives In Online Gaming: Optimal Policy Design with Dynamic Causal Machine Learning

Zhikun Lu, Emory University, Decatur, GA, United States, Ruomeng Cui

The video game industry has experienced remarkable growth over the past few decades, with online gaming emerging as a key driver of its recent expansion. Fueled by an engagement-centric business model, game developers are increasingly relying on data-driven insights to optimize player engagement, particularly through incentive programs that reward players with virtual items. This paper explores the design of such reward systems, focusing on the trade-off between offering in-game currency (which provides player autonomy) and algorithmically assigned specific items (which represent system control). We examine this trade-off in the context of Honor of Kings, a highly popular mobile multiplayer online game developed by Tencent. Using real-time player data, we find that in-game currency outperforms specific virtual items in some cases, but not universally, highlighting the importance of aligning rewards with players' understanding and experience. Our findings also reveal significant heterogeneity in player responses, suggesting that personalized reward strategies are crucial for maximizing engagement. To address this gap, we propose a data-driven framework for optimizing sequential treatment assignments in incentive programs under resource constraints, integrating dynamic causal machine learning with dynamic programming. It maximizes long-term user retention by dynamically adjusting reward allocations based on real-time player features. Our approach demonstrates substantial improvements in user retention and provides valuable insights that can extend beyond the gaming industry.

3 - No More Hidden Fees: The Impact of California's Honest Pricing Law on Vacation Rentals

Serkan Mehder, University of Colorado Boulder, Boulder, CO, United States, Maxime Cohen, Armin Khamoshi, Ovunc Yilmaz

Hidden fees are a common and controversial pricing practice in the short-term lodging industry. In July 2024, California implemented the Honest Pricing Law, requiring platforms to display all-in prices upfront. To study the impact of this regulation on host and customer behavior, we collaborate with the Expedia Group—the parent company of Vrbo—and analyze U.S.-wide click-level data covering more than one million vacation rental properties. Using a quasi-experimental approach, we examine how the law influenced consumer booking behavior and host pricing decisions.

4 - Generative AI and Content Homogenization: the Case of Digital Marketing

S. Alex Yang, London Business School, London, United Kingdom, Chaoran Liu, Tong Wang

Traditionally, entrepreneurs and small businesses, constrained by limited resources, struggle to create high-quality marketing content, which limits consumer engagement and hampers growth. Generative artificial intelligence (Gen AI) presents an affordable, powerful tool to overcome this challenge. However, the widespread adoption of Gen AI may have unintended consequences. Specifically, content generated by popular large language models may lead to increased homogenization, reducing consumer engagement and diluting brand uniqueness over time. To examine this possibility, we study the restaurant industry—a highly fragmented sector where 70% of the establishments are owned by independent entrepreneurs. We leverage the country-wise ChatGPT ban in Italy during April 2023 as a natural experiment to examine how access to Gen AI affects the content homogenization, consumer engagement, and volume of social media marketing content created by small business owners. Our study shows that the treatment group experienced significant decreases in different similarity measures during the ban, suggesting that access to ChatGPT leads to content homogenization. We also find the ban has a non-negligible effect on consumer engagement. By better underscoring an unintended consequence of Gen AI adoption, this research aims to provide valuable insights to entrepreneurs and small businesses on how to better harness Gen AI's benefits while mitigating potential drawbacks.

5 - A Deep-DiD Method to Estimate Heterogeneous Treatment Effects: Application to Content Creator Selection

Yan Cheng, Shanghai University of Finance and Economics, Shanghai, China, People's Republic of, Jingbo Wang, Xinyu Cao, Zuojun Max Shen, Yuhui Zhang

In this paper, we propose a Deep-DiD method that incorporates two deep neural networks in a difference-in-difference (DiD) framework to estimate heterogeneous treatment effects (HTEs). The dual-network architecture contains one neural network modeling HTEs as a nonparametric function of pre-treatment features, and another neural network capturing individual and time fixed effects. Through a series of simulations, we show that our method can uncover the true HTEs with high accuracy under various settings and demonstrates more robust estimation performance compared to existing methods like linear models and random forests. We apply this method to an empirical setting where a large video-sharing platform introduced a "Creator Signing Program" aimed at signing creators and motivating them to generate more high-quality video content. Leveraging a matched dataset of signed and unsigned creators, we employ our Deep-DiD method to estimate the HTEs of the signing program. Our method can help the platform optimize creator selection by identifying creators with the highest estimated treatment effects. Through out-of-sample tests, we show that creators selected by the Deep-DiD method experienced substantially larger actual performance jumps than those selected by the platform. Creator selection based on the Deep-DiD method also consistently outperforms that based on linear models.

6 - The Impact of Recommender Systems on Content Consumption and Production: Evidence from Field Experiments and Structural Modeling

Zhiyu Zeng, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhiqi Zhang, Tat Chan, Dennis Zhang

Online content-sharing platforms such as Facebook and TikTok, where users act as both content creators and consumers, have become integral to daily life, relying on complex algorithms to recommend user-generated content (UGC). While prior research and industry efforts have primarily focused on designing recommender systems to encourage users to consume more content, the impact of the content recommended to users on their own content production remains understudied. To address this gap, we conducted a large-scale randomized field experiment on a major video-sharing platform. Users were randomly assigned to either a treatment or control condition, and we manipulated content recommendations by excluding a subset of highly popular creators from being recommended to treated users. This reduced recommendation quality of treated users compared to control counterparts. Our results indicate that this decline led to a 1.34% decrease in video-watching time but a 2.71% increase in videos uploaded by treated users. These findings reveal a trade-off in recommender system design: while higher recommendation quality boosts consumption, it may suppress production. To optimize recommendations, we developed a structural model in which users' choices between consuming and producing content are inversely affected by recommendation quality. Counterfactual analyses suggest that slightly lowering recommendation quality—rather than prioritizing the most popular creators—can maximize the overall value of both production and consumption for platforms. This highlights the need to balance content consumption and production when designing recommender systems on these social media platforms.

1 - Long-Term Policy Prediction with Causal Graphs: Insights from Healthy Grocery Shopping

Nur Kaynar, Cornell University, Ithaca, NY, United States, Dmitry Mitrofanov

Policymakers often implement short-term interventions (e.g., temporary healthy food subsidies) to achieve long-term outcomes (e.g., sustained healthy eating habits). However, the delay in observing long-term effects complicates the immediate evaluation of policy effectiveness. To address this, we introduce a causal structure learning algorithm that identifies the causal relations among policy intervention, short-term variables, and long-term outcomes.

Our algorithm combines short-term experimental and long-term observational data, producing a graph that specifies causal links through directed edges. This approach identifies (i) which short-term variables are influenced by policy changes and (ii) which of these variables subsequently impact the long-term outcome. By mapping these pathways, we provide a framework for selecting short-term surrogates as early indicators of long-term effects. We then derive a closed-form expression to estimate long-term treatment effects without waiting for the long-term data to materialize.

We apply the framework to data from the U.S. Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) to assess the lasting effects of temporary healthy food subsidies. Our findings indicate that targeting subsidies toward younger consumers in urban areas with historically low healthy product consumption leads to long-term dietary improvements. Identifying effective short-term surrogates reduces the need for prolonged monitoring, minimizing costs and delays in policy evaluation. Overall, our paper provides policymakers with valuable insights and practical tools to enhance public healthy product subsidy strategies. By allowing them to evaluate long-term impacts through short-term randomized controlled trials, the framework we present helps refine policy design and optimize effectiveness.

2 - Food Safety Risk Propagation in the Agri-Food Supply Chain

Jane Wang, Massachusetts Institute of Technology, Cambridge, MA, United States, Retsef Levi, El Ghali Zerhouni, Yanchong Zheng

Food adulteration poses a serious global public health threat, particularly in countries with complex and fragmented agri-food supply chains (SCs) such as China. These risks can emerge at various points along the SC and propagate downstream to consumers. China's current food inspection strategy primarily targets retail stores, with the intent of encouraging safer sourcing from upstream suppliers. This study examines whether such downstream-focused testing effectively mitigates the propagation of adulteration risks. Using a self-constructed database of over 12 million food safety test records, it builds a panel dataset to quantify adulteration risks across multiple SC locations over time. Then, it develops a causal inference assessment of the product- and adulterant-level propagation effect of risks in wholesale markets and wet markets (WSMs/WMs) and manufacturers on risks in more downstream SC locations such as retail stores and restaurants. It provides strong evidence that adulteration risks propagate downstream, and existing testing strategies fail to mitigate this propagation. To design effective food inspection strategies, regulators should consider the introduction points and propagation paths of different adulteration risks. For instance, pesticide and veterinary drug residues—mainly introduced at farms—should be tested at WSMs/WMs, where fresh products are aggregated before reaching consumers. In contrast, food additives in processed products are best intercepted at the manufacturer level. This study highlights the limitations of existing testing strategies and provides a roadmap for more systematic risk-based food inspection policies within agri-food SCs.

3 - Systemic Analysis of U.S. Household Exposure to Food Ingredients and Nutritional Components

Cen hao Zhu, Massachusetts Institute of Technology, Cambridge, MA, United States

Access and consumption of “healthy foods” are increasingly recognized for their impact on human health and specifically on the prevalence of obesity and related chronic diseases. There are several public health policies and regulatory activities (the Healthy, Hunger-Free Kids Act of 2010, and MyPlate Plan by USDA, etc.) that aim at increasing access to healthy food, as well as ensuring that food products have appropriate nutrients and do not contain hazardous or unhealthy ingredients. However, many of the existing public health policies and much of the related research do not rely on sufficiently comprehensive and rigorous data. In this study, we employ advanced text analytics techniques to create the first large-scale dataset of branded food products sold in the U.S., delineating their corresponding ingredients and nutritional components, by combining multiple structured and unstructured data sources. Utilizing this data, we empirically characterize the prevalence of different food ingredients within specified product categories; the nutritional characteristics of typical household diets based on food products purchased; the overall exposure of households to different food ingredients; temporal changes over time; and differences among households across different regions. The resulting systematic understanding of household exposure to food ingredients and nutritional components will offer an essential scientific foundation for related public policy designs.

4 - Optimal Subsidy Design: Application to Food Assistance Programs

Zhicon Hu, INSEAD, Singapore, Singapore, Kamalini Ramdas, Ali Aouad, Alp Sungu

In the design of subsidy programs, a significant challenge lies in balancing policy efficiency with the flexibility of individual choice. Traditional paternalistic approaches often prioritize optimal social outcomes, such as promoting the consumption of nutritious but less-popular foods, potentially at the cost of individual preferences. This can lead to low take-up of the subsidy or low compliance, undermining the policy's effectiveness. Conversely, flexible subsidies, such as cash transfers, may result in suboptimal impact on nutrition. This study introduces the *optimal subsidy design problem*, which embeds a probabilistic choice model to represent the beneficiaries' decision to avail of an offered subsidy. Our formulation can optimize over various subsidy mechanisms, including in-kind bundles, assortments, vouchers, or cash-plus-in-kind mixes. After calibrating our model to data from a randomized controlled trial (RCT) on staple-food subsidies in India and synthetic data from AI simulations, we run counterfactuals to identify optimal subsidy designs. The analysis shows that pairing an in-kind staple subsidy with a modest cash top-up can outperform both pure in-kind and pure cash schemes on social outcomes and beneficiaries' choices.

5 - Improving Farming Practices Through LLM-Powered Digital Extension Services: a Randomized Controlled Trial with 2,000 Smallholder Rice Farmers

Canberk Ucel, ESSEC Business School, Paris, France, Ali Aouad, Alp Sungu, Niyazi Taneri, El Ghali Zerhouni

Low adoption and ineffective implementation of agricultural technologies continue to undermine productivity and sustainability in smallholder farming systems. This study presents one of the first large-scale randomized controlled trials (RCTs) testing the use of Large Language Model (LLM)-based AI advisory bots to address these challenges. We examine whether delivering contextualized, on-demand agricultural guidance via common messaging platforms on farmers' smartphones can improve farm management practices and the adoption of Direct-Seeded Rice (DSR) technology—a practice with demonstrated environmental and economic benefits. Our ongoing experiment targets smallholder rice farmers across five major rice-growing regions in the Philippines and India. Participants are randomly assigned to a control group or one of two treatment arms: access to an AI advisor bot, or access with additional incentives designed to encourage initial engagement. The advisory bot integrates technical content from Bayer CropScience and public sources and is tailored to local farming contexts. We collect detailed survey and interaction data throughout the growing season and evaluate technology adoption, farmer engagement, productivity, and AI-human interaction patterns. Findings will inform policy and industry efforts aimed at improving agricultural productivity, climate resilience, and the cost-effectiveness of extension services in developing countries. The study advances research at the intersection of agricultural development, operations management, and AI deployment in low-resource environments.

1 - The Ratings Trap: Prior Ratings, Gender and Instructor Evaluations

Kamalini Ramdas, London Business School, London, United Kingdom, Monika Heller, Tong Wang

Prior ratings, often used as quality signals in service management, can unintentionally introduce bias in follow-up evaluations. We conducted preregistered online experiments to test how prior ratings influence instructor evaluations when teaching quality is held constant. Our experimental evidence reveals sizeable negative effects of publishing low prior ratings, concentrated among inexperienced learners and on instructor-focused outcomes. Furthermore, male learners tend to correct unfairly low ratings only for male instructors, introducing a gender bias against female instructors. Learners exposed to high prior ratings tend to increase their ratings for instructors of the same gender, exhibiting confirmation bias. We also examine how different ratings displays influence evaluation bias and explore the underlying mechanisms. Our findings aim to identify operational strategies to mitigate bias, enhancing fairness and transparency in service delivery.

2 - Beyond Food Deserts: How Product Availability Explains Regional Disparities in Diet

Na Hyun Kim, The Wharton School, Philadelphia, PA, United States, Serguei Netessine, Dmitry Mitrofanov

Eating habits have long been correlated with socioeconomic status, fueling theories around food deserts—areas with limited access to nutritious foods—as key drivers of unhealthy diets. Such theories have significantly influenced federal policies and public health programs in the United States. However, recent research has challenged the assumption that eating habits are primarily supply-driven, suggesting consumer demand plays a more crucial role. This study revisits these claims by examining product availability. Product availability has been extensively studied in operations management and identified as pivotal to consumer behavior; however, its role in the context of healthy eating has received limited attention.

Leveraging a rich dataset from a leading U.S. online grocery delivery platform, we capture both stocking levels (product availability) and actual sales transactions. By assessing differences in healthy food access at the zip code level, our study explores heterogeneous impacts of product availability on grocery consumption and systematic differences in grocers' stocking behavior.

We hypothesize that current policies focusing on price subsidies, store openings, or healthier product assortments may fall short due to insufficient consideration of grocers' inventory stocking decisions. Ultimately, this research will provide novel insights on operational strategies of grocers operating in food-insecure/-secure markets and inform policymakers.

3 - Reputation and Reserve Dynamics of Non-Profit Organizations

Boyang Mu, CREST-Institut Polytechnique de Paris, Palaiseau, France, Mahyar Eftekhari

This study examines how nonprofit organizations (NPOs) can strategically manage financial reserves and reputation amid uncertainty. We develop a dynamic model in which key organizational decisions—such as spending on mission-driven programs and fundraising activities—affect both liquidity and perceived organizational credibility. These interdependent factors evolve dynamically, modulating donor contributions sensitive to both external conditions and internal actions. The model highlights trade-offs NPOs face: program expenditures amplify visibility and societal impact, yet excessive reserve accumulation or aggressive fundraising may erode donor confidence. The objective is to optimize long-term mission sustainability and operational continuity amidst financial volatility and reputational pressures. We also present empirical evidence to illustrate how these dynamics play out in practice. Our findings offer guidance for NPOs seeking to harmonize immediate impact with enduring resilience in resource-scarce settings. By optimizing reserve buffers and reputation management, NPOs can safeguard future operational capacity, fostering sustained donor trust and mission efficacy despite economic turbulence and evolving public sentiment.

4 - Process Configurations for Digital Government-to-Person (G2p) Payments and Uptake of Social Assistance

Rakesh Allu, Cornell University, Ithaca, New York, United States, Maya Ganesh, Sarang Deo, Sripad Devalkar

Government-to-Person (G2P) payments are being increasingly digitized in low- and middle-income countries. Traditionally, these payments were processed through a decentralized configuration, wherein each welfare program independently manages its funds and electronically credits payments to citizens. Lately, there has been a movement towards a centralized configuration, wherein funds across all welfare programs are pooled into a central bank account and disbursed using an account mapper that leverages citizens' universal identity. Despite the potential benefit of efficient fund utilization, such a centralized configuration can undermine citizen welfare owing to the techno-managerial complexity of its implementation due to the coordination required among multiple entities, the banks, the welfare programs, and the account mapper. We empirically examine the effect of configuration choice in the context of India's workfare program by assembling a unique dataset of 5.7 million digital payments made to 263,498 citizens over 30 months in one state, where 65% of the citizens gradually transitioned from a decentralized to a centralized configuration. Using this natural experiment, we find that centralization decreases average monthly work uptake per citizen by 50.3%. The key mechanism driving the decline is “redirection of wages”, i.e., disbursement of the wages to a different bank account under centralization compared to the one under decentralization. In our dataset, over 22% of citizens on centralized configuration experienced wage redirection and their work uptake was 11.36% lower compared to those without redirection. We further find that the reduction in work is larger among citizens whose wages were redirected to a geographically farther bank.

1 - Prediction-Guided Active Experiments

Hongyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States, David Simchi-Levi, Ruicheng Ao

In this work, we introduce a new framework for active experimentation, the Prediction-Guided Active Experiments (PGAE), which leverages predictions from an existing machine learning model to guide sampling and experimentation. Specifically, at each time step, an experimental unit is sampled according to a designated sampling distribution, and the actual outcome is observed based on an experimental probability. Otherwise, only a prediction for the outcome is available. We begin by analyzing the non-adaptive case, where full information on joint distribution of the predictor and the actual outcome is assumed. For this scenario, we derive an optimal experimentation strategy by minimizing the semi-parametric efficiency bound for the class of regular estimators. We then introduce an estimator that meets this efficiency bound, achieving asymptotic optimality. Next, we move to the adaptive case, where the predictor is continuously updated with newly sampled data. We show that the adaptive version of the estimator remains efficient and attains the same semi-parametric bound under certain regularity assumptions. Finally, we validate PGAE's performance through simulations and a semi-synthetic experiment using data from the US Census Bureau. The results underscore the PGAE framework's effectiveness and superiority compared to other existing methods.

2 - How to Sell a Service with Uncertain Outcomes

Alec Sun, University of Chicago, Chicago, IL, United States, Krishnamurthy Iyer, Haifeng Xu, You Zu

Motivated by the recent popularity of machine learning training services, we introduce a contract design problem in which a provider sells a service that results in an outcome of uncertain quality for the buyer. The seller has a set of actions that lead to different distributions over outcomes. We focus on a setting in which the seller has the ability to commit to an action and the buyer is free to accept or reject the outcome after seeing its realized quality. We propose a two-stage payment scheme where the seller designs a menu of contracts, each of which specifies an action, an upfront price and a vector of outcome-dependent usage prices. Upon selecting a contract, the buyer pays the upfront price, and after observing the realized outcome, the buyer either accepts and pays the corresponding usage price, or rejects and is exempt from further payment. We show that this two-stage payment structure is necessary to maximize profit: only upfront prices or only usage prices is insufficient. We then study the computational complexity of computing a profit-maximizing menu in our model. While computing the exact maximum seller profit is NP-hard even for two buyer types, we derive a fully-polynomial time approximation scheme (FPTAS) for the maximum profit for a constant number of buyer types. Finally, we prove that in the single-parameter setting in which buyers' valuations are parametrized by a single real number that seller revenue can be maximized using a menu consisting of a single contract.

3 - Proof-of-Learning with Incentive Security

Yuan Zhou, Tsinghua University, Beijing, China, People's Republic of, Zishuo Zhao, Zhixuan Fang, Xuechao Wang, Xi Chen, Hongxu Su, Haibo Xiao

Most concurrent blockchain systems rely heavily on the Proof-of-Work (PoW) or Proof-of-Stake (PoS) mechanisms for decentralized consensus and security assurance. However, the substantial energy expenditure stemming from computationally intensive yet meaningless tasks has raised considerable concerns surrounding traditional PoW approaches. The PoS mechanism, while free of energy consumption, is subject to security and economic issues. Addressing these issues, the paradigm of Proof-of-Useful-Work (PoUW) seeks to employ challenges of practical significance as PoW, thereby imbuing energy consumption with tangible value. While previous efforts in Proof of Learning (PoL) explored the utilization of deep learning model training SGD tasks as PoUW challenges, recent research has revealed its vulnerabilities to adversarial attacks and the theoretical hardness in crafting a byzantine-secure PoL mechanism. In this paper, we introduce the concept of incentive-security that incentivizes rational provers to behave honestly for their best interest, bypassing the existing hardness to design a PoL mechanism with computational efficiency, a provable incentive-security guarantee and controllable difficulty. Particularly, our work is secure against two attacks, and also improves the computational overhead. Furthermore, while most recent research assumes trusted problem providers and verifiers, our design also guarantees frontend incentive-security even when problem providers are untrusted, and verifier incentive-security that bypasses the Verifier's Dilemma. By incorporating ML training into blockchain consensus mechanisms with provable guarantees, our research not only proposes an eco-friendly solution to blockchain systems, but also provides a proposal for a completely decentralized computing power market in the new AI age.

4 - Experimental Design in the Presence of Supply Chain Spillovers

Yunhong Wang, National University of Singapore, Singapore, Singapore, Hanzhang Qin, Jinglong Zhao

In this paper, we develop a framework to design experiments for a regionalized supply chain, especially in the presence of supply chain spillover effect. Interferences are common in online platforms, and we identify a new interference pattern from the spillover effect of regionalization fulfillment, different from the previous setting in online platforms. We also propose different experimental designs and corresponding standard estimators for estimating the global treatment effect. We model customer purchase behavior via time-dependent choice model and use mean-field limit to capture the system dynamics. Finally, we provide sign and bias analysis for the standard inverse probability weighting estimator and propose some alternative estimators that can use more system information than the standard estimator.

5 - Imaged-Based Similarity for Demand Forecasting: a Novel Multimodal Method to Exploit Images&Rscquo; Latent Information

David Simchi-Levi, MIT, Cambridge, MA, United States, Junyi Sha, Hanwei Li, Yuxiang Liu, Michelle Wu

Demand forecasting for new fashion products is particularly challenging due to the lack of historical data. While companies often rely on textual information, few recent studies have explored incorporating product images as an additional data source. In this paper, we propose novel methods to utilize both textual descriptions and visual representations of fashion products, demonstrating their impact on forecasting new product sales. We examine different models to study the use of textual features, image features, and their combination for forecasting purposes. Specifically, we introduce a novel hybrid model that integrates an Autoencoder, a pre-trained Transformer, and the gradient boosting-based model Catboost. The data used in this study comes from a European fashion company. The model that shows the highest performance with purely textual information is selected as our baseline. Our proposed model leverages the concept of product similarity for image-based instance selection. This approach significantly improves prediction accuracy in certain fashion categories and enhances overall prediction accuracy by more than 8.5% in terms of both root-mean-square error (RMSE) and median absolute percentage error (MdAPE). A robustness test on another open fashion dataset, VISUELLE, confirms that our proposed models consistently improve demand forecasting accuracy in similar contexts. The hybrid model's incorporation of both textual and visual data significantly enhances the accuracy of demand forecasting for new fashion products. The innovative approach of using product similarity for image-based instance selection effectively addresses dataset imbalance issues, ensuring more reliable forecasts across various fashion categories.

1 - A Scalable Surrogate Approach for Multi-Purchase Assortment Optimization Under A General Random Utility Model

Wenhao Gu, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Anton Braverman, Tarek Abdallah

We consider the problem of multi-purchase assortment optimization under a general random utility model. We introduce a surrogate problem capable of handling random basket sizes and general utility distributions. The surrogate model approximates the original problem by leveraging asymptotic structure and remains effective even at moderate problem scales. We further develop algorithmic techniques—including dimension reduction via distributional clustering and a linear programming relaxation—to enable efficient optimization over large product sets and heterogeneous demand profiles. We provide rigorous performance guarantees for the surrogate and its relaxations, with provably vanishing error under mild conditions. Numerical experiments demonstrate strong empirical performance and significant runtime improvements over existing methods, particularly in large-scale settings.

2 - Assortment Optimization for Online Video Games

Yunlong Wang, Shanghai Jiao Tong University, Shanghai, China, People's Republic of

We consider an assortment optimization problem for a class of online video games where the in-game virtual store has a unique structure with two sections: Featured and Just For You (JFY). All customers (players) are offered the same Featured section assortment, whereas the JFY section is used for personalized recommendations. Our paper is the first to study assortment optimization for the gaming industry under discrete choice models; it is also the first to devise both exact and approximate solution approaches for the constrained mixture-of-nested-logit model. We model customer choice under a constrained mixture-of-nested-logit model and propose a number of solution methods for the resulting assortment optimization problems, including an exact mixed-integer nonlinear programming (MINLP) formulation and three approximate solution methods: a fully polynomial time approximation scheme (FPTAS), a mixed-integer linear programming (MILP) formulation, and a fast heuristic algorithm. We provide theoretical performance guarantees for the FPTAS, MILP formulation, and heuristic algorithm. Numerical experiments show that our approaches perform well across a variety of settings based on conversations with our industry partner to mimic the instances found in their video game stores. These experiments demonstrate that the MINLP can obtain optimal solutions efficiently. Our work provides guidance for how online video game stores can manage assortments for effective revenue maximization. We propose an "assortment" of solution approaches that allows practitioners to choose a method that best suits their environment. Furthermore, we conduct simulations based on ground-truth instances to demonstrate that considering the nests in the mixture-of-nested-logit model can better capture consumer behavior.

3 - Data Driven Decision Making from Censored Demand

Boxuan Zhou, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Lavanya Marla, Yunzong Xu

We address the single-period newsvendor problem with censored demand by developing a distributionally robust optimization framework that leverages empirical CDF bounds at sampled demand levels. Our ambiguity set imposes moment-type constraints on observed sales and censored observations to capture the complete data structure. Under a nonparametric assumption, we derive a closed-form robust order quantity via an integral equation that equalizes worst-case regret around the critical quantiles. By discretizing lower and upper CDF bounds at gridpoints, we obtain an explicit, efficiently computable implementation formula. The framework extends to parametric settings, enables quantile-convergence analysis, and paves the way for feature-based, multi-period inventory and pricing extensions under demand censoring.

4 - Play-to-Earn Blockchain Video Games: a Glimpse into the Future of Work

Lifei Sheng, University of Houston Clear Lake, Houston, TX, United States, Hubert Pun

“Play-to-Earn” games allow consumers monetize in-game achievements by trading leveled-up digital assets, thanks to the smart contract and traceability capabilities of blockchain. We model a video game publisher’s decision to allow tradability, analyzing its effects on consumer behavior and revenue. While making an asset tradable would introduce competition for the publisher, tradability may still be allowed even when it generates no trading revenue and incurs administrative costs. Our findings reveal strategic trade-offs for publishers and offer insights into broader applications of blockchain in digital markets.

1 - Assortment Optimization Without Prediction: An End-to-End Framework with Transaction Data

Shaoyu Wang, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Pin GAO, Andre Cire, Ningyuan Chen

Firms leverage assortment optimization to identify a set of products to offer to consumers in order to maximize the potential revenue. Traditionally, firms first use the historical transaction data to estimate a discrete choice model that predicts the choice behavior of future consumers, and subsequently solve the optimal assortment with such an estimated discrete choice model. This is typically referred to as the **predict-then-optimize** approach. In this paper, we propose an alternative approach that maps the data to the assortment decision in an **end-to-end** fashion, without the need to estimate a discrete choice model. The formulation extracts the partial orders induced from each customer in the historical transaction data. The assortment is then selected to maximize the worst-case revenue for a new customer when his/her preference is uniformly drawn from historical partial orders. We establish the NP-hardness of this problem and develop a mixed-integer programming formulation for exact solutions. Furthermore, we provide a number of approximation algorithms with theoretical guarantees.

To demonstrate the external validity of the framework, we show the recommended assortment can achieve 1/2 of the optimal revenue when the data is generated by a rank-based choice model.

The numerical result shows that the end-to-end framework is particularly attractive when (1) the data is scarce so that estimating model parameters can be unstable or (2) when the consumer behavior is complex and a pre-determined discrete choice model is likely to be misspecified.

2 - Joint Inventory Placement, Assortment Personalization, and Order Fulfillment for Substitutable Products

Mikhail Fadin, Cornell Tech, New York, NY, United States, Omar El Housni, Huseyin Topaloglu

Modern e-commerce platforms leverage distributed warehouse networks to store inventory and directly fulfill customer orders in near real time. A key challenge is coordinating (i) how to allocate inventories across network facilities subject to capacity and supply constraints; (ii) how to dynamically select personalized product assortments based on customer context and real-time stock levels; and (iii) how to route chosen orders to warehouses to maximize net profit. We formalize this joint optimization problem and give approximation algorithms. Extensive numerical experiments demonstrate that in practice our method achieves near-optimal net profits even for relatively low capacities and supply levels and, combined with simple additional heuristics, can perform even better and scale extremely well computationally.

3 - Service Design Using Personal Information

Bogyeom Lee, University of Michigan, Ross School of Business, Ann Arbor, MI, United States, Hyun-Soo Ahn, Joline Uichanco

We study how a firm should design personalized services when customers differ in both their valuation for base service and their sensitivity to add-ons. Due to regulatory and operational limits, firms often cannot observe both dimensions of heterogeneity. We model a monopolist choosing between collecting full information, partial information (on one dimension), or offering uniform service, and compare these to an indirect mechanism design approach. Our results show that partial information can often substitute for full information at a lower cost and can also outperform indirect mechanism design when information is verifiable. In addition, customers may voluntarily disclose private information when it improves service quality. When information is not verifiable, misreporting typically harms the firm but can also be beneficial by helping avoid market failure.

4 - Who Should Fulfill? the Role of Return Policies in E-Commerce Fulfillment Strategy

Serdar Simsek, The University of Texas at Dallas, Richardson, TX, United States, Ozalp Ozer, Jiarui (Gary) Wei

Third-party sellers on e-commerce platforms can fulfill their orders either through the platform’s own logistics service—Fulfillment by Platform (FBP)—or by managing fulfillment independently using carriers such as UPS or FedEx, referred to as Fulfillment by Seller (FBS). This paper examines how lenient return policies offered under FBP affect consumers’ purchase decisions and sellers’ revenues. We develop a stochastic model to capture the dynamics of consumer purchasing and return behavior under varying return policies. Lenient return policies can both increase product sales by reducing consumers’ perceived risk and raise return rates, potentially eroding seller profitability. We analyze how the relative value of FBP versus FBS varies with consumers’ return hassle cost, perceived value of FBP, product valuation uncertainty, and heterogeneity in consumer preferences. Our findings offer practical insights for sellers evaluating fulfillment options and for platforms seeking to design effective return policies and align their logistics services with suitable seller and product types.

1 - Selling Heterogeneous Objects to Unit-Demand Bidders

Nina Bobkova, Rice University, Houston, TX, United States

We study sequential auctions of heterogeneous objects when bidders have unit demand. We characterize equilibrium bidding behavior when bidders observe their current valuation but face uncertainty about future objects. Bidders with low current values strategically delay participation to preserve the option value of competing for future

objects. Two opposing forces shape bidding behavior over time: the resource effect, as the value of waiting diminishes with fewer objects remaining, and the competition effect, as fewer active bidders increase expected payoffs in later rounds. We characterize the symmetric equilibrium in first-price, second-price, and English auctions, showing when revenue equivalence holds despite strategic delay. Compared to the classical homogeneous-object setting of Milgrom and Weber (1982), heterogeneous goods introduce nontrivial thresholds for participation. We discuss implications for the disclosure of information about future objects and the optimal order of sale.

2 - Optimal Platform Design

Cole Wittbrodt, Columbia University, New York, NY, United States

Search and matching increasingly takes place on online platforms. These platforms have elements of centralized and decentralized matching; platforms can alter the search process for its users, but are unable to eliminate search frictions entirely. I study a model where platforms can change the *distribution* of potential partners that an agent searches over and characterize search equilibria on platforms. When agents possess private information about their match characteristics and the platform designer acts as a profit maximizing monopolist, I characterize the optimal platform. If match characteristics are complementary and utility is transferable, I show that the solution to this screening problem is efficient, despite the presence of hidden information and market power. Matching under the optimal platform is perfectly assortative --- there is no equilibrium mismatch.

3 - Optimal Auction Design for Dynamic Stochastic Environments: Myerson Meets Naor

Andrew Choi, University of Michigan, Ann Arbor, MI, United States, Yeon-Koo Che

Allocation of goods and services often involves both stochastic supply and stochastic demand. Motivated by applications such as cloud computing, gig platforms, and blockchain auctions, we study the design of optimal selling mechanisms in an environment where buyers with private valuations arrive stochastically and are assigned goods that also arrive stochastically, and either buyers or goods can be held in a queue at costs until allocation. The optimal mechanism dynamically leverages competitive pressure across times by managing the queue of buyers and inventory of goods, using reserve prices that increase with queue length and an auction to allocate the goods.

4 - Optimal Auction Design for Dynamic Stochastic Environments: Myerson Meets Naor

Andrew Choi, University of Michigan, Ann Arbor, MI, United States, Yeon-Koo Che

Allocation of goods and services often involves both stochastic supply and stochastic demand. Motivated by applications such as cloud computing, gig platforms, and blockchain auctions, we study the design of optimal selling mechanisms in an environment where buyers with private valuations arrive stochastically and are assigned goods that also arrive stochastically, and either buyers or goods can be held in a queue at costs until allocation. 1 - Data-Driven Mechanism Design: Jointly Eliciting Preferences and Information

Marek Bojko, Yale University, New Haven, CT, United States, Dirk Bergemann, Paul Dütting, Renato Paes Leme

"We study mechanism design when agents have private preferences and private information about a common payoff-relevant state. We show that standard message-driven mechanisms cannot implement socially efficient allocations when agents have multidimensional types, even under favorable conditions. To overcome this limitation, we propose data-driven mechanisms that leverage additional post-allocation information, modeled as an estimator of the payoff-relevant state. Our data-driven mechanisms extend the classic Vickrey-Clarke-Groves class. We show that they achieve exact implementation in posterior equilibrium when the state is either fully revealed or the utility is affine in an unbiased estimator. We also show that they achieve approximate implementation with a consistent estimator, converging to exact implementation as the estimator converges, and present bounds on the convergence rate. We demonstrate applications to digital advertising auctions and large language model (LLM)-based mechanisms, where user engagement naturally reveals relevant information.

2 - Robust Dynamic Staffing with Predictions

Rad Niazadeh, Chicago Booth School of Business, Chicago, IL, United States, Yiding Feng, Vahideh Manshadi, Saba Neyshabouri

We consider a natural dynamic staffing problem in which a decision-maker sequentially hires staff over a finite time horizon to meet an unknown target demand at the end. The decision-maker also receives a sequence of predictions about the demand that become increasingly more accurate over time. Consequently, the decision-maker prefers to delay hiring decisions to avoid overstaffing. However, workers' availability decreases over time, resulting in a fundamental trade-off between securing staff early (thus risking overstaffing) versus hiring later based on more accurate predictions (but risking understaffing). This problem is primarily motivated by the staffing challenges that arise in last-mile delivery operations. A company such as Amazon has access to flexible gig economy workers (through Amazon Flex) whose availability decreases closer to the target operating day, but they can be hired at any time before that day if they are available. We study the above problem when predictions take the form of uncertainty intervals that encompass the true demand. The goal of the decision-maker is to minimize the staffing imbalance cost at the end of the horizon against any sequence of prediction intervals being chosen by an adversary. Our main result is the characterization of a simple and computationally efficient online algorithm that obtains the optimal worst-case imbalance cost; said differently, it is minimax optimal. At a high level, our algorithm relies on identifying a restricted adversary against which we can characterize the minimax optimal cost by solving a certain offline LP.

3 - A Stochastic Growth Model for Online Platforms

Farbod Ekbatani, Chicago Booth School of Business, Chicago, IL, United States, Rene Caldentey

We investigate the growth trajectory of online platforms operating as market makers in two-sided matching markets. Their expansion, often referred to as the "chicken-and-egg dilemma" in the literature, poses an inherent challenge; service providers find value in joining the platform due to the presence of customers, while customers are drawn to the platform by the availability of diverse services. This endogenous network effect influences the growth trajectory and propels emerging platforms towards "get big fast" type of strategies to rapidly achieve critical mass on both sides. Much of the existing literature tackles the chicken-and-egg dilemma using a static market-clearing approach, where network externalities determine a platform's resulting equilibrium size. However, this approach overlooks the inherent dynamics of gradually recruiting servers and attracting new customers. Embedded in this growth process are compensation schemes and the related intertemporal incentive-compatibility constraints that a platform must satisfy to sustain its expansion. These are fundamental aspects that static models cannot fully capture. To explicitly capture the stochastic dynamics of a platform's gradual growth, we model the system as a Markov process. Service providers join according to a Poisson process whose intensity is modulated by the platform's compensation structure. Meanwhile, customers are transitory, arriving according to a Poisson process with an intensity that is non-decreasing in the number of active servers, reflecting their preference for larger platforms. Under mild conditions, we characterize the optimal server compensation schemes the platform should adopt and establish upper bounds on how rapidly and extensively the platform can grow.

4 - Approximately Optimal Online Mechanism for Multiunit Demand Buyers with Post-Allocation Inspection

Xuanjie Li, Duke University, Durham, NC, United States, Alexandre Belloni, Ali Makhadmeh

We consider a mechanism design problem where an auctioneer allocates k units of an item to multiunit demand buyers arriving in an online fashion, each with a constant private marginal value. The auctioneer can inspect buyers allocated to learn their types and use this information to lower payments to reward truthful buyers. By using tools from the Calculus of Variations, we fully characterize the optimal mechanism for a single-buyer problem subject to an upper bound on the allocation expectation. In particular, we characterize the optimal allocation strategy as the solution of an ordinary differential equation and establish that it is a continuous and

monotonically increasing function of the buyer's types. With the solution to the single-buyer problem, and by using connections to the prophet inequality literature, we design an online mechanism that achieves $1 - \sqrt{\alpha_{\text{max}}}$ of the optimal (offline) revenue, where α_{max} denotes the highest fraction of all units a buyer requests.

5 - Battery Operations in Electricity Markets: Strategic Behavior and Distortion

Jerry Anunrojwong, University of Washington, Seattle, WA, United States, Santiago Balseiro, Omar Besbes, Bolun Xu

Electric power systems are undergoing a major transformation as they integrate intermittent renewable energy sources, and batteries to smooth out variations in renewable energy production. As privately-owned batteries grow from their role as marginal “price-takers” to significant players in the market, a natural question arises: How do batteries operate in electricity markets, and how does the strategic behavior of decentralized batteries distort decisions compared to centralized batteries? We propose an analytically tractable model that captures salient features of the highly complex electricity market. We derive in closed form the resulting battery behavior and generation cost in three operating regimes: (i) no battery, (ii) centralized battery, and (ii) decentralized profit-maximizing battery. We establish that a decentralized battery distorts its discharge decisions in three ways. First, there is quantity withholding, i.e., discharging less than centrally optimal. Second, there is a shift in participation from day-ahead to real-time, i.e., postponing some of its discharge from day-ahead to real-time. Third, there is reduction in real-time responsiveness, or discharging less in response to smoothing real-time demand than centrally optimal. We also quantify the impact of the battery market power on total system cost via the Price of Anarchy metric, and prove that it is always between 9/8 and 4/3. That is, incentive misalignment always exists, but it is bounded even in the worst case. We calibrate our model to real data from Los Angeles and Houston. Lastly, we show that competition is very effective at reducing distortions, but many market power mitigation mechanisms backfire, and

1 - Understanding What Keeps Indian Users Engaged with Femtech Apps: A Mixed-Methods Study

SHREYA MUKHERJEE, IIT Kharagpur, Kharagpur, India, SAINI DAS

The FemTech sector, which includes a range of technological innovations aimed at addressing women's health and wellness, has witnessed remarkable global growth in recent years. These technologies cover areas such as menstrual tracking, fertility monitoring, maternal health, and mental well-being. However, in the Indian context, where discussions around women's health and hygiene are often hindered by longstanding social taboos and cultural stigma, there is limited scholarly attention on what drives users to continue engaging with FemTech applications after initial adoption. This study seeks to fill that research gap by adopting a sequential two-stage mixed-methods approach. In the first phase, qualitative data were collected through in-depth interviews with Indian FemTech users, and the narratives were analyzed using inductive thematic analysis. The second phase involved quantitative testing of an integrated model, combining elements from the Technology Acceptance Model (TAM), Diffusion of Innovation (DOI) theory, and the emergent qualitative themes. Survey data collected from a diverse group of FemTech users across India was analysed to validate the model using SmartPLS. Findings from the study reveal that Perceived Usefulness (PU), Perceived Ease of Use (PEOU), and Perceived Enjoyment (PEN) play a critical role in shaping users' intentions to continue using FemTech apps. These results offer valuable implications for app developers, government agencies, and health policymakers, highlighting the need to prioritize user-centric design and culturally sensitive strategies to foster long-term engagement and improve women's health outcomes in India.

2 - Overcoming Vaccine Hesitancy by Multiplex Social Network Targeting

Marzena Fügenschuh, Berliner Hochschule für Technik, Berlin, Germany, Feng Fu

Understanding the impact of social factors on disease prevention and control is one of the key questions in behavioral epidemiology. The interactions of disease spreading and human health behavior such as vaccine uptake give rise to rich dueling dynamics of biological and social contagions. In light of this, it remains largely an open problem for optimal network targeting in order to harness the power of social contagion for behavior and attitude changes. Here we address this question explicitly in a multiplex network setting. Individuals are situated on two layers of networks. On the disease transmission network layer, they are exposed to infection risks. In the meantime, their opinions and vaccine uptake behavior are driven by the social discourse of their peer influence network layer. While the disease transmits through direct close contacts, vaccine views and uptake behaviors spread interpersonally within a long-range potentially virtual network. Our comprehensive simulation results demonstrate that network-based targeting with initial seeds of pro-vaccine supporters significantly influences the ultimate adoption rates of vaccination and thus the extent of the epidemic outbreak.

3 - Transformers with Koopman-Enhanced Graph Convolutional Network for Spatiotemporal Dynamics Forecasting

Zekai Wang, Fairfield University, Fairfield, CT, United States, Bing Yao

Spatiotemporal forecasting is essential for understanding and controlling dynamic systems in fields ranging from transportation to biomedicine. However, modeling these processes remains challenging due to irregular spatial geometries, nonlinear dynamics, and long-range temporal dependencies. In this study, we propose a novel two-stage predictive framework, Transformer with Koopman-enhanced Graph Convolutional Network (T-KGCN), to address these challenges. Our approach integrates graph convolutional networks (GCNs) to model complex spatial structures, Koopman operator theory to embed the system's state into a latent space with approximately linear dynamics, and a transformer to capture long-range temporal dependencies. Our contributions include: (1) a unified architecture combining GCN, Koopman embedding, and transformers; (2) a principled approach to model nonlinear dynamics with latent linear evolution; and (3) enhanced performance in long-range forecasting. While demonstrated in a cardiac setting, our framework is broadly applicable to diverse spatiotemporal prediction tasks.

4 - Uncovering Patterns of Comorbidity in Rheumatoid Arthritis: a Data Analytics Approach

Hamid Hadidi, Oklahoma State University, Stillwater, OK, United States, Kazi Arman Ahmed, Mohammad Fili, Dursun Delen, Guiping Hu, Lizhi Wang

Rheumatoid arthritis (RA) is a chronic autoimmune disorder affecting an estimated 1.5 million Americans and 18 million people worldwide, often accompanied by a complex array of comorbidities. Current understanding of the conditions that precede RA onset or develop subsequently remains limited. This investigation utilizes the extensive, longitudinal Oracle Real-World Data, formerly known as Cerner Real-World Data, to elucidate these patterns. We aim to: (1) identify potential antecedent conditions that may contribute to RA, and (2) characterize the spectrum of comorbidities emerging post-RA diagnosis. This study seeks to generate novel predictive insights which could be crucial for developing targeted interventions for high-risk individuals and for optimizing the management of RA patients by anticipating and mitigating comorbid conditions.

5 - AI-Assisted Systematic Review and Meta-Analysis in Diet-Microbiome-Kidney Research

Olzhas Zhorayev, George Mason University, Arlington, VA, United States, Meng-Hao Li, Xiaoyu Chen, Nithin Rogan Arulsamy, Naoru Koizumi

Chronic kidney disease (CKD) affects over 35 million U.S. adults and imposes a substantial burden on the healthcare system, as Medicare covers much of the costly treatments. Emerging research suggests that microbiome-targeted dietary interventions may slow disease progression and reduce healthcare burden. Existing evidence, however, remains fragmented and inconclusive. To address this gap, we introduce an AI-assisted tool that automates and accelerates a systematic review and meta-analysis of the diet-microbiome-kidney nexus by integrating web-scraping techniques and large language models (LLMs).

To manage the scope and complexity of the literature, we established a pipeline that automates each stage of the review process – literature search, screening, data extraction, and quality assessment. Our custom web-scraping tool retrieved 1,896 study records from Google Scholar, supplemented by 236 from PubMed (2000-2025). We then used OpenAI's LLMs to screen 2,132 records and identified 171 relevant studies, including 30 randomized controlled trials eligible for meta-analysis. Human

validation showed that GPT-o1 outperformed GPT-4o, achieving an 88% accuracy rate. Overall, LLM-based screening was 25 times more time-efficient than manual review. We further developed a local multimodal RAG-based tool to extract structured data on statistical measures, diet types, disease characteristics, and bacterial taxa for meta-analysis. Finally, study quality was assessed automatically, including evaluation of incomplete reporting, using predefined criteria.

This AI-assisted pipeline demonstrates substantial gains in scale, efficiency, and reproducibility of systematic reviews and meta-analyses. Beyond the CKD application, it is broadly adaptable and can support researchers, clinicians, and policymakers in generating timely, high-quality insights across diverse health domains.

1 - Branch-Price-and-Cut for Patient Planning and Surgeon Scheduling

Babak Akbarzadeh, University of Gent, Gent, Belgium, Matthias Bogaert, Broos Maenhout

We address the problem of patient planning and surgeon scheduling in operating theatres, where patients must be scheduled alongside assigning time blocks to surgeons. The timing and length of the allotted time blocks depend on the patient characteristics on the surgeons' waiting lists. Solving this problem in an exact manner is challenging due to the large number of rooms, surgeons, and patients involved. To overcome this challenge, we propose an efficient branch-price-and-cut algorithm to find an optimal solution in an acceptable time span. For that purpose, we include different dedicated mechanisms to accelerate the solution-finding process. In this regard, the branch-price-and-cut tree is set up using an intelligent branching scheme, the nodes are searched in order of the lowest number of fractional variables, and improved bounds are computed to prune nodes earlier. To tighten the convex hull of the linear programming relaxation in each node, the algorithm relies on a row generation mechanism for adding valid inequalities. We conducted various computational experiments to demonstrate the performance of our algorithm and validate for each component the contribution of the implemented optimisation principles. Additionally, we show the superior performance of the proposed algorithm to alternative optimisation procedures.

2 - Regulation of Online Consultations Quality on Two-Sided Online Healthcare Platforms

Yumeng Zhang, Shandong University, Jinan, China, People's Republic of, Zizhuo Wang, Jianghua Zhang

As an emerging business model in the platform economy, online healthcare platforms have expanded rapidly. However, the information asymmetry between doctors and patients creates challenges for the quality of online consultations and threatens the stability of the online healthcare market. To prevent market failure, improving the regulation of online consultation quality while ensuring platform operations is a critical issue for online healthcare platforms. Through a game-theoretic model of a monopolistic online healthcare platform with two-sided market characteristics, we discuss the conditions for the platform's regulatory decision and the impact on price, the number of users, and patient surplus. Additionally, we described the equilibrium results under various scenarios. The analytical results show that increasing the level of platform regulation does not always lead to more patients or fewer doctors. This outcome is related to the losses patients experience from low-quality online consultations. Moreover, platform regulatory decisions depend on the losses to both patients and the platform from low-quality online consultations. When patient losses exceed a certain threshold, the platform becomes inoperable. Interestingly, our results also show that the optimal price, the number of users (patients and physicians), and patient surplus with regulation are not necessarily superior to those without regulation. This further confirms the significant impact of losses to patients and the platform from low-quality online consultations on platform operations. Moreover, depending on the extent of losses to both patients and the platform, either platform regulation or non-regulation can achieve a win-win situation for both the platform and patients.

3 - Appointment Scheduling Under Patient Preferences and Delay-Dependent No-Show

Hakan Kılıç, University of Toronto, Toronto, ON, Canada, Olga Bountali, Ningyuan Chen, Andre Cire

Patients with chronic diseases constitute a vulnerable group that has increased dramatically over the last decade. They require systematic medical attention and delay in their care can lead to severe health outcomes. These delays can arise from the limited capacity of the healthcare provider such that the patients cannot book an appointment on time or due to the patients not showing up to an appointment that was on time. To address these issues, we propose a Markov decision process framework that provides each patient a subset of appointments from which they can book, i.e., adjusted booking window, based on the patient's preferences regarding their appointment time. We leverage the booking window to manage both capacity and to mitigate no-shows, which are expected to increase with longer delays between appointment requests and appointment dates. We investigate the structure of the optimal policy and provide numerical insights.

4 - Pareto-Improving Bump Policies in Shared Operating Room Scheduling Systems

Hung Do, University of Vermont, Burlington, VT, United States, David Novak, Mitchell Tsai, Andrey Ukhov

For hospitals using shared operating rooms for scheduled and emergent cases, a bumping policy is needed to facilitate emergent cases when they arrive, but it often operates with competing objectives. The current bumping policies do not offer efficient access to capacity (i.e., Operating Rooms) as well as any mechanism for collaboration. We introduce, model and analyze a bumping policy called First-In-First-Out (FIFO) Bump Policy in the context of Operating Room Scheduling that facilitates more efficient use of capacity with pooling effect and offers a collaborative mechanism with potential positive behavioral effects to speedup service rates.

5 - Distributionally Robust Optimization for Appointment Scheduling in the Presence of Patient and Provider Lateness, Emergency, and No-Show Patients

Secil Sozuer, Lehigh University, Bethlehem, PA, United States, Karmel Shehadeh, Robert Storer

We address a single-provider scheduling problem given a fixed sequence of appointments with uncertain durations, patient unpunctuality, provider lateness, no-shows and emergencies. The aim is to optimize the decision of scheduling an arrival time for each patient, or equivalently, assigning appointment intervals between patients, along with first patient's arrival time. We remove the assumption that the probability distributions of the uncertain parameters in the scenario creation are known. To address this issue, we develop a distributionally robust optimization (DRO) model with an ambiguity set constructed to represent the uncertainty of the various distributions. Our DRO model finds the optimal appointment slots that minimize the worst-case expected operational cost over probability distributions residing in the ambiguity set. In our DRO model, we utilize a mean support ambiguity set that incorporates the mean, lower and upper bounds of the lateness, no-show, emergency, and appointment durations. We derive an equivalent mixed integer linear programming (MILP) reformulation of our proposed DRO model. We present the computational experiments along with the managerial insights.

1 - Optimizing Multi-Objective Inventory Management Using Pareto-Conditioned Networks

SunJin Han, POSTECH, Pohang, Korea, Republic of, Dong Gu Choi, Daiki Min

Multi-objective inventory management problems have been extensively studied over the years. Given the trade-offs among multiple objectives, this study aims to approximate the Pareto front rather than seeking a single optimal solution. We employ a Pareto-conditioned network for the continuous review(r, Q) system. By leveraging the structural properties of the continuous review(r, Q) system, we propose a variation of the Pareto-conditioned network to improve the efficiency of identifying the Pareto front. The proposed method optimizes multiple objectives simultaneously rather than optimizing each objective individually. We compare the proposed algorithm against conventional evolutionary heuristic algorithms commonly used in prior research, demonstrating superior performance in terms of convergence speed and solution quality.

2 - A Reinforcement Learning Approach for Artillery Unit Routing and Target Scheduling with Resource Constraints

Jaewon Kim, Korea University, Seoul, Korea, Republic of, Hyungjoo Cha, DongKyun Kim, Euijin Lee, Taesu Cheong

This study presents a reinforcement learning (RL) framework for solving a complex routing and scheduling problem involving multiple artillery units in field operations. The problem involves coordinating multiple artillery units that must travel between nodes to engage enemy targets while minimizing the maximum mission completion time. Each unit begins from a depot, visits locations sequentially to engage different enemy targets, and returns to the depot upon mission completion. The system incorporates multiple ammunition types with varying ranges and limited inventory constraints. To address the computational complexity of this integrated routing and resource allocation challenge, we develop an online RL algorithm based on Masked Proximal Policy Optimization (Masked PPO) that masks invalid actions to ensure feasible decision-making in dynamic environments. Additionally, we implement curriculum learning by progressively increasing the difficulty of the simulation environment during training. The proposed RL approach is evaluated against traditional optimization models and Genetic Algorithm (GA) baselines across various scenarios. Experimental results demonstrate that the Masked PPO framework delivers robust solutions with competitive performance, particularly excelling in large-scale instances where optimization models exceed time limits and genetic algorithms fail to produce feasible solutions. These findings demonstrate the potential of reinforcement learning for complex military scheduling and routing applications requiring rapid adaptation and real-time decision-making.

3 - Procurement Lead TIME Estimation and Supplier Recommendation for Improving Supply Chain Resilience

Teppei Inoue, Hitachi America, Ltd., Santa Clara, CA, United States, Haiyan Wang

Recently, there have been a lot of supply chain disruptions caused by Covid 19, wars, and natural disasters, so supply chain resilience is getting attention. To improve the resilience, it is important to monitor and predict the supply chain operating parameters such as procurement Lead Time (LT) so that we can detect business environment change at an early stage. Furthermore, there is a risk that manufactures cannot receive parts and materials from their suppliers due to the disruptions, so it is necessary to be prepared with alternative suppliers. To address these issues, this presentation proposes procurement LT estimation using procurement transaction data and supplier recommendation using LLM and web scraping. In the LT estimation, we explore different modeling approaches to address many-to-many relationships among items, buyers, and suppliers, such as one model for any item-buyer-supplier tuple, one model for each item or multiple models for each item. Moreover, the models include external factors such as industrial production index and news articles to consider business environment changes. Based on the LT prediction, we find suppliers with supply delay risks and recommend alternative suppliers combining LLM and web search. The recommendation result includes the detailed information such as productionable products, ISO certification and sentiment analysis result for relevant news of each candidate to support optimal supplier selection. We demonstrate the effectiveness of our approach through the experiments with real procurement transaction data.

4 - Asymmetric Mapping with Wasserstein Loss: A Two-Stage Aae Framework for Classification Under Multi-Class Imbalance

JiSoo Hwang, Yonsei University, Seoul, Korea, Republic of, Chang Ouk Kim

In semiconductor manufacturing fault detection and classification (FDC) systems, defective samples are far fewer than normal ones, causing severe class imbalance and making the classification of defective and normal samples challenging. To ensure robust classification performance in such environments, oversampling methods are essential. In this study, we adopt an approach based on the Adversarial AutoEncoder (AAE) among existing oversampling techniques. We propose AMAAE-WL(Asymmetric Mapping Adversarial AutoEncoder with Wasserstein Loss). First, asymmetric mapping is applied to construct class-specific latent spaces for minority classes, thereby enhancing inter-class separability. Second, Wasserstein loss is incorporated to mitigate the training instability of AAEs, enabling more stable generative learning based on the distance between two distributions. Third, a step-wise decoder fine-tuning strategy using classification loss is introduced, ensuring that generated samples directly contribute to improving classification performance. The proposed method has the potential to generate high-quality, class-specific synthetic samples in multi-class imbalance scenarios while organically integrating the generative model with the classification model to maximize classification accuracy.

5 - Consistent Knn-Based Dataset Reduction with Optimal Weighting for Stochastic Optimization

Efe Sertkaya, University of Maryland, College Park, MD, United States, Alexander Estes

Dataset reduction techniques aim to construct a compact yet informative subset of a given dataset to improve computational efficiency while preserving statistical properties. Existing methods often rely on submodular optimization, leveraging heuristics such as gradient proximity or log-likelihood estimators to select representative data points. However, these approaches frequently lack formal consistency guarantees and do not provide optimal weighting schemes for use in downstream tasks, raising concerns about their reliability and efficacy. In this paper, we propose a novel dataset reduction method grounded in the k-nearest neighbors (kNN) framework and establish its asymptotic consistency. We show that, as the dataset size increases, the selected subset yields an estimator that converges to the true loss minimizer, thereby preserving the statistical fidelity of the full dataset. Crucially, our method also provides an optimal weighting scheme for the selected subset, which can be integrated into learning algorithms or optimization-based pipelines to improve generalization and solution quality. Extensive empirical evaluations on standard machine learning benchmarks and stochastic integer programming tasks demonstrate the practical performance of our approach.

1 - Wasserstein Autoregressive Moving Average Model for Distribution-Valued Time Series Analytics

Yujing Huang, University at Buffalo, Buffalo, NY, United States, Xiaoyu Chen

Distribution-valued time series (DVTS), where each observation at time t is a probability distribution, are widely encountered. For example, in critical care settings such as intensive care units (ICUs), the daily distribution of systolic blood pressure (SBP) of each patient varies over time due to physiological changes, interventions, and patient heterogeneity. Most existing statistical tools are limited to data in vector space, hence being not suitable to analyze such DVTS. We propose a Wasserstein autoregressive moving average (WARMA) model based on Riemannian geometry to directly analyze DVTS. The merits of WARMA will be explored using ICU blood pressure data from the publicly available MIMIC-IV database.

2 - A Dual-Modal Large Language Model for Medical Time Series-Text Multimodal Learning

Ziyue Li, University of Cologne, Cologne, Germany

The recent rapid advancements in language models (LMs) have garnered attention in medical time series-text multimodal learning. However, existing contrastive learning-based and prompt-based LM approaches tend to be biased, often assigning a primary role to time series modality while treating text modality as secondary. We classify these approaches under a temporal-primary paradigm, which may overlook the unique and critical task-relevant information embedded in text modality like clinical reports, thus failing to fully leverage mutual benefits and complementarity of different modalities. To fill this gap, we propose a novel textual-temporal multimodal learning paradigm that enables either modality to serve as the primary while being enhanced by the other, thereby effectively capturing modality-specific information and fostering cross-modal interaction.

3 - Identifying Ptsd Through Multimodal Analysis of Sleep Dynamics

Cheng-Bang Chen, University of Miami, Coral Gables, FL, United States, Yujie Wang, Diane Lim

Accurate identification of Post-Traumatic Stress Disorder (PTSD) remains challenging due to subjective diagnostic criteria and overlapping symptoms with other conditions. Individuals cannot consciously alter sleep patterns, and sleep dynamics can reliably reflect health conditions, such as PTSD. This study hypothesizes that sleep, a complex dynamic process, can objectively indicate PTSD status. We developed a novel multimodal dynamic analysis framework utilizing polysomnography (PSG) signals to objectively detect PTSD. We leveraged state space representation to integrate Electrocardiogram (ECG), four-channel Electroencephalogram (EEG), and peripheral oxygen saturation (SpO₂) data to capture the complex, nonlinear, and nonstationary dynamics inherent in sleep. A multi-level heterogeneous recurrence quantification analysis (MHRQA) method was applied, analyzing sleep data from 108 participants. Hyperoctree Aggregate Segmentation was employed to enhance delineation within the state space, segmenting it into distinct regions. Sleep trajectories were transformed into symbolic sequences representing transitions across these segmented subspaces. Subsequently, an iterated function system projected these sequences into fractal circles, effectively capturing intricate sleep dynamics. Recurrence dynamics within each 30-second sleep epoch were quantified via MHRQA, generating rich dynamic features for identifying PTSD. An ensemble machine learning classifier classified epochs as PTSD-related or not. Performance validation using an 80/20 training-test split demonstrated high epoch-level accuracy (accuracy: 0.975, sensitivity: 0.964, specificity: 0.981, AUC: 0.996). Additional leave-one-out cross-validation indicated robust predictive performance at the patient level, achieving 0.75 accuracy. This multimodal dynamic analysis framework thus provides an objective, systematic, and reliable tool for PTSD detection based on sleep patterns, demonstrating considerable potential for clinical application and personalized care.

4 - Neurodegenerative Impact of Alzheimer's with Lewy Body Co-Pathology Characterized Through MRI-Based Brain Age Modeling with Deep Learning

Babak Ahmadi, University of Florida, Gainesville, FL, United States, Melissa Armstrong, Breton Asken, Mostafa Reisi, Abbas Babajani-Feremi

Alzheimer's disease (AD) and Lewy body (LB) pathology frequently co-occur, yet only recently have cerebrospinal fluid (CSF) α -synuclein seed amplification assays (SAA) enabled the in vivo detection of LB pathology, creating new avenues for examining its joint effects with AD on neurodegeneration. In this study, we developed a deep learning model trained on multi-cohort MRI data from 4,355 cognitively unimpaired individuals to estimate brain age, then applied it to 803 cognitively impaired participants. These individuals were categorized into four AD/LB pathology groups based on the p-tau181/A β 42 ratio for AD pathology and SAA status for LB pathology. Among these groups, the co-pathology subgroup (AD+LB+) demonstrated the greatest acceleration in brain aging, with saliency maps indicating more extensive neurodegeneration—a finding echoed by steeper longitudinal atrophy across multiple brain regions and associated cognitive declines. These findings underscore LB pathology's synergistic role in amplifying AD-related neurodegeneration, highlighting the importance of combined biomarker assays and targeted interventions for individuals harboring co-existing AD and LB pathology.

5 - Multimodal Learning for Health Data Integration with Missing Modality

Meng Zhao, Lehigh University, Bethlehem, PA, United States

Multimodal learning has emerged as a cornerstone of modern healthcare applications, integrating diverse data sources to build comprehensive patient representations for downstream clinical predictive tasks. However, in real-world clinical settings, one or more modalities are often absent due to cost constraints, sensor failures, or institutional data heterogeneity. In this work, we address this “missing modality” challenge by formulating it as a joint matrix recovery problem in which entire patient profiles (rows) may be unobserved in either data view. We develop a novel completion model which can jointly factorize all modalities and handle the row-wise data missing. Experiments demonstrate the benefits of our proposed method on multimodal data representation with incomplete modalities.

1 - Counterfactual Visual Explanation Process: Ranking and Utilizing Critical Features to Analyze a Machine Learning Model's Classification

Jian Hu, University of Michigan - Dearborn, Dearborn, MI, United States

Machine learning is increasingly utilized across diverse industries for automation, necessitating a clear understanding of model predictions to ensure accountability and foster user trust. In computer vision, counterfactual explanations provide insights by visually presenting changes in input images that significantly alter model outputs, thereby highlighting influential features. Our research introduces a novel approach to generate a series of visual explanations aimed at identifying critical, yet often-overlooked, features that impact model accuracy. We develop a ranking and feature reduction method to quantitatively assess the influence of these features on classification and prediction tasks. Our findings demonstrate that this approach not only enhances model transparency but also optimizes feature selection, thereby improving overall model efficiency. This work contributes to advancing the interpretability and reliability of machine learning models in practical applications.

2 - Utilizing Game Theory and Machine Learning in Policy Making

Gokce Dayanikli, University of Illinois at Urbana-Champaign, Champaign, IL, United States

In this talk, we introduce the Stackelberg mean field game problem to approximate the continuous-time, dynamic, and stochastic game between a principal and a large number of agents which can be used for different real life policy making applications such as epidemic mitigation. After introducing the general mathematical model, we discuss how to rewrite this bi-level problem as a single-level problem to propose an efficient numerical solution. In the model, the agents in the population play a non-cooperative game and choose their controls to optimize their individual objectives by interacting with the principal and other agents in the population through the population distribution. The principal can influence the resulting mean field game Nash equilibrium through incentives to optimize her own objective. After analyzing this game by using a probabilistic approach, we rewrite this intrinsically bi-level problem as a single-level problem and propose a machine learning approach to solve the Stackelberg mean field game. We conclude by discussing different applications such as mitigation of epidemics with non-pharmaceutical interventions and prevention of systemic risk in banking system with a regulator.

3 - Optimize Building Operations Using Data and AI

Gulai Shen, Harvard University, Cambridge, MA, United States, Ali Mehmani

Buildings are one of the largest energy consumers and carbon emitters. Due to the significant energy demand with increasing onsite generation and storage, buildings play a critical role in decarbonizing and regulating the electric grid. At the same time, the impact of indoor environment quality (IEQ) on occupants' wellness and productivity is substantial. These objectives together create complexity in finding optimal ways to manage building operations for reduced cost, energy, and emissions, together with better indoor environment and human-building interaction. Utilizing increased availability of data and AI technologies, we proposed novel frameworks, ways of

measuring, benchmarking, and controlling commercial office buildings with an occupant-centric approach. Case studies performed on buildings using the novel metrics like Indoor Environmental Wellness Index (IEW-Index) and PeopleHour show potential of improving building operations and enabling scalable AI solutions. In addition, AI algorithms with physics-infused hybrid models using predictive controls and reinforcement learning are implemented and maintained in real buildings. Results show 5% to over 10% energy and carbon reduction for test buildings, with over \$28M savings potential for the US General Service Administration (GSA) portfolio.

4 - Physics-Informed Machine Learning Enhanced Temperature Estimation of Pouch Cell with Indirect Liquid Cooling

Zheng Liu, University of Michigan-Dearborn, Dearborn, MI, United States

With the development of the indirect liquid cooling system for the pouch cell in energy storage systems, temperature estimation becomes an essential factor in design and operation. Traditional methods rely on experiments and finite element simulations, which are time-consuming and costly. Thus, data-driven methods are needed to accelerate the temperature estimation process while reducing the cost of designing and operating the energy storage systems. However, most data-driven methods require a large training dataset to achieve the desired accuracy, resulting in enormous computational costs for finite element simulation. Therefore, an approach to building a high-fidelity surrogate model with less training data is needed. This research proposes a physics-informed machine learning enhanced surrogate model to estimate the temperature of the pouch with the indirect liquid cooling. By integrating the information of the heat transfer partial differential equation into the loss function, the proposed surrogate model can achieve a high-fidelity temperature estimation with less training data. As a result, the proposed method achieved high-fidelity temperature estimation with over 50% reduction of the training data.

5 - Dynamic Parameter Calibration of Digital Twins Using Surrogate-Based Kalman Filtering

Jaeshin Park, University of Michigan, Ann Arbor, MI, United States, Chenfei Li, Eunshin Byon, William Bailey, Quazi Hussain, Yashodeep Lonari

Digital twins require accurate parameter estimation to remain consistent with their physical systems. We propose a dynamic calibration method that integrates a Kalman filter with a surrogate model, enabling real-time updates without costly simulator runs. The approach is demonstrated through a digital twin for thermal climate control in electric vehicles.

1 - Classifying and Contextualizing the Unknown: a Continuous Abatement-Based Algorithm for Open Set Recognition

Steven Wang, University at Buffalo, Buffalo, NY, United States, Kyle Hunt, Zachary Steever, Chase Murray, Junsong Yuan, Mark Karwan

Open set recognition (OSR) tasks require classifiers to both assign labels to known classes and identify inputs from unknown categories. Traditional OSR approaches often rely on thresholding mechanisms and fail to provide insight into how unknown samples relate to known data. This paper introduces a novel threshold-free OSR framework that integrates a convolutional neural network with a continuous abatement model. The abatement model modifies class probabilities based on nearest-neighbor similarity in learned feature space, producing $|K| + 1$ confidence values—one for each known class and one for the open set. This formulation allows unknown inputs to be interpreted as distributions over both known and unknown regions of feature space, facilitating both detection and contextualization. We evaluate the framework using a synthesized benchmark constructed from MNIST and EMNIST and show that it outperforms a leading threshold-based OSR method across multiple performance metrics. Beyond image data, we extend our approach to contextualize unknown instances in the domain of integer programming classification, demonstrating the flexibility and generalizability of the method. By removing the need for arbitrary thresholds and enabling interpretability for unknowns, this work contributes a new perspective to the OSR literature and offers a practical tool for open-world machine learning applications.

2 - Mapping Industry-Wide Concerns in Hemp Agriculture by Applying Nlp to Public Sentiment on Youtube

Yihan Huang, North Carolina State University, Raleigh, NC, United States, Md Abdul Quddus, David Suchoff, Md Fashiar Rahman

Industrial hemp is now emerging as a valuable crop with wide applications in textiles, construction, and sustainable agriculture. However, serious obstacles still exist in the industry, including strict regulatory environments, inconsistent policies, market volatility, and limitations in processing infrastructure. This study how different hemp stakeholders express their experiences and concerns through public online platforms. By using natural language processing methods, we analyze over twenty-one thousand comments posted on YouTube videos related to industrial hemp. The analysis reveals two dominant themes. First, there is clear frustration surrounding legal restrictions, particularly the low THC threshold and conflicting regulations across regions. Second, many comments reflect growing optimism about the future of hemp, especially in sustainable building materials, technical textiles, and low-input farming systems. To better understand these discussions, we applied advanced sentiment analysis and topic modeling tools to extract emotion, intent, and major talking points from the comments. We also developed a statistical model showing a significant relationship between public sentiment and actual hemp production data, suggesting that online discourse can serve as an early indicator of industry performance. This research highlights the value of combining digital communication and data science to monitor agricultural sectors in real time. The findings offer practical insights for farmers, investors, and policymakers seeking to understand and respond to the rapidly developing hemp market.

3 - Adaptive Imputation Sensor Data with Scheduled Shutdowns

Mohammad Maydanchi, Auburn University, Auburn, AL, United States, Gregory Purdy, Daniel Silva

This study proposes an agentic imputation framework for time series sensor data that selects the most effective imputation model by evaluating its performance. The framework compares three candidate models: SAITS, a recurrent neural network (RNN)-based imputer, and a vector retrieval-driven imputer inspired by Retrieval-Augmented Generation (RAG). To determine the most suitable model for each missing value, the system retrieves similar historical patterns, masks the corresponding data points, and computes standard error metrics such as MAE, MAPE, and RMSE. The model that consistently achieves the lowest aggregated error across the retrieved patterns is then applied to impute the original missing value. Beyond this adaptive selection process, the study also conducts a direct comparative analysis of the three models under varying temporal and structural conditions. Experimental results show that the proposed framework improves imputation accuracy and demonstrates robustness across diverse time series behaviors.

4 - The Trap of Complexity in Experimentation

Yudi Huang, Kellogg School of Management, Northwestern University, Evanston, IL, United States, Sebastien Martin, Zhiwei Qin

In the tech industry, firms increasingly rely on continuous experimentation to guide system updates and improve performance. This paper reveals a subtle, often overlooked cost of such improvements: certain changes that yield immediate gains can increase the system's complexity, ultimately slowing future innovation. Complexity imposes two distinct burdens. First, it diminishes the likelihood of discovering additional successful changes; second, it forces the adoption of more intricate and time-consuming experimental designs, reducing the total number of experiments that can be conducted. Crucially, these future slowdowns remain invisible to standard experimental evaluations, which focus solely on immediate treatment effects.

By modeling this dynamic as a Markov Decision Process, we uncover a surprising pattern. When complexity is low, the firm naturally guards against increasing it. Yet once complexity surpasses a certain threshold, the firm's best response—despite full awareness of the long-term consequences—is to continue implementing complexity-increasing changes, locking itself into a high-complexity, low-innovation regime. Early-stage companies, driven by near-term goals, are especially susceptible to complexity "debt" that undermines their long-run adaptability. These findings caution that while quickly adopting profitable updates may seem optimal in the short term, preserving the ability to innovate at scale demands proactively managing complexity. In doing so, managers can balance immediate opportunities against the need to sustain experimentation and growth over the long term.

5 - Federated Wasserstein Barycenter by Dual Decomposition

Zhengqi Lin, Rutgers University, Piscataway, NJ, United States

We propose an efficient federated dual decomposition algorithm for calculating the Wasserstein barycenter of several distributions. The algorithm does not have access to local data and uses only highly aggregate information. The algorithm exhibits very low complexity of each iteration and significant scalability. We illustrate its virtues on several examples of mixture models.

6 - When More Isn't Better: Understanding the Marginal Impact of Robot Deployment on Campus Food Delivery Performance

Rang Gong, The Ohio State University, Columbus, OH, United States, Xiang Wan

Autonomous delivery robots are increasingly used to enhance last-mile logistics by reducing labor costs and increasing flexibility. However, it remains unclear whether simply adding more robots always leads to better operational performance. This study examines the impact of increasing the number of autonomous robots on delivery efficiency within a campus food delivery system. We utilize a comprehensive dataset that includes delivery logs from a robot company, class and event schedules, and weather data. To estimate the causal relationship between the number of robots and delivery time, we apply a double machine learning approach. In addition to estimating the overall impact, we investigate how this relationship may vary depending on the number of robots already existing in the system and the level of road congestion. Although the study is grounded in a university campus setting, the methodology and insights aim to inform broader applications of autonomous delivery systems, such as urban parcel logistics and drone-based delivery. This research contributes to the literature on automation and operational management by challenging assumptions of straightforward scalability and by offering guidance for more effective deployment and infrastructure planning.

Manufacturing and Service Operations Management (MSOM)

Chair: Sytse Wijnsma, UC Berkeley Haas, Berkeley, CA, United States

1 - Design of Points-Based Systems

Elisabeth Paulson, Harvard Business School, Somerville, MA, United States

This work considering the design of points-based systems commonly used in public sector contexts to allocate scarce resources such as public housing, organs, and visas. Points-based systems rank applicants according to a score, which is the weighted sum of a combination of indicator variables. The weight on a certain feature can be interpreted as the "points" assigned to that feature. In this paper, we provide a framework for determining an optimal score function, taking into account both the accuracy of the function and the cost of including each feature. In terms of feature costs, we consider the cost to applicants of acquiring/reporting the feature, as well as the cost to the administrator of verifying each feature.

2 - Labor Cost, Skills, and Productivity in Circular Operations

Cerag Pince, Quinlan School of Business, Loyola University Chicago, Chicago, IL, United States

As organizations pursue circular initiatives, they face non-traditional challenges in scaling operations. Among the most pressing concerns is labor cost, given that product recovery processes often require manual labor of varying skill levels. However, the variability in input flows and the difficulty of standardizing processes lead organizations to make complex trade-offs in selecting workforce capacity. Motivated by our interactions with a re-X service provider, we examine how circular organizations should determine their labor capacity. The unique features of the re-X context allow us to uncover novel insights into the interplay between labor costs, skill composition, productivity, and the role of process standardization. Our findings address a gap in the sustainable operations literature and offer actionable guidance for managing the distinct challenges of circular operations.

3 - Reducing Food Waste: the Impact of Online Grocery Shopping

Jimin Park, Massachusetts Institute of Technology, Cambridge, MA, United States, Yanchong Zheng

With online grocery shopping growing rapidly in recent years, an important question arises as to how it may impact food waste at the consumer and retail levels. This paper combines an analytical model and numerical analysis calibrated with real-world data to answer this question. In particular, we develop a bi-level optimization model in which the lower level captures consumers' repeat purchase decisions, and the upper level captures the retailer's inventory management problem. A key methodological contribution of our work is to endogenize consumers' repeat purchase decisions and translate them into the stochastic demand faced by the retailer. To tackle this complexity, we establish the unimodality of the retailer's inventory optimization problem within a perishability threshold that is satisfied by most products in practice. Building on this insight, we are able to characterize an asymptotically optimal base-stock policy for the retailer's problem. Our results show that online grocery shopping has the potential to reduce food waste at both the consumer and retail levels, but this potential critically depends on targeting the "right" consumers and products. To counter the increased risk of receiving less fresh products, online retail must enable more frequent purchase by lowering access costs and prioritize products with lower perishability and consumption. Under this strategy, the retailer can also decrease the safety stock held in the system, thereby reducing food waste also at the retail level. These insights highlight that online shopping can create an alignment between the reduction of food waste and greater cost efficiency for the retailer.

4 - Payments for Ecosystem Services: Balancing Upfront and Ex-Post Payments to Overcome Financial Barriers

Zhuoyang Liu, Stanford University, Stanford, CA, United States, Itai Ashlagi, Dan Iancu

Payments for Ecosystem Services (PES)—also known as payments for environmental services—are voluntary transactions in which providers receive compensation conditional on complying with prescribed natural resource management practices. PES schemes have proliferated as tools for environmental conservation and rural economic development in low-income regions with weak regulatory enforcement. Despite their popularity, PES programs suffer from severe adverse selection, rewarding landholders who would have conserved regardless of incentive payments. Moreover, by disbursing funds only after participants have successfully completed costly conservation actions, traditional PES excludes the most financially constrained providers, limiting overall effectiveness and skewing participation toward wealthier landholders.

Although there is ample evidence of adverse selection and financial barriers in PES implementation, no prior work systematically explores how to structure PES payments that mitigate both issues simultaneously. We fill this gap by studying how to optimally design two-stage PES schemes that incorporate both upfront and ex-post payments. Specifically, we develop a novel *two-stage* principal-agent screening model, grounded in contract theory, to analyze the interaction between a resource-constrained ecosystem service provider (the agent) and a buyer (the principal). We characterize the optimal contract structures that balance liquidity support and incentive compatibility, derive managerial insights for improving PES scheme design through coordinated upfront and performance-contingent payments, and calibrate our model with field data to demonstrate the validity and effectiveness of these insights.

5 - Interpretable Data-Driven Policy for Index-Based Yield Protection

Jingsheng Song, Duke University, Durham, NC, United States

Index-based yield protection is an alternative to traditional crop insurance that compensates farmers based on a predefined index (such as rainfall) rather than on actual yield losses. In this research, we propose a data-driven framework to determine the optimal subsidy payment under a government index-based yield protection policy. Our approach requires only minimal changes to widely adopted policies but significantly improves effectiveness. Specifically, it addresses two key limitations of existing policies: First, it accounts for the distinct impact of yield prediction errors on risk-averse farmers across different yield levels, enhancing the robustness to model misspecification. Second, it explicitly incorporates index accuracy when determining payments to farmers. In addition, we provide high-probability convergence guarantees for the parameter estimates used in our algorithm, and extend these to performance guarantees in terms of net benefit (i.e., total farmer surplus minus government expenditure). Finally, we calibrate our model using real-world data to demonstrate the advantages of our proposed approach.

1 - Gold-Medalist Performance in Solving Olympiad Geometry with Alphageometry2**Hoang Nguyen, Georgia Institute of Technology, Atlanta, GA, United States**

We present AlphaGeometry2, a significantly improved version of AlphaGeometry introduced in (Trinh et al., 2024), which has now surpassed an average gold medalist in solving Olympiad geometry problems. To achieve this, we first extend the original AlphaGeometry language to tackle harder problems involving movements of objects, and problems containing linear equations of angles, ratios, and distances. This, together with support for non-constructive problems, has markedly improved the coverage rate of the AlphaGeometry language on International Math Olympiads (IMO) 2000–2024 geometry problems from 66% to 88%. The search process of AlphaGeometry2 has also been greatly improved through the use of Gemini architecture for better language modeling, and a novel knowledge-sharing mechanism that enables effective communication between search trees. Together with further enhancements to the symbolic engine and synthetic data generation, we have significantly boosted the overall solving rate of AlphaGeometry2 to 84% for all geometry problems over the last 25 years, compared to 54% previously. AlphaGeometry2 was also part of the system that achieved silver-medal standard at IMO 2024 <https://dpmd.ai/imo-silver>. Last but not least, we report progress towards using AlphaGeometry2 as a part of a fully automated system that reliably solves geometry problems directly from natural language input.

2 - Tight Finite TIME Bounds of Two-Time-Scale Linear Stochastic Approximation with Markovian Noise**Shaan Ul Haque, Georgia Institute of Technology, ATLANTA, GA, United States, Sajad Khodadadian, Siva Theja Maguluri**

Stochastic approximation (SA) is an iterative algorithm for finding the fixed point of an operator using noisy samples and widely used in optimization and Reinforcement Learning (RL). The noise in RL exhibits a Markovian structure, and in some cases, such as gradient temporal difference (GTD) methods, SA is employed in a two-time-scale framework. This combination introduces significant theoretical challenges for analysis.

We derive an upper bound on the error for the iterations of linear two-time-scale SA with Markovian noise. We demonstrate that the mean squared error decreases as $\text{Trace}(\Sigma^k)/k + o(1/k)$ where k is the number of iterates, and Σ is an appropriately defined covariance matrix. A key feature of our bounds is that the leading term, Σ , exactly matches with the covariance in the Central Limit Theorem (CLT) for the two-time-scale SA, and we call them tight finite-time bounds. We illustrate their use in RL by establishing sample complexity for off-policy algorithms, TDC, GTD, and GTD2.

A special case of linear two-time-scale SA that is extensively studied is linear SA with Polyak-Ruppert averaging. We present tight finite time bounds corresponding to the covariance matrix of the CLT. Such bounds can be used to study TD-learning with Polyak-Ruppert averaging.

3 - A General-Purpose Theorem for High-Probability Bounds of Stochastic Approximation with Polyak Averaging**Sajad Khodadadian, Virginia Tech, Blacksburg, VA, United States**

Polyak–Ruppert averaging is a widely used technique to achieve the optimal asymptotic variance of stochastic approximation (SA) algorithms, yet its high-probability performance guarantees remain underexplored in general settings. In this paper, we present a general framework for establishing non-asymptotic concentration bounds for the error of averaged SA iterates. Our approach assumes access to individual concentration bounds for the unaveraged iterates and yields a sharp bound on the averaged iterates. We also construct an example, showing the tightness of our result up to constant multiplicative factors. As direct applications, we derive tight concentration bounds for contractive SA algorithms and for algorithms such as temporal difference learning and Q-learning with averaging, obtaining new bounds in settings where traditional analysis is challenging.

4 - Online Learning with Limited Switches (and Private Online Learning)**Karan Singh, Tepper School of Business, Carnegie Mellon University, Pittsburgh, PA, United States**

Online algorithms succeed by adapting to new information, but changing decisions often incur significant deployment costs. In this talk, we will see that folklore solutions to this problem are extraordinarily brittle.

Instead, we will address this problem in the online convex optimization framework, where learners can revise their decisions only a few times. We will give near-optimal algorithms for this setting. The resulting regret guarantee captures the *dimension-free* nature of regret bounds typical to OCO and improves prior results.

This problem connects directly to differentially private online learning, where each decision update risks privacy loss. As a key application, we will see the first private online learning algorithm that matches optimal *non-private* regret bounds for sub-constant privacy regimes.

Causal Inference and Predictive Modeling in Complex Systems

Contributed Session

Contributed

Chair: Jungwoo Kim, KAIST, Yuseung-gu, Korea, Republic of

1 - Data-Secure Dual Transfer Learning from Heterogeneous Low-Rank and Sparse Panel Var Model**Yuchen Xu, University of California, Los Angeles, Los Angeles, CA, United States, George Michailidis**

Transfer learning (TL) enhances high-dimensional inference by borrowing strength from auxiliary data sets. We extend TL to multivariate time series settings through a panel Vector Autoregression (VAR) model, whose coefficients decompose into heterogeneous low-rank and sparse components. The proposed algorithm treats the two components independently and automatically detects the transferable auxiliary sources for each. Importantly, it operates solely on pre-trained estimators from the auxiliary panel, thereby preserving data privacy. We establish that the source detection mechanism achieves high accuracy under mild technical conditions. The proposed TL approach delivers significant performance improvements in data-scarce regimes—precisely the scenarios that motivate transfer learning. Extensive numerical experiments based on synthetic data, conducted for both correctly specified and misspecified time series models, along with applications to macroeconomic time series, confirm the practical effectiveness of our method. The results highlight the potential of TL to enhance predictive tasks in complex multivariate time series models when primary data are limited.

2 - Weighted Data Valuation for Statistical Learning via Nonconvex Programming Methods**Hassan Nojavan, Southern Methodist University, Dallas, TX, United States, Miju Ahn, Chul Moon**

We propose a new formulation of empirical risk minimization that accounts for the weights of data points. The proposed formulation aims to simultaneously estimate the model parameters while selecting significant data points. We propose an alternate weakly-convex search algorithm, which is a generalization of the alternate convex search method, and show the convergence results. The proposed method is applied to regression for outlier detection and the top N recommender system problems for data

valuation. Our numerical experiments demonstrate that the proposed approaches deliver high-quality solutions, outperforming some of the existing methods used in practice, while effectively identifying data anomalies.

3 - Tracing the Impact of Macro-Shocks on Annual S and P 500 Direction with Tree-Augmented Naïve Bayes

Taha Gulal, Pioneer Academy, Wayne, NJ, United States, Pervin Erdem, Arjon Bushaj, Serhat Simsek

As events like wartime mobilizations, global pandemics, presidential transitions, and recessions unfold, their immediate ripple effects across key macroeconomic indicators remain difficult to disentangle. Conventional analyses often consider these shocks piecemeal, missing how each one directly reconfigures factors such as interest rates, inflation, unemployment, and investor sentiment. In this study, we deploy a data-driven Tree Augmented Naïve (TAN) Bayes methodology to pinpoint which variables each high-impact event most strongly and directly influences—and to clarify how those links, in turn, steer the S&P 500's annual direction (“Up” vs. “Down”). The resulting model is parsimonious yet preserves accuracy, sensitivity, and specificity, providing investors, risk managers, and policymakers with a transparent map of event-factor pathways that can guide year-over-year asset allocation and contingency planning.

4 - Digital Transformation Disclosures and Inventory Volatility: Evidence from Text Analysis of 10-K Filings

Can Akbas, Southern Illinois University Edwardsville, Edwardsville, IL, United States, Stanislaus Solomon, Minseok Kim

This study investigates whether firms that emphasize digital transformation (DT) in their annual reports exhibit greater supply chain stability, as measured by inventory volatility. We develop a novel firm-year DT intensity score by applying a curated TF-IDF-based dictionary to 10-K filings for U.S. public companies from 2011 to 2023. This textual measure is then matched with Compustat quarterly inventory data to construct intra-year inventory volatility, a key operational indicator of stability and resilience.

Our empirical strategy employs panel regression models with firm and year fixed effects, incorporating standard controls (firm size, leverage, ROA) and supply chain–relevant factors (inventory intensity, demand uncertainty). The study also examines how the DT–volatility relationship varies across uncertainty levels, inventory intensity, and industry type. This research contributes to the growing intersection of supply chain management, digital transformation, and textual analytics. By grounding DT measurement in firm disclosures and linking it to operational outcomes, the study offers a scalable approach to capturing digital strategy execution.

5 - Data Fusion for Predicting Operational Speed

Julio Jurado, University of Oklahoma, Norman, OK, United States, Ali Shirazi

Operational speed plays a critical role in various traffic management activities, such as capacity estimation, safety improvement, and travel time reliability. Traditional models typically rely on statistical approaches and limited data sources. However, the growing availability of high-resolution, multi-source data allows for the development of more accurate predictive models. Leveraging this data requires advanced models capable of integrating and analyzing diverse inputs. This study presents a framework that aggregates data from various sources and uses deep neural networks to estimate traffic speed. Two datasets collected on Interstate 80 (I-80) in Utah and Wyoming are used for modeling. The data includes high-resolution data from speed sensors (aggregated at 5-minute intervals for Utah and 2-minute intervals for Wyoming), weather stations (10-minute intervals), and roadway features. Separate neural network models are trained for each dataset to capture region-specific patterns. These models are then integrated into a stacked model to improve the prediction power using a unified dataset. Evaluation results show that the proposed framework reasonably predicts operational speed under varying conditions.

6 - Combinatorial Latent Class Choice Model for Capturing Multidimensional Preference Heterogeneity

Jungwoo Kim, KAIST, Daejeon, Korea, Republic of, Taesik Lee

Latent Class Choice Models (LCCMs) are widely used to capture taste heterogeneity in discrete choice analysis. However, their single-membership structure constrains all utility coefficients to share a common latent segmentation, leading to three major issues: *oversplitting* (duplicated coefficients for near-identical effects), *undersplitting* (compression of heterogeneity into too few classes), and *misalignment* (inability to accommodate variable-specific segmentations). To relax these restrictions, we propose the *Combinatorial Latent Class Choice Model* (CLCCM). CLCCM first decomposes the utility function into interpretable components and assigns each component an independent latent class structure, so that the overall utility is constructed by combining the class memberships chosen for each component. We develop an EM-based estimation algorithm and apply the model to the data from a discrete choice experiment on breast cancer screening policies in Belarus. Compared with standard LCCMs, CLCCM delivers superior goodness-of-fit, more precise coefficient estimates, offering enhanced insights into class membership and estimated coefficients. These advantages highlight CLCCM's practical utility in uncovering nuanced preference structures, enabling more targeted, data-driven interventions.

1 - Quantifying Discrimination in Outcome Tests

Hans Gaebler, Harvard University, Cambridge, MA, United States

The robust outcome test (Gaebler & Goel, 2025) is a simple and statistically sound strategy for measuring discrimination: If lenders approve fewer loans to one group, but that group repays its loans more often, it suggests lenders subjected that group to a stricter standard, only lending to its most qualified members. This simple logic can reveal that lenders have a double standard, but not how different the standards are. Researchers have developed alternative methods that can quantify the degree of discrimination, but with important tradeoffs: opaque statistical assumptions, restrictive data requirements, and often implausible expectations about decision maker rationality. In this talk, I'll introduce a modified robust outcome test that quantifies discrimination by transparently incorporating prior beliefs about how predictable the outcome (e.g., loan repayment) is. Using our method, we analyze 68 million traffic stops from across the U.S., finding evidence of widespread discrimination—including many instances the robust outcome test would have missed. Across 34 U.S. cities and states, we estimate that 10% to 25% fewer searches of minority drivers would occur under uniform evidentiary standards.

2 - Dynamic Contextual Pricing with Doubly Non-Parametric Random Utility Models

Lan Gao, University of Tennessee Knoxville, Knoxville, TN, United States

In the evolving landscape of digital commerce, adaptive dynamic pricing strategies are essential for gaining a competitive edge. This paper introduces novel doubly nonparametric random utility models that eschew traditional parametric assumptions used in estimating consumer demand's mean utility function and noise distribution. Existing nonparametric methods like multi-scale Distributional Nearest Neighbors (DNN and TDNN), initially designed for offline regression, face challenges in dynamic online pricing due to design limitations, such as the indirect observability of utility-related variables and the absence of uniform convergence guarantees. We address these challenges with innovative population equations that facilitate nonparametric estimation within decision-making frameworks and establish new analytical results on the uniform convergence rates of DNN and TDNN, enhancing their applicability in dynamic environments. Our theoretical analysis confirms that the statistical learning rates for the mean utility function and noise distribution are minimax optimal. We also derive a regret bound that illustrates the critical interaction between model dimensionality and noise distribution smoothness, deepening our understanding of dynamic pricing under varied market conditions. These contributions offer substantial theoretical insights and practical tools for implementing effective, data-driven pricing strategies, advancing the theoretical framework of pricing models and providing robust methodologies for navigating the complexities of modern markets.

3 - Uncertainty Estimation by Density Aware Evidential Deep Learning

TaeSeong Yoon, KAIST, Daejeon, Korea, Republic of, Heeyoung Kim

Evidential deep learning (EDL) has shown remarkable success in uncertainty estimation. However, there is still room for improvement, particularly in out-of-distribution (OOD) detection and classification tasks. The limited OOD detection performance of EDL arises from its inability to reflect the distance between the testing example and training data when quantifying uncertainty, while its limited classification performance stems from its parameterization of the concentration parameters. To address these limitations, we propose a novel method called Density Aware Evidential Deep Learning (DAEDL). DAEDL integrates the feature space density of the testing example with the output of EDL during the prediction stage, while using a novel parameterization that resolves the issues in the conventional parameterization. We prove that DAEDL enjoys a number of favorable theoretical properties. DAEDL demonstrates state-of-the-art performance across diverse downstream tasks related to uncertainty estimation and classification.

4 - High-Dimensional (Group) Adversarial Training in Linear Regression

Yiling Xie, Georgia Tech, Atlanta, GA, United States

Adversarial training can achieve robustness against adversarial perturbations and has been widely used in machine-learning models. This paper delivers a nonasymptotic consistency analysis of the adversarial training procedure under ℓ_∞ -perturbation in high-dimensional linear regression. It will be shown that, under the restricted eigenvalue condition, the associated convergence rate of prediction error can achieve the minimax rate up to a logarithmic factor in the high-dimensional linear regression on the class of sparse parameters. Additionally, the group adversarial training procedure is analyzed. Compared with classic adversarial training, it will be proved that the group adversarial training procedure enjoys a better prediction error upper bound under certain group-sparsity patterns.

5 - Optimal Classification-Based Anomaly Detection with Neural Networks: Theory and Practice

Tian-Yi Zhou, Georgia Institute of Technology, Atlanta, GA, United States

Anomaly detection is an important problem in many application areas, such as network security. Many deep learning methods for unsupervised anomaly detection produce good empirical performance but lack theoretical guarantees. By casting anomaly detection into a binary classification problem, we establish non-asymptotic upper bounds and a convergence rate on the excess risk on rectified linear unit (ReLU) neural networks trained on synthetic anomalies. Our convergence rate on the excess risk matches the minimax optimal rate in the literature. Furthermore, we provide lower and upper bounds on the number of synthetic anomalies that can attain this optimality. For practical implementation, we relax some conditions to improve the search for the empirical risk minimizer, which leads to competitive performance to other classification-based methods for anomaly detection. Overall, our work provides the first theoretical guarantees of unsupervised neural network-based anomaly detectors and empirical insights on how to design them well.

Interpretable Machine Learning

Invited Session

Data Mining

Chair: Cynthia Rudin, Duke University, Durham, NC, United States

Co-Chair: Srikar Katta, Duke University, Durham, NC, United States

1 - Interpretable Neural Networks with Prototypes

Zhicheng Guo, Duke University, Durham, NC, United States

Interpretable machine learning holds transformative potential in high-stakes medical domains, where model transparency is critical for clinical adoption. In this talk, we present a prototypical part-based neural network designed to assist clinicians in classifying EEG patterns along the Ictal–Interictal–Injury continuum to prevent serious brain damage. The model leverages case-based reasoning by grounding decisions in clinically meaningful waveform prototypes, resulting in improved diagnostic accuracy and interoperability. However, developing high-performing interpretable models remains heavily constrained by the availability of machine learning expertise and the efficiency of collaboration between ML researchers and domain experts. To address this challenge, we introduce a framework for editing prototype-based models in real time using Rashomon sets - collections of diverse models with similarly high performance. This approach alleviates the interaction bottleneck by enabling users to explore and generate high-performance, personalized models that align with their domain-specific priors in just minutes, all without requiring a machine learning expert. By shifting control into the hands of clinicians and other domain experts, this Rashomon-based editing paradigm democratizes the creation of trustworthy, interpretable models across a variety of high-stakes medical applications. Together, these contributions advance human-centered AI in medicine, where the collaboration between models and experts is both intuitive and transparent.

2 - Robust Fine-Tuning with LLM Knowledge and Reasoning: News Headline Generation

Tong Wang, Yale University, New Haven, CT, United States, K. Sudhir, Hengguang Zhou

We address reward-hacking failures that arise when aligning language models through preference-based fine-tuning. Our method, **Knowledge-Regularized Alignment (KRA)**, augments each training prompt with concise, validated explanations of *why* one response is preferred over another. These explanations are first hypothesized by a large language model via abductive reasoning, then checked against data before being prepended to the prompt. The added “why-knowledge” guides the model toward behavior justified by coherent reasoning rather than superficial reward cues. Applied to abstractive headline generation, KRA improves both catchiness and relevance while markedly reducing reward-hacking artifacts. The framework is model-agnostic and complements existing techniques such as Direct Preference Optimization.

3 - Simultaneous Inference for Heterogeneous Treatment Effects in Observational Causal Inference

Srikar Katta, Duke University, Durham, NC, United States

While traditional causal inference methods answer whether a treatment works on average, modern causal questions require understanding *for whom* and *under what conditions* a treatment is effective. This shift toward personalized causal inference has led to the explosion of integrating flexible statistical and machine learning methods into the causal inference pipeline. However, as questions surrounding heterogeneity often explore a vast space of potential subgroups or covariate interactions, they implicitly give rise to a multiple hypothesis testing problem. Existing approaches typically either neglect this issue or apply simplistic corrections that are ill-suited to the adaptive nature of modern estimation procedures. Consequently, many subgroup findings risk being false discoveries, undermining the credibility of empirical claims. We present a solution to this problem, prove that our proposed estimator exhibits useful double robustness properties, enables simultaneous inference, and is end-to-end interpretable. Our simulations highlight the issues with existing approaches and demonstrate that our procedure is both more accurate and more flexible than alternatives.

4 - Explaining the Explanations

Xuefei Lu, SKEMA Business School, Suresnes, France, Emanuele Borgonovo, Cynthia Rudin, Elmar Plischke

Explainable artificial intelligence (XAI) is increasingly essential for regulatory compliance and model transparency. Concerns have arisen regarding the explanations generated by widely used methods such as SHAPs, LIME, or other permutation-based techniques. These issues include extrapolation or out-of-distribution problems inherent in many XAI approaches, where synthetic inputs used to calculate explanations may fall outside the data manifold or be impractical in real-world applications. Consequently, this may result in misleading or untrustworthy outcomes. We propose a systematic framework to evaluate the trustworthiness of popular XAI methods by incorporating both statistical and visual diagnostic techniques. Our methodology includes non-parametric tests of model outputs on original and synthetic predictions, as well as anomaly detection of less likely input combinations. We emphasize the importance of identifying these issues to ensure reliable and robust XAI results. The proposed methods are demonstrated using both analytical and real datasets.

Constraint Learning: When a Neural Network Walks into an Optimization Model

Invited Session

Computing Society

Chair: Thiago Serra, University of Iowa, Iowa City, IA, United States

1 - Neural Heuristics for Mathematical Optimization via Value Function Approximation

Justin Dumouchelle, University of Toronto, Toronto, ON, Canada, Rahul Patel, Esther Julien, Jannis Kurtz, Merve Bodur, Elias B. Khalil

Mathematical optimization is an invaluable framework for modeling and solving decision-making problems with many successes in single-level deterministic problems (e.g., mixed-integer linear or nonlinear optimization). However, many real-world problems require accounting for uncertainty or the reaction of another agent. Paradigms such as stochastic programming, bilevel optimization, and robust optimization can model these situations but are much slower to solve than their deterministic counterparts, especially when discrete decisions must be made. This work demonstrates how a single framework based on value function approximation and optimizing over trained neural networks can be adapted to all three domains. Empirically, we find solutions of similar, and in some cases significantly better, quality than state-of-the-art algorithms in each field, often within a fraction of the running time. The datasets and three frameworks, Neur2SP (NeurIPS'22), Neur2RO (ICLR'24), and Neur2BiLO (NeurIPS'24), are open-sourced for further research.

2 - Optimization over Deep Relu Networks Using Penalty Methods

Anirudh Subramanyam, The Pennsylvania State University, University Park, PA, United States, Waquar Kaleem, Henri Lefebvre, Taehyeon Kwon

Optimization over trained ReLU networks is critical for tasks such as verification, compression, and embedding learned constraints into decision-making models. However, exact methods like MILP reformulations and cutting-plane approaches scale poorly with network depth and size, leading to large constraint systems and weak relaxations. We propose a Penalty Alternating Direction Method (PADM) that enforces ReLU complementarity through penalty terms in the objective, avoiding the use of binary variables. Under mild assumptions, we prove convergence to stationary points. Experiments on benchmark problems with very deep networks show that PADM quickly finds high-quality feasible solutions.

3 - Strategies for Solving Mixed Integer Linear Optimization Problems with Embedded Relu Artificial Neural Networks

Alexander Klimek, Max Planck Institute for Dynamics of Complex Technical Systems, Magdeburg, Germany, Christoph Plate, Mirko Hahn, Caroline Ganzer, Kai Sundmacher, Sebastian Sager

When artificial neural networks (ANNs) are formulated with the ReLU activation function, they can be integrated into mixed integer linear programming problems (MILP) using a big-M reformulation. This enables optimization over trained surrogate models using established MILP methods. However, these optimization tasks appear to become challenging for increasing number of neurons and layers, and for optimization problems with multiple ANNs embedded. One reason are the big-M coefficients arising in the reformulation which grow exponentially with the number of layers.

In this work, we examine four ways to speed up MILP optimization over trained ReLU ANNs:

1. Optimization-based bound tightening (OBBT)
2. Novel *a posteriori* ReLU scaling
3. Clipped ReLU
4. Regularization

Our results suggest that OBBT is effective for all trained networks, reducing big-M coefficients by half. The ReLU scaling or clipped ReLU decrease big-M coefficients to a similar degree. Regularization delivers the highest reduction of the big-M coefficients by up to two orders of magnitude. However, only OBBT and regularization appear successful in lowering computational time significantly, to around half, and to as low as 3% of the original time, respectively. This implies that reducing big-M coefficients alone does not suffice. Analysis of the number of linear regions and the number of stable neurons reveals the effectiveness of regularization in improving both, while OBBT does not incur changes in either. Importantly, regularization greatly raises the number of instances that can be solved at all within the specified time limit.

4 - Optimization over Trained Neural Networks: Difference-of-Convex Algorithm and Application to Data Center Scheduling

Xinwei Liu, University of Michigan, Ann Arbor, MI, United States, Vladimir Dvorkin

When solving decision-making problems with mathematical optimization, some constraints or objectives may lack analytic expressions but can be approximated from data. When an approximation is made by neural networks, the underlying problem becomes optimization over trained neural networks. Despite recent improvements with cutting planes, relaxations, and heuristics, the problem remains difficult to solve in practice. We propose a new solution based on a bilinear problem reformulation that penalizes ReLU constraints in the objective function. This reformulation makes the problem amenable to efficient difference-of-convex algorithms (DCA), for which we propose a principled approach to penalty selection that facilitates convergence to stationary points of the original problem. We apply the DCA to the problem of the least-cost allocation of data center electricity demand in a power grid, reporting significant savings in congested cases.

5 - Optimization over Trained (and Sparse) Neural Networks: a Surrogate Within a Surrogate

Thiago Serra, University of Iowa, Iowa City, IA, United States, Hung Pham, Aiden Ren, Ibrahim Tahir, Jiatai Tong

We can approximate a constraint or an objective function that is uncertain or nonlinear with a neural network that we embed in the optimization model. This approach, which is known as constraint learning, faces the challenge that optimization models with neural network surrogates are harder to solve. Such difficulties have motivated studies on model reformulation, specialized optimization algorithms, and—to a lesser extent—pruning of the embedded networks. In this work, we double down on the use of surrogates by applying network pruning to produce a surrogate of the neural network itself. In the context of using a Mixed-Integer Linear Programming (MILP) solver to verify neural networks, we obtained faster adversarial perturbations for dense neural networks by using sparse surrogates, especially—and surprisingly—if not taking the time to finetune the sparse network to make up for the loss in accuracy. In other words, we show that a model with bad classification performance can still be a good—and more efficient—optimization surrogate.

1 - Dimension Reduction via Variable Selection in Importance Sampling

Chenfei Li, University of Michigan, Ann Arbor, MI, United States, Jaeshin Park, Eunshin Byon

Importance sampling is a powerful variance reduction technique used to minimize uncertainty in stochastic simulation. However, it often faces the curse of dimensionality, as the input dimension grows. Grounded in the parsimony principle, we introduce a variable selection metric, which helps reduce input dimension. Additionally, we devise a new cross-validation procedure which accounts for unique challenges present within the importance sampling context. Our method balances concentrating on key variables while exploring broader input areas, thereby enhancing the robustness of estimated outcomes. While broadly applicable, we demonstrate its effectiveness in a nonparametric importance sampling setting.

2 - Wavelet Gaussian Process for Multi-Scale Monitoring of Imaging Data

Runsang Liu, The Pennsylvania State University, University Park, PA, United States, Hui Yang

Advanced sensing brings a plethora of imaging data to handle process variations in additive manufacturing (AM). Realizing the full potential of sensor-based statistical process control (SPC) methods greatly depends on the delineation of defect characteristics and anomalous patterns. However, traditional methods primarily focus on analyzing and monitoring AM images in a single scale. It is common that these images contain hidden patterns pertinent to process deviations that are not accessible in a single-scale view. This paper presents a new wavelet Gaussian process (WGP) framework for multi-scale analysis of variance (ANOVA) and image-guided SPC of AM. First, AM imaging data are examined through multi-scale wavelet lenses to reveal hidden defects in different spatial-frequency resolutions. Second, WGP models are developed to analyze different variance components in wavelet coefficients. Specifically, we separate the variance contribution of stochastic variation, spatial-temporal effects, and process shifts. We further design generalized likelihood ratio (GLR) formulation and multi-scale hypothesis testing approaches to fuse test statistics from different wavelet sub-bands for AM quality monitoring. The proposed WGP approach is evaluated and validated through simulation and real-world case studies. Experimental results demonstrated the effectiveness of the proposed WGP method for multi-scale analysis and monitoring of imaging data.

3 - State Space Model with Random Effects for Autocorrelated Multivariate Ordinal Data

Zengchenghao Xia, University of Iowa, Iowa City, IA, United States

Multivariate ordinal data, frequently manifested as Likert-scale responses, are ubiquitous in healthcare evaluations and fatigue assessment where items are collected repeatedly from numerous subjects. These intensive longitudinal data exhibit both cross-sectional correlations between items and temporal autocorrelations within subjects. However, current statistical methodologies often lack frameworks specifically designed to systematically model the crucial multivariate dependencies inherent in such ordinal longitudinal data structures.

To address this limitation, we propose a state-space modeling framework that systematically accommodates both the ordinal nature of multivariate Likert-scale responses and inter-individual variability via subject-specific random effects. The underlying latent states are posited to follow vector auto-regressive (VAR) dynamics, a specification inherently accommodating flexible contemporaneous and lagged correlation structures. Within the observation model, these latent states then determine the ordinal response for each Likert item relative to a set of ordered thresholds, which themselves evolve dynamically via random walks to capture temporal shifts in response patterns. Parameter estimation, employing a Monte Carlo Expectation-Maximization (MCEM) algorithm with integrated particle filtering and smoothing techniques, yields satisfactory estimators for both model parameters and latent process variables. The practical utility and advantages of this approach are confirmed through numerical simulations and a case study, which highlights its accurate parameter estimation and outperformance of traditional benchmarks in accurately representing the complex interdependencies of multivariate ordinal responses.

4 - On-Demand Machine Learning for Resource-Constrained Classification

Xiaochen Xian, Georgia Institute of Technology, Atlanta, GA, United States, Dongmin Li, Minsung Kang, Gonen Singer, Hongcheng Liu, Md Mahmudul Hasan

In many real-world applications, classification tasks are subject to resource constraints, such as limited resources and budgetary restrictions, which limit the number of testing samples that can be classified into a particular label. While existing methods integrate prediction and optimization models to enhance classification performance, there is a lack of a general approach that incorporates the constraints into the learning process to optimize misclassification cost while ensuring constraint in compliance on testing data. To address this gap, we introduce a novel machine learning framework, “on-demand learning (OL),” which adapts label assignments on testing data based on resource constraints to minimize misclassification cost. OL incorporates cost-sensitive learning techniques, introducing a dynamic class weight into the loss function to integrate prediction and optimization. Leveraging simulated annealing, OL iteratively adjusts the class weight based on prediction results and constraints to identify the optimal classifier. This constraint-dependent adjustment makes the learned model adaptive, adjusting feature prioritization based on constraints, which enables flexible and efficient resource allocation under real-world constraints and costs. Experiments on synthetic and real-world datasets demonstrate the adaptability of OL and its superiority over benchmark methods across multiple classification metrics, highlighting the benefits of incorporating resource constraints into the learning process.

Data-Driven Discovery: Integrating Statistics and AI for Scientific Insights

Invited Session

Quality, Statistics and Reliability

Chair: Ridwan Olabiyi, Arizona State university, Tempe, AZ, 85281, United States

Co-Chair: Yuhao Zhong, Virginia Tech, Blacksburg, VA, 77840, United States

1 - Uncertainty Aware Data Driven Discovery of Governing Equations

Yuhao Zhong, Virginia Tech, Blacksburg, VA, United States

In complex physical systems where domain knowledge is limited or undeveloped, dimensional analysis serves as a powerful tool for characterizing system behavior and discovering governing equations from observed data. However, traditional approaches face two key limitations. First, they often produce non unique dimensionless groups and rely on ad-hoc strategies to infer governing laws. Second, in the absence of comprehensive domain knowledge, these approaches lack mechanisms to handle data uncertainty, making it difficult to quantify the reliability or confidence of the resulting equations. To address these challenges, we propose a two-stage framework that blends projection pursuit Gaussian process (GP) regression with dimensional analysis. In the first stage, we identify physically invariant combinations of input variables. In the second stage, we model the system’s response using a GP over the projected dimensionless space, enabling uncertainty quantification through the GP’s posterior distribution.

2 - Candice: Causal Discovery of Nonlinear Dynamics Through Counterfactual Explanations

Ridwan Olabiyi, Arizona State university, Tempe, AZ, United States

Discovering governing equations from data is a core challenge in scientific research, particularly for complex systems where first-principles derivations are impractical. Recently, sparse learning techniques have been used to extract physics from high-dimensional, noisy data. However, the recovered equations either include extraneous terms or miss critical ones, limiting their generalizability. To overcome this, we propose CaNDiCE—Causal Discovery of Nonlinear Dynamics through Counterfactual Explanations—a parsimonious learning approach to recover the governing equations by identifying causal physics terms. Counterfactuals are generated by minimally perturbing the parameters of the candidate governing equations such that the perturbed system behavior is out-of-distribution with respect to the observed data. The physics terms that drive this transition are deemed causal. We demonstrate the effectiveness of CaNDiCE on benchmark systems, including the Lotka–Volterra and Lorenz systems, where it eliminates extraneous terms while closely matching ground-truth dynamics, outperforming baseline methods by roughly 93% in terms of mean squared error. Our results show that counterfactual explanations serve as a powerful approach for physics discovery, and the proposed methodology is readily extendable to other data-driven applications, enhancing both trust and interpretability.

3 - Machine Learning Powered Graph Network Analysis for Solid-State Battery Cathodes

Zebin Li, University of Wisconsin-Madison, Madison, WI, United States, Shimao Deng, Yijin Liu, Jiamian Hu

The microstructure of particulate composites, particularly the phase boundaries and interfacial contacts, can critically affect the system performance. However, the processes and mechanisms that govern the relationship between microstructure, property, and performance remain highly complex and insufficiently understood. Thus, developing deep insights of how microstructural features impact performance is crucial. Here, we take the composite cathode of SSBs as an example, where triple phase boundaries (TPBs) between particles of mixed active cathodes (e.g., $\text{LiNi}_x\text{Mn}_y\text{Co}_z\text{O}_2$, $x + y + z = 1$, denoted as NMC), solid-state electrolytes (SSE), and conductive carbons (e.g., graphite) play a crucial role in battery performances. X-ray microscopy is a powerful non-destructive imaging technique that enables high-resolution analysis of microstructures. However, it is a computational challenge to process and analyze the high-dimensional and large-volume data with high accuracy, automation, efficiency. In this work, we propose an automated phase segmentation framework supporting particle network analysis for SSBs cathodes based on deep learning. In particular, three components in cathodes, i.e., NMC, SSE, and graphite, are first segmented into three phases using U-Net. Then, graphs are constructed based on the segmentation maps to reflect the connections among different phases. Furthermore, according to the constructed graphs, the TPBs can be searched in a quick and automatic way, enabling the functional relevant analysis for the cathode of SSBs. Our work not only provides an automatic pipeline enabling the analysis from X-ray images to TPBs of SSBs, but also reveals the electrochemical properties of TPBs for better understanding of the mechanism of SSBs.

1 - Feature-Dependent Marginal Values of One Data Point: Active Label Acquisition in Assortment Optimization

Mo Liu, University of North Carolina-Chapel Hill, Chapel Hill, NC, United States, Junyu Cao, Zuo-Jun Shen

Predicting customers' preferences based on their features is crucial for personalized assortment optimization. When building this prediction model, using informative data can significantly increase the expected revenue from personalized assortments. This paper studies how to sequentially collect informative data to construct this prediction model. We introduce a novel concept, the 'value of one data point,' which evaluates the marginal contribution of acquiring a specific customer's preference to the expected revenue in personalized assortment optimization, given the existing training set. Notably, this value drops to zero once the optimal assortment for this specific customer is determined. To estimate this value and identify important customers for acquiring their preferences, we derive a feature-dependent upper bound. This bound provides significant insights into the importance of each data point for revenue growth. Based on this upper bound, we develop a personalized incentive policy for effectively collecting survey data from customers to obtain their preferences. We provide non-asymptotic guarantees for both the cumulative incentives and the revenue from the final prediction model. Theoretically, we show that our personalized incentive policy requires smaller cumulative incentives than any fixed incentive policy to achieve the same level of revenue. Additionally, our numerical experiments with real-world and synthetic datasets validate the effectiveness of our personalized incentive algorithms over fixed strategies.

2 - More Data or Better Data? Impact of Costly Data Collection on the Newsvendor Problem

Zijin Zhang, Carroll School of Management, Boston College, Chestnut Hill, MA, United States, Hyun-Soo Ahn, Lennart Baardman

Data-driven algorithms and policies have flourished in many areas of operations management. While many applications can utilize preexisting data, there are many cases where collecting more and better data is cost-prohibitive and time-consuming. Previous research has mainly focused on improving decision-making for given data, leaving a gap in understanding the optimal quantity and quality of data needed. Our paper studies how the volume (quantity) and noise (quality) of a dataset jointly affects the outcome of data-driven decision-making in the newsvendor problem. We show that, when noise is present, the traditional data-driven methods can result in mediocre outcomes regardless of how large the dataset is. To mitigate the effect of noise, we propose a novel policy that denoises the dataset in order to minimize the noise-robust in-sample cost. Using this denoised approach, we analyze the retailer's out-of-sample newsvendor cost as a function of sample size and noise scale. Our analysis quantifies the marginal newsvendor cost on each dimension, and we find that the newsvendor outcome is non-monotone in both the quantity and quality dimensions. Furthermore, given the cost of data collection, we develop a series of data collection policies and show that collecting a dataset of well-balanced quantity and quality is important.

3 - End-to-End Optimization Framework for Selective Decision-Making

Michael Huang, CUNY Baruch College, New York, NY, United States, Bradley Rava

Modern Artificial Intelligence (AI) tools have reached a point where policymakers can potentially engage in fast and autonomous large-scale decision-making in high-risk settings. However, despite advancements, the adoption of AI in these settings remains controversial as they can be inaccurate and disproportionately affect minority or underrepresented groups and individuals. As a result, many policymakers revert to human-based decision-making, which, unfortunately, can be equally ineffective as decisions are often delayed or require high labor costs. To obtain the best of both worlds, we propose a synergistic Human-AI decision-making framework that efficiently splits decision-making between humans and AI. The framework should rigorously control the trade-off between human decision-making cost vs. AI decision-making cost and be flexible enough to accommodate fairness considerations across different groups.

4 - Learning to Price with Resource Constraints: from Full Information to Machine-Learned Prices

Ruicheng Ao, MIT, Cambridge, MA, United States, Jiashuo Jiang, David Simchi-Levi

We study the dynamic pricing problem with knapsack, addressing the challenge of balancing exploration and exploitation under resource constraints. We introduce three algorithms tailored to different informational settings: a Boundary Attracted Re-solve Method for full information, an online learning algorithm for scenarios with no prior information, and an estimate-then-select re-solve algorithm that leverages machine-learned informed prices with known upper bound of estimation errors. The Boundary Attracted Re-solve Method achieves logarithmic regret without requiring the non-degeneracy condition, while the online learning algorithm attains an optimal $\mathcal{O}(\sqrt{T})$ regret. Our estimate-then-select approach bridges the gap between these settings, providing improved regret bounds when reliable offline data is available. Numerical experiments validate the effectiveness and robustness of our algorithms across various scenarios. This work advances the understanding of online resource allocation and dynamic pricing, offering practical solutions adaptable to different informational structures.

5 - Dissecting the Impacts of Model Misspecification in Data-Driven Optimization

Haixiang Lan, Columbia University, New York, NY, United States, Adam Elmachtoub, Henry Lam, Haofeng Zhang

Data-driven optimization aims to translate a machine learning model into decision-making by optimizing decisions on estimated costs. Such a pipeline can be conducted by fitting a distributional model which is then plugged into the target optimization problem. While this fitting can utilize traditional methods such as maximum likelihood, a more recent approach uses estimation-optimization integration that minimizes decision error instead of estimation error. Although intuitive, the statistical benefit of the latter approach is not well understood yet is important to guide the prescriptive usage of machine learning. In this paper, we dissect the performance comparisons between these approaches in terms of the amount of model misspecification. In particular, we show how the integrated approach offers a "universal double benefit" on the top two dominating terms of regret when the underlying model is misspecified, while the traditional approach can be advantageous when the model is nearly well-specified. Our comparison is powered by finite-sample tail regret bounds that are derived via new higher-order expansions of regrets and the leveraging of a recent Berry-Esseen theorem.

1 - Why Full Refunds Prevail: A Product Fitness Perspective

Chuanshuai Ru, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Fangruo Chen, Weitao Ren, Wenqiang Xiao

This paper investigates the design of return policies in online markets characterized by consumer heterogeneity, product misfit risk and information asymmetry. We consider a monopolistic seller serving a dual-segment market, consisting of informed and uninformed consumers. Departing from prior studies that advocate cost-based partial-refund strategies, we identify product fitness, rather than cost, as the central driver of return policy design. Our analysis reveals that the optimal policy can be implemented via a full-refund contract, achieving operational simplicity without sacrificing profitability. We also find that when mismatched products have residual values, the seller may shift to lower selling prices and partial (or no) refunds to encourage product retention and minimize returns, especially when uninformed consumers dominate the market. The analysis further reveals that full-refund policies are more appropriate for low-value goods, while partial-refund policies better fit high-value products. Our findings offer a unified framework linking product fitness and return strategies, delivering both theoretical contributions and practical insights for online sellers managing returns.

2 - Digital Nudging for Display Optimization in Online Product Listing Pages

Alara Tascioglu, ESCP Business School, Paris, France, Gurhan Kok, Selcuk Karabati

Problem definition: As digital commerce continues to expand, retailers must optimize their Product Listing Pages (PLPs) to guide consumer attention and maximize profitability. While prior research has largely focused on product rankings, the influence of product display on a PLP (location and size) on consumer choice remains underexplored.

Methodology/results: We introduce a location-based Multinomial Logit (LMNL) model for customer choice and jointly optimize default rankings and location sizes to enhance expected profit margins per customer. We also develop a computationally efficient heuristic that closely approximates the model.

Through three structured lab experiments, we find that consumer behavior aligns with LMNL, and varies by device: desktop users exhibit a centripetal U-shaped viewing pattern with faster diminishing returns to space, while mobile users focus more on later scrolls. We optimize PLPs based on parameters estimated in the experiments and verify through additional experiments that these optimized PLPs increase expected profit by 15.13% compared to PLPs with identical location sizes, while randomly selected large displays and products lower them by 18.17%.

Managerial implications: These findings highlight the limitations of test-and-learn approach (A/B testing) due to the combinatorial nature of PLP design and the need for a model-based and data-driven approach. We provide a structured framework for parameter estimation and scalable PLP optimization across devices and PLP structures. By bridging digital nudging, choice modeling, online display optimization, and experimental analysis, our research improves interface design and customer experience.

3 - The Impact of Positive Review Reward on Consumer Review and Product Return: Effect of Reference Point

Huimin Wang, Tianjin University, Tianjin, China, People's Republic of, Yize Li, Min Cai

Online reviews shapes consumer purchase decisions. To encourage positive review, many sellers implement the positive review rewards strategy (PRRS). While PRRS may compromise review authenticity despite regulatory restrictions, their actual impact remains unclear. Drawing on reference point theory, this study empirically examines how PRRS influences consumer reviewing and product returns. Analyzing survey data from 634 consumers in China, we find that PRRS effectively increases genuine positive reviews without significantly boosting fake ones. However, the surge in positive reviews raises consumers' reference point of the product value, leading to subsequent dissatisfaction and negative reviews that counteract the initial boost in purchasing and product returns. Overall, PRRS enhances product sales and consumer surplus. Moreover, our findings indicate low-income consumers in the early stages of their careers are more susceptible to this strategy, making them more prone to posting fake reviews.

4 - From Browsing to Purchasing: Exploring the Influence of User Comments on the Desire Infiltration of Short-Video Sales

Tong Li, Guangdong University of Foreign Studies, Guangzhou, China, China, People's Republic of

With the growing prevalence of short-video e-commerce, consumers experience a complex and dynamic information perception process as they transition from interest-driven browsing to emotion-driven purchasing behavior. Based on the Desire Infiltration Theory, this study explores how information perception in comment sections can guide users to form purchase intentions, aiming to address marketing conversion challenges in the era of interest-based e-commerce and social commerce. Using a dataset from the Douyin platform, we obtained a dataset of 28341 product-promoting short videos and their corresponding 236870 comments, and analyzed the impact of the degree of consumer purchase confidence represented in comments on short-video sales. As each comment in short videos receives a different number of likes, and the number of likes will affect the order of comments in the comment section, we found that 80% of the cumulative total likes came from 20% of the comments, confirming the validity of Pareto's Law. Further empirical testing revealed that the consumer purchase confidence reflected in the top 20% of highly liked comments has a positive impact on short-video sales, while the purchase confidence reflected in all comments shows no significant effect on sales. Our research confirms that in the era of fragmented information in short videos, users under fast-paced information browsing patterns do not have the patience to read all information completely. Therefore, short-video e-commerce platforms need to effectively understand the key influences of users' information perception during the desire infiltration process, so as to formulate effective marketing strategies based on key information perception.

5 - Review Vs Tips: Which One is More Influential? Investigating the Impact of Yelp Tips on Restaurant Reputation

Aindrila Chakraborty, Metro State University, St Paul, MN, United States, Jaymeen Shah

Online recommendation platform Yelp significantly shapes consumer perceptions and informed decisions about local businesses through reviews and Tips. While Reviews mainly focus on detailed user experiences with a business, Tips are more concise, significantly shorter than reviews, and primarily focus on providing immediate, specific insights and recommendations, especially to mobile users. An extensive body of literature exists about the different aspects of reviews and their impact. However, Yelp Tips, which provides concise and more time-sensitive business recommendations, has yet to be explored in the literature. In this study, we aim to bridge this gap by examining the restaurant businesses and investigating whether Yelp Tips, apart from reviews, have any effect on overall restaurant reputation. Utilizing a text analytics-based approach combined with feature engineering on a nationwide dataset of restaurants on Yelp, this study provides significant insights into the distinct role of Tips in shaping customer expectations. Results suggest a substantial impact of Tips on time-sensitive user decisions by forming a quick, real-time, immediate reputation of restaurants to time-sensitive users, especially if they are traveling and in a new place. The insights from this study will enable business owners to make informed decisions about critical business functions to improve customer satisfaction and to manage their online reputation more effectively.

6 - Explainable Recommendations with Personalized Review Summaries

Shuzhang Cai, The University of Texas at Dallas, Richardson, TX, United States, Shaojie Tang

Online platforms such as TripAdvisor now provide AI-generated summaries to condense user reviews for hotels, restaurants, tourist attractions, etc. While these summaries help users quickly acquire a general overview, they often lack personalization and fail to align with individual user preferences across different aspects. In this work, we propose a novel framework that integrates contrastive learning and graph learning to capture nuanced user-item interactions and deliver explainable recommendations in the form of personalized summaries.

1 - Automating Attribute-Based Access Control with LLM Distillation and Graph-Based Policy Modeling

Mian Yang, Rutgers Business School, Newark, NJ, United States

Modern enterprises require scalable and explainable access control systems to enforce security and compliance. However, deriving fine-grained Attribute-Based Access Control (ABAC) rules from policy documents written in natural language remains a significant challenge. In this study, we propose an end-to-end framework for automating ABAC rule extraction and enforcement using Large Language Models (LLMs), knowledge distillation, and graph-based representations.

Our first contribution is a novel flow graph model that encodes ABAC rules as directed graphs with support for permit/deny decisions, conflict detection, and redundancy checking. These graphs enable efficient enforcement and policy reasoning via graph database queries.

Our second contribution introduces a distilled LLM pipeline that identifies subject, object, and action components from natural language access control policies (NLACPs), transforming unstructured sentences into structured ABAC rules. By combining distillation techniques with fine-tuned BERT models, we significantly reduce model complexity while preserving high extraction accuracy.

Together, our approach bridges the gap between natural language policy documents and machine-enforceable access control systems. Experimental results demonstrate the effectiveness of our framework in automating policy extraction, ensuring rule correctness, and enabling scalable enforcement via Neo4j-based graph querying.

2 - Automating Invoice Processing with Rpa and LLM Knowledge Distillation

Yang Li, The George Washington University, Washington DC, DC, United States, Mian Yang

Traditional business processes such as invoice handling remain time-consuming and error-prone in enterprise financial operations. This study presents an end-to-end automated invoice processing pipeline that integrates Robotic Process Automation (RPA), Optical Character Recognition (OCR), and fine-tuned BERT-based models to extract key information from PDF and JPG invoice documents. To improve model efficiency and enable practical deployment, we introduce a knowledge distillation framework that transfers knowledge from a large pretrained language model to a lightweight student model. This allows for faster inference while preserving high extraction accuracy. Extracted data is automatically validated and integrated into enterprise resource planning (ERP) systems through RPA bots. The proposed solution is scalable, cost-effective, and capable of reducing manual workload in real-world financial workflows. Experimental results demonstrate strong generalizability and minimal need for human intervention across diverse invoice formats.

3 - Generating Controllable Visual Stimuli Using Stable Diffusion: a Guide for Behavioral Experimental Research

Joann Liu, University of Florida, Gainesville, FL, United States, Jia Liu, Xinyi Sun

Visual stimuli, such as human faces and product presentation, are pivotal in studying human perception, judgment, and decision-making. Traditional methods for creating experimental stimuli involve significant challenges, including labor-intensive workflows, limited scalability and generalizability, and difficulties in isolating specific visual features. This paper bridges the gap between AI innovation and behavioral research by introducing Stable Diffusion that can generate high-fidelity, controllable visual stimuli in a scalable but cost-effective manner. Stable Diffusion also holds the potential to provide visually interpretable constructs by fine-tuning annotated image datasets. These capabilities can empower researchers to unlock great research opportunities on visual perception and decision-making. This paper starts by explaining the key concepts and techniques, followed by two sets of applications of Stable Diffusion to behavioral experimental research. These applications include systematic manipulations of facial features (e.g., smile intensity, gender neutrality, age progression, and beauty effort) and of product-related images (e.g., visual complexity, packaging design, and background setting), some of which are replications of the stimuli used in the existing literature. The paper further outlines future research directions for integrating generative AI with behavioral science, neuroscience, and adaptive experimental paradigms.

4 - Solving Multi-Stage Stochastic QUBOs with QAOA

Anthony Wilkie, University of Tennessee-Knoxville, Knoxville, TN, United States, Rebekah Herrman, Jim Ostrowski

Multi-stage stochastic optimization models sequential decision-making under uncertainty, where decisions at stage t are made prior to the realization of uncertainty in stage $t+1:t+T$. In many formulations, uncertainty is represented by discrete scenarios evolving between stages, leading to an exponential increase in problem size as the number of stages and scenarios grows. This poses a major challenge for classical solution techniques, particularly for binary decision problems. Quantum computing offers a promising framework for tackling such problems, especially in the domain of combinatorial optimization. The Quantum Approximate Optimization Algorithm (QAOA) is one such variational quantum algorithm designed to solve discrete optimization problems on near-term quantum devices. Extending our previous work, we propose two circuit encoding strategies for solving multi-stage stochastic quadratic unconstrained binary optimization (SQUBO) problems using QAOA. The first approach encodes the deterministic equivalent (DE) formulation by introducing separate decision variables for each scenario. The second employs scenario-qubits (SQ) to compactly represent uncertainty, using conditional unitaries to apply stage- and scenario-specific cost and mixing terms. We compare the performance of QAOA under both encodings in identifying optimal stage-wise decisions, and analyze the associated quantum resource requirements, including qubit counts and circuit complexity.

5 - Learning and Optimization for Low-Altitude Decision-Making: a Resource Allocation Framework Under Self-Imposed Information Constraints

Yuchen Liang, Tsinghua University, Beijing, China, People's Republic of, Chen Wang, Lefei Li

Long-range remote sensing missions often face predictable, intermittent communication with a central coordinator. In such cases, decision-making agents may operate without real-time connectivity, creating a decision setting with self-imposed information constraints. This setting poses two linked challenges: maintaining autonomous performance with limited information and allocating scarce computational resources. We develop a resource allocation framework that balances centralized guidance and local autonomy under these conditions, capturing trade-offs among information acquisition, resource allocation, and task performance. By abstracting physical details into decision-relevant parameters, the study provides a general formulation applicable to a range of intermittent-information problems.

1 - Generative AI Review Summaries: Cognitive and Behavioral Implications for Online Purchase Environments**Akshat Lakhiwal, University of Georgia - Terry College of Business, Bloomington, IN, United States**

Generative artificial intelligence review summaries (GARS) are increasingly deployed on online platforms to condense vast volumes of peer-generated feedback aimed at enhancing product evaluation; however, their current implementations may not align with traditional evaluative cues such as star ratings and detailed user comments. Drawing on prior research on mixed emotions and decision-making in online environments, this study theorizes that the congruence between GARS and conventional representations is vital for coherent information processing. Employing a multi-method experimental design that integrates eye-tracking, fNIRS, and behavioral analyses, we assess the effects of GARS-representation alignment on visual attention, neural activation, and purchase behavior. Our findings reveal that inconsistencies between AI-generated and user-generated content disrupt attentional focus, elevate cognitive effort, and reduce purchase likelihood, thereby underscoring the imperative for robust platform governance in GARS implementations. We discuss implications for platforms, including the need for regular audits of review synthesis processes and interventions to ensure representational congruence, thereby sustaining informed decision-making and preserving the integrity of digital marketplaces.

2 - A Bias-Aware Evaluation of AI Skill Recommendation Systems in Online Labor Markets**Brittany Green, University of Louisville, Louisville, KY, United States**

Online labor platforms increasingly use AI-based systems to recommend skills and guide freelancer development. While these systems offer personalization and efficiency, they may unintentionally interact with well-documented employer bias, leading to unequal and potentially harmful outcomes for underrepresented groups. Prior research has demonstrated that algorithmic systems can reinforce bias over time, yet the fairness implications of skill recommendation systems remain understudied. This study investigates how these systems promote or constrain advancement for groups disproportionately affected by employer bias. We model several skill recommendation strategies and evaluate their long-term impact on freelancer outcomes, including earnings and reputational trajectories. We parameterize a simulation model with hiring data from a major online labor market to assess how these strategies perform under varying levels of employer bias and to quantify disparities in outcomes across freelancer groups. Our findings contribute to the ethical design and governance of AI recommender systems by showing how personalization may mitigate or exacerbate systemic inequities in online labor markets.

3 - Measuring Social and Equity Impacts of LLMs to Assist Staff in Social Service Agencies**Jennah Gosciak, Cornell University, Ithaca, NY, United States**

We aim to evaluate efficacy-bias tradeoffs in AI systems as applied to public services, specifically through a LLM rollout (run by a non-profit partner) aimed to reduce administrative burdens in programs like SNAP (formerly known as food stamps). We first use representative data about statewide SNAP program rules to generate a benchmark dataset of common questions that a social service worker might receive from a SNAP client. We then perform a randomized experiment comparing accuracy in question-answering among (a) social workers, (b) social workers who can see LLM responses to the benchmark questions, and (c) LLMs themselves. In the experiment, we vary the accuracy of the LLM responses shown to different survey participants in order to observe the degree to which social workers may over-rely on LLM responses (even when they are incorrect). We also vary attributes (such as age, disability status, household citizenship status) to observe whether social workers or LLMs disproportionately answer questions incorrectly for certain potential SNAP clients. Finally, we calculate disparities in accuracy across dimensions related to biases, as well as measure changes in time-based efficiency and survey-based administrative burdens when LLMs are provided as a resource. Findings will have significant impacts on LLM procurement in government services; we aim to study whether balance can be achieved between easing administrative burdens while also improving benefits access for all clients.

4 - Shaping the Moral Boundaries of AI Systems: a Regulatory Focus Perspective of Hate Speech Detection by Generative Language Models**Kofi Arhin, Lehigh University, Bethlehem, PA, United States**

Automated content moderation systems rely on human-labeled data to train models that detect and flag harmful content online. Much of the existing literature has focused on improving inter-annotator agreement and intra-annotator consistency through clearer guidelines or better training. Yet, the task of labeling hate or offensive speech is not objective; it is shaped by the moral boundaries of annotators—boundaries that determine what is considered offensive, harmful, or acceptable. As such, existing efforts overlook the question of why annotators disagree in the first place. This question becomes even more pressing as generative AI (genAI) systems assume annotation responsibilities, either by supporting or substituting human labelers. It is therefore important to examine how the labeling decisions of genAI systems reflect context-sensitive moral reasoning similar to that of people. In this study, we examine how annotation guidelines, grounded in the regulatory focus theory, shape the labeling behavior of three genAI systems. We prompt each model with promotion-focused, prevention-focused, and neutral guidelines to classify 450 text samples each as offensive or not offensive. We find that both cross-model variability is influenced by how annotation guidelines are framed, and that these effects are moderated by the degree of linguistic ambiguity in offensive messages and target group saliency. We theorize these effects as evidence of AI moral drift to explain the malleability of genAI moral judgment in response to motivational framing and linguistic ambiguity. Our findings contribute to existing and emerging work on fairness and reliability in AI-assisted content moderation.

FinTech in Information Systems: Blockchain, Decentralized Organizations and GenAI

Invited Session

Information Systems

Chair: Ye Liu, University of Washington, Seattle, United States

1 - Distributed Insurance**Baikun Leng, University of Washington Seattle, Seattle, WA, United States, Rowena Gan**

In the traditional insurance industry, the evaluation of claims is often biased due to the inherent interest of claim assessors in maximizing company profits. We explore the potential of decentralized insurance, powered by blockchain technology, as an alternative approach to mitigate such biases. In decentralized insurance models, claims are evaluated by a "court" of assessors who are independent of the insurance company. These assessors vote collectively to determine the outcome of a claim, with their compensation tied to their alignment with the majority decision. This mechanism incentivizes assessors to provide judgments that reflect the consensus of the group, rather than the financial interests of the insurance company.

2 - Optimal Arbitrage Timing Between Decentralized and Centralized Exchanges**Gustavo Grivol, New York University, NEW YORK, NY, United States, Josh Reed**

In decentralized finance, the timing in which blocks are released on a blockchain is influenced by the existence of arbitrage opportunities. We study a single agent arbitraging a risky asset between a decentralized exchange and a centralized exchange. The decentralized exchange is defined by a bonding function specifying the relationship between the amounts of the risky asset and a numéraire asset in a liquidity pool and the price of the risky asset on the centralized exchange follows an exogenous process that is assumed to be a semimartingale. Our first result shows there exists an equivalence between the bonding function of the decentralized exchange and its arbitrage profit function. We next rigorously define the notion of an arbitrage policy in our framework and its corresponding cumulative profit over a finite time horizon. We then study the problem of determining the optimal arbitrage policy to maximize the agent's expected cumulative profit over a finite time horizon. It turns out that the form of the optimal arbitrage policy varies depending on whether the price process is a martingale, sub- or super- martingale. These results provide insights into how blockchain latency depends on price dynamics. We also extend our results to settings including a discount rate as well as competition between agents.

3 - Genai and Corporate Disclosure: An Empirical Study**Yan Wu, Georgia Institute of Technology, Atlanta, GA, United States, Pan Li, Mingfeng Lin, Dongjun Wu**

The unprecedented capabilities of Generative Artificial Intelligence (GenAI) in text-generation, editing, and comprehension are driving its increasing adoption in corporate disclosures. In this study, we examine the relationship between GenAI and corporate disclosures using publicly available data. Specifically, we focus on the changes in the narrative style of corporate disclosures after Generative AI tools became available. Our preliminary results show changes in the sentiment of corporate disclosures. Practical implications for corporations, investors, as well as regulators are also discussed. This study provides insights into the shifting role of GenAI in corporate disclosures and its potential impact on market reactions.

4 - Governance Interlocks in Blockchain-Based Decentralized Autonomous Organizations

Jing Tian, The Pennsylvania State University, University Park, PA, United States, Ling Xue, Jingzhao An, Xi Zhao

A key phenomenon in the governance of decentralized autonomous organizations (DAOs) is member interlock, in which individual members concurrently engage in the governance of multiple DAOs. Although this practice resembles board interlock in traditional corporate governance, the understanding of individual-level interlock motivations and activities remains limited. In this study, we specifically consider the differential motivations of knowledge acquisition and knowledge utilization for DAO members' interlocks. We utilize a unique context of token airdrop used by Optimism Collective (OP) to attract members from other DAOs. Our analysis illustrates that members utilize their existing governance knowledge in other DAOs to OP governance, such as voting on related governance proposals. Furthermore, interlocking members acquire new knowledge from OP governance, which is applied subsequently in their home DAO governance. Leveraging the special setting to compare airdropped members and non-airdropped members, our analysis reveals that interlocking costs primarily hinder individuals' knowledge acquisition motivation for interlocking. Finally, we find that the interlocking DAO members can influence the voting outcomes of novel OP proposals, and token airdrop can foster this influence by facilitating the contributions from more interlocking members with knowledge acquisition motivation. Our study contributes to multiple streams of research on interlocks, DAO governance, and blockchain token airdrops.

1 - Unveiling the Relationship Between Algorithmic Controls and Fairness Monitoring

Liuliu Qin, Old Dominion University, Norfolk, VA, United States, Yuming He, Lan Cao

As algorithmic management systems increasingly assume key managerial functions such as evaluation, direction, and discipline, concerns about fairness in the workplace have grown. This study examines the relationship between employees' perceptions of algorithmic control and their fairness monitoring behaviors. Drawing on the conceptual frameworks of algorithmic control and fairness monitoring, we investigate how distinct control mechanisms—recommending, restricting, recording, rating, replacing, and rewarding—influence employees' focused attention on distributive, procedural, and informational fairness. Through a two-study design involving scenario-based experiments and field surveys, our research contributes to the literature by integrating fairness monitoring into the algorithmic control discourse and identifying how distinct controls influence perceptions of justice. Practically, the findings can inform organizations on how to align control strategies with fairness expectations to foster trust and engagement.

2 - Monitoring Illegal Content on Digital Platforms

Jishnu Hazra, Indian Institute of Management Bangalore, Bengaluru, India, Tarun Jain

Illegal content uploads on social platforms have grown rapidly in recent years. We consider the situation in which along with the subscription-based legal content on the platform, there is free illegal content that may generate revenues through advertisements for the platform. We analyze three scenarios of illegal content monitoring. We study the optimal content pricing and illegal content monitoring strategies for the content developer and platform firm. We find conditions content monitoring strategies that generate higher payoffs for the digital platform and the content provider.

3 - Improper Modeling of Competing Risks: Impact on Risk Estimation and Algorithmic Fairness

Vincent Jeanselme, Columbia University, New York, NY, United States, Brian Tom, Jessica Barrett

Accurate time-to-event prediction is integral to decision-making in healthcare and beyond, influencing treatment recommendations, resource allocation, and policy guidelines. Survival analysis — the statistical framework used to model time-to-event data — accounts for patients who do not experience the event of interest during the study period, known as censored patients. However, many patients experience events that prevent the observation of the outcome of interest. These *competing risks* are often treated as censoring, a practice frequently overlooked due to a limited understanding of its consequences.

This work theoretically demonstrates why treating competing risks as censoring introduces substantial bias in survival estimates, leading to systematic overestimation of risk and potential disparities in clinical recommendations. First, we formalize the problem of misclassifying competing risks as censoring and quantify the resulting error in survival estimates. Specifically, we develop a framework to estimate this error and demonstrate the associated implications for predictive performance and algorithmic fairness. Further, we assess how differing risk profiles across demographic groups result in group-specific errors, potentially widening disparities in medical delivery. Our findings, supported by simulations and empirical analysis of cardiac event prediction, demonstrate that ignoring competing risks disproportionately impacts the most at-risk groups, potentially amplifying inequity.

By quantifying the error and highlighting the fairness implications of the common practice of considering competing risks as censoring, our work provides a critical insight into the development of time-to-event models: practitioners must account for competing risks to reduce disparities in risk assessment and downstream decision-making.

4 - Effects of Cybersecurity Readiness on Firm Performance: Evidence from Conference Calls

Minh Nguyen, Michigan State University, East Lansing, MI, United States

This work introduces a novel firm-level measure of cybersecurity, termed cybersecurity readiness, developed using text mining techniques. We then employ various empirical methods to estimate the causal effects of this cybersecurity readiness measure on firm performance. Our findings indicate that cybersecurity readiness positively influences firm performance, and this effect remains robust across multiple conditions. These results suggest that firms can benefit from investing in the cybersecurity aspects of information technology and data privacy.

5 - From Black Box to Boardroom: the Role of XAI in High-Stakes Decision-Making

Farzaneh Moghadam, University of North Texas, Denton, TX, United States

In today's fast-moving and uncertain business environment, leaders are increasingly turning to Artificial Intelligence (AI) to guide critical decisions. But as these systems grow more complex, they often become harder to understand—leaving executives to question not just what the AI recommends, but why. This study explores how Explainable AI (XAI) can help decision-makers feel more confident, informed, and in control.

We focus on two key human responses: how well leaders understand the AI's reasoning (AI Awareness), and how much they trust it. Drawing on Decision Theory, we propose that XAI improves decision quality not directly, but by increasing both awareness and trust. To test this idea, we designed an experiment where participants faced a simulated high-stakes decision using either a black-box AI system or one that provided clear explanations for its recommendations.

The results were striking: participants who saw how the AI reached its conclusions felt more assured and made better decisions—faster and with more clarity. Trust and awareness played a crucial role in this improvement.

Our findings offer more than just technical insight—they highlight the psychological bridge that explainability builds between humans and machines. For organizations investing in AI, the message is clear: empowering decision-makers means going beyond performance metrics. It means designing systems that people can understand, relate to, and rely on—especially when the pressure is high.

This research adds to the growing conversation around human-centered AI and offers a roadmap for making advanced technologies more effective, ethical, and usable in the real world.

1 - Potential-Based Greedy Matching for Dynamic Delivery Pooling

Matias Romero, Columbia Business School, New York, NY, United States, Hongyao Ma, Will Ma

We study the pooling of multiple orders into a single trip, a strategy widely adopted by online delivery platforms. When an order has to be dispatched, the platform must determine which (if any) of the other available orders to pool it with, weighing the immediate efficiency gains against the uncertain, differential benefits of holding each order for future pooling opportunities. In this paper, we demonstrate the effectiveness of using the length of each job as its opportunity cost, via a potential-based greedy algorithm (PB). The algorithm is very simple, pooling each departing job with the available job that maximizes the savings in travel distance minus a half of its distance (i.e. the potential). On the theoretical front, we show that PB significantly improves upon a naive greedy algorithm in terms of worst-case performance: as the density of the market increases, the regret per job vanishes under PB but remains constant under naive greedy. In addition, we show that the potential approximates the marginal cost of dispatching each job in a stochastic setting with sufficient density. Moreover, we conduct extensive numerical experiments and show that despite its simplicity, PB consistently outperforms a number of benchmark algorithms, including (i) batching-based heuristics that are widely used in practice, and (ii) forecast-aware heuristics that estimate the marginal costs of dispatching different jobs using historical data.

2 - Analytics for on-Demand Food Delivery: A Hurwicz Perspective for Three-Sided Platforms

Qinghe Sun, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, Ziao Zhao, Li Chen

Problem definition: We study operational decision-making in three-sided on-demand food delivery (OFD) platforms, which coordinate customers, restaurants, and couriers under uncertainty. The key challenge is to dynamically optimize order assignment and courier relocation to balance competing stakeholder objectives—minimizing delivery delays and expired orders while preserving courier availability and ensuring fair workload distribution—amid ambiguity in order arrivals and transit times. **Methodology/results:** We develop a multi-period, multi-objective optimization model that balances stakeholder-specific goals. To manage uncertainty flexibly and effectively, we propose a Hurwicz satisficing optimization (HSO) framework that determines the minimal level of optimism under which the decision-maker's objectives remain attainable despite ambiguity. Leveraging the nice properties of the proposed certainty equivalent, we derive tractable reformulations of the proposed HSO model. Implemented via a rolling-horizon mixed-integer program, the HSO model consistently outperforms heuristics and deterministic baselines in real-data experiments, achieving superior trade-offs among the performance dimensions. **Implications:** Our findings underscore the critical importance of accommodating uncertainties in balancing stakeholder objectives in a three-sided market. The results demonstrate the value of ambiguity-aware decision-making and offer actionable insights for platform operators. This work also contributes to the broader literature on robust and multi-stakeholder optimization in OFD operations under uncertainty.

3 - Optimization of Courier-Order Matching and Delivery Performance for in-TIME Delivery Systems

Keji Wei, Tongji University, Shanghai, China, People's Republic of, Yi Fan, Yufeng Cao, Xi Xiong

Meal delivery services face growing demand, making it essential for platforms to improve efficiency and delivery speed. To address this, we introduce the Adaptive Delivery Matching with Agent-based Courier Reinforcement Optimization (AD-MACRO) framework, which tackles the match-delivery decision problem for delivery platforms.

Our approach employs a two-layer decision framework designed for multi-agent environments, leveraging distributed reinforcement learning and optimization methods to manage decision-making challenges. To deal with the complexity of large numbers of agents, we propose the Grouped-Actor Policy Proximal Optimization (GAPPO) algorithm. GAPPO reduces decision-making complexity by grouping agents with similar characteristics, effectively handling the heterogeneity between platform-employed and crowdsourced couriers.

We validate the framework using real dispatch data from Meituan, showcasing its ability to enhance delivery performance. Additionally, to improve practical relevance, we incorporate couriers' rejection behaviors, modeled through fixed probabilities and economic incentives. By integrating these factors along with transportation equity considerations, our framework optimizes both order assignments and delivery performance. The results include a 77.61% reduction in delay rates and a 50.52% increase in couriers' leisure time.

This leads to an effective solution that benefits all parties involved—platforms, couriers, and customers—by improving efficiency, reducing delays, and ensuring fairer working conditions for couriers.

4 - Data-Driven Real-Time Online Platform Food Delivery Optimization: The Meituan Case

Nicolas Kuttruff, Technical University of Munich (TUM), Munich, Germany, GOLMAN RAHMANIFAR, MOSTAFA MOHAMMADI

Dynamic and uncertain environments in Online Food Delivery (OFD) systems present major challenges for real-time courier-order assignment, particularly under tight spatiotemporal constraints and behavioral uncertainties. Motivated by the 2024 INFORMS TSL–Meituan Data-Driven Research Challenge, this study proposes a real-time optimization framework for the courier-order assignment problem, formulated as a Continuous Markov Decision Process (CMDP). In contrast to batch-based dispatching, the CMDP supports event-driven, order-level decision-making, enabling agile responses to evolving system conditions. A Matching Degree (MD) function guides assignment by incorporating spatial feasibility, detour cost, workload balance, and timing penalties. To further enhance operational performance, a postponement mechanism defers assignments when advantageous, allowing the system to exploit future information and improve order consolidation. Courier acceptance behavior is modeled using a Discrete Choice Model (DCM), capturing context-specific acceptance probabilities based on delivery distance, time of day, and demand intensity. The CMDP framework is benchmarked against a Rolling Horizon Assignment (RHA) policy, which makes myopic assignments without considering future demand variations. Numerical experiments show that CMDP outperforms the benchmark RHA strategy with higher responsiveness (≤ 0.41 seconds), higher throughput (1,887 vs. 1,558 orders), and lower rejection rates (19.33% vs. 29.87%). The framework also scales efficiently, with minimal computational overhead as order volume doubles. Moreover, CMDP leads to higher courier utilization (78% vs. 15%), reflecting improved allocation effectiveness.

5 - Delay-Risk Minimizing Order Dispatch in Online Food Delivery Platforms

Ning Zhu, University of Science and Technology of China, Hefei, Israel

The rapid growth of the meal delivery industry and increasing market competition have intensified the need for efficient and reliable delivery operations to enhance customer satisfaction. This paper addresses the order assignment problem for on-demand meal delivery platforms, aiming to minimize delay risks under delivery time uncertainty. We propose a delay-risk minimization model based on two delay-related metrics: total expected delivery delay (TEDD) and joint delay probability (JDP), which capture the severity and frequency of late deliveries. To account for uncertainty, we adopt a distributionally robust optimization (DRO) framework with a mean-variance ambiguity set constructed from historical delivery data and predictions from a linear regression tree (LRT) model. The DRO model is reformulated into a linear assignment problem, enabling efficient real-time optimization and deeper analysis of delivery trade-offs. Numerical experiments on real-world data validate our model's effectiveness, showing that robust assignment strategies significantly reduce delay risks while balancing delivery efficiency and reliability. Unlike traditional delivery time-based objectives, which fail to translate shorter delivery times into lower delay risks, the delay-related metrics improve service reliability with only a minimal compromise in efficiency. These findings highlight the practical value of our approach for enhancing operational performance in dynamic delivery environments.

1 - Penalty Functions for Truck-and-Drone Routing Problems

Ke Xu, University of Southern California, Los Angeles, CA, United States, John Carlsson

Drones are increasingly being integrated into last-mile delivery networks to alleviate reliance on conventional ground trucks. This collaboration can involve various combinations of trucks and drones and incorporate diverse operational constraints tailored to specific delivery requirements. In previous studies, however, each problem variant is typically addressed by a specialized solution method. In this study, we introduce a versatile heuristic approach based on the Lin-Kernighan-Helsgaun algorithm with penalty functions to solve a wide range of drone-assisted delivery variants with a unified solution framework. Its flexibility and effectiveness are demonstrated through numerical experiments on benchmark instances designed for several representative problem variants, including the Flying Sidekick Traveling Salesman Problem (FSTSP), the Traveling Salesman Problem with Multiple Drones (TSP-MD) and the Vehicle Routing Problem with Drones (VRPD).

2 - Predict-Then-Optimize Inventory Placement in Modern Warehousing

Ahtesham Bakht, USF, Tampa, FL, United States, Hadi Gard

The evolution of modern warehousing—driven by e-commerce, robotics, and AI—signals a paradigm shift from static, rule-based inventory placement to dynamic, data-driven strategies. In this study, we propose a predict-then-optimize framework that integrates demand forecasting and pairwise co-order frequencies with integer programming to generate optimized inventory placement plans. Our approach enables smarter, more adaptive warehousing by aligning item locations with predicted order patterns. We demonstrate the effectiveness of our method through numerical experiments and a real-world case study focused on order picking efficiency.

3 - A Novel Approach for Dynamic Pallet Allocation in Next-Generation Logistics Systems

Dilhani Marasinghe, University of Tennessee at Chattanooga, Chattanooga, TN, United States, Pubudu Jayasekara

Efficient pallet assignment plays a vital role in optimizing warehouse operations within next-generation logistics systems. This study presents an optimization model for dynamic pallet allocation to both outbound trucks and storage locations, with the objective of minimizing total operational costs. The model operates within an open horizontal collaborative network, where facilities differ from traditional cross-docks and breakbulk terminals. Unlike conventional systems, freight in this setting lacks a predetermined route from origin to destination, requiring real-time, adaptive decision-making. Experimental results from a simulated environment representing this new type of logistics facility show notable improvements in efficiency and resource utilization over conventional rule-based strategies. To further enhance operational performance, we explore the use of a machine learning algorithm that enables the system to learn from historical patterns and adapt to dynamic logistics conditions.

4 - Optimizing Volunteer Deployment and Routing in Food Banking Systems with Equity Constraints

Hiruni Niwunhella, North Carolina State University, Raleigh, NC, United States, MehrSadat Salami, Leila Hajibabai, Faisal Alkaabneh

Efficient volunteer deployment and routing are critical for ensuring equitable and timely food distribution in non-profit food banking systems. This study presents an optimization approach to assign volunteers to service locations and design routing plans while upholding equity constraints. The objective is to minimize operational costs (efficiency) and ensure fair assignment distribution (equity), considering factors such as volunteer availability, service center demand, vehicle capacity, and time windows. The problem is defined as a vehicle routing problem with pickup and delivery with equity constraints (VRPPD-e) and formulated using a mixed-integer linear program. To address scalability and improve computational performance, heuristic refinements and decomposition strategies are incorporated to solve the problem. Specifically, we develop a customized branch-and-price algorithm incorporating Lagrangian relaxation to solve large-scale instances of the developed model. Numerical experiments conducted on a test network highlight the model's effectiveness in achieving both efficiency and equity. It is also extended to a large-scale implementation in Durham, NC, involving more volunteers, service centers, and operational complexities. This work offers a practical approach to optimizing volunteer logistics in food banking, supporting equitable and efficient service.

1 - Flood-Resilient Electric Vehicle Infrastructure: a Bi-Level Optimization Framework for Urban Transportation Networks

Wencheng Bao, University of Illinois Urbana-Champaign, Urbana, IL, United States, Eleftheria Kontou

Rapid growth in electric-vehicle travel, combined with more frequent flooding events, is challenging the resilience of urban-transportation-systems. The advent of electric road transportation and its infrastructure, like charging stations, underline the need for fortification against hazardous flooding events. We present a novel optimization framework that jointly prescribes road hardening, and charger retrofits to mitigate transportation systems performance reduction during flooding. The problem is set as a bi-level program: the upper level minimizes expected transportation system disruption costs subject to budget for retrofits, while the lower level models traveler response through a stochastic user equilibrium assignment that embeds: (i) flooding impact link travel times, (ii) M/G/K/∞ queue for en-route Level-2 and DC-fast-charging dwell times, and (iii) reachable-demand-chain that filters paths by battery range. We solve the lower level with Method-of-Successive-Averages and wrap the bi-level search in a tabu-guided-hyper-heuristic. The framework is implemented to the Chicago Metropolitan Area's road network. Workflow data include Sentinel-1-derived-flood-depth-rasters processed with the Floodwater-Depth-Estimation-Tool, K-means-clustered charger inventories, and Deep-Gravity-origin-destination matrix generation. Simulation over a 12-hours storm shows flooding event disables 41.4% of origin-destination pairs. Prescribed targeted repairs restore up to 94.3% of those trips while remaining within the retrofit budget. Incremental investments cut mean in-vehicle time from 153 to 77 mins and curb average charging queues from 33.9 to 8.44 mins. The analysis shows the value of behavior-driven prioritization for infrastructure fortification. The framework equips planners with a new model for allocating limited resilience funds across roads and charging assets as electric-vehicle adoption accelerates and hazardous events intensify.

2 - Scalable Optimization of EV Charging Networks: Combining Column Generation with RL-Driven Pricing

Iason Liagkas, University of Michigan Ann Arbor, Ann Arbor, MI, United States, Neda Masoud, Shiyue Zhao

The growing adoption of electric vehicles (EVs) necessitates a robust, strategically deployed charging infrastructure. This research introduces a two-level decision-making framework for optimal EV charger placement and dynamic pricing. We integrate mathematical optimization for charger siting with reinforcement learning (RL) for real-time price adjustments, addressing both long-term spatial allocation and short-term demand fluctuations. To solve the large-scale optimization problem, we employ a **column generation approach** that iteratively explores profitable charging configurations. Four specialized heuristics are designed to enhance this exploration: (1) **Greedy Demand-Based Heuristic**, prioritizing high-traffic zones based on historical demand; (2) **Dual Price-Guided Heuristic**, leveraging dual prices from the master problem to identify zones with the greatest marginal value; (3) **Hybrid Greedy + RL-Informed Sampling**, combining demand estimates with RL-driven profitability insights for refined zone selection; and (4) **Monte Carlo Sampling with Constraints**, exploring diverse configurations to discover non-obvious, high-potential placements. Each candidate configuration is evaluated using RL-based pricing strategies to determine profitability, ensuring only the most promising are added to the master problem. This joint optimization-pricing model provides a scalable, data-driven solution for EV infrastructure planning, dynamically responding to user behavior and competitive pricing. Our results demonstrate that this integrated framework maximizes revenue while ensuring accessibility, offering practical insights for urban mobility planners and investors.

3 - Optimizing Infrastructure and Charging Strategies for Electric Delivery Fleets Under Pv, Grid, and Cost Constraints

Joel Weingart, ZHAW - School of Engineering, Zurich, Switzerland, Maike Scherrer

The electrification of commercial delivery fleets introduces complex trade-offs between infrastructure investment, operational flexibility, and energy cost efficiency. This study presents a strategic optimization model designed to support long-term planning decisions for electric vehicle (EV) fleets and corresponding charging infrastructure. The model focuses on minimizing the Total Cost of Ownership (TCO) by jointly optimizing the sizing of photovoltaic (PV) systems, stationary battery storage, vehicle batteries, and grid connection capacity. It also incorporates fast and bidirectional charging capabilities to enhance system flexibility and reduce grid dependency.

Formulated as a Mixed-Integer Linear Programming (MILP) problem, the model evaluates a wide range of infrastructure configurations under realistic boundary conditions, using one-hour time steps. Key input data include high-resolution, year-long PV generation profiles, dynamic electricity tariffs, vehicle energy consumption patterns, and operational schedules derived from a real-world parcel logistics case study in Switzerland. The model is embedded in a scenario-based framework, allowing for the systematic exploration of infrastructure sizing options and their associated cost-performance trade-offs.

Results demonstrate how the temporal alignment between PV production and fleet availability, as well as the capacity to store and redistribute energy within the fleet, significantly influence cost optimization outcomes. The model highlights the value of bidirectional charging and seasonal planning in reducing peak grid demand and operational expenses. This work provides a scalable decision-support tool for logistics operators seeking to transition to electric fleets while maintaining cost control and energy resilience.

4 - Charging Station Operation Optimization for Middle-Mile Commercial EVs with Travel Behavior and Time-Varying Energy Costs

Yuta Tsutsumi, The University of Osaka, Suita, Japan, Katsuya Sakai, Hiroshi Morita

The adoption of electric vehicles (EVs) in logistics has been rapidly expanding, particularly in last-mile delivery operations. However, the transition to EVs for middle-mile deliveries, which refer to trips between distribution centers, remains limited due to the short driving range of EVs. To enable widespread use of EVs in middle-mile logistics, it is essential to consider not only the deployment of charging infrastructure but also its efficient operation. Although many existing studies have focused on the optimal placement of charging stations, research on optimizing their operation under dynamic electricity pricing remains scarce. In this study, we propose a mathematical optimization model to determine time-dependent charging prices at each station, aiming to minimize the total social cost, which includes vehicle travel distance, traffic congestion, and electricity consumption. The model assumes that each commercial EV independently chooses its route and charging schedule to minimize its own generalized cost, defined as the sum of travel time, travel distance, and charging price. By incorporating time-varying electricity prices that increasingly reflect fluctuations in renewable energy supply, lower charging prices can be interpreted as indicators of enhanced renewable energy utilization and reduced societal energy costs. To capture temporal variations in charging demand, we introduce time windows for charger availability. This addition enables the model to represent both the spatial and temporal dynamics of EV logistics operations. The proposed framework provides a socially optimal strategy for operating existing charging infrastructure and offers valuable insights into the integration of transportation and energy systems for sustainable logistics planning.

5 - A Two-Stage Stochastic Optimization Model for the Equitable Deployment of Fixed and Mobile Electric Vehicle Charging Stations

Hamid Najafzad, University of Texas at San Antonio, San Antonio, TX, United States, Omar Abbaas, Gabriel Nicolosi, Moddassir Khan Nayeem, Fuhad Ahmed Opu, Yara Altarawneh

A major barrier to wide Electric Vehicles (EVs) adoption is the absence of a reliable and equitable charging infrastructure. Rigid and poorly situated charging stations create coverage gaps and slow down EV adoption especially in underserved communities. This paper proposes a two-stage stochastic mixed-integer programming model for the optimal deployment of Fixed and Mobile Charging Stations (FCSs and MCSs) across multiple zones and periods. At the beginning, a finite dominating set of candidate locations is identified using the Edge Scanning Search (ESS) algorithm, an exact and continuous location method. We modify the ESS algorithm to incorporate existing public charging stations within the network, thereby avoiding redundant coverage and enhancing solution efficiency. In the first stage of our model, FCSs are allocated based on long-term traffic patterns, budgetary constraints, and socioeconomic factors to ensure stable baseline coverage. The second stage dynamically assigns MCSs in response to short-term demand fluctuations and uncertainties, aiming to minimize relocation costs while maximizing coverage. We use a scenario-based framework to capture variability in demand during peak and off-peak hours. Numerical experiments on realistic networks demonstrate the model's capacity to enhance system resilience and reduce unmet demand. Additionally, comparative results reveal that hybrid deployment strategies integrating both FCSs and MCSs outperform fixed-only approaches in terms of cost-efficiency, adaptability, and social equity. These findings offer practical insights for planners and policymakers focused on developing accessible and demand-responsive EV charging infrastructure.

Ridesharing Operations

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Yifan Shen, University of Washington, SEATTLE, WA, United States

1 - Models to Balance Stability and Efficiency in Multi-Rider Ridesharing Systems

Hoda Atef-Yekta, James Madison University, Potomac, MD, United States, Mohsen Emadikhav

Most ridesharing research focuses on enhancing overall efficiency, such as reducing total travel distance or increasing platform profits. However, focusing only on efficiency does not ensure a stable solution. In shared rides, a rider's experience is shaped not only by cost but also by the combination of the co-riders, impacting the pickup time and the route distance. If a subset of dissatisfied riders can collectively improve their outcomes by deviating from the platform's assigned matches and form a new group, they create what is known as a blocking coalition. The presence of such coalitions can lead to instability, making the platform vulnerable to losing riders to competing services that offer more attractive ride options.

We propose two optimization paradigms to address stability in multi-rider ridesharing systems. In the first approach, we develop integer and mixed-integer programming models that explicitly encode stability requirements as constraints. In the second approach, we introduce a novel side-payment scheme, where monetary incentives are used to subsidize certain riders and discourage the formation of blocking coalitions. We highlight the effectiveness of our proposed approaches to balance efficiency and stability under various scenarios.

2 - On-Trip Matching for Shared Rides

Yifan Shen, University of Washington, SEATTLE, WA, United States, Julia Yan, Chiwei Yan

This research studies pricing and matching decisions for shared rides, where multiple passengers are pooled into the same vehicle. The predominant shared rides model is based on non-bipartite matching, and makes all matching decisions pre-trip: riders are either matched with each other before dispatch, or sent out alone, with no further matching allowed. This provides a parsimonious model of platform operations, but fails to explicitly consider the continued matching potential of riders initially dispatched solo – who may later be matched as compatible requests arrive.

We focus on on-trip matching, which allows riders to be dynamically matched with others while en route. In this setting, requests are dispatched immediately, avoiding rider waiting time, but have continued matching potential throughout their trip. This opens up the possibility of multi-party matching and enables the formation of trip chains, where a vehicle serves a sequence of pick-ups and drop-offs across compatible riders. While such strategies may be already heuristically used in practice, the dynamically varying matching values of riders on-trip are not captured in existing optimization models.

We aim to analyze the value of on-trip matching – identifying the conditions under which it improves system outcomes relative to pre-trip policies. We also study how platforms should price under this matching policy, and develop scalable algorithms to solve the pricing and matching problem.

3 - Two-Stage Matching in Ridehailing Systems

Xiyitao Zhu, University of Illinois Urbana-Champaign, Champaign, IL, United States, Hai Wang, Lavanya Marla

In nowadays ride-sourcing markets, it is common for ride-sourcing platforms (e.g., Uber, Lyft) to hold unserved passengers and idle vehicles for a short period of time and then batch match them for better systemic performances. The intuition is that better matching outcomes could be obtained in a denser bipartite graph with more supply and demand information accumulating over time through waiting. However, in current practice of the batch matching framework, such information accumulation is only captured by the batch matching time interval. To more effectively utilize information gained through waiting beyond the batch matching time interval, this work proposes a passenger-based two-stage matching framework, which features two stages of waiting with duration T_1 and T_2 enforced by the platform for each passenger. In this framework, each waiting passenger only receives an initial vehicle assignment from the platform after the first successful match and the platform could improve his final vehicle assignment later. This study models the system equilibrium of the dynamic matching process under the two-stage matching framework, and analyze how different system performance metrics (expected matching rate, expected waiting time, etc) are influenced by platform decisions, duration of the two stages and maximum matching radius. The theoretical findings are then validated by both analytical results, which are collected by solving a system of non-linear equations, as well as simulation results, which are collected from an agent-based simulator. It is shown that with proper selection of values for platform decisions, this two-stage matching framework improves performances of the ride-hailing systems.

4 - The Value of Learning in Peer-to-Peer Transportation Matching Problems

Ran Hu, Rensselaer Polytechnic Institute, Troy, NY, United States, James Bailey, Marlin Ulmer

We consider a dynamic matching problem where an online matching platform (e.g., UberEATS) assigns on-demand delivery requests to a fleet of crowdsourced suppliers/drivers. Throughout the day, customers arrive in the system and request delivery from stores to their home locations. Suppliers, operating independently, have the option to accept or decline delivery offers based on features such as location, distance, and expected compensation. However, online matching platforms do not have direct knowledge of the suppliers' choice/decision functions, which adds additional uncertainty to the online matching problem. To address this problem, we introduce online learning techniques to learn a supplier's choice function based on past accept/reject decisions to accurately predict supplier behavior. Motivated by methods in reinforcement learning, we create a closed feedback loop that balances speedy deliveries with preference learning, enabling adaptive and efficient supplier-customer matching under uncertainty.

5 - Who Gets to Ride? Comparing Transportation Eligibility Policies for Saanich Public Schools

Olivia Phillips, Georgia Tech, Atlanta, GA, United States, Arthur Delarue, Sebastien Martin

In public school transportation, eligibility policies determine which students get to ride the bus and which do not. Determining the operational cost of individual eligibility policies is an intractable problem and school districts must often make decisions with incomplete information. We collaborate with the Saanich School District in British Columbia, Canada, to develop methodologies to evaluate the costs and benefits of various eligibility policies. Our work involves both analyzing the current policy as well as designing optimization models that maximize utility while keeping costs below a given threshold.

Invited Session

Analytics Society

Chair: Bahareh Kargar, New Jersey Institute of Technology, Martin Tuchman School of Management, Newark, NJ, United States

1 - Enhancing Meat Supply Chain Decision-Making Using Fine-Tuned Vision-Language Models and Robust Optimization

Bahareh Kargar, New Jersey Institute of Technology, Newark, NJ, United States, Majid Baqeri, Hamed Jahani

The meat supply chain (MSC) faces significant challenges due to the perishability of products, leading to substantial economic and environmental costs. Traditional monitoring and logistics methods often fail to provide real-time predictive insights needed to mitigate spoilage risks. In this study, we propose an AI-driven framework integrating fine-tuned vision-language models (VLMs) — specifically NVILA and Qwen-VL — with a robust optimization model for improving freshness prediction and logistics management in MSCs. Using the Meat Freshness Image Dataset, we fine-tune VLMs to classify meat into freshness categories and employ these predictions within a distributionally robust optimization (DRO) model to manage storage, transportation, and spoilage decisions under uncertainty. Our framework leverages Wasserstein-based DRO to model uncertainties in freshness, demand, and transportation times, leading to improved cost efficiency, service levels, and supply chain resilience. Extensive numerical experiments demonstrate that our approach significantly reduces worst-case costs and spoilage compared to nominal optimization methods, offering a scalable and effective solution for perishable supply chain management.

2 - Transforming Early Autism Detection by AI-Powered Video-Based Gait Analysis

Ziteng Wang, Northern Illinois University, Dekalb, IL, United States, Sinan Onal, Allison Gladfelter, Milijana Buac

Although children show clinical signs of autism early in their development, many children are not diagnosed until well into preschool years, and children from low-resourced, underserved, and rural backgrounds are diagnosed at an even later age. Moreover, current practices designed to detect autism rely solely on parent reports and clinician observations. There is a critical need for accessible, innovative, and more inclusive tools for early detection of autism. The objective of this research is to develop an easily accessible early autism screening web-based application to objectively assess children's walking gait to provide an autism index. The research is not intended to replace current diagnostic practices, but rather to offer a cost-effective, readily accessible way to screen for autism. We created a mobile-friendly website where a user (for instance, parent of the child being screened) can upload phone-recorded videos of the child walking, along with basic demographic information, and will receive an autism likelihood index, with an interpretation guide and suggested actions, as output. We use AI-powered gait models and deep learning models to predict the child's likelihood of autism. The preliminary test shows over 80% accuracy.

3 - Integrating Generative Adversarial Networks and Distributionally Robust Optimization for Green Manufacturing Capacity Planning

Xin Zhou, Antai College of Economics and Management, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Bo Zeng, Zhengsong Lu, Na Geng

Green manufacturing has become a strategic priority for firms seeking to enhance environmental sustainability and fulfill social responsibilities. This study addresses a real-world capacity planning problem in collaboration with a multi-factory manufacturer. We develop a two-stage distributionally robust optimization (DRO) model that considers both demand and climate-related uncertainties. To improve computational efficiency, a generative AI network is integrated into the solution scheme of DRO, leveraging AI's pattern recognition capabilities to enhance solving efficiency. The effectiveness of the proposed model and the AI-enhanced framework is validated through experimental analysis.

4 - Modeling Supply Chains via Graph Neural Networks

Zhaonan Qu, Columbia University, New York, NY, United States

5 - Debiasing Negotiation: Enhancing Intelligent Decision-Making and Human-AI Collaboration in Complex Supply Chain Deals

Vatsal Mitesh Tailor, University of Illinois Urbana-Champaign, Champaign, IL, United States, Shi Qiu

Negotiations in Supply Chain Management (SCM) are high-stakes, complex processes hindered by human cognitive limitations—such as anchoring and overconfidence—and the static nature of existing Decision Support Systems (DSS). This research proposes an AI-powered negotiation coach leveraging Large Language Models (LLMs) and reinforcement learning to augment human decision-making. The system analyzes real-time dialogues to interpret counterpart strategies, delivers context-aware recommendations, mitigates biases via feedback, and clarifies multi-issue trade-offs. Crucially, it also investigates embedded biases within AI negotiator and their impact on Human-AI collaboration for negotiation.

Supply chain contract negotiations are inherently uncertain and cognitively demanding, with human negotiators constrained by bounded rationality. While AI agents can enhance strategies and provide real-time support, their efficacy hinges on ethical model design and alignment with human preferences. Our study introduces a multi-agent LLM framework for SCM negotiations, evaluating its performance across diverse scenarios. Results demonstrate that human-AI collaboration improves efficiency and outcome alignment. By integrating dynamic behavioral analysis with bias-aware AI training, the framework addresses limitations of traditional DSS/NSS tools, which lack adaptive guidance. The work emphasizes proactive debiasing of LLMs—tackling inherited human biases and algorithmic distortions—to ensure equitable recommendations. It further explores optimizing Human-AI synergy, balancing AI-driven tactical insights with human judgment. This research advances intelligent negotiation tools by bridging behavioral science, AI ethics, and SCM, offering a pathway to mitigate cognitive barriers while safeguarding against AI-driven inequities.

1 - AI and Cyber Powered Drone Warfare Innovations: Information-Theoretic Analysis of Emergent Cybersecurity Risks Across Military and Business Applications

Katya Drozdova, Seattle Pacific University, Seattle, WA, United States

Drone warfare is driving battlefield AI and business innovations. In particular, the Russia-Ukraine war has generated an unprecedented drone arms-race, including First-Person View (FPV) technologies as well as electronic warfare, offences and defenses across informational and physical domains. Existing commercial and military technologies have been adapted. Entirely new systems have emerged. These innovations are not only in technical design and practical deployment but also in intelligence, entrepreneurship, and production. For example, Ukraine's menacing Baba Yaga evolved from an agricultural drone; Russia's Upr 'Vampire' drone advanced from a volunteer enthusiast's hand-made creation through wartime testing to industrial production; 'Geranium-2' kamikaze drone is an iteration of Iranian 'Shahed' loitering munition build from a downed and reverse-engineered U.S. military Sentinel UAV. Innovations in AI-powered systems, naval drones, ground and underground robotics as well as civil-military collaborations have sprung up. Concurrently, an offense-defense arms race is revolutionizing electronic warfare, cybersecurity, evasion, and information operations. These developments are reshaping global conflicts and peacetime risks. Effective responses require strategic reorientation. In our cyberspace-reliant world—where public and defense IT infrastructures are interdependent—practically no one or nothing is safe from FPV drones and AI-powered systems. Moreover, cyberwarfare has outpaced civilian applications, threatening public safety and profitability of commercial drone markets, if risks are not properly addressed. Toward developing the necessary understanding, this research systematizes key technological advances, use cases, and vectors of emergent applications. Information-theoretic analysis is used to identify threat indicators and warning—with metrics for uncertainty reduction, risk management, and strategy optimization.

2 - Strengthening Intervention Design for Illicit Supply Chains: A Network Dynamics-Based Framework

Rashid Anzoon, University of Illinois Urbana-Champaign, Urbana, IL, United States, Rakesh Nagi, Chrysafis Vogiatzis

Illicit trade remains a persistent global threat, continuously seeking to expand through their covert supply chain networks. Efforts to disrupt these networks often yield limited success, as intervention in one area frequently triggers resurgence in another, a phenomenon commonly known as the balloon-and-cockroach effect. These unintended operational consequences complicate the design of effective intervention strategies, which must anticipate and counter the evolving nature of illicit supply chains. In this talk, we introduce a network dynamics-based framework that leverages structural vulnerabilities within the supply network to design targeted interventions. We also discuss optimal resource allocation strategies to maximize the impact of these efforts.

3 - Comparative Study of Calibration Frameworks for Flight Scheduling

Jared Erickson, OpsLab, Austin, TX, United States, Christopher Montez, Chris Biggins, Sujeevraja Sanjeevi

Effective flight scheduling for warfighters requires balancing multiple competing objectives, including mission fulfillment, equitable pilot workload, and timely pilot advancement. We present a comparative study of calibration frameworks designed to empower users to easily configure optimization models that reflect operational priorities of flying squadrons. The goal is to provide intuitive mechanisms for tuning objective coefficients, enabling users to obtain schedules that align with their expectations and squadron goals.

Our study evaluates multiple calibration approaches. These methods are assessed using historical scheduling data, with a focus on user interpretability, flexibility, and the quality of the resulting schedules. Rather than tuning coefficients automatically, our frameworks are designed to facilitate user-driven adjustment, supporting a more transparent and controllable scheduling process.

4 - Drone Routing in GPS-Denied Environments

Chase Murray, University at Buffalo, Amherst, NY, United States

While we have grown to rely on GPS for navigation, in many contexts GPS cannot be relied upon to provide localization. Several strategies have emerged for accurate drone navigation without the aid of satellites. Most of these involve some combination of computer vision processing fused with the measurements of the drone's onboard sensors (e.g., gyroscopes, altimeter, accelerometer, and compass). This talk defines a new problem where a drone must collect imagery data without the aid of satellite

navigation. The images collected during these runs may be subsequently used to provide more accurate navigation in future missions. Results from experiments with real drones validate the algorithm's performance.

5 - Agent-Based Modeling of Search Operations in Undersea Warfare

Nipun Galande, Virginia Tech , Blacksburg, VA, United States, Esra Toy, Anna Svirsko, Daphne Skipper

This work presents a novel agent-based simulation framework that integrates dynamic weather modeling with a Bayesian updating mechanism to enhance maritime search operations. We incorporate these Bayesian updates within the simulation and a Mixed-Integer Programming (MIP) model, comparing their solutions and performance under uncertainty. Our contributions include an innovative culling heuristic, pruning low-probability target paths, and extensive simulation replications to robustly quantify search performance under varying conditions. An Agent-Based Model (ABM) simulates and optimizes the dynamics of searchers and high-risk targets within a maritime environment. The ABM incorporates complex operational assumptions and constraints, facilitating a comprehensive analysis of search strategies and resource allocation. A key objective of this research is to address the impact of weather uncertainties on search operations, which a deterministic optimization model may not capture. Weather conditions, including wind speed, visibility, precipitation, and storm occurrences, are dynamically modeled to impact the operational capabilities of search assets. The simulation incorporates Areas of Uncertainty (AOUs) that expand over time after the detection of a submarine vessel by surveillance assets. These AOUs are also influenced by changing weather conditions, necessitating adaptive search strategies to maintain operational effectiveness. Our heuristic optimizes the search asset pathfinding process, enabling searchers to navigate AOUs more effectively by prioritizing areas with a higher probability of target presence, improved observation capabilities, and greater strategic value. The findings aim to inform the development of optimized search strategies and resource deployment plans, resulting in robust maritime security operations even in the face of environmental uncertainties.

6 - The Art of Hiding: Exploring Hiding and Rendezvous Tactics in a Contested Environment

John Becker, USNA, Annapolis, MD, United States, Samuel Zimmerman

Search is often studied as a symmetric game where the searcher's logic and payoff calculations inform how we expect the hider to behave. However, that is often not the case in practice as the hider's purpose and reasoning for behavior may not be in line with the searcher's reasoning. This research aims to explore and expand this facet of search which we call hiding theory. We look to answer how hiding policies can be evaluated and determine if optimal policies can be generated with limited information. Based on our findings, we hope to uncover general principles which are analogous to those found in search theory (e.g. "sweep rate"). Applications of hiding theory include how a downed pilot in enemy-controlled territory should behave to avoid detection and be rescued, how in-country terrorists may behave while awaiting orders, and how ballistic missile submarines should conduct deterrence patrols if they do not wish to be detected.

7 - Stop that Flow! Reinforcement Learning for Network Interdiction

Matthew Webb, Massachusetts Institute of Technology, Cambridge, MA, United States, Chris Caplice

Network interdiction problems are critical for modeling real-world security challenges including disruption of drug trafficking networks, military logistics during combat, and critical infrastructure protection. This presentation introduces a novel reinforcement learning (RL) approach to solve the maximum flow network interdiction problem for both deterministic and stochastic interdiction outcomes. By framing interdiction as a Markov decision process, our method trains RL agents capable of achieving comparable accuracy to mixed-integer optimization-based approaches, while achieving faster solve times for problems at scale. Our method also flexibly handles partial capacity reductions and multiple interdiction attempts without requiring structural reformulations of traditional optimization models. Unlike machine learning-assisted methods, which depend on pre-labeled training data and are vulnerable to labeling errors, this RL approach is immune to such issues as it learns interdiction policies through environment interaction rather than supervised data. This work bridges RL and combinatorial optimization, and offers a template for tackling other network interdiction problems beyond maximum flow.

Co-Chair: Guiyu Hong, Shanghai University of Finance and Economics, Shanghai, N/A

1 - Online Learning for Dynamic Pricing with Delay-Sensitive Customers

Guiyu Hong, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Xinyun Chen, Yunan Liu

Motivated by sharing economy and online marketplaces, we propose an online learning approach to optimize a state-dependent pricing policy in service systems where customers are delay sensitive. Leveraging the underlying queueing structures, the proposed online learning method is featured with improved sample efficiency and faster convergence rate, compared to standard online learning algorithms.

2 - Exploring the Operational Potential of Queue-Ratio Policies in Multiclass Queueing Networks

Lucy Huo, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Jim Dai, Jin Guang

Motivated by the recent stability analysis of multiclass queueing networks under queue-ratio policies by Zhao, Gurvich, and Hasenbein (2024), we build on their results to explore the operational implications of this policy class. Under their assumptions, together with a P -matrix reflection matrix, we establish that, in a multi-scale heavy traffic regime, the stationary distribution of the scaled workload converges to a product-form limit with exponentially distributed marginals. Together with state space collapse, the scaled queue lengths are also exponentially distributed in the limit. These results yield a tractable closed-form approximation for steady-state performance evaluation without simulation. Leveraging the closed-form approximations, we investigate their potential as a robust engineering tool for operational optimization, for example, identifying near-optimal policies for objectives such as delay minimization and resource balancing. We present numerical experiments and report our ongoing exploration in this direction, concluding with a discussion of open problems.

3 - Sample Path Large Deviations for Multivariate Heavy-Tailed Hawkes Processes

Xingyu Wang, University of Amsterdam, Amsterdam, Netherlands, Jose Blanchet, Roger Laeven, Bert Zwart

Hawkes processes capture the amplification and cascade effects of risks through temporal and spatial feedback, which prevail in various scientific, engineering, and business contexts. This talk develops sample path large deviations for multivariate Hawkes processes with power-law heavy tails in the mutual excitation rates. Our results address a broad class of rare events in Hawkes processes at the sample path level and, via the cluster representation of Hawkes processes, unravel the most likely configurations of (multiple) large clusters that could trigger the target events. These results also lay the foundation for precise theoretical insights and efficient rare-event simulation in practical systems subject to clustering and mutually exciting risks.

Our proof hinges on several technical developments. First, we provide a detailed probabilistic analysis of the spatiotemporal structure of large jumps in multi-type branching processes, which helps reveal the hidden regular variation that arises endogenously in the tail behavior of Hawkes process clusters. Next, we establish the asymptotic equivalence, in terms of M -convergence, between a suitably scaled multivariate Hawkes process and a coupled Lévy process with multivariate hidden regular variation. Along the way, we derive a sample-path large deviations principle for such Lévy processes, which is also of independent interest given the importance of Lévy models and the prevalence of hidden regular variation.

4 - Near-Optimal Control and Design of Critically Loaded Service Systems when Service and Patience TIMES are Dependent

Lun Yu, Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Ohad Perry

Customer behavior has significant impacts on the operations and performance of service systems. For example, even a small amount of abandonment, which is due to customer impatience, has dramatic impacts on key performance measures, and in turn, on the optimal staffing and control of such systems. However, in contrast to the prevalent models in the literature, the time that customers are willing to wait in queue for service often depends on their service requirement, and the impacts of this dependence can be sufficiently substantial so as to render those existing models futile.

In this paper, we consider large service systems that handle customers with dependent service and patience times, when those systems are staffed according to the Square-Root Staffing (SRS) rule in order to operate in the quality-and-efficiency (QED) asymptotic regime. We first develop bounds for the steady-state queue, delay and customer loss and show that the value of a single dependence scalar determines whether SRS guarantees that the system operates in the QED regime. We then propose design-and-control mechanisms that guarantee that SRS is near-optimal, in the sense that the QED regime is achieved. We further show that our near-optimality results are robust to the dependence structure, requiring no knowledge of the exact service-patience distribution, which is hard to estimate in practice. Finally, we provide simple methods for computing the optimal control parameters. The effectiveness of our analytical results and of our proposed solutions to the dependence-caused congestion are supported by extensive simulation studies.

1 - Statistical Inference of Controlled Markov Chains: CLT for Transition Probabilities and Applications to Offline RL

Ziwei Su, Northwestern University, Evanston, IL, United States, Imon Banerjee, Diego Klabjan

We develop a central limit theorem (CLT) for the nonparametric estimator of the transition matrices in controlled Markov chains (CMCs) with finite state-action spaces. Our results establish precise conditions on the logging policy under which the estimator is asymptotically normal, and reveal settings in which no CLT can exist. We then build upon it to derive CLTs for the value, Q -, and advantage functions of any stationary stochastic policy, including the optimal policy recovered from the estimated model. Goodness-of-fit tests are derived as a corollary, which enable us to test whether the logged data is stochastic. These results provide new statistical tools for offline policy evaluation and optimal policy recovery, and enable hypothesis tests to distinguish whether observed data come from an MDP or a bandit.

2 - Artificial Replay and Thompson Sampling for Historical Data in Bandits

Christopher Martin, Yale University, New Haven, CT, United States, Siddhartha Banerjee, Sean Sinclair

We consider applications of the multi-armed bandit problem where some amount of historical data is available upfront, and additional data is collected adaptively through online interactions. Artificial Replay is a powerful meta-algorithm for bandit problems with historical data which has been shown to effectively reduce the use of redundant data without sacrificing regret when used with a wide class of underlying algorithms including UCB. In this paper, we apply the classic bandit algorithm Thompson Sampling to this historical-data bandit problem, and compare Artificial Replay to a full warm-start approach. We show a tight problem-dependent bound on the performance of Full-Start Thompson Sampling for K -armed Bernoulli bandits. We then complement this theoretical result with an empirical comparison of Artificial Replay and Thompson Sampling. In the K -armed bandit setting, while Artificial Replay does not guarantee the same regret as Full Start in general, it actually can outperform it in expectation under certain distributions of historical data. Additionally, we explore whether these findings apply to a broader context with empirical simulation of Gaussian Process Thompson Sampling and compare a Full-Start approach to our own Artificial Replay-style algorithm.

3 - Fooling Algorithms in Non Stationary Bandits

Gal Mendelson, North Carolina State University, Raleigh, NC, United States, Eyal Tadmor

This work is concerned with constructing worst case instances to prove lower bounds on the regret under various algorithms in non stationary bandit problems. We develop a new method for constructing such instances that fools algorithms to believe a sub optimal arm is optimal for a long period of time. This allows us to obtain new and better bounds than are currently known for popular algorithms such as UCB and sliding window UCB.

4 - Delayed Allocation in Marginalized Flow Models for Weakly Coupled Markov Decision Processes

Selva Nadarajah, University of Illinois Chicago, Chicago, IL, United States, Andre Cire

We introduce a process interpretation of fluid policies derived from Lagrangian relaxation of weakly coupled Markov decision processes (WDPs), revealing that existing approaches follow an "allocate-then-correct" sequence: first allocating marginal probability flows to component actions fluid linear program, then correcting for constraint violations. We identify that these feasibility corrections can be costly, degrading expected policy performance and increasing sample path variability, which we term fluid-model feasibility risk.

We propose delayed allocation, which reverses this process by identifying feasible actions before allocation. This creates a hierarchy of structure-aware fluid models that restrict actions to subsets of provably feasible solutions, operating on convex hulls of feasible action sets rather than linear relaxations. Our hierarchy converges in the limit to exact-feasible models from the literature, but remains computationally tractable at intermediate levels.

For a broad class of problems, we establish transferability results showing that approximation guarantees for deterministic constraint systems carry over to our stochastic formulations. We prove that polynomial-time approximation algorithms yield polynomial-time delayed allocation models, even when exact-feasible formulations require exponential representation – a striking complexity difference supporting intermediate models in our hierarchy.

Numerical experiments on dynamic assortment and maintenance problems demonstrate that delayed allocation reduces optimality gaps of standard approaches, while also decreasing performance variability. Our models also reduce reliance on frequent reoptimization, broadening applicability to environments where regular reoptimization is costly or impractical.

5 - Multiscale Replay: a Robust Algorithm for Stochastic Variational Inequalities with a Markovian Buffer

Milind Nakul, Georgia Institute of Technology, Atlanta, GA, United States, Tianjiao Li, Ashwin Pananjady

We introduce the Multiscale Experience Replay (MER) algorithm to solve stochastic variational inequalities (VIs) in settings where samples are collected in a Markovian buffer. MER utilizes a multi-scale scheme to emulate the behavior of independent and identically distributed (i.i.d.) samples, thereby mitigating the effects of data correlation without requiring knowledge of the Markov chain's mixing time. Our algorithm and its analysis demonstrate how the so-called "experience replay" heuristic from reinforcement learning can be applied in a provable and statistically efficient manner with dependent data. We discuss the implications of our results for temporal difference methods in policy evaluation and generalized linear models with dependent data.

1 - The Stationary Behavior of Reflecting Coupled Brownian Motions with Applications to Shortest Remaining Processing Time Queues

Amber Puha, California State University-San Marcos, San Marcos, CA, United States, Sixian Jin, Marvin Pena

With the objective to characterize the stationary behavior of the scaling limit for shortest remaining processing time (SRPT) queues with a heavy-tailed processing time distribution, as obtained in Banerjee, Budhiraja, and Puha (BBP, 2022), we study a collection of reflecting coupled Brownian motions (RCBM) indexed by the nonnegative real numbers. These RCBM arise by regulating certain coupled Brownian motions (CBM) to remain nonnegative. In the context of the BBP (2022) scaling limit, the regulated Brownian motion indexed by the nonnegative real number a represents the scaling limit of the amount of work in the system of size a or less. Thus, for the BBP (2022) scaling limit, the time t values of the RCBM describe the random distribution of the size of the remaining work in the system at time t . Our principal results characterize the stationary distribution of the RCBM in terms of a maximum process associated with the CBM. We obtain an explicit representation for its finite-dimensional distributions and a simple formula for its covariance. We further show that the RCBM converge in distribution to the maximum process as time approaches infinity. From this, we deduce the stationary behavior of the BBP (2022) scaling limit, including obtaining an integral expression for the stationary queue length in terms of the associated maximum process. While its distribution appears somewhat complex, we compute the mean and variance explicitly, and we connect with the work of Lin, Wierman, and Zwart (2011) to offer an illustration of Little's Law.

2 - Fluctuations of the Atlas Model from Inhomogeneous Stationary Profiles

Peter Rudzis, University of North Carolina, Chapel Hill, NC, United States, Sayan Banerjee, Amarjit Budhiraja

Brownian particle systems with singular (local time-mediated) interactions have important applications in queueing theory, mathematical finance, and models for physical surface growth. One such particle system is the Atlas model, a prototypical example in the class of rank-based diffusions from stochastic portfolio theory. Focusing on the infinite-dimensional version of this model, we establish fluctuation-type scaling limits for the occupation measure and order statistics of the system started from any stationary regime in which the particle density grows at an exponential rate. We show that the fluctuations can be described by an explicit Gaussian process, characterized as the solution to a stochastic partial differential equation (SPDE) in which the initial condition is Brownian motion, the linear operator is the infinitesimal generator of geometric Brownian motion, and the equation is driven by a certain additive space-time noise that is white in time and colored in space. The result yields precise insights about the large-scale properties of the system, including a simple and explicit description for the fluctuations of a tagged particle started from the bulk of the initial configuration.

3 - Some Large Deviation Principles for Load-Balancing Queueing Systems

Ruoyu Wu, Iowa State University, Ames, IA, United States, Amarjit Budhiraja, Eric Friedlander

We consider the large-scale load balancing queueing system under the Join-the-Shortest-Queue- $d(n)$ policy with diverging $d(n)$. The system consists of one dispatcher and n servers. When a task arrives at the dispatcher, $d(n)$ servers are chosen uniformly at random, and then the task is routed to the one with the shortest queue length. We establish large deviation principles for the system occupancy process, when $d(n)=n$ or in general $d(n)$ diverges. Proofs rely on certain variational representations for exponential functionals of Poisson random measures, stochastic controls, and weak convergence arguments. This is based on joint works with Amarjit Budhiraja and Eric Friedlander.

4 - Thompson Sampling Algorithm for Stochastic Games

Cohen Asaf, University of Michigan, Ann Arbor, MI, United States, Ruolan He, Yuqiong Wang

We study a stochastic differential game with N competitive players in a linear-quadratic framework with ergodic cost, where d -dimensional diffusion processes govern the state dynamics with an unknown common drift (matrix). Assuming a Gaussian prior on the drift, we use filtering techniques to update its posterior estimates. Based on these estimates, we propose a Thompson-sampling-based algorithm with dynamic episode lengths to approximate strategies. We show that the Bayesian regret for each player has an error bound of order $O(\sqrt{T \log(T)})$, where T is the time-horizon, independent of the number of players. This implies that average regret per unit time goes to zero. Finally, we prove that the algorithm results in a Nash equilibrium.

5 - Functional Limit Theorems for Pricing Dynamics in Limit Order Books with State-Dependent Multivariate Hawkes Processes

Ben Buran, Rice University, Houston, TX, United States, Bo Li, Guodong Pang

We study a tick-by-tick asset price model for a set of assets in one industrial sector (such as a technology sector) which is formed by a state-dependent Hawkes multivariate processes, representing the associated positive and negative jumps for each asset. In particular, both the baseline rate functions and the self-exciting functions in the stochastic intensities of the Hawkes processes depend on the price vector. We first show that the asset price model is well defined under certain regularity conditions. We then establish a functional law of large numbers (FLLN) and a functional central limit (FCLT) for the price dynamics. The FLLN limit for the price is given by the unique solution to a system of nonlinear ODEs. The FCLT limit for the price can be represented by the unique solution to a system of stochastic Volterra integral equations driven by Brownian motion, with the kernel functions depending on the FLLN limit for the price. The FCLT limit indicates both the path-dependent (memory) and state-dependent properties of the asset price dynamics. In the proofs, we develop a novel approach to establish the convergence of the LLN and CLT scaled processes, in order to tackle the challenges arising from the state dependency in the intensity processes.

1 - Crossing the Rubicon of Rival Revelation: Dynamic Information Design in Competition

Yue Feng, Tianjin University, Tianjin, China, People's Republic of, Yunchuan Liu, Yi Liu, Jianxiong Zhang

In this paper, we study how firms strategically design information either about themselves or their rivals to influence consumer purchase decisions in dynamic competition. In particular, we focus on environments in which consumers' prior beliefs differ across the two firms' products, while consumers simultaneously face an outside option. We construct a dynamic Bayesian persuasion model in which a leader firm and a follower firm sequentially design and send their information to consumers to strategically shape consumers' beliefs on the two firms' products. In the model, both the leader firm and the follower firm can decide whether to manipulate consumers through information design, and whether to design to reveal information about either themselves or their competing rival. Our analysis shows that, strikingly, the leader firm may choose to "serve" the competing rival firm with a high risk gambler strategy of fully providing the rival information to consumers, especially when consumers have moderate prior beliefs for the leader firm. In addition, when consumers have relatively high prior beliefs for the leader firm, the leader firm may surprisingly choose a *downward twisted self-revelation* strategy, intentionally disseminating unfavorable signals about itself despite favorable product match, in a way to enhance the persuasiveness of its information. Finally, we show that an increase in competition may intensify information manipulation.

2 - Truthful Capacity Allocation Under Asymmetric Information: Leveraging Premium Pricing to Mitigate Ration Gaming

Burak Çelik, Aalto University School of Business, Espoo, Finland, Heikki Peura, FANG LIU

Ration gaming arises when downstream firms place orders exceeding their optimal quantity in response to a capacity shortage at their upstream supplier. Its negative effects can be mitigated through truthful allocation rules that incentivize firms to report their actual needs. We consider asymmetric downstream firms as they possess private information regarding their selling prices and operational costs, which determine their individual profitability. We propose novel capacity allocation mechanisms that utilize a premium wholesale price to provide priority allocation to downstream firms compared to those ordering at a standard wholesale price. We show that all the proposed mechanisms incentivize downstream firms to report truthfully, leading them to reveal their true demands in equilibrium. The first two proposed mechanisms prioritize fairness among the downstream firms with respect to allocation quantities, similar to uniform allocation. In contrast, the final mechanism overcomes a key limitation of existing mechanisms under private downstream information by maximizing supply chain profit in a decentralized supply chain, a performance level equivalent to a centralized system. This is accomplished by utilizing order quantities observed at premium wholesale price level to identify downstream firms with higher profit margins, and prioritizing capacity allocation to them. We subsequently characterize the strategies of the downstream firms and analyze the resulting equilibria for each mechanism. We evaluate the performance of the proposed mechanisms with respect to supply chain profit, using the uniform allocation rule as a benchmark. Our results also establish a connection between capacity allocation and auction theory via the Vickrey–Clarke–Groves mechanism.

3 - Strategically Robust Game Theory via Optimal Transport

Nicolas Lanzetti, ETH Zürich, Zürich, Switzerland, Sylvain Fricker, Saverio Bolognani, Florian Dörfler, D P

In many game-theoretic settings, agents are challenged with taking decisions against the uncertain behavior exhibited by others. Often, this uncertainty arises from multiple sources, e.g., incomplete information, limited computation, bounded rationality. While it may be possible to guide the agents' decisions by modeling each source, their joint presence makes this task particularly daunting. Toward this goal, it is natural for agents to seek protection against deviations around the emergent behavior itself, which is ultimately impacted by all the above sources of uncertainty. To do so, we propose that each agent takes decisions in face of the worst-case behavior contained in an ambiguity set of tunable size, centered at the emergent behavior implicitly defined. This gives rise to a novel equilibrium notion, which we call strategically robust equilibrium. Building on its definition we show that, when judiciously operationalized via optimal transport, strategically robust equilibria (i) interpolate between Nash and security strategies; (ii) come at no additional computational cost compared to Nash equilibria; (iii) often lead to better decisions and higher payoffs. Through a variety of experiments including bi-matrix games, congestion games, and Cournot competition, we show that strategic robustness protects against uncertainty in the opponents' behavior and, surprisingly, results in higher equilibrium payoffs – an effect we refer to as coordination via robustification.

4 - Timing the Life Cycle of Remanufactured Product Versions as New Product Generations Evolve

Ana Muriel, University of Massachusetts Amherst, Amherst, MA, United States, Yue Jin

As new product generations are launched, the firm must decide when to release the remanufactured version of the newest model and when to discontinue that of the previous one. We propose a steady state model that breaks the product generation interval into two stages. The new product is introduced at the beginning of Stage 1 and competes with the remanufactured version of the old generation. At some point, remanufacturing the new generation product will become feasible and the company will transition to Stage 2, offering remanufactured products of the new generation, which is more appealing to the customer. Two remanufacturing strategies are considered in the second stage: 1) offering only the new-generation remanufactured model, thus discontinuing the previous one, and 2) offering both the old and new remanufactured models. We quantify the benefits associated with the two-period strategy in steady state under the two options for old-gen discontinuation and analyze the timing decision for offering the new version of the remanufactured product, as well as the sensitivity to various model parameters.

Information Operations in Social Media: Identifying and Countering Threats

Tutorial session

Tutorials

Chair: Yao Xie, Georgia Institute of Technology, Atlanta, GA, United States

1 - Information Operations In Social Media: Identifying and Countering Threats

Tauhid Zaman, Yale University, New Haven, CT, United States, Yen-Shao Chen

The battlefield of information warfare has moved to online social networks, where influence campaigns operate at unprecedented speed and scale. As with any strategic domain, success requires understanding the terrain, modeling adversaries, and executing interventions. This tutorial introduces a formal optimization framework for social media information operations (IO), where the objective is to shape opinions through targeted actions. This framework is parameterized by quantities such as network structure, user opinions, and activity levels—all of which must be estimated or inferred from data. We discuss analytic tools that support this process, including centrality measures for identifying influential users, clustering algorithms for detecting community structure, and sentiment analysis for gauging public opinion. These tools either feed directly into the optimization pipeline or help analysts interpret the information environment. With the landscape mapped, we highlight threats such as coordinated bot networks, extremist recruitment, and viral misinformation. Countermeasures range from content-level interventions to mathematically optimized influence strategies. Finally, the emergence of generative AI transforms both offense and defense, democratizing persuasive capabilities while enabling scalable defenses. This shift calls for algorithmic innovation, policy reform, and ethical vigilance to protect the integrity of our digital public sphere.

1 - Uncertainty in Vulnerability of Metro Transit Networks: a Global Perspective

Nazanin Tajik, Mississippi State University, Mississippi State, MS, United States, Alireza Ermagun, Hani Mahmassani, Fatemeh Jannatabadi

This study measures the “uncertainty in vulnerability” of 50 metro transit networks in the most populated cities across the globe under benign and malicious attack scenarios. Uncertainty in vulnerability delineates the gap between the performance loss trajectory formed by link percolation under benign and malicious attacks. Three observations are discerned. First, vulnerability and uncertainty in vulnerability are a function of both size and physics of the network explained by connectivity measures. A 1% increase in the ratio of links to nodes increases the vulnerability by 0.50% and increases the uncertainty in vulnerability by 2.24%. A 1% increase in the ratio of the number of links to the maximum possible number of links decreases vulnerability by 0.03% and the uncertainty in vulnerability by 0.12%. Second, the topology of metro transit networks with <100 nodes follows one of the three analogous forms of tree-shaped networks, networks with one undirected cycle, or single depot networks, while the topology of metro transit networks with ≥100 nodes is closer to grid and matching pairs. Third,

metro transit networks (i) are less likely to resume the operation under malicious attacks, (ii) are more likely to resume the operation under benign attacks, and (iii) are susceptible to both severe and non-severe degradations under random attacks. Overall, it is shown that the most vulnerable transit networks experience the maximal uncertainty in vulnerability and own a topology analogous to a single depot.

2 - RL-Based Pricing for Decentralized EV Charging Control

Nima Rashgi Shishvan, University of Texas at Austin, Austin, TX, United States, Zhaomiao Guo

Electric Vehicles (EVs) offer a sustainable alternative to internal combustion engines by reducing greenhouse gas emissions. However, large-scale EV adoption poses challenges for power grid stability due to uncoordinated charging, which can lead to peak loads and accelerated infrastructure degradation. Centralized control approaches provide effective load management but are impractical due to privacy concerns. Pricing-based strategies formulated using bilevel optimization offer indirect control over charging behavior, yet requires full knowledge of users' travel patterns, which is often unrealistic. To address this limitation, we propose a Reinforcement Learning (RL)-based pricing framework that learns optimal charging incentives without any prior information about individual travel schedules. In this framework, the pricing agent adapts over time by interacting with EV users who make charging decisions based on past and current prices and personal constraints. Results show that, despite lacking access to user-specific data, the RL-based pricing policy achieves load distributions that closely approximate those of a full-information bilevel optimization benchmark. This demonstrates the potential of RL for scalable and privacy-preserving EV charging coordination.

3 - Simulation and Analytics for Safer, Greener, and More Equitable Transport Infrastructure

Jessica Boakye, University of Massachusetts Amherst, Amherst, MA, United States

Transportation infrastructure is critical for urban mobility, yet its deterioration or failure poses complex and far-reaching challenges to resilience, sustainability, safety, and equity within large-scale networks. These challenges extend beyond immediate financial costs, impacting public health, daily accessibility, and the social well-being of communities. Simulation and analytics offer powerful, data-driven approaches to quantify, predict, and mitigate such impacts, especially where real-world data may be limited or incomplete.

This talk explores simulation-based methodologies for understanding and improving the performance of transportation infrastructure under both hazard and non-hazard scenarios. The hazard-focused case study models culvert (road-stream crossing) failures during flooding events. By simulating multiple failures across a representative county, we analyze their effects on network accessibility, route criticality, and the distribution of impacts across different neighborhoods, highlighting risks for populations that may already face mobility barriers. The non-hazard case addresses pavement deterioration and its effect on user costs, such as excessive fuel consumption, which can be a significant component of a network's environmental footprint. Here, simulation is used to reconstruct representative home-to-work commutes, generating actionable insights even in the absence of comprehensive travel surveys or individual trip records.

Both studies employ publicly available datasets and emphasize methodological transparency to ensure that results are robust and transferable to other urban contexts. Finally, the talk underscores the importance of accounting for equity in infrastructure planning and investment, demonstrating how simulation can reveal disparities and support more inclusive decision making for resilient, sustainable, and safe urban networks.

4 - How Long Should Supermarkets Wait to Donate? Optimal Policies for Donating Perishables with Profit and Food Waste Considerations

Shabnam Salehi, The University of Alabama, Tuscaloosa, AL, United States, Irem Orgut, Emmett Lodree

Food waste is a significant problem with economic, environmental, and social impacts. Supermarkets help reduce food waste by donating perishables nearing expiration, which reduces disposal costs, provides tax relief, and enhances their social image. Food banks re-purpose food that would otherwise be wasted by collecting, sorting, and distributing donations to food-insecure households through networks of charitable agencies. Conflicting objectives between supermarkets and food banks can create inefficiencies in the food bank supply chain that increase food waste. This paper examines supermarket donation policies and investigates the trade-off between supermarket profitability and total food waste in the food bank supply chain. We develop a stochastic dynamic programming model that specifies the optimal time and quantity of perishable items to donate under stochastic demand. We simulate a robust set of operating conditions to compare the optimal policy to two practical benchmarks, and evaluate the trade-off between profit and waste among the three policies. Our results show that the optimal policy not only maximizes supermarket profit but also significantly reduces total waste compared to last-minute donation strategies. Thus, higher supermarket profits and less waste in the supply chain can be achieved by the optimal policy, which shows that there is often no trade-off between two seemingly conflicting objectives. Lastly, it is especially important for policymakers to introduce high tax credits for items with lower holding costs to incentivize early donations and substantially reduce waste in the food bank supply chain.

5 - Optimizing Pricing Strategies Through Learning the Market Structure

Ezgi Karabulut, Sabanci University, İstanbul, Turkey, Khosroparviz Naderivarandi, Burak Gokgur

This study explores the integration of market structure learning into pricing strategies to maximize revenue in e-commerce and retail environments. We consider the problem of determining the revenue maximizing price of a single product in a market of heterogeneous consumers segmented by their product valuations; and analyze the pricing strategies for varying levels of prior market structure knowledge. In our problem, the seller sets the price of the product independently of the arriving customer profile; observes only the customer's decision to purchase or not depending on their respective product valuation; and updates the estimations for the unknown market parameters and the price for the new customer based on the purchase preference data. The proposed pricing mechanisms utilize customer preference data, and adopt a two-stage approach: an offline learning stage that focuses on learning market structure, including the number of segments and their sizes and valuations, and an online learning stage that prioritizes revenue maximization and iteratively updates these estimates to refine pricing strategies dynamically. In this seller-customer dynamic, we analyze the impact of different levels of prior market information on the collected revenue; and customize our algorithms for different information levels. Experimental results demonstrate the effectiveness of these methods in adapting to different levels of market knowledge, revealing the economic value of learning market structure in achieving near-optimal revenues. Our findings suggest that even with limited prior market knowledge, firms can benefit from incremental learning strategies to reach profit levels that are relatively close to those achieved in full-information scenarios.

Software for Optimization Modeling and Deployment 2

Invited Session

Computing Society

Chair: Susanne Heipcke, FICO, Xpress Optimization, Birmingham, United Kingdom

Co-Chair: Robert Fourer, AMPL Optimization Inc., Evanston, IL, United States

1 - Accelerating Optimization Workflows Across All Platforms with Fico Xpress Workbench and Insight Docker Images

Alexander Biele, FICO, Darmstadt, Germany

Deploying optimization software often involves challenges like software dependencies and compatibility issues. FICO Xpress Workbench and Insight Docker images address these needs, enabling seamless deployment across platforms. This eliminates installation hassles, enhances user experience, and allows developers to focus on optimization.

This talk will highlight the benefits of Docker, demonstrating the ease of setup and minimal configuration needed for a unified development experience across Workbench and Insight. We will showcase the end-to-end deployment of a Python-based optimization model into a fully operational application with Xpress Insight, including remote

debugging capabilities for scenarios on a remote server.

This presentation will provide practical insights into leveraging Docker for optimization workflows, making development and deployment more efficient. Additionally, we will share key lessons learned from distributing pre-configured Docker images tailored for client use and training purposes.

2 - Automated Discovery of Optimization Algorithms

Ilias Mitrai, The University of Texas at Austin, Austin, TX, United States, Nikolaos Sahinidis

We propose a novel mathematical programming-based formulation for the automated discovery of optimization algorithms. Specifically, we model iterative algorithms as an expression tree of fixed depth. This modeling approach can represent many functional forms for the update function, i.e., a superstructure of candidate algorithms using simple mathematical operators (addition, multiplication, division, subtraction). This formulation allows the search for new update functions that satisfy a given convergence criterion while a desired objective, such as the complexity of the update function, is optimized. The resulting problem is a Mixed Integer Nonlinear Programming problem, which can be solved with state-of-the-art global optimization solvers such as BARON. We use the proposed approach to discover new first-order optimization algorithms for unconstrained optimization problems.

3 - A Cpu/Gpu Implementation of Randomized Rounding for Symbolic Regression

Xingjian Tao, Georgia Institute of Technology, Atlanta, GA, United States, Nikolaos Sahinidis

Symbolic regression aims to uncover interpretable, closed-form expressions that map input variables to observed outputs. While state-of-the-art solvers—such as Operon and PySR—rely on genetic programming, recent work has approached symbolic regression as a mixed-integer nonlinear program (MINLP) and introduced STAR, a randomized rounding algorithm to obtain high quality solutions of the MINLP. In this work, we develop a novel GPU-accelerated implementation of STAR. We describe the algorithms utilized, including redundancy elimination, constant optimization, and regularization. Finally, we present extensive computational results with problems from SRBench.

4 - Mathematical Programs with Embedded Surrogate Models Using Gamspy

Adam Christensen, GAMS Development Corp, Fairfax, VA, United States, Steven Dirkse

Recent advances in ML/AI have commoditized the development of surrogate models using tools such as PyTorch, Scikit-Learn, and TensorFlow. These surrogate models simplify inherently non-linear phenomena, approximating complex behaviors so they can serve as constraints in optimization frameworks. Embedding these models in algebraic modeling languages (AMLs) like GAMS remains challenging: designed for sparse algebra, AMLs lack seamless integration with third-party software. The rise of Python in data science has motivated a paradigm shift, inspiring tools that bridge classical AMLs and current computational techniques. We introduce GAMSPy, a native Python AML combining the mathematical transparency and scalability of traditional AMLs with Python's ecosystem. Its set-driven constructs and operator overloading preserve the syntax of handwritten algebra while supporting dense matrix operations—matrix multiplication, transposition, norms—essential to ML/AI. While the GAMS “classic” engine excels at indexed algebra, GAMSPy extends its capabilities to accommodate ML workflows. We demonstrate embedding a neural network trained in PyTorch to model an energy system as a constraint within an optimization problem, enabling system engineers to optimize plant operations with detailed energy conversion models. This workflow exemplifies applications spanning weather forecasting and market behavior modeling. We also compare GAMSPy to existing approaches, discuss future developments, and highlight innovative intersections of mathematical modeling and machine learning. GAMSPy represents a significant convergence of AML rigor and Python-driven ML versatility. Its design prioritizes computational efficiency, syntactic clarity, and scalability, offering a robust platform that overcomes integration hurdles and unlocks new possibilities at the intersection of optimization and data science.

5 - Towards Intelligent, Adaptive, and Explainable Strategy Designing Through Neurosymbolic AI: Integrating LLMs and Symbolic Reasoning

Mayank Bhalerao, University of Oklahoma, Norman, OK, United States, Siavash Mandegari, Janet Allen, Farrokh Mistree

Modern supply chains are increasingly exposed to disruption from geopolitical shocks, cyber threats, and climate-related events. However, most current strategy tools remain static, optimization-driven, and opaque; unable to adapt or explain decisions in dynamic conditions. This creates a critical gap in supply chain resilience, where strategic choices must balance adaptability with traceability and managerial alignment. In this paper, we propose a conceptual neurosymbolic framework for strategy design, combining Large Language Models (LLMs) for disruption perception, Graph Neural Networks (GNNs) for risk propagation, and symbolic planners for constraint-based decision generation. We model strategy as an evolving Cyber-Physical-Social System (CPSS), where physical assets, digital intelligence, and human governance co-evolve. We validate the framework through a detailed, hypothetical disruption scenario in an electronics supply chain, demonstrating how the system senses, reasons, plans, and explains in real time. Through our approach we enable satisfying-based, explainable strategies that adapt to uncertainty while aligning with operational and managerial goals. In this paper we address the following research question - How can strategy be designed, modeled and supported as an evolving Cyber-Physical-Social System through a neuro-symbolic AI framework that balances adaptability, traceability, and cognitive boundedness under disruption?

Keywords: Neorymbolic AI, Large Language Models, Evolving Cyber Physical Social System, Supply Chain, Strategy Design

Industrial Loads as Flexible Resources in the Future Power Grid

Invited Session

ENRE: Energy

Chair: Constance Crozier, Georgia Institute of Technology, Atlanta, GA, United States

Co-Chair: Elnaz Kabir, Texas A&M University, College Station, TX, United States

1 - Understanding Resource Variability in High Renewables Systems to Inform Design of Flexible Industrial Technologies

Micah Ziegler, Georgia Institute of Technology, Atlanta, GA, United States, Aliza Khurram, Shannon Huang, Jessica Trancik

In energy systems that rely primarily on solar and wind power, resource fluctuations can both challenge efforts to meet demand reliably and potentially present opportunities for flexible technologies. Thus, there is considerable interest in deploying technologies that can modulate their use of electrical energy. In this research, we characterize the dynamics of fluctuations in solar and wind resources to understand how industrial processes could be designed to increase utilization of electricity infrastructure and ease a transition to high renewables systems. Using four decades of high-resolution weather data, empirical estimates of power demand, and a parsimonious energy system model, we simulate the operation of cost-minimizing, high renewables systems that include energy storage. From these simulations, we identify common characteristics of times when potentially excess energy might be generated, accounting for high uncertainty regarding technology costs and the overall level of reliance on renewable resources and storage. We further quantify how these characteristics might change under different scenarios, which include deploying additional energy storage, expanding transmission infrastructure, and relying on alternative power generators. The results provide insights that can guide the design and operation of industrial processes to enable greater utilization of renewable energy resources and inform efforts to plan and build energy systems to help mitigate climate change.

2 - On the Potential of Electrified Supply Chains to Provide Long Duration Demand Flexibility

Rina Davila Severiano, Georgia Institute of Technology, Atlanta, GA, United States, Constance Crozier

Demand flexibility can offset some of the variability introduced on the supply-side by variable renewable generation. However, most efforts (e.g. control of residential vehicle charging) focus on short durations -- typically on the scale of minutes to hours. This paper investigates whether a fully electrified supply chain (transport and manufacturing) could provide demand flexibility over longer durations, exploiting the latency that typically exists between the processing of raw material to the delivery of finished product. Using a case study of the cement industry along the East Coast of the United States, we demonstrate that electrified supply chains could shift gigawatt-hours (GWh) of electricity demand for durations of more than a week, largely following wind power variability. Furthermore, we show that this occurs using low levels of carbon taxing (below \$50/t), at which battery storage is not economically viable. A sensitivity analysis shows potential to provide flexibility in all considered cost

scenarios, although where the flexibility comes from can change (e.g. transport vs manufacturing). We show that today's cost of electrified heavy goods vehicles are the most significant parameter -- with substantially lower costs yielding a more demand-flexible supply chain.

3 - Towards Energy-Resilient Pharmaceutical Supply Chains: Integrating Network Design with Power Systems Modelling

Miriam Sarkis, Texas A&M Energy Institute, College Station, TX, United States, Halil Iseri, Eleftherios Iakovou, Efstratios Pistikopoulos

As power grids transition towards renewable integration and decentralization, industrial demand-side flexibility becomes a key enabler of grid stability. In the pharmaceutical industry space, manufacturing steps are often energy-intensive and many efforts in decarbonizing pharmaceutical supply chain operations have increased the reliance on renewable energy grids. This effectively increases the potential exposure of manufacturing networks to renewable energy variability and pressures decision-makers to develop mitigation strategies against uncertainty, including flexible adjustments to production schedules. Renewable energy-related variability is combined with inherent process and demand uncertainty for novel pharmaceuticals, highlighting a critical need for systematic frameworks towards energy-resilient and uncertainty-aware operation for the decarbonization and digitalization of the industry.

To this end, we present a framework based on mixed-integer linear programming and a rolling horizon solution methodology for pharmaceutical supply chain design and planning integrating power systems modelling. Given technology costs and capacity constraints, pharmaceutical demand profiles and parameter uncertainties, the optimization problem is solved to investigate the flexibility of supply chain networks in meeting demand targets, minimizing cost and leveraging on available energy and material-related production and storage capacity. The impact of uncertainty is also considered through a scenario-based approach, enabling the investigation of the potential bottlenecks emerging in pandemic scenarios.

Results illustrate a critical trade-off with respect to cost, demand satisfaction and reliance on the renewables energy grid. We highlight the significance of this systematic trade-off approach for informed decision-making in establishing increasingly electrified and digitalized pharmaceutical supply chains.

4 - Supply Chain Design and Manufacturing Planning Exploring Spatio-Temporal Variability of Electricity Prices

Elnaz Kabir, Texas A&M University, College Station, TX, United States

Current supply chain designs assume continuous energy availability, making them vulnerable to energy market volatility and disruptions. These risks are further amplified by the growing electricity demand from data centers, AI, and the resurgence of domestic manufacturing. At the same time, the global transition to variable renewable energy (VRE) sources introduces significant spatiotemporal variability in energy supply, deepening reliance on weather conditions and grid infrastructure. This evolving landscape demands a new generation of supply chains that are resilient, adaptable, and tightly coupled with dynamic energy systems. In this work, we develop a unified, data-driven framework to optimize energy-intensive supply chains by integrating energy use directly into manufacturing and logistics decisions. Our approach explicitly accounts for spatiotemporal variability in energy supply over extended time scales (e.g., weeks to months), which is often overlooked in existing studies. The framework supports dynamic production scheduling and storage optimization. Using real-world case studies, we demonstrate how our model improves operational resilience and energy adaptability in supply chain networks. Results show that by co-optimizing logistics and energy-aware manufacturing decisions, firms can significantly reduce costs, mitigate energy-driven disruptions, and better align operations with variable energy availability. This research provides actionable insights for industries seeking to future-proof their supply chains in the face of increasing energy uncertainty.

Carbon Emissions and Green Innovation

Contributed Session

Contributed

Chair: Aqi Dong, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States

1 - Radical vs. Incremental Green Innovation: Differential Effects on Environmental Misconduct

Prem Thapamagar, University of Science and Technology of China, Hefei, China, People's Republic of, Yan Zhou, Nisar Ahmad, Noor ul Amin, Ali Akbar, Mohammad Eqbal Rizaie

Drawing upon the Natural Resource Based View of a firm and the Fraud Triangle theory, we develop a framework for examining the effects of incremental and radical green innovations on environmental misconduct. Analysing a panel dataset on Chinese firms, we find that radical green innovation significantly reduces the likelihood of environmental misconduct, whereas incremental green innovation increases it. This relationship operates through two distinct mechanisms: (1) both innovation types enhance ESG performance, though radical innovations show stronger effects, which deter firms from committing environmental misconduct; and (2) radical innovation reduces financial constraints, which leads to a decline in the likelihood of environmental misconduct; incremental innovation increases them, creating conditions that the Fraud Triangle suggests may motivate misconduct. These findings demonstrate how organizational ambidexterity in innovation strategy affects corporate environmental behaviour. For managers and policymakers, our results suggest that prioritizing radical green innovations may simultaneously advance environmental compliance, legitimacy, and financial stability, resolving the apparent paradox between economic and ecological objectives more effectively than incremental approaches alone.

2 - Smart Contract and Carbon Adoption Levels in Supply Chains: a Two-Echelon Model

JINHO CHA, Gwinnett Technical College, Georgia, GA, United States

The integration of environmental sustainability practices and technological innovations such as smart contracts is reshaping modern supply chains. This paper explores the interaction between smart contract adoption and carbon adoption levels within a two-echelon supply chain framework, focusing on the retailer's decision-making process with multiple suppliers. We introduce a dynamic pricing model for suppliers, where prices are influenced by market conditions, demand fluctuations, and smart contract adoption, alongside fixed and variable costs. We also account for production capacity constraints and the flexibility of suppliers to scale operations based on demand and technological advancements. Given the inherent uncertainties in supply chain operations, including demand variability and risk factors, we propose a model incorporating stochastic demand processes (Pareto, Weibull, Lognormal, and Exponential distributions) and risk-adjusted procurement costs and production capacity. The model optimizes procurement decisions for the retailer, balancing the costs of carbon adoption and smart contract implementation with the need to meet customer demand and maintain efficiency. This framework provides valuable insights into how supply chain managers can make better decisions under uncertainty, incorporating both cost reductions from smart contracts and the challenges of environmental sustainability. Our findings highlight the trade-offs between operational efficiency and sustainability goals, offering actionable recommendations for retailers integrating smart contracts and carbon adoption strategies.

3 - Carbon Fee Policy with Credit Guarantee Mechanism in Taiwan

Cheng-Feng Wu, National Taipei University, Taipei, Taiwan

In the global trend towards net-zero emissions, businesses must simultaneously respond to government carbon policy regulations while facing supply chain issues. To achieve net-zero goals and align with international standards, Taiwan has pioneered a carbon fee policy as a carbon pricing mechanism. However, for countries with numerous small and medium-sized enterprise suppliers (such as Taiwan), this not only involves regulatory and cost considerations arising from the policy but also requires careful thought on selecting appropriate green suppliers to ensure sustainable development of businesses and supply chains. This study focuses on the buyer-manufacturer's perspective, and examine how buyer-manufacturers can use incentive contracts to reveal suppliers' private information and employ credit guarantee mechanisms to assist financially constrained suppliers and reduce supply risks, thereby achieving optimal financing and procurement decisions under the carbon fee policy. Specifically, this study constructs a financing and procurement model that considers the carbon fee policy's impact while addressing issues of supplier information asymmetry, financial constraints, and supply risks. In the model, buyer-manufacturers design incentive contracts to identify suppliers' efficiency attributes, namely production costs and carbon emission efficiency. Meanwhile, for financially constrained suppliers, buyer-manufacturers can better share risks with banks through credit

guarantee mechanisms after identifying suppliers, thus help them obtain necessary operating capital and achieving a triple win situation. Through model analysis, this study explores how policy parameters, macroeconomic factors, and supply chain elements influence buyer-manufacturer decisions, providing theoretical foundations for Taiwan's carbon fee policy design and practical recommendations for government and businesses during implementation.

4 - Collaborative Transportation Under Uncertainty with Emission Considerations

Secil Savasaneril, Orta Dogu Teknik Universitesi, Ankara, Turkey, Banu Yüksel

We examine coalition formation among shippers who co-load to optimize cost savings. Using a cooperative game model under uncertainty, we analyze the stability of the cost game through core existence, proposing allocation schemes. An emission game is defined to address the problem of a fair allocation of emissions while minimizing costs. Factors that ensure stable allocations of cost-savings and emissions are identified and the performance of the allocation schemes in attaining the core are assessed.

5 - Characterizing Farmer Heterogeneity in Smallholder Carbon Sequestration Programs: a Hierarchical Bayesian Approach

Aqi Dong, Embry-Riddle Aeronautical University, Daytona Beach, FL, United States, Shanan Gibson, James Gibson

Smallholder carbon sequestration programs represent a rapidly growing segment of global carbon markets, yet the heterogeneity among participating farmers poses significant challenges for portfolio risk assessment and program optimization. Using comprehensive data from 11,000 farmers in The International Small Group and Tree Planting Program (TIST) across Kenya, Uganda, Tanzania, and India, we develop a hierarchical Bayesian framework to identify farmer typologies and quantify uncertainty in carbon credit delivery. The dataset encompasses 102 variables spanning socioeconomic indicators, agricultural practices, carbon metrics, and community characteristics. We employ Bayesian mixture modeling to uncover latent farmer classes, revealing distinct profiles based on income (ranging from \$0.50 to \$15.80 USD per day), land holdings, crop diversity, and tree planting patterns. Hierarchical models capture uncertainty at multiple scales—individual farmers nested within communities, communities within districts—while accounting for measurement error in tree counts and growth rates.

Our analysis addresses a critical gap in carbon market operations: the lack of rigorous methods for assessing heterogeneity-driven risk in smallholder programs. By characterizing farmer typologies and associated uncertainty distributions, we enable portfolio construction strategies that optimize the risk-return profile of carbon credit investments. The framework has immediate applications for corporate procurement decisions, where understanding delivery variance is essential for meeting emissions reduction commitments. Beyond carbon markets, the methodology provides insights into the intersection of climate mitigation and rural development, demonstrating how statistical rigor can enhance both environmental and social outcomes in sustainability initiatives.

Frontiers in Healthcare Analytics

Invited Session

Health Applications Society

Chair: Hossein Hejazian, Harvard University, Cambridge, MA, 02138, United States

1 - Causal Dag-Informed Reward Design

Ziping Xu, Harvard University, Allston, MA, United States

In reinforcement learning (RL) problems, different reward functions may lead to the same optimal policy, while some reward functions can be substantially easier to learn. In this talk, we propose a framework for reward design by constructing surrogate rewards with mediators informed by causal directed acyclic graphs (DAGs), which are often available in real-world applications through domain knowledge. We show that under the surrogacy assumption, the proposed reward is unbiased and has lower variance. Specifically, we propose an online reward design agent that adaptively learns the target surrogate reward in an unknown environment. Feeding the surrogate rewards to standard online learning oracles, we show that the regret bound can be improved. The improvement is evaluated through simulation studies based on mobile health datasets, where RL is used for digital interventions delivery.

2 - Multi-Location, Dynamic Staff Planning for a Healthcare System

Kumar Rajaram, University of California-Los Angeles, Los Angeles, CA, United States

We develop and implement a multi-stage robust optimization model to dynamically assign anesthesiologists across hospital locations under uncertain demand. The model incorporates on-call flexibility, fairness, and location constraints, and is solved using a nested column-and-constraint generation method. Implemented at the University of Pittsburgh Medical Center, it achieves 12% annual cost savings (~\$800,000) and demonstrates the value of forecast accuracy and staffing flexibility. The framework is generalizable to other healthcare workforce planning problems, such as nurse staffing.

3 - Does Order of Diagnosis Matter? Data-Driven Insights into Comorbid Hypertension and Diabetes Treatment Planning

Ezgi Gursel, University of Tennessee, Knoxville, TN, United States, Faezeh Bagheri, Supriya Sarker, Nafiseh Payani, G. Anthony Wilson, Bing Yao, Anahita Khojandi

This study analyzes treatment trajectories in patients with comorbid hypertension (HTN) and type 2 diabetes mellitus (T2DM) using retrospective cohort data from multiple Tennessee health systems. It aims to characterize differences in treatment planning as a function of the order in which the conditions are diagnosed. By exploring how treatment planning may be influenced by diagnosis order, this study seeks to identify patterns in clinical decision-making. Insights from this work may inform more personalized and effective care planning for patients managing comorbid conditions.

4 - A Numerical Framework for Describing the Transient Dynamics of Mt/Mt/1 Queues

Lingfei Zhang, Texas A&M University, College Station, TX, United States, Hrayr Aprahamian, Hadi El-Amine

This talk examines the transient behavior of queueing systems with non-stationary Markovian processes. We propose a novel, scalable Fourier-based approach to numerically characterize transient behavior under any functional form of the arrival and service processes. Our approach provides both the full distribution of the number of entities in the system and the expected sojourn time. Through extensive numerical experiments, we demonstrate that our technique accurately captures the transient behavior of non-stationary queues with high precision. Furthermore, we embed our approach within an optimization framework by introducing a Bayesian optimization procedure that efficiently optimizes stochastic systems with a limited number of function evaluations. Finally, we present a case study on college counseling centers using real data, showing that our approach identifies effective server allocation strategies, reducing total customer sojourn time by nearly 60% compared to current practices.

1 - Per-Group Distributionally Robust Optimization (Per-Gdro) with Learnable Ambiguity Set Sizes via Bilevel Optimization

Jangho Park, Sungkyunkwan University, Suwon, Korea, Republic of, Seobeom Jung, Woojae Lee, Sophia Hamm, Jihun Hamm

Group structures frequently influence model behavior; however, group membership is often unobserved during inference, limiting explicit control over group-specific performance. This can result in models performing well on certain groups but underperforming in others, leading to concerns about fairness. Moreover, each group may

follow a different distribution, and a subset of groups may be more susceptible to distributional shifts due to external factors, such as policy changes or environmental variation. To address these challenges, we propose a Per-Group Distributionally Robust Optimization (Per-GDRO) framework. It ensures fairness across groups and robustness to group-specific distributional shifts. In this framework, a ϕ -divergence ambiguity set governs adversarial group reweighting, and Wasserstein ambiguity sets capture local uncertainty within each group. We then develop an iterative algorithm that alternates between model updates and adversarial distributions across and within groups. Worst-case distributions over ambiguity sets can be directly determined through convex optimization. We employ a derivative-free surrogate optimization method to determine the size of these ambiguity sets in an adaptive manner. The experimental results demonstrate that the proposed method consistently enhances worst-group accuracy while preserving intra-group robustness.

2 - Machine Learning-Powered Lagrangian Relaxation for a Location-Partition Problem

Wen Luo, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Shiming Deng, Chu Chu

Instant retailers are increasingly establishing micro-fulfillment centers (MCs) to effectively serve their designated nearby communities. This location-partition problem can be formulated as an integer programming model and solved using Lagrangian relaxation (LR). To enhance the computational efficiency of repeatedly optimizing the relaxed sub-problem in LR, we propose a novel method that integrates ML techniques within the LR framework. Our ML-powered LR method maintains the LR framework while adopting pre-trained ML models to predict the most challenging aspects of the relaxed sub-problem. By utilizing feasible solutions derived from these predictions, this integration leverages surrogate subgradient theory to find a proper surrogate subgradient direction. In contrast to conventional end-to-end ML strategies, our approach significantly reduces reliance on the training and prediction accuracies of ML models and simplifies the collection of training samples by imitating a smaller-scale relaxed sub-problem. We explore various ML techniques, including decision trees and neural networks, to validate the proposed method. Experimental results indicate that the ML-powered LR method can achieve time savings of up to 48.62%, while also potentially yielding superior outcomes compared to the benchmark LR.

3 - Machine Learning and Regularization-Based Outer Approximation for Convex Minlp and Steel Production Optimization

Shengnan Zhao, National Frontiers Science Center for Industrial Intelligence and Systems Optimization, Northeastern University, Shenyang, China, People's Republic of, Lixin Tang, Fengyuan Shi

In this study, we introduce a novel outer approximation algorithm enhanced by machine learning and regularization techniques, designed specifically for convex Mixed Integer Nonlinear Programming (MINLP) problems. This approach employs machine learning to analyze cut generation patterns during iterations of the outer approximation algorithm, integrating the regularization information of the master problems feasible solutions to significantly enhance convergence efficiency. We test the effectiveness of the proposed algorithm on a plate design problem which is derived from real world application, as well as a set of models from an MINLP benchmark library. The numerical results show advantages of using machine learning and regularization combined with the outer approximation algorithm.

4 - Learning Acceleration Algorithms for Fast Parametric Convex Optimization with Worst-Case Guarantees

Rajiv Sambharya, University of Pennsylvania, Philadelphia, PA, United States, Jinho Bok, Nikolai Matni, George Pappas

We introduce a machine-learning framework to learn hyperparameter sequences for accelerated first-order methods (*e.g.*, the step size and momentum sequences in accelerated gradient descent) to quickly solve parametric convex optimization problems while maintaining worst-case performance guarantees. Robustness with respect to the problem parameter is incorporated directly into the learning process by augmenting the training objective with a regularization term that certifies worst-case performance over a broad class of problems (*e.g.*, the minimization of all L -smooth convex functions). The regularization term is derived from the Performance Estimation Problem (PEP) framework and relies on solving a semidefinite program (SDP) in which the algorithm hyperparameters appear as problem data. We show how to differentiate through this regularization term in the computational architecture, enabling the use of gradient-based training that balances the performance over the parametric family and worst-case guarantees over a much larger set of parameters. We showcase the effectiveness of this learned acceleration framework on a variety of numerical examples that span several different first-order methods including the accelerated versions of gradient descent, proximal gradient descent, and the alternating direction method of multipliers. Applications include parametric problems from signal processing, control, and statistics. Notably, our approach is highly data-efficient in that we only use ten training instances in all of the numerical examples.

5 - Predicting Patterns of Forecasting Failures in AI-Enabled Devices

Matthew Bobea, Institute of Service Science, National Tsing Hua University, Hsinchu, Taiwan, Galit Shmueli, Soumya Ray

Forecasting is used in a vast array of decision-making systems, including those based on AI-enabled devices such as wearable health monitors, smart energy grids, and smart home systems. The heavy reliance on time-series forecasting in these systems has given rise to an urgent need to address extreme forecasting failures that significantly impact organizations. Such errors can arise due to the nature of forecasting algorithms and their interaction with data patterns. In response to this challenge, we introduce TreeAlert, a novel framework designed to identify, interpret, and forecast patterns of extreme forecasting errors. TreeAlert uses regression trees to detect failure-prone conditions and explicitly links them to contextual and timing patterns to help improve models. We translate these conditions into human-readable rules to generate actionable insights and facilitate stakeholder understanding. TreeAlert forecasts future failure periods, thereby providing a forward-looking tool that empowers decision-makers to proactively anticipate vulnerabilities. We demonstrate TreeAlert on heart rate data from an IoT device. By bridging error analysis with forecasting we offer an interpretable solution for enhancing forecast driven support systems and for minimizing risks.

6 - Training Neural Networks with User-Defined Dimension-Specific Unimodality

HYUNHO KIM, KAIST, Daejeon, Korea, Republic of, Jong-Seok Lee

Unimodal functions, characterized by a single extremum, facilitate global optimization and play a crucial role in various mathematical fields such as optimization theory and probability. In this study, we propose a novel neural network architecture for effectively approximating unimodal functions over a user-specified subset of features. To estimate these dimension-specific unimodal functions, we decompose a network into monotonic and convex components and then recombine them to approximate a quasi-convex function for each constrained dimension. The monotonic and convex properties are achieved through specially designed units that utilize exponentiated weights and suitable activation functions. These units are integrated into a partially connected neural network structure, which ensures unimodality in the designated dimensions without compromising the network's expressive capability. Numerical experiments illustrate the effectiveness and practical applicability of the proposed approach.

7 - Bilevel Container Relocation Problem

Yeonjun Choi, Pohang University of Science and Technology, Pohang, Korea, Republic of, Insoo Park, Seokyun Hong, Kangbok Lee

We study a practical yet underexplored extension of the container relocation problem (CRP) where a limited number of pre-marshalling relocations are allowed before retrieval begins. This anticipatory step enables proactive improvements to downstream operations. We formulate the problem as a bilevel optimization model: the upper level selects pre-marshalling moves, while the lower level executes a given CRP policy—optimal or heuristic—on the resulting configuration. To our knowledge, this is the first work to model and solve such problems using a unified bilevel framework.

We develop an efficient exact tree search algorithm that explores all pre-marshalling sequences up to a given depth. We incorporate pruning and dominance rules based on structural properties to reduce computation without sacrificing optimality. The framework supports arbitrary CRP solvers, ensuring both generality and practical relevance. Computational results show that dominance rules improve efficiency, and our method outperforms MIP-based approaches under comparable time limits. The proposed framework offers a unified and efficient approach to container yard planning with realistic operational flexibility.

1 - Using Bin Packing Optimization to Investigate the Transportation Challenges Impeding School Start Time Changes in Wake County Public Schools

Warren Kay, United States Military Academy, West Point, NY, United States, Brandon McConnell, Kristin Thoney-Barletta, Russell King, Russell Nelson

In 2014 the American Academy of Pediatrics (AAP) recommended later school start times (after 8:30 AM) for adolescents to promote their health and academic success. Wake County Public School System (WCPSS) is the largest school district in North Carolina, with nearly 200 schools and over 160,000 students, and all its middle school and high school students start school at 8:30 AM or earlier. In the 2023–2024 school year, a national bus driver shortage exacerbated daily student transportation challenges and delayed the school board's ability to prioritize school start time changes. This study uses a mathematical optimization model following a bin packing approach to minimize the number of buses required to complete all the routes in the nine sub-districts within Wake County. Scenarios that changed the school start times to abide by AAP recommendations were generated and tested using bus route information from the 2023–2024 school year. Results show that areas with a higher concentration of magnet and special schools require a greater increase in the number of buses needed to swap elementary and high school start times. The results also indicate significant interactions between the sub-districts, which challenge WCPSS's ability to logistically isolate a sub-district to use as a case study for start time changes. This research investigates the current relationship between transportation requirements and school start times. It provides analysis that could inform decision-making and planning as WCPSS hires more bus drivers and pursues the best outcomes for its students.

2 - A PPP-Based Planning Model for Enhancing Customer Experience at A State-Managed Transport Facility

N Ravichandran, Professor (Retired), Indian Institute of Management Ahmedabad, Ahmedabad, India, Nikunj Kumar Patel

This study presents a strategic planning model developed for the Gujarat State Road Transport Corporation (GSRTC) to optimize bus port infrastructure through Public-Private Partnerships (PPP), aiming to enhance customer experience in state-managed transport facilities. Drawing insights from 15 PPP projects executed in two phases, the research formulates a simulation-based decision model that allows sensitivity analysis across key parameters such as land allocation, terminal operations area, and commercial space utilization.

The model distinguishes between two core development components: (i) the Bus Terminal Facility (BTF), leased for 30 years, and (ii) the commercial complex, leased for 90 years. A detailed financial framework estimates construction costs, operational expenses (maintenance, security, utilities), and potential revenue streams (commercial leases, advertising, parking). The Net Present Value (NPV) and profitability for concessionaires are calculated to inform bidding and policy decisions. In parallel, GSRTC's potential revenue realization and strategic land use planning are integrated within the model's outputs.

Key reflections include the need for GSRTC to preserve long-term operational flexibility, adopt shared service arrangements for housekeeping and security, and secure revenue shares from commercial operations. The model transforms transport terminals into multifunctional public spaces—enhancing passenger amenities and creating urban value through retail, entertainment, and social infrastructure.

This integrated modeling approach offers a scalable blueprint for transport authorities to structure PPPs in a financially viable, socially beneficial, and operationally sustainable manner. It balances public objectives and private incentives, turning transport nodes into catalysts for community-centric urban regeneration.

3 - Workforce Scheduling for Efficient and Equitable Access to Education

Mohsen Emadikhiaiv, Florida Atlantic University, Boca Raton, FL, United States, Carlos Cardonha, Mahyar Eftekhari, David Bergman

Nonprofits supporting schools with extracurricular programs face unique challenges in efficiently assigning their skilled trainers. This research stems from our collaboration with New York Sun Works (NYSW), a nonprofit organization committed to delivering sustainability science and climate education to K-12 students across New York City. In this talk, we present optimization models and algorithms designed to address variants of the workforce scheduling problems encountered by NYSW.

4 - A Bi-Objective Robust Optimization Model for Equitable Allocation of Field Hospitals in Surgical Backlog Reduction

Jorge Acuna, Universidad Adolfo Ibáñez, Viña del Mar, Chile, Sofía Zúñiga

In 2023, over 330,000 patients in Chile awaited elective surgeries in the public healthcare system, with wait times frequently exceeding 400 days. This situation emphasized persistent disparities in surgical access and the need for capacity expansion strategies. To address this challenge, we formulated a bi-objective robust optimization model for the strategic allocation of field hospitals and the coordination of interregional patient transfers. The proposed model simultaneously maximizes the number of patients treated (efficiency) and minimizes regional disparities in access to care (equity). Disparities were quantified using a Gini index focused on unmet surgical needs, highlighting functional differences across health regions rather than population size. Demand uncertainty was addressed through a budgeted uncertainty set, ensuring solution feasibility under adverse conditions. Employing the triangle splitting method, we constructed the Pareto frontier of non-dominated solutions. We applied the Nash Bargaining Solution to guide policy selection, treating the two objectives as cooperative players negotiating a Pareto-optimal compromise. Using real healthcare data from Chile, we evaluated various investment levels and examined how model-driven transfer decisions influenced system performance. Results show that combining field hospitals with targeted patient transfers leads to improved regional balance and system throughput. This framework provides robust, data-driven insights to support mid-term planning for surgical backlog reduction and more equitable healthcare delivery.

Recent Advances in Stochastic Nonlinear Optimization II

Invited Session

OPT: Nonlinear Optimization

Chair: Sen Na, Georgia Institute of Technology, Atlanta, 30339, United States

Co-Chair: Miaolan Xie, University of Chicago, Chicago, IL, United States

1 - Reliable and Adaptive Stochastic Optimization in the Face of Messy Data

Miaolan Xie, University of Chicago, Chicago, IL, United States

Solving real-world stochastic optimization problems presents two key challenges: the messiness of real-world data, which can be noisy, biased, or corrupted due to factors like outliers, distribution shifts, and even adversarial attacks; and the laborious, time-intensive requirement of manually tuning step sizes in many existing algorithms. I will introduce a simple adaptive optimization framework that avoids the need for manual step size tuning by adaptively adjusting the step size in each iteration based on the progress of the algorithm. To address the issue of messy data, the algorithm only assumes access to function-related information through probabilistic oracles, which may be biased and corrupted. This framework is very general, encompassing a wide range of algorithms for both unconstrained and constrained optimization. It is applicable to multiple problem settings, such as expected loss minimization in machine learning, simulation optimization, and derivative-free optimization. Under reasonable conditions on the oracles, we provide an analytical framework that bounds the iteration complexity with high probability for settings with highly noisy and corrupted gradients.

2 - Towards Parameter Free Decentralized Optimization

Gesualdo Scutari, Purdue University, West- Lafayette, IN, United States

We consider decentralized optimization where multiple agents minimize the average of their (strongly) convex, smooth losses over a communication graph. Convergence of the existing decentralized methods generally hinges on an apriori, proper selection of the stepsize. Choosing this value is notoriously delicate: (i) it demands global knowledge from all the agents of the graph's connectivity and every local smoothness/strong-convexity constants—information they rarely have; (ii) even with perfect information, the worst-case tuning forces an overly small stepsize, slowing convergence in practice; and (iii) large-scale trial-and-error tuning is prohibitive. This work

introduces a decentralized algorithm that is fully adaptive in the choice of the agents' stepsizes, without any global information and using only neighbor-to-neighbor communications--agents need not even know whether the problem is strongly convex. The algorithm retains strong guarantees: it converges at linear rate when the losses are strongly convex and at sublinear rate otherwise, matching the best-known rates of parameter-dependent methods.

3 - Online Statistical Inference of Constrained Stochastic Optimization via Sequential Quadratic Programming

Sen Na, Georgia Institute of Technology, Atlanta, GA, United States

Constrained stochastic nonlinear optimization problems have attracted significant attention due to their ability to model complex real-world scenarios in physics, economics, and biology. As datasets continue to grow, online inference methods have become essential for enabling real-time decision-making without storing historical data. In this talk, we introduce an online inference procedure for constrained stochastic optimization by leveraging a method called Sketched Stochastic Sequential Quadratic Programming (SSQP). As a direct generalization of sketched Newton methods, SSQP approximates the objective with a quadratic model and the constraints with a linear model at each step, then applies a sketching solver to inexactly solve the resulting subproblem. Building on this framework, we propose a new online inference procedure called random scaling. Specifically, we construct a test statistic based on SSQP iterates whose limiting distribution is free of unknown parameters. Compared to existing online inference procedures, our approach offers two key advantages: (i) it enables the construction of asymptotically valid confidence intervals, and (ii) it is matrix-free, meaning that the computation involves only primal-dual SSQP iterates $(\mathbf{x}_t, \lambda_t)$ without requiring any matrix inversions. We validate our theory through numerical experiments on nonlinearly constrained regression problems and demonstrate the superior performance of our random scaling method over existing inference procedures.

4 - Neural Collapse and AI Optimization

X.Y. Han, Chicago Booth, Chicago, IL, United States

In the performance-dominated landscape of AI development, systematic understanding is difficult: Any architecture is fair game as long as it can climb the leaderboard. Yet, even among the overwhelming multimodality of neural networks, one motif remains: data is transformed layer-by-layer and iteration-by-iteration into high-dimensional representations with which predictions are eventually made. Thus, examining the geometry of these representations offers a powerful lens for the analysis of AI. Neural Collapse is a striking example, evident late in the training of predictive AI: Originally observed in classification networks during a 'Terminal Phase of Training' (TPT) – where training error vanishes but loss continues decreasing – Neural Collapse reveals a fundamental inductive bias. It encompasses four interconnected geometric regularities in the final layer representations: (NC1) Within-class variability of activations collapses towards zero as they converge to their class means; (NC2) These class means arrange themselves into a maximally separated, symmetric structure (a Simplex Equiangular Tight Frame); (NC3) The classifier vectors align with these class means in a self-dual configuration; (NC4) The model's decision mechanism effectively simplifies to Nearest Class-Center rule. This emergent geometric simplicity is linked to improved generalization, robustness, and interpretability. I will discuss the core Neural Collapse phenomenon, its theoretical underpinnings, and recent updates and extensions since its discovery.

5 - Online Scaled Gradient Methods

Madeleine Udell, Stanford University, Stanford, CA, United States

We introduce a framework to accelerate the convergence of gradient-based methods with online learning. The framework learns to scale the gradient at each iteration through an online learning algorithm and provably accelerates gradient-based methods asymptotically. In contrast with previous literature, where convergence is established based on worst-case analysis, our framework provides a strong convergence guarantee with respect to the optimal stepsize for the iteration trajectory. We obtain the first convergence guarantee for the widely-used hypergradient descent method (HDM) and for new variants with heavy-ball momentum (HDM-HB) and Nesterov momentum. HDM-HB significantly outperforms other adaptive first-order methods, and often matches the performance of L-BFGS using less memory and cheaper iterations.

Recent Advance in Optimization Under Uncertainty: Theory and Applications

Invited Session

OPT: Optimization Under Uncertainty

Chair: Karmel Shehadeh, University of Southern California, Los Angeles, CA, United States

1 - Multistage Stochastic Programming for Hurricane Relief Logistics Planning with Rolling Forecast Uncertainty

Yongjia Song, Clemson University, Clemson, SC, United States, Sudhan Bhattarai

In this talk, we will discuss multi-stage stochastic programming (MSP) models and solution approaches for humanitarian relief logistics planning in hurricane disasters. Specifically, we study how the rolling forecast information can be integrated in an MSP model via the Martingale Model of Forecast Evolution (MMFE) to provide optimal adaptive logistics decision policies. We investigate state-space modeling to address the high-dimensional state space as a result of the MMFE model. Our numerical results and sensitivity analyses demonstrate the value of MSP for hurricane relief logistics planning compared to approaches that utilize rolling forecast information in a rolling-horizon fashion. We also investigate various trade-offs between policy flexibility, solution quality, and computational effort, from which we gain valuable managerial insights for the practitioners.

2 - Capacitated Spatial Newsvendor

Xian Yu, The Ohio State University, COLUMBUS, OH, United States, Jinhui Han, Ming Hu

We revisit the classical newsvendor problem by introducing capacitated supply and spatial transportation in a setting where a firm needs to position available supplies across a service region to meet random demand over the space. Leveraging optimal transport theory, we derive optimality conditions that minimize the sum of aggregate newsvendor loss and transportation expenses in a general framework, accounting for demand over continuous space or discrete locations or a combination of both. The solution structure retains the simplicity of the classical newsvendor solution but also differs due to the interplay of demand, transportation, and supply constraints. The demand effect drives supply placement to high-demand areas, the transportation effect prioritizes nearby demand, and the supply constraint restricts the ability to fully meet all demand, especially when the total supply is insufficient. The solution is explicitly characterized using Laguerre cell division in a specific semi-discrete setting, where initial supplies are stored at discrete facilities and demands are distributed over a continuous space. This structure reveals how transportation costs adjust the optimal demand quantile and how limited local supply influences this quantile through Laguerre cells' weight parameters. The derived optimality conditions further inform the development of numerical algorithms in both semi-discrete and fully discrete settings.

3 - Sequential Quadratic Optimization for Solving Expectation Equality Constrained Stochastic Optimization Problems

Haoming Shen, University of Arkansas, Fayetteville, AR, United States, Yang Zeng, Baoyu Zhou

A sequential quadratic programming method is designed for solving general smooth nonlinear stochastic optimization problems subject to expectation equality constraints. We consider the setting where the objective and constraint function values, as well as their derivatives, are not directly available. The algorithm applies an adaptive step size policy and only relies on objective gradient estimates, constraint function estimates, and constraint derivative estimates to update iterates. Both asymptotic and non-asymptotic convergence properties of the algorithm are analyzed. Under reasonable assumptions, the algorithm generates a sequence of iterates whose first-order stationary measure diminishes in expectation. In addition, we identify the iteration and sample complexity for obtaining a first-order ϵ -stationary iterate in expectation. The results of numerical experiments demonstrate the efficiency and efficacy of our proposed algorithm compared to a penalty method and an augmented Lagrangian method.

4 - Algorithmic Approaches for Identifying the Trade-off Between Pessimism and Optimism in A Stochastic Fixed Charge Facility Location Problem

Man Yiu Tsang, Texas Tech University, Lubbock, TX, United States, Karmel Shehadeh

We present algorithmic strategies for identifying the trade-off (TRO) between adopting a distributional belief and hedging against distributional ambiguity for modeling demand uncertainty in a capacitated fixed charge facility location problem (CFLP). First, we introduce a TRO model for the CFLP (TRO-CFLP), which finds the optimal number and location of facilities that minimize the fixed cost of establishing them and the maximum expected operational costs evaluated over all distributions residing within a TRO set. The TRO set is characterized by the empirical distribution, an ambiguity set, and a TRO parameter that controls the trade-off between solving the problem under the empirical distribution and the worst-case distribution within the ambiguity set. Our TRO-CFLP model enables decision-makers to explore a spectrum of location decisions, from optimistic to conservative ones. Second, we propose a Spectrum Search Algorithm to identify the full spectrum of optimal solutions for the TRO-CFLP. Third, we propose a decomposition framework for solving the TRO-CFLP model with a fixed TRO parameter. This framework is employed as a subroutine in the Spectrum Search Algorithm and includes a new hybrid primal-dual column-and-constraint generation (hC&CG) algorithm. Our numerical results demonstrate the efficiency of the Spectrum Search Algorithm and the superior computational performance of hC&CG over state-of-the-art decomposition algorithms. Our results also highlight the practical benefits of adopting solutions on the TRO-CFLP's spectrum over those obtained using traditional models. While the proposed algorithms are motivated by the TRO-CFLP problem, they can be tailored to other applications.

5 - Inventory Design for Mobile Food Markets Considering Customer Purchasing Behavior

Zijian Wang, University of Minnesota, Minneapolis, MN, United States, Yiling Zhang, William Cooper

Food insecurity, driven in part by limited access to grocery stores, affects millions across the U.S., including over 9% of Minnesotans. Mobile markets, which bring affordable and healthy foods directly to underserved communities via vehicles, have emerged as a promising solution to alleviate this issue. However, many mobile markets struggle with operational inefficiencies and financial sustainability.

In this study, we investigate how to optimize mobile market operations by focusing on inventory decisions and their relationship to customer purchasing behaviors. We model this as a bilevel optimization problem, where the mobile market operator chooses the inventory to load onto the vehicle, and sequentially visited customers make purchasing decisions based on product availability and budget constraints.

To address the computational challenges of this bilevel model, we develop an exact reformulation and propose a heuristic approach that balances solution quality and efficiency. Our numerical experiments demonstrate the effectiveness of these methods and provide insights into inventory planning for mobile markets. Numerical experiments also demonstrate the robustness of our methods in diverse scenarios.

This work offers a novel decision-making framework for mobile market operators, helping to improve service equity and operational efficiency. Future work will extend this framework to incorporate additional factors, such as routing decisions, pricing strategies, and stochastic customer behavior.

OPT: Computational Optimization and Software

Chair: Shuvomoy Das Gupta, Rice University, Houston, TX, United States

1 - Tradeoffs Between Memory and Oracle-Complexity in Convex Optimization

Moïse Blanchard, Columbia University, New York, NY, United States

How much memory do convex optimization algorithms need? Algorithms for first-order convex optimization are usually divided into two categories: gradient-descent-based algorithms and cutting plane algorithms. While gradient descent methods only need to store a few vectors, which requires $\tilde{O}(d)$ bits, they require $1/\epsilon^2$ gradient queries to reach an ϵ -approximate solution. On the other hand, cutting plane methods converge exponentially: they only require $O(d \log 1/\epsilon)$ queries in dimension d . However, these are significantly more memory intensive since they require storing a matrix with d^2 bits. Towards understanding this memory/query-complexity landscape, a natural question is whether the optimal convergence rate for low-memory algorithms should always be polynomial (query-complexity polynomial in $1/\epsilon$) or can be exponential (query-complexity logarithmic in $1/\epsilon$). We provide memory/query-complexity lower bounds for the related feasibility problem, in which the goal is to find a point in a convex feasible set with access to a separation oracle. In particular, we show that deterministic algorithms always require a polynomial query-complexity in $1/\epsilon$ if they have less than quadratic memory in d . This reveals a sharp phase transition since cutting plane methods only require $O(d \log 1/\epsilon)$ queries using quadratic memory in d . To the best of our knowledge, these are the first exponential memory/query-complexity lower bounds in continuous optimization.

2 - Bridging Convex and Nonconvex Approaches: Geodesic Strong Convexity of Qcqp's from Tightness and Strict Complementarity of Sdr

Jinxin Wang, The University of Chicago, Chicago, IL, United States, Huikang Liu, Chonghe Jiang, Anthony So

Nonconvex quadratically constrained quadratic programs (QCQPs) have received increasing attention in recent decades. Two typical approaches to tackling such challenging problems are convex semidefinite relaxation (SDR) and nonconvex iterative methods (e.g., gradient descent). Although the convex SDR and nonconvex approaches have been extensively studied, they have been largely explored in parallel, and few things can be said about their connections. This paper takes the first step in building connections between convex and nonconvex approaches. Under the tightness and strict complementarity of SDR, we find that nonconvex QCQPs admit nice geometric properties, including quadratic growth, error bound, and (quotient) geodesic strong convexity. These structured properties quantify the growth behavior of optimization problems around global optimal solution sets and can imply fast convergence rates of various nonconvex iterative methods.

3 - Optimal Convergence Rates of Alternating Gradient Descent-Ascent in Bilinear Games

Shuvomoy Das Gupta, Rice University, Houston, TX, United States

We study the alternating gradient descent-ascent (AltGDA) algorithm in two-player zero-sum games. Alternating methods, where players take turns to update their strategies, have been recognized as simple and practical approaches for learning in games, exhibiting much better numerical performance than their simultaneous counterparts. However, the theoretical understanding of alternating algorithms remains limited---either restricted to the unconstrained setting or with suboptimal convergence rates. Notably, the behavior of AltGDA in constrained settings (e.g., over the probability simplex) has not been studied. We prove that AltGDA leads to constant regret for each player, and thus an optimal $O(1/T)$ ergodic convergence rate in terms of the duality gap. Our proof has several interesting departure points from classical proofs of convergence in saddle-point settings. Notably, we are unable to conclude our result from a simple "descent inequality", and must instead reason across iteration intervals that are defined by when the dynamics touch the relative boundary of the simplices. While our eventual proof is purely theoretical, we arrived at our hypothesis that AltGDA achieves $O(1/T)$ convergence via a computer-assisted methodology called the performance estimation problem (PEP) framework.

4 - Enhancing Average-Reward Reinforcement Learning via Anchoring

Jongmin Lee, Seoul National University, Seoul, Korea, Republic of, Ernest Ryu, Cominetti Roberto, Mario Bravo

Anchoring-based acceleration, first introduced by Halpern, has been actively studied in the fixed-point iteration and minimax optimization literature. More recently, anchoring acceleration has shown promise in Reinforcement Learning (RL) setups, particularly when applied to Value Iteration, one of the foundational RL algorithms. In this talk, we will introduce Anchored Value Iteration and discuss how it improves convergence and sample complexity across various average-reward RL settings, including the tabular setup, the generative model setup, and offline RL with function approximation.

Co-Chair: Cristiana Lara, Amazon, Bellevue, WA, United States

1 - Algorithms for Hub Location with Network Connectivity Constraints

Ozgun Elci, Amazon, Seattle, WA, United States

In transportation and logistics networks, hub location problems arise when it is necessary to route flows between origin-destination pairs through a set of hub facilities. We study developing algorithms to solve large-scale hub location problems. This problem involves selecting the best locations for hubs to connect origin-destination pairs. We consider a variant with network connectivity constraints in which we minimize the total weighted distance subject to capacity constraints on each hub, ensuring network connectivity between hubs, aiming to balance transportation costs and hub congestion. The mixed-integer programming formulation becomes computationally intractable as the number of candidate hub locations increases. We explore both exact optimization techniques and heuristic approaches to efficiently solve the underlying hub location problem.

2 - The Single-Vehicle Routing Problem with Precedence Constraints

Qie He, Amazon, Santa Clara, CA, United States, Michael Rice, Renato Werneck

The single-vehicle routing problem is a fundamental model in transportation and logistics. Many practical applications impose additional constraints, such as precedence constraints among nodes. We present an efficient heuristic to solve this problem.

3 - Large Scale Resource Allocation: a Column Generation Multi-Device Gpu Based Algorithm

Marcus Poggi, Amazon, Bellevue, WA, United States, Qi Chen, Ozlem Bilginer, Granville Paules, Zsolt Csizmadia

Resource allocation problems involve a set of tasks, each with a list of fulfillment options that consume available resources at varying levels. The objective is to minimize the sum of option assignment costs plus a linear function of resource usage. Our application context requires both primal allocations and dual lower bounds within strict time constraints—one or two orders of magnitude faster than commercial solvers need to compute linear relaxations. To meet these requirements, we employ preprocessing techniques alongside dual and primal algorithms to hot-start a Dantzig-Wolfe decomposition of the original problem. Our Column Generation algorithm coordinates agents distributed across multiple GPU devices that simultaneously solve the master linear programming problem, address column generation subproblems, search for improved primal allocations, and enhance dual bounds. We present computational results for instances involving tens of millions of tasks, demonstrating the evolution of primal and dual bounds over time. Our approach outperforms existing alternative methods.

4 - Gpu Acceleration of First Order Methods for Large Scale Resource Assignment - Benchmark Platform and Results

Qi Chen, Amazon, Bellevue, WA, United States, Ozlem Bilginer, Marcus Poggi, Zsolt Csizmadia, Granville Paules

While GPU acceleration has transformed predictive analytics, its widespread application to prescriptive analytics (optimization) is only recently emerging. At Amazon, large scale capacitated resource assignment optimization problems are prevalent across multiple business domains, yet often exceed commercial solver scalability limits. This has motivated competing implementations of various first order methods. We present a vectorized modeling approach for resource assignment problems designed for GPU accelerated first order algorithms. Using our new internal benchmark platform, we demonstrate significant performance improvements, including a 700x runtime reduction against the equivalent vectorized CPU implementation for one production instance. Compiling a library of internally-relevant instances, we evaluate algorithm sensitivity to various tuning parameters. Additionally, we demonstrate extensibility of our modeling approach to nested assignment structure. Our results build trust in the practicality of GPU accelerated optimization for business-relevant scale instances.

5 - Scenario-Optimal Recourse Policy for the Vehicle Routing Problem with Stochastic Demands

Matheus Ota, University of Waterloo, Waterloo, ON, Canada, Ricardo Fukasawa

The Vehicle Routing Problem with Stochastic Demands (VRPSD) is a well-studied variant of the Capacitated Vehicle Routing Problem in which customer demands are random variables, and the objective function accounts for the expected recourse cost. Existing exact algorithms for the VRPSD rely on strong assumptions about the probability distribution of the demands to ensure computational tractability. In contrast, the general stochastic programming community often models uncertainty using a finite set of scenarios, enabling the approximation of more realistic and diverse probability distributions through sampling. In this work, we propose a *scenario-optimal recourse policy* that assumes perfect information of the demand realization under each scenario. Leveraging known results from network-flow and polyhedral theory, we show that the resulting recourse function can be fully described by certain cuts that resemble the well-known rounded capacity inequalities (RCI's). This scenario-optimal recourse policy is then used to under-approximate the classical recourse policy. Computational experiments show that our method yields stronger bounds than an approach that is based on an extension of a recently proposed integer L-shaped-based method.

1 - Equitable and Stochastic Humanitarian Relief Network Design for Disaster Preparedness

Chun Peng, Beijing Jiaotong University, Beijing, China, People's Republic of

In this study, we propose an equitable stochastic humanitarian relief network design problem for disaster preparedness when the demand is uncertain. Specifically, we develop an inequity-averse aggregation function to capture the equity by balancing humanitarian benefits and allocation efficiency. Using sample average approximation technique, we reformulate the two-stage stochastic model as a large-scaled optimization problem, which can be further efficiently solved by Benders decomposition algorithm with accelerating strategies. We finally demonstrate the value of our methodology in mitigating inequities using both synthetic and real-life data.

2 - Flight Delay Dynamics: Unraveling the Impact of Airport-Network-Spilled Propagation on Airline on-time Performance

Yi Tan, The University of Alabama in Huntsville, Huntsville, AL, United States, Yajun Lu, Lu Wang, Hieu Pham

Flight delay prediction has attracted increasing attention in airline operations. Early identification of potential flight delays is crucial for improving airport scheduling and airline operations while mitigating associated costs. This study investigates the influence of the potential propagation of flight delays throughout the airport network via interconnected flights, a mechanism we term Airport-Network-Spilled Propagation (ANSP). To model the ANSP mechanism, we develop a novel time-dependent, network-based approach that decays the importance of past delays. From this network, we extract a real-time ANSP score for each airport to measure the influence of propagated delays. To evaluate our proposed approach, we employ four state-of-the-art machine learning models using domestic airline on-time performance data from the 30 Large Hub airports in the United States. The results demonstrate that integrating the ANSP score with established features from airline operations literature significantly enhances flight departure delay prediction performance, achieving an increase in AUC of up to 5.49%. Furthermore, we conduct an explainable AI analysis using Shapley additive explanations (SHAP), which reveals that our ANSP score ranks as the most important predictor among all features tested.

3 - Sparsity-Induced Gradient-Free Optimization of Heterogeneous Information Perturbations in Transportation Networks

Shiwei Liu, University of Florida, Gainesville, FL, United States, Hongcheng Liu, Lili Du

Urban navigation platforms can alleviate traffic congestion by subtly altering the travel-time information they broadcast, thereby nudging drivers toward routes that benefit the overall network performance. This paper proposes a Heterogeneous Perturbation Optimization Model (HPOM), which assigns a distinct perturbation weight to each link within a Coordinated Routing Mechanism with Mixed-strategy Information Perturbation (CRM-M-IP). The objective of HPOM is to minimize total system travel

time while explicitly constraining both the average and worst-case user sacrifice. We introduce a two-stage solution framework to solve HPOM. Stage 1 employs a self-adaptive mirror descent (MD) routine to compute each mixed-strategy perturbed equilibrium routing decision (MP-ERD) in real time, with a convergence rate of $O(1/K)$. Stage 2 incorporates a Sparsity-Inducing Stochastic Gradient-Free (SI-SGF) algorithm to solve HPOM with a dimension-insensitive $O(1/K)$ convergence rate for convex objectives, and it extends gracefully to non-convex settings. A golden-section search algorithm further accelerates convergence, making the approach suitable for real-time deployment. Comprehensive experiments on the Sioux Falls and Chicago networks demonstrate that the proposed MD algorithm outperforms simultaneously-updating distributed algorithm (SDA) in solving MP-ERD, particularly when high convergence precision is required or when the problem scale is large. Furthermore, compared to the no-perturbation baseline, the heterogeneous perturbation framework reduces total travel time by up to 25.67% more than the homogeneous approach, while keeping user sacrifice low.

4 - Single Allocation Hub Line Location Problems: Model Formulations and Exact Solution Methods

Chanchal Kumar Salode, Indian Institute of Technology Delhi, New Delhi, India, Prasanna Ramamoorthy

In this study, we introduce the Single Allocation Hub Line Location Problem, which focuses on locating a set of hubs connected in the form of a line, while assigning non-hub nodes to hubs under a single allocation scheme. This problem finds applications in various domains such as public transportation, telecommunications, and rapid transit systems, where the cost of designing networks is high compared to routing costs, making full interconnection of hubs impractical. The objective is to minimize the total transportation cost between all pairs of origin-destination nodes. To address this problem, we propose path-based and flow-based Mixed Integer Linear Programming (MILP) models. Furthermore, to efficiently solve large-scale instances, we develop a Benders Branch-and-Cut algorithm incorporating state-of-the-art enhancements. Computational results on two sets of benchmark instances demonstrate the efficiency of the proposed algorithm, which significantly outperforms a general-purpose solver in both speed and scalability.

1 - Broken Records, Broken Products: How Data Integrity Shapes Recall Risk

Chunjie Zhao, Clark University, Worcester, MA, United States, Anqi Wu

Product recalls represent critical events that can severely disrupt business operations, damage brand reputation, and impose substantial financial costs. Despite extensive research on the operational and regulatory aspects of product recalls, the role of data integrity violations, defined as breaches in data accuracy, consistency, and reliability, remains underexplored in the literature on information systems. This study investigates the impact of data integrity violations on the timing and likelihood of product recalls. Using survival analysis in a longitudinal data set of product recall events, we find that products linked to data integrity violations face a 13% higher risk of being recalled compared to those affected by other factors. This risk increases to approximately 15% within product quality-focused project domains. These findings highlight the critical role of data integrity in ensuring product safety and organizational resilience. The study contributes to the literature by establishing an empirical connection between data governance and operational risk and offers actionable insights for firms aiming to enhance product quality and recall prevention through improved data management practices.

2 - Reducing Transparency? the Hidden Gender Cost of Ehr Adoption in Organ Discards

YUYING CAI, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, Kai-Lung Hui

The U.S. organ transplant system faces a dual crisis: a persistent organ shortage coexists with high discard rates, despite many unused organs being of comparable quality to those successfully transplanted. Gender disparities further compound this inefficiency, as organs from female donors, who represent a larger share of deceased donors, are disproportionately discarded. This study examines whether Electronic Health Record (EHR) adoption in donor hospitals mitigates or exacerbates gender disparities in organ discards, particularly through its spillover effects on Organ Procurement Organizations (OPOs). Using hospital-level EHR adoption data from the AHA IT Supplement and individual-level deceased donor records from UNOS (1987–2019), we employ a generalized difference-in-differences (DiD) design to address selection bias. Contrary to the expectation that EHRs improve transparency and equity, we find that EHR adoption widens the gender gap in discard rates, with organs from female donors facing significantly higher discard probabilities. We further conduct a series of robustness checks to confirm this finding. Our study contributes by revealing unintended consequences of EHRs, challenging assumptions about their uniformly positive effects. It also bears immediate relevance for Health Information Exchange (HIE) policymakers and transplant stakeholders aiming to ensure that digital technologies promote, rather than hinder, equitable healthcare delivery.

3 - Bridging the Digital Divide: An Experimental Investigation of Telehealth Adoption in Pakistan

Edwin (Yuchen) Wang, University of Massachusetts Boston, Boston, MA, United States, Adeela Gulzari

While digital health platforms hold promises for expanding access to care, their effectiveness hinges on users' ability to adopt and trust these systems, especially in low-resource and rural contexts. We designed an experiment to investigate the key barriers to online healthcare adoption among countryside residents in Pakistan. We recruit adult participants and randomly assign them to one of two versions of a prototype telemedicine application: (1) a basic interface offering text-only consultations and appointment scheduling, and (2) an enhanced version featuring video consultations, interactive health education content, and a peer-support forum. We hypothesize that richer media features and social support tools will significantly increase trust and perceived usefulness, thereby improving adoption rates. Our findings will contribute to the imbalance of healthcare resources by (i) isolating context-specific design principles for telehealth in developing regions, (ii) empirically validating the roles of trust and media richness in digital-health uptake, and (iii) offering actionable guidelines for policymakers and practitioners seeking to bridge rural healthcare gaps through information technology.

4 - From Deception to Perception: the Surprising Benefits of Deepfakes for Detecting and Measuring Nuanced Bias Patterns in Facial Regions

Yizhi Liu, University of Maryland, College Park, College Park, MD, United States, Balaji Padmanabhan, Siva Viswanathan

While deepfake technologies are often criticized for their misuse, we demonstrate their surprising utility for bias detection and measurement in high-stakes decision-making contexts. We develop a novel methodological framework that uses deepfake-generated facial images to precisely manipulate sensitive attributes (e.g., race, age) while holding all other visual features constant. Applying this approach to pain assessment, a domain where subjective interpretation of facial expressions influences clinical decisions, we uncover systematic patterns of bias across assessor groups. Using a series of crowdsourced experiments, we find that racial and age-based biases are not only prevalent but also region-specific. In particular, White assessors show greater bias in upper facial regions, while Black assessors exhibit stronger bias in lower facial regions. This AU-level analysis offers unprecedented granularity in understanding the perceptual mechanisms behind biased decision-making. Our findings reveal how deepfake-driven visual correspondence studies overcome longstanding limitations in experimental control, enabling more accurate and fine-grained bias measurement. This work not only advances the methodological frontier of bias research but also offers practical implications for designing fairer human and AI-based assessment systems in visual decision-making contexts.

Drug and Treatment Development: The Role of Clinical Trials, Post-Approval Data, and Incentives

Invited Session

Health Applications Society

Chair: Ozge Yapar, Indiana University, Bloomington, IN, United States

1 - Optimal Push, Pull, and Failure Funding for Global Health

Chenxi Xu, Duke University, Durham, NC, United States, David Ridley, Peng Sun

Malaria caused over 600,000 deaths in 2021, yet commercial incentives are weak for drug and vaccine development for malaria and other tropical diseases. Governments and nonprofits address these market failures through push (e.g., grants) and pull (e.g., prizes). We propose a third mechanism in which the funder only pays when the firm fails. That is, the funder reimburses the firm a share of its testing costs, which we refer to as "insurance." Insurance is optimal when the commercial market is large enough to reward success, but too small to induce investment. The optimal mechanism addresses adverse selection and moral hazard. For most tropical diseases, including malaria, we recommend pull funding with supplementary push support. Insurance is optimal for tuberculosis if testing costs are less than a billion dollars. These findings challenge current practices dominated by push funding and extend to funding innovations in other sectors.

2 - Clinical Trials and Conditional Approval Schemes: Implications for Healthcare Systems and Companies

Ozge Yapar, Indiana University, Bloomington, IN, United States, Andres Alban

Traditionally, companies complete Phase III trials before applying for a healthcare payer's approval. Conditional approval schemes allow earlier market entry based on preliminary evidence, with full approval contingent on further data demonstrating health-economic value. The use of these schemes alters the incentives around the design of trials by decoupling market entry from trial completion.

These schemes may encourage companies to enroll more patients, generating stronger evidence for the new treatment. However, companies choose how much evidence to generate before applying for conditional approval. Some may apply early with limited data, speeding up patient access but increasing uncertainty. Others may wait for more interim data, delaying patient access and making comparisons to traditional timelines less clear.

We use a Bayesian decision-theoretic model in which a company chooses the trial's sample size and timing of an interim analysis based on anticipated outcomes of cooperative bargaining with a payer. Negotiations at interim and final analysis determine approval decision and pricing. These negotiations are modeled with a Nash cooperative bargaining model in which the company maximizes profits, and the payer maximizes population health value.

We find conditional approval schemes increase the overall sample size of trials, but market entry timing depends on the company's beliefs about expected profit.

3 - Underrepresentation Bias in Clinical Trials: the Ripple Effect on Medical Decision-Making and Patient Outcomes

Xiaoshan Peng, Indiana University, Bloomington, IN, United States, Ling Li, Kurt Brethauer

Failures of health equity are closely intertwined with biases in healthcare treatment, such as bias due to race, ethnicity, gender, and age. This paper studies how underrepresentation bias in clinical trials affects physician decision-making, patient outcomes, and equity. We propose a behavioral model to analyze physicians' treatment decisions, which are influenced by two distinct cognitive systems: the rational and the intuitive systems. We aim to explore whether these decision-making systems exacerbate healthcare disparities by relying on biased clinical trial results or if they can adapt to mitigate underrepresentation bias. The rational system is modeled as a multi-armed bandit problem with Bayesian updating. The intuitive system is modeled as a Markov decision process using a "win-stay, lose-shift" heuristic. Physicians may alternate between the two cognitive systems, following a dual process model. We find that the impact of the underrepresentation bias depends on the effectiveness of the new treatment. If a less effective or equally effective treatment is introduced, the rational system will correct the impact of the bias and choose the optimal treatment eventually. Otherwise, the physicians' treatment decision may not converge to the optimal one. The impact is amplified by the size of the clinical trials. In contrast, the dual process model corrects the impact of the bias such that the physician eventually chooses the more effective treatment under mild conditions. Furthermore, we present a case study on how gender underrepresentation in clinical trials affects the use of low-dose aspirin for preventing myocardial infarction and ischemic stroke.

4 - Incentivizing Drug Rediscovery: Exclusivity Extension and Priority Review for Repurposed Therapeutics

Elodie Adida, University of California, Riverside, CA, United States, Fernanda Bravo

Drug repurposing consists in identifying new indications for existing drugs. Compared to de novo drug development, drug repurposing incurs less risk and costs and requires less time. However, it is currently under-utilized, primarily due to a lack of financial incentives for drug manufacturers. A new drug enjoys only a limited time with protected market exclusivity. After then, the drug is often subject to competition with a generic drug and the potential for profits drops sharply, making investment in developing new indications often cost-ineffective. While a new indication is granted a temporary exclusivity period, it is often too short to recoup investment costs. We study two mechanisms to better incentivize drug repurposing: (i) granting an extension of the exclusivity period for the primary indication upon approval of a new (secondary) indication, and (ii) offering priority in the review process to speed up approval of the secondary indication. For each mechanism, we investigate how to best design the intervention and what the effect is on the welfare of patients of each indication and the overall effect on patient welfare. We also compare the two types of intervention in terms of patient welfare. We find that while both interventions can be effective in improving the incentive to engage in drug repurposing, they may hurt the welfare of patients of the primary indication and the overall patient welfare. We find that priority review is more likely to be beneficial to patients than exclusivity extension and thus appears to be the dominant type of intervention.

Emerging Technologies in Integrated Risk Management

Invited Session

MSOM: iForm

Chair: Danko Turcic, UCR, Riverside, CA, United States

Co-Chair: Ye (Angelina) Liu, Syracuse University, Syracuse, NY, United States

1 - Fragmentation and Visibility in Supply Networks

Nikolay Osadchiy, Emory University, Atlanta, GA, United States, Maxi Udenio, Vishal Gaur

Supply network visibility is a key for resilient supply chains, yet, in practice, visibility beyond tier-1 suppliers is still rare. Because of that, many firms are caught off-guard by disruptions to their upper-tier suppliers. Using the state-of-the-art firm-level buyer supplier relationship data, we construct a time evolving supply network and explore its structure, with the goal of improving visibility into the network. We find that the network is highly dynamic, rewiring about 25% of its links each year. The network is also fragmented, i.e., it contains communities of firms that are densely connected to each other yet sparsely connected to other communities via a distinct set of firms. Moreover, the fragmentation increases over time, meaning that the network has more communities and communities equalize in size. Based on this structure, we propose an efficient network exploration algorithm that enables firms to find a disrupted supplier in their networks faster. The performance of the algorithm improves as the network becomes more fragmented.

2 - Cvar Based Risk Sensitive Policy Learning

Jingyuan Wang, New York University, New York, NY, United States, Zhimei Ren, Zhengyuan Zhou

The conventional offline multi-action policy learning literature aims to find a policy that performs well in terms of the average policy effect (APE) on the population, i.e. the social welfare. However, in many settings, including healthcare and public policies, the decision-maker also concerns about the risk of implementing certain policy. The optimal policy that maximizes social welfare could have a risk of negative effect on some percentage of the worst-affected population, hence not the ideal policy. In this paper, we investigate risk sensitive offline policy learning with conditional value at risk (CVaR) of covariate-conditional average policy effect (CAPE) as a risk measure. To this end, we first provide a doubly-robust estimator for the CVaR of CAPE, and show that this estimator enjoys asymptotic normality even if the nuisance parameters suffer a slower than $1/n^{1/2}$ estimation rate (n being the sample size). We then propose a risk sensitive learning algorithm that finds the policy maximizing the weighted sum of APE and CVaR of CAPE, within a given policy class. We also show that the sub-optimality gap of the proposed algorithm is in the same order of the canonical policy learning schemes that maximizes APE. The proposed methods are evaluated empirically, demonstrating that by sacrificing not much of the social welfare, our methodology improves the outcome of the worst-affected population.

3 - Energy-Weighted Flow Matching for Offline Reinforcement Learning

Weitong Zhang, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Shiyuan Zhang, Quanquan Gu

This paper investigates energy guidance in generative modeling, where the target distribution is defined as $q(\mathbf{x}) \propto p(\mathbf{x})\exp(-\beta E(\mathbf{x}))$, with $p(\mathbf{x})$ being the data distribution and $E(\mathbf{x})$ as the energy function. To comply with energy guidance, existing methods often require auxiliary procedures to learn intermediate guidance during the diffusion process. To overcome this limitation, we explore energy-guided flow matching, a generalized form of the diffusion process. We introduce energy-weighted flow matching (EFM), a method that directly learns the energy-guided flow without the need for auxiliary models. Theoretical analysis shows that energy-weighted flow matching accurately captures the guided flow. Additionally, we extend this methodology to energy-weighted diffusion models and apply it to offline reinforcement learning (RL) by proposing the Q-weighted Iterative Policy Optimization (QIPO). Empirically, we demonstrate that the proposed QIPO algorithm improves performance in offline RL tasks. Notably, our algorithm is the first energy-guided diffusion model that operates independently of auxiliary models and the first exact energy-guided flow matching model in the literature.

4 - Optimization of Multi-Product (R,S,Q) Inventory Policies Under Aggregate Service Level Constraints for Spare Parts Management

Patrick Helm, Technical University of Munich, Munich, Germany, Stefan Minner, Gudrun Kiesmüller

Managing spare part inventories is challenging since demand is highly intermittent and replenishment decisions must be made based on very limited data. Nevertheless, high service levels must be ensured to avoid costly stock-outs.

In contrast to prior work, we consider the peculiarities of real-world spare parts demand data. Thus, we develop a classification scheme to select the right demand model for each SKU such that it generalizes well without overfitting the few available observations. Moreover, we use chance constraints to make sure that service targets are reached in a short horizon, despite the randomness of service measures. Finally, we consider demand correlation across products and time, which is habitually neglected in existing work.

We focus on multi-product (R,s,Q) inventory policies, subject to an aggregate fill rate constraint. We set up a nonconvex mixed-integer optimization problem to jointly determine the cost-optimal policy parameters for all SKUs in a segment. We develop a scalable algorithm based on Lagrangian Relaxation coupled with continuous optimization and gradient-based rounding to solve even large instances efficiently.

We validate the proposed algorithm on a real-world demand data set of an after-sales platform in the machinery industry. The algorithm scales easily to segments of more than 5000 SKUs. We demonstrate the effectiveness of the chance constraints in ensuring that fill rate targets are achieved in a short horizon. Finally, we also show the effects of neglecting demand correlation on the fill rate performance and highlight the importance of choosing the right model for demand intermittency for each SKU.

5 - Decision Simulation with LLMs: Value of Deliberation and Natural Language

Mahtab Raeisdanaei, University of Illinois Chicago, Chicago, IL, United States, Selva Nadarajah, Daniel Jiang

Large language models offer new opportunities to simulate human decision making, but most systems rely on static user profiles, symbolic features, or demographic traits. In contrast, real decisions emerge from how individuals reason about the specific structure of the problem they face. Research in decision science and cognitive psychology shows that these reasoning processes are not random but the outcome of internal deliberation that can be captured in natural language. Building on these foundations, we present a framework that uses language models to predict decisions within a specific business domain, using energy procurement as a testbed. Our approach starts from natural language reasoning traces and organizes them into structured natural language components such as risk, values, and tradeoffs based on known decision theoretic frameworks. This structured trace is used to predict the final decision. This setup captures how individuals prioritize different aspects of the same problem. Some may focus on risk, others on value alignment. By structuring reasoning rather than relying solely on demographic and problem features, we show how large language models can support decision simulation grounded in theoretical frameworks of how people think, thereby uncovering the value of capturing internal deliberation in natural language form.

Chair: Kun Soo Park, Seoul National University, Seoul, Korea, Republic of

1 - Joint Assortment and Inventory Optimization for the Front-End Warehouse

Kexin Wu, National University of Singapore, Singapore, Singapore, Xiaobo Li, Xue-Ming Yuan

This study examines assortment and inventory optimization in a two-warehouse e-commerce system that seeks to balance delivery speed with cost efficiency. The system consists of a front-end warehouse, strategically positioned near customers to support rapid order fulfillment but limited by capacity constraints, and a back-end warehouse, which holds a larger inventory but entails higher fulfillment costs and longer shipping times. We model this system as a joint assortment and inventory optimization problem, where initial assortment and inventory decisions are made for the front-end warehouse prior to customer demand realization. Once orders are placed, the e-commerce company must decide the quantity of each order type to fulfill from the front-end warehouse, with the remaining quantities fulfilled from the back-end warehouse. Our approach uses a two-stage stochastic programming model to minimize total fixed assortment costs and non-fulfillment costs. We derive the closed-form optimal policies for specific order structures, including distinct single-item sales with non-overlapping bundles, as well as configurations like series and star cover bundles. For more general order structures, we develop an approximation algorithm and establish a tight performance guarantee bound. Furthermore, we demonstrate that the joint assortment and inventory optimization problem is NP-hard, even for simplified scenarios with deterministic demand and single-item order types. To address this complexity, we introduce a heuristic algorithm that enables efficient assortment decision-making. We conduct the numerical experiments using simulated data to evaluate the effectiveness of our proposed policies. The results show that our solutions achieve a good balance between optimality and computational efficiency.

2 - Model Predictive Control for Inventory Management with Advanced Order Information in Supply Chain Planning

Olorunfunmi Osinubi, The University of Texas at Arlington, Arlington, TX, United States

In supply chain planning, it is very important to forecast changes in the market in order to maintain an inventory level that is just enough to satisfy customer demand. This poster presents a Model Predictive Control (MPC) framework that optimizes inventory management by incorporating advanced order information (AOI). Our case study centers on a small-scale additive manufacturing (AM) business, where production and inventory decisions are tightly constrained by limited resources. The proposed

model captures daily inventory dynamics influenced by production rates, customer product demands, and waste collection schedules. Deliveries are categorized by urgency—next-day, speed, and standard—to reflect real-world logistics practices where businesses prioritize shipments based on customer urgency and delivery deadlines. By leveraging AOI, the model anticipates future demands and adjusts production accordingly. The MPC formulation minimizes a cost function that penalizes deviations from target inventory levels and inefficient production effort. Solved iteratively over a finite prediction horizon, this approach remains responsive to system changes in real time. Overall, the proposed solution offers a scalable, adaptive strategy that enhances inventory efficiency, supports reliable order fulfillment, and strengthens planning for small AM business supply chains under demand uncertainty.

3 - A Newsvendor Approximation for Inventory Management with Shoplifting

Dincer Konur, Texas State University, San Marcos, TX, United States

Shoplifting has been on the rise and it makes inventory management even more challenging. In this study, we investigate a single-product single-season inventory control in the presence of shoplifters. First, we conduct detailed simulation and analyze the impact of shoplifting on order decisions and profits. Then, a novel newsvendor model is formulated to approximate the simulation outcomes. The model and simulation give similar results and produce parallel insights about the effects of shoplifting for seasonal inventory management. Particularly, we observe that shoplifting tends to increase the optimal order quantity while decreasing the profits. We also discuss how to use the model to quantify the economic impact of shoplifting beyond the direct losses due to shoplifted amount. Finally, we extend the model to consider optimum levels of investments in different shoplifting countermeasures.

4 - Analyzing Inventory Models for Maintenance and Repair Operations (Mro)

Sundaravalli Narayanaswami, Indian Institute of Management, Ahmedabad, India

Inventory management holds great importance in effective running of core industries. MRO inventory is particularly challenging because of its importance in routine plant operations and the uncertain nature of the demand. Organizations often face a trade-off: high inventory levels tie down working capital and the products can become Non-Moving inventory (NMI) due to technology obsolescence while low inventory could lead to stock-outs affecting production.

This study aims at improving the MRO inventory control through the application of more sophisticated inventory control techniques like the Just-In-Time (JIT) and the Economic Order Quantity (EOQ). The objective is to reduce holding and procurement cost and guarantee that the required MRO inventory is available.

An extensive literature on current inventory management practices is conducted. Inventory models were evaluated by using real life data to understand their relevance in managing MRO inventory. Typically, organizations adopt an ABC (based on volume) or FSN (Fast-, slow-, non- moving) categorization of inventory as a standard inventory management practice. Using Poisson distribution to model uncertainty of demand, we develop a Pareto optimization model to minimize inventory costs, improve availability of inventory, and to better decision-making through categorization and analysis. As a testbed, we have considered organizations from oil industry and automobile manufacturing. Our findings indicate that a VED (Vital, Essential, Desirable) approach is more suited than current practices in reducing financial inefficiencies and to enhance operational sustainability by addressing risks associated with NMI. Results of our analysis are reported.

5 - Bandit Algorithm for Online Learning in Inventory Problems with Lead TIMES

JeongWook Lim, Seoul National University, Seoul, Korea, Republic of, Byeongkwon Lee, Kun Soo Park

We study data-driven inventory management problems using a bandit algorithm. While many data-driven approaches have been successfully applied to inventory problems, there is a lack of truly online and universal algorithms. While prior work explored deep reinforcement learning approaches as a universal methodology for inventory problems, they lack the online learning capability that bandit algorithms offer. To address issues with applying bandit algorithms to inventory problems, our algorithm has following three key concepts: 1) low-risk exploitation through a virtual inventory system, 2) management of a candidate arm set, 3) efficient exploration via Thompson sampling. We evaluate the performance of our algorithm and obtain regret upper bounds.

Capacity Management and Service Design for Emerging Platforms

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Sheng Liu, University of Toronto, Toronto, ON, Canada

1 - Should I Continue to Search? Mechanism Design for TIME-Sensitive Freight Matching Platform Auctions

Ziyan Wei, Tilburg University, Tilburg, Netherlands, Chong Zhang, Jan Fransoo, Pieter Kleer

The rapid growth of digital freight matching platforms—such as Uber Freight (U.S.), Sennder (Europe), and Full Truck Alliance (China)—is evident. These platforms operate under unique time pressure: shippers face strict shipment deadlines and carriers seek to fill limited capacity quickly. However, current platform mechanisms often overlook the complexities of decision-making under such time-sensitive constraints.

This study investigates shipper's behavior across three search modes: passive (waiting for platform bids), active (seeking outside options), and hybrid (multi-homing or alternating). Motivated by real-world practices, we model the platform as a first-price sealed-bid auction with a finite deadline. Carriers may withdraw bids any time and shippers may terminate the auction upon accepting an offer. A central challenge is shipper's declining probability of successful recall—that is, the chance a previously seen bid remains available—which we model as decreasing with both time and bid value.

We characterize shipper's search process and identify a reservation utility or threshold as the optimal strategy. Our analysis confirms that the reservation utility increases with the probability of recall, consistent with prior work. However, we extend the literature by introducing an availability assurance mechanism that requires carriers to hold bids open for a minimum duration. We note that the mechanism may impact bid arrivals and values. We establish conditions under which the mechanism is beneficial for the platform to reduce multihoming and derive the optimal mechanism length.

Our findings contribute to auction theory and platform design by offering insights into search behavior, auction dynamics with recall uncertainty under time constraints.

2 - On TIME, Every Time: Integrating Autonomous Vehicles in Food Delivery

Neda Mirzaeian, The University of Texas at Dallas, Richardson, TX, United States, Soraya Fatehi, Milind Dawande, GANESH JANAKIRAMAN

Food-delivery platforms traditionally rely on crowdsourced human-driven vehicles (HVs), but leased autonomous delivery vehicles (ADV)s are emerging as an alternative. A major challenge for such platforms is keeping costs low while meeting tight delivery time commitments. We address this challenge by analyzing how to optimally manage HV and ADV fleets and whether a hybrid fleet benefits the platform, even if ADVs become more cost-effective than HVs. We develop three robust optimization models: Pure HV (using only HVs), Pure ADV (using only ADVs), and Hybrid (using both). The hybrid model enforces delivery time constraints separately for HVs and ADVs, preventing the optimal hybrid solution from being trivially superior to the pure-optimal solutions. First, in the pure settings, we determine optimal capacity levels (number of HVs/ADV)s and compensation rates to HVs (impacting their availability) and ADVs (affecting the ADV supplier's profitability from leasing its ADVs). Building on these solutions, we optimize the hybrid setting by determining HV and ADV capacity levels and compensation rates, along with demand allocation between HVs and ADVs. By comparing the three optimal solutions, we identify when the hybrid setting is optimal and estimate resulting cost savings through a calibrated numerical study. We extend these models to a non-stationary case with an off-peak and a peak period. We optimally adjust the HV supply in each period while maintaining the same ADV level (as leases span much longer periods than the peak and non-peak periods). Our calibrated numerical study then uncovers the cost advantage of the optimal hybrid strategy.

3 - Capacity Configuration in Non-Stationary Environments: the Operational Value of Prediction and Dynamic Decision-Making

Piao Hu, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Jiashuo Jiang, Guodong Lyu, Hao Sun

We study how volume flexibility, when properly configured into production systems, can be used to determine the optimal capacity level while satisfying designated performance targets, particularly when the demand is not only random but also exhibits variations in its distribution across the planning horizon. To address this challenge, we develop an online two-stage stochastic optimization framework over a finite planning horizon. During each period of the planning horizon, the planner makes the first-stage decision for capacity configuration prior to demand realization, and then allocates the capacity to fulfill multiple performance targets at the second stage when the demand is realized.

We propose an adversarial learning approach to iteratively solve the capacity configuration and allocation problem in an online manner. Our main results show that this approach provides a provably near-optimal performance guarantee while offering great computational efficiency. Furthermore, we demonstrate the value of volume flexibility in capacity configuration to minimize potential losses, particularly when the underlying stochastic inputs follow non-stationary distributions. This extends previous studies that focused on stationary inputs and paves the way for establishing a transparent data-driven oracle that can be applied to a wide range of two-stage online decision-making problems. Through extensive numerical experiments, we underscore the benefits of demand distribution information in non-stationary environments and showcase how volume flexibility, in addition to the classic process flexibility, can help mitigate the misalignment between supply and demand. Furthermore, we apply these techniques and insights to address a crowdsourcing walker deployment problem arising in last-mile delivery operations.

4 - Division of Labor and the on-Demand Economy: Implications for System Design

Milind Sohoni, University at Buffalo, The State University of New York, Buffalo, NY, United States

We study service systems in the on-demand economy that rely on a flexible workforce. Server reliability is endogenously influenced by system parameters or design choices through the division of labor. Using a queueing-theoretic framework, we show how behavioral factors shape server reliability and specialization, thereby impacting optimal capacity planning and system design.

5 - Transportation Service Region Design Under Distributional Uncertainty

Yidi Miao, Carnegie Mellon University, Pittsburgh, PA, United States, Eojin Han, Peter Zhang

We propose a novel framework for the design of stochastic clearing systems, aimed at optimizing waiting and traveling costs through the partitioning of the service region. By leveraging the accumulated operational data over time, our framework assumes that dedicated regions for vehicles can be effectively managed. To address the inherent uncertainty in demand realization, we adopt a data-driven distributionally robust optimization approach, preventing decisions from out-of-sample effects. Our primary objective is to partition the entire service area into several contiguous districts, while minimizing overall waiting and traveling costs under distributional uncertainty. This is achieved through a discrete approximation of the worst-case distribution within the ambiguity set, coupled with contiguity constraints on partitioning decisions to ensure practical implementation. The proposed framework is robust and adaptable, making it applicable to similar transportation and logistics problems.

Advances in Causal Effect Estimation and Decision Making

Invited Session

Decision Analysis Society

Chair: Justin Whitehouse, Stanford University, Pittsburgh, PA, United States

Co-Chair: Vasilis Syrgkanis, Stanford University, Stanford, CA, United States

1 - A Meta-Learner for Heterogeneous Effects in Difference-in-Differences

Hui Lan, Stanford University, Stanford, CA, United States, Haoge Chang, Eleanor Dillon, Vasilis Syrgkanis

We address the problem of estimating heterogeneous treatment effects in panel data, adopting the popular Difference-in-Differences (DiD) framework under the conditional parallel trends assumption. We propose a novel doubly robust meta-learner for the Conditional Average Treatment Effect on the Treated (CATT), reducing the estimation to a convex risk minimization problem involving a set of auxiliary models. Our framework allows for the flexible estimation of the CATT, when conditioning on any subset of variables of interest using generic machine learning. Leveraging Neyman orthogonality, our proposed approach is robust to estimation errors in the auxiliary models. As a generalization to our main result, we develop a meta-learning approach for the estimation of general conditional functionals under covariate shift. We also provide an extension to the instrumented DiD setting with non-compliance. Empirical results demonstrate the superiority of our approach over existing baselines.

2 - Orthogonal Causal Calibration

Justin Whitehouse, Stanford University, Stanford, CA, United States, Steven Wu, Vasilis Syrgkanis, Bryan Wilder, Christopher Jung

Estimates of heterogeneous treatment effects such as conditional average treatment effects (CATEs) and conditional quantile treatment effects (CQTEs) play an important role in real-world decision making. Given this importance, one should ensure these estimates are calibrated. While there is a rich literature on calibrating estimators of non-causal parameters, very few methods have been derived for calibrating estimators of causal parameters, or more generally estimators of quantities involving nuisance parameters. We develop general algorithms for reducing the task of causal calibration to that of calibrating a standard (non-causal) predictive model. We study a notion of calibration defined with respect to an arbitrary, nuisance-dependent loss ℓ , under which we say an estimator θ is calibrated if its predictions cannot be changed on any level set to decrease loss. For losses ℓ satisfying a condition called universal orthogonality, we present a simple algorithm that transforms partially-observed data into generalized pseudo-outcomes and applies any off-the-shelf calibration procedure. For losses ℓ satisfying a weaker assumption called conditional orthogonality, we provide a similar sample splitting algorithm that performs empirical risk minimization over an appropriately defined class of functions. Convergence of both algorithms follows from a generic, two term upper bound of the calibration error of any model. We demonstrate the practical applicability of our results in experiments on both observational and synthetic data. Our results are exceedingly general, showing that essentially any existing calibration algorithm can be used in causal settings, with additional loss only arising from errors in nuisance estimation.

3 - Partial Identification for Long-Term Causal Inference

Xiaojie Mao, Tsinghua University, Beijing, China, People's Republic of, Songliang Chen

Long-term causal inference studies the treatment effect of a certain intervention (e.g., a product design or a therapy) on some long-term outcome of interest (e.g., users' long-term satisfaction or patients' long-term health). This problem is very challenging: randomized experiments are gold-standard for causal inference but they are often expensive and have short durations, so long-term outcome observations may not be available; observational studies can be cheaper and more likely to collect observations for long-term outcomes, but they are susceptible to confounding bias. Existing literature proposes to address this challenge by combining experimental and observational data and leveraging their complementary strengths, but this combination requires various important assumptions to achieve exact identification. We show that some common assumptions such as the well-known statistical surrogacy condition and external validity condition are prone to violation. To achieve robust long-term causal inference, we propose to relax these assumptions and derive the corresponding partial identification bounds, under both a nonparametric model and a semiparametric partially linear model. We also provide estimation and inference methods for these partial identification bounds.

4 - Causal Inference with High-Dimensional Treatments

Edward Kennedy, Carnegie Mellon University, Pittsburgh, PA, United States

In this work we consider causal inference when the number of treatment levels is comparable to or larger than the number of observations. This setting brings two unique challenges: first, the treatment effects of interest are a high-dimensional vector rather than a low-dimensional scalar and, second, positivity violations are unavoidable. We first discuss fundamental limits of estimating effects in such settings, showing consistent estimation is impossible without further assumptions. We go on to propose new

doubly robust thresholding/penalized estimators, and analyze them under exact and approximate sparsity assumptions. We then derive minimax lower bounds to characterize optimal rates of convergence. Finally we illustrate the methods in an education application studying school effects on test scores, where the number of treatments (schools) is in the thousands. This is joint work with Patrick Kramer (CMU) and Isaac Oppen (RAND).

1 - Nationwide Cash Forecasting and Optimization System for Multi-Currency Banking Operations

Wilder Avalos, Banco de Crédito del Perú, Lima, Peru, Jan Nauta

We deployed a nationwide cash supply forecasting and optimization system for BCP, the leading banking institution in Perú, managing over 1,790 ATMs and 340 branches. This end-to-end solution significantly enhanced operational efficiency, improving ATM uptime by 4.2% and reducing cash logistics costs by 8.7% while ensuring sufficient and reliable provisioning across all locations. The system integrates 42 machine learning models to forecast daily demand across three channels and two currencies (local and US\$) which feed into a linear optimization framework that incorporates complex business constraints. We also discuss new modules for emerging ATM types, and extending the optimization framework to include positive interest cash-flows that emerge from temporal cash deposits at the Central Bank of Perú.

2 - Privacy of the Last Iterate in Cyclically-Traversed DP-Sgd on Nonconvex Composite Losses

Weiwei Kong, Google Research, New York, NY, United States, Monica Ribero

Differentially-private stochastic gradient descent (DP-SGD) is a family of iterative machine learning training algorithms that privatize gradients to generate a sequence of differentially-private (DP) model parameters. It is also the standard tool used to train DP models in practice, even though most users are only interested in protecting the privacy of the final model. Tight DP accounting for the last iterate would minimize the amount of noise required while maintaining the same privacy guarantee and potentially increasing model utility. However, last-iterate accounting is challenging, and existing works require strong assumptions not satisfied by most implementations. These include assuming (i) the global sensitivity constant is known - to avoid gradient clipping; (ii) the loss function is Lipschitz or convex; and (iii) input batches are sampled randomly.

In this work, we forego any unrealistic assumptions and provide privacy bounds for the most commonly used variant of DP-SGD, in which data is traversed cyclically, gradients are clipped, and only the last model is released. More specifically, we establish new Renyi differential privacy (RDP) upper bounds for the last iterate under realistic assumptions of small stepsize and Lipschitz smoothness of the loss function. Our general bounds also recover the special-case convex bounds when the weak-convexity parameter of the objective function approaches zero and no clipping is performed. The approach itself leverages optimal transport techniques for last iterate bounds, which is a nontrivial task when the data is traversed cyclically and the loss function is nonconvex.

3 - Finding the Best Arm Privately in Unimodal Bandits

Irem Nur Keskin, Duke University, Durham, NC, United States, Jiaming Xu

This paper introduces a novel private bandit learning problem where the learner aims to find the highest reward arm in a continuous set with unknown, unimodal expected rewards. The learner, facing an adversary who observes their actions but not the rewards, must minimize arm queries while preserving privacy. We propose the Replicated Golden Section Search (RGSS) strategy, which efficiently narrows down the subset of potentially optimal arms while replicating arm queries to obscure adversary observations. For an α -smooth unimodal reward function and a target privacy level L , our analysis demonstrates that RGSS can locate the best arm within ϵ -accuracy using $O(L \log(1/\epsilon)/\epsilon^{2\alpha})$ queries, while hindering the adversary's success to a probability no greater than $1/L$. Additionally, we introduce an adaptive algorithm that eliminates the need for prior knowledge of α . We further establish a lower bound, showing that any private strategy requires at least $\Omega(L/\epsilon^{2\alpha})$ arm queries. These findings reveal that our methods are nearly optimal, with the multiplicative factor of L being a necessary price to pay for privacy. This contrasts sharply with prior research in first-order convex optimization, which suggested that an additive L factor was sufficient for privacy preservation.

4 - Nonlinear Fixed Points and Stationarity: Economic Applications

Giacomo Lanzani, Harvard University, Cambridge, MA, United States, Simone Cerreia-Vioglio, Roberto Corrao

We consider the fixed points of nonlinear operators that naturally arise in games and general equilibrium models with endogenous networks, in dynamic programming, in models of opinion dynamics with stubborn agents, and in financial networks. We study limit cases that correspond to high coordination motives, infinite patience, vanishing stubbornness, and small exposure to the real sector in the applications above. Under monotonicity and continuity assumptions, we provide explicit expressions for the limit fixed points. We show that, under differentiability, the limit fixed point is linear in the initial conditions and characterized by the Jacobian of the operator at any constant vector with an explicit and linear rate of convergence. Without differentiability, but under additional concavity properties, the multiplicity of Jacobians is resolved by a representation of the limit fixed point as a maxmin functional evaluated at the initial conditions. In our applications, we use these results to characterize the limit equilibrium actions, prices, and endogenous networks, show the existence and give the formula of the asymptotic value in a class of zero-sum stochastic games with a continuum of actions, compute a nonlinear version of the eigenvector centrality of agents in networks, and characterize the equilibrium loss evaluations in financial networks.

5 - Presolving Techniques for Minlps

Anna Deza, University of California-Berkeley, Berkeley, CA, United States, Andres Gomez, Alper Atamturk

We present pre-processing techniques for scaling mixed integer non-linear optimization problems with indicator variables, including mixed-integer conic and semidefinite programs. A growing body of research has produced strong relaxations for many such problems, often yielding very tight bounds. However, in contrast to mixed-integer linear or quadratic settings, current commercial solvers often fail to fully exploit these relaxations during branch-and-bound operations, resulting in limited scalability. In this work, we show how to leverage strong relaxations in order to infer optimality conditions, fix variables, and add cuts prior to the full optimization step. To illustrate the significant potential for speed-up and enhanced scalability, we apply our techniques to mixed-integer quadratic multi-period problems and sparse principle-component analysis.

1 - Brainnormalizer: Reconstructing Healthy Brain Images from Tumor Mris Using Masked Controlnet with Edge Conditioning

Mingu Kwak, Georgia Institute of Technology, Atlanta, GA, United States, Yeonju Lee, Hairong Wang, Jing Li

Brain tumors significantly alter neural tissue and cause global deformation, creating challenges for clinicians attempting to visualize tumor boundaries and progression. Current methods often struggle to accurately reconstruct healthy brain representations from tumor-affected images, limiting intuitive comparative analysis. We propose BrainNormalizer, a novel approach using ControlNet diffusion models with three key contributions: (1) a specialized masking strategy during fine-tuning that focuses on tumor region restoration, (2) edge map conditioning that addresses global deformation while preserving brain structure, and (3) strategic text prompts that instruct the model to interpret tumor images as healthy ones. BrainNormalizer effectively transforms tumor-containing images into their healthy counterparts by conditioning the generative process with the carefully designed inputs. Evaluations on the Brain Tumor Segmentation (BraTS) dataset demonstrate that our approach successfully generates high-quality healthy brain images while maintaining structural integrity. BrainNormalizer outperforms existing methods particularly in handling complex deformation patterns and preserving anatomical consistency. This work provides clinicians with an intuitive comparative visualization tool that enhances diagnostic capabilities and offers potential applications in treatment planning, medical education, and supplementary analysis for neuro-oncological tasks.

2 - Quantum Boolean Circuit Design via Gate Pattern-Based Column Generation

Jihye Jung, Georgia Institute of Technology, Atlanta, GA, United States, Jae Hyeok Lee, Changhyun Kwon, Jaehwan Lee

Quantum computing has recently gained attention for the potential boost it promises to computational power by exploiting the probabilistic nature of quantum mechanical concepts. That being said, development on quantum machines has taken major steps so far. However, a considerable gap still exists in building a fully reliable quantum machine, highlighting the strong need for error minimization. One thread of these efforts is to design an efficient quantum circuit with the fewest operational units required to implement the target computation, which leads to a complex decision-making process. This study specifically focuses on implementing Boolean functions in the quantum environment using a series of logical gates called Multiple-Control Toffoli gates, where the exponential space of gate configurations directly determines how the gate operates. Few studies have already proposed optimization-based approaches to this problem, but they still face scalability challenges due to the exponential nature inherent in quantum computation. We explore the capability of our new mixed-integer programming model that formulates the problem directly based on gate configuration patterns.

3 - Centralized Control for Integrated Production and Distribution Planning via Reinforcement Learning

Kim Haneul, Korea University, Seoul, Korea, Republic of, Taesu Cheong

Deep reinforcement learning (DRL) has recently emerged as a promising approach for addressing multi-echelon supply chain management problems under stochastic environments. However, existing DRL-based studies often fall short in capturing the operational constraints and structural intricacies of real-world supply chains. Moreover, there remains a significant lack of empirical evidence validating the transferability of learned policies across varying demand distributions. In this study, we propose a DRL model that makes node-level production and edge-level distribution decisions. The policy network employs a spatio-temporal graph neural network (GNN) encoder to capture supply chain dynamics. Furthermore, the model incorporates structured policy design through action chunking, enabling it to effectively accommodate various operational constraints. Experiments are conducted to compare the proposed method with constrained reinforcement learning baselines in terms of learning efficiency. Robustness against alternative policies is validated, and transferability is assessed across a range of demand variability scenarios.

4 - An Exact Algorithm for Vehicle Routing Problem with Availability Profiles

Hyungjoo Cha, Korea University, Seoul, Korea, Republic of, Joonghoo Park, Chungmok Lee, Taesu Cheong

This talk presents a branch-and-cut approach for the VRP with Availability Profiles (VRPAP). The VRPAP generalizes the well-known VRPTW by introducing multiple time windows with variable values available upon arrival. We present a novel extended formulation for the problem that provides a stronger LP relaxation bound than the previous one in the literature. We then develop a branch-and-cut algorithm to address the exponentially many constraints efficiently. Moreover, we also show that the optimal AP value on the fixed routes can be obtained by dynamic programming, which is incorporated into the branch-and-cut algorithm as a primal heuristic. Computational experiments show that the proposed algorithm outperforms the existing approaches.

5 - Uncertainty Aware Tweedie Hybrid Loss for Intermittent and Erratic Demand Forecasting

Hwayong Jeong, Kwangwoon University, Nowon-gu, Korea, Republic of, Seungjoon Baek, Jiyun Woo, Younggi Kim, Haejoong Kim, Dae-Eun Lim, Sangmin Lee

Online retail demand often exhibits intermittent zero-inflation and erratic spikes. These violate normality and homoscedasticity assumptions, challenging variance-sensitive loss functions like MSE. We present a hybrid loss which combines Tweedie negative log-likelihood and Huber losses for forecasting irregular demand patterns. Further, we enhance forecasting robustness by reweighting loss via aleatoric and adjusting learning rates via epistemic uncertainty. Our method is implemented on N-Beats to jointly predict the mean and dispersion of a Tweedie distribution. Experiments show 13.27% lower MAE, 9.31% lower RMSE, and 5.19% lower MAPE compared to baseline methods. The results confirm that the proposed approach effectively handles zero-inflation, outliers, and instability in demand, leading to better predictions.

1 - Reputation Farming: A Structural Model of Freelancers' Bidding Strategy

Xi Nan, University of Washington, Seattle, WA, United States, Xingchen Xu, Yong Tan

The online freelance labor market has experienced rapid growth driven by advances in digital technologies and a rising demand for flexible work arrangements. To mitigate information asymmetries, most platforms implement reputation systems that enable clients to provide reviews, thereby guiding the choices of future clients. However, this structure imposes a significant entry barrier for new freelancers, who encounter a “cold start” problem: without initial reviews, they struggle to secure jobs, and without jobs, they cannot obtain reviews or build their reputation. This dynamic may incentivize freelancers to bid strategically, submitting lower bids early in their tenure and gradually increasing bids as their reputational capital grows. To examine the prevalence of such strategic behavior, we develop a dynamic discrete choice model with multi-level heterogeneities and empirically estimate it using a large-scale dataset. Our findings reveal that over 20% of freelancers exhibit forward-looking behavior, with an approximately 5% higher likelihood of bidding lower-tier prices compared to their myopic counterfactuals. Additional robustness checks and policy simulations are conducted to offer market design recommendations for improving efficiency and welfare.

2 - Estimating Effects of Long-Term Treatments

Jinglong Zhao, Boston University, Boston, MA, United States, Shan Huang, Chen Wang, Yuan Yuan, Brocco Zhang

A/B tests struggle to capture long-term treatment effects, as product changes last far beyond typical experiments. We propose a longitudinal surrogate framework that links long-term outcomes to user attributes, short-term metrics, and treatments. Tested on two million-user WeChat experiments, our approach outperforms existing methods.

3 - Learning How to Learn: Adaptive Algorithms for Long-Term Memory

Xufei Liu, Wharton, University of Pennsylvania, Philadelphia, PA, United States, Kenneth Moon, Gad Allon

Algorithms present tremendous potential for guiding human learning in many contexts, from markets to workplaces. Yet, there exists few data-driven methods which actively recognize and exploit the relevant structure of human knowledge. We collaborate with a popular language app to design dynamic algorithms that achieve lasting learning by teaching users to gradually strengthen their use of linguistic context as a form of broader knowledge, in order to drive more efficient and durable learning outcomes. Our work has three primary goals: (1) to model how knowledge evolves during language learning and identify key drivers of accelerated learning; (2) to capture

how knowledge transfers between related tasks; and (3) to optimally schedule review intervals that both maximize retention and enhance students' long-term learning capabilities. We use a student's latent memory parameter distributions to descriptively find similarities and patterns for students of the same caliber. Then, we can construct a dynamic programming question that will maximize their reward by shifting their distribution of learning parameters so that students learn faster and more effectively over time.

4 - Ship-Then-Shop as a Promotional Tool: Evidence from An Online Omnichannel Fashion Retailer

Yiwei Wang, Zhejiang University, Haining, China, People's Republic of

The ship-then-shop (STS) model allows customers to receive a preselected assortment of products to try at home before making purchase decisions. While STS enhances the online shopping experience by providing access to physical products, its impact on retailer profitability remains largely unexplored. Using field experiment data from an online omnichannel fashion retailer, we study the impact of a short-term non-subscription STS promotional program on customer behavior. We uncover a demand spillover effect of STS promotion: beyond their direct purchases from STS shipments, treated customers exhibited increased transactions in the retailer's online sales and subscription rental channels. During the treatment period, demand spillovers to online sales were weaker than those to subscription rentals. After the program ended, demand spillovers to online sales amplified, while those to subscription rentals declined. We provide suggestive evidence for four mechanisms underlying these patterns. First, STS shipments increased sales of both promoted (i.e., included) brands and unpromoted brands—what we refer to as the brand promotion and customer engagement effects, respectively. However, both effects were limited to previously consumed brands. Second, ending the STS program led to a demand migration to online sales of unpromoted, previously consumed brands, suggesting that the brand promotion effect was transient, while the customer engagement effect was persistent. Third, STS shipments exerted a reminder effect on rental subscription customers. Fourth, customers exhibited cross-channel complementarity between buying and renting. Based on the heterogeneous profit implications of STS promotion across customer segments, we propose a data-driven customer targeting strategy.

5 - When Clinicians Edit AI: Classifying and Measuring Documentation Errors in Primary Care

Ruozhu (Savannah) Wang, Boston university, Boston, MA, United States

AI-based ambient documentation tools that automatically transcribe clinician-patient conversations have been increasingly used to reduce the burden in primary care. However, there are limited studies investigating the documentation errors made by AI and clinicians' ability to manage them. Using a dataset of clinician-patient consultation vignettes and corresponding medical notes, we identify and categorize previously unrecognized documentation errors made by clinicians and AI. We develop two taxonomies to classify the error types present in clinician-written and AI-generated notes, and investigate clinicians' performance by quantifying their ability to identify and correct documentation errors in clinician-written and AI-generated notes. This study provides a novel approach for assessing clinician-AI collaboration and contributes to the broader understanding of care quality in AI-assisted clinical environments.

1 - Active Learning: Recent Developments, Current State, and Open Challenges

Steve Musmann, Georgia Institute of Technology, Atlanta, GA, United States

Active learning is a vital component in the machine learning toolbox, particularly in scenarios where labeled data is scarce or expensive to obtain. This talk surveys developments in active learning, including recent innovations in query strategies, novel use cases, and the impact of advances in representation learning. The current landscape will be contextualized through empirical findings, conceptual insights, and case studies. This talk aims to provide a critical synthesis of the field and outline promising directions for future research in active learning within the broader machine learning ecosystem.

2 - Paper Skygest: Personalized and Personalizable Recommendations for Academics on Bluesky

Sophie Greenwood, Cornell Tech, New York, NY, United States, Nikhil Garg

Social media platforms are an important way for many academics to announce emergent work and discuss existing work with the global research community. Which users see a post is intermediated by the feed recommendation and ranking algorithm. On most platforms, the recommendation algorithm is (1) opaque and outside a platform user's direct control and (2) not built with academics in mind. A large cohort of researchers recently migrated to Bluesky, a rising social media platform that allows individuals to build feeds for themselves and other users. We developed a personalized feed for academic content on Bluesky, *Paper Skygest*, which shows a user posts about papers by accounts she is following, in reverse chronological order. We launched publicly in March 2025; since then the feed has had substantial usage. In this presentation, we will give an introduction to Bluesky's decentralized feed ecosystem and describe ongoing work leveraging Paper Skygest to study academic recommendations. In particular, we aim to explore users' preferences for fine-grained control over their recommendations, as well as the market-level implications of user control.

3 - Impatient Bandits: Optimizing for the Long-Term Without Delay

Kelly Zhang, Imperial College London, London, United Kingdom, Thomas Baldwin-McDonald, Kamil Ciosek, Lucas Maystre, Daniel Russo

Increasingly, recommender systems are tasked with improving users' long-term satisfaction. In this context, we study a content exploration task, which we formalize as a bandit problem with delayed rewards. There is an apparent trade-off in choosing the learning signal: waiting for the full reward to become available might take several weeks, slowing the rate of learning, whereas using short-term proxy rewards reflects the actual long-term goal only imperfectly. First, we develop a predictive model of delayed rewards that incorporates all information obtained to date. Rewards as well as shorter-term surrogate outcomes are combined through a Bayesian filter to obtain a probabilistic belief. Second, we devise a bandit algorithm that quickly learns to identify content aligned with long-term success using this new predictive model. We prove a regret bound for our algorithm that depends on the $\text{Value of Progressive Feedback}$, an information theoretic metric that captures the quality of short-term leading indicators that are observed prior to the long-term reward. We apply our approach to a podcast recommendation problem, where we seek to recommend shows that users engage with repeatedly over two months. We empirically validate that our approach significantly outperforms methods that optimize for short-term proxies or rely solely on delayed rewards, as demonstrated by an A/B test in a recommendation system that serves hundreds of millions of users.

4 - Advancing Synthetic Control Methods for Individual Level Causal Inference

Saeyoung Rho, Columbia University, New York, NY, United States

Synthetic control is a widely used method in causal inference for evaluating policy interventions, such as tariffs or tax reforms. While traditionally applied to aggregate-level data, recent work has begun to extend synthetic control to disaggregated datasets, including individual health records and targeted marketing data. Such datasets pose new challenges: we may observe vastly more units (e.g., millions of individuals instead of a single state) or obtain much longer time series for a smaller cohort (e.g., longitudinal studies). These distributional shifts call into question the assumptions underlying standard synthetic control methods. In this talk, I will present two new algorithms that adapt synthetic control to individual-level analyses. Cluster Synthetic Control (ClusterSC) is designed for settings with many units but short time horizons; it introduces a donor selection step to improve the accuracy of prediction. Time-Aware Synthetic Control (TASC) addresses settings with few units but long time series, leveraging temporal dynamics in a latent space to better estimate counterfactuals. Both methods are theoretically grounded and achieve provable accuracy gains across distinct data regimes, offering new tools for extending synthetic control to richer and more complex datasets.

Analytics and Aisles: Bridging Theory and Practice in Retail Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Rim Hariss, McGill University, Montreal, QC, Canada

1 - Out-of-Stock, Out-of-Store? Estimating Cross-Store Substitution via Customer Journey Tracking

Rim Hariss, McGill University, Montreal, QC, Canada, Sanjith Gopalakrishnan, Hamidreza Moshrefi, Saibal Ray

Stockouts remain a persistent and costly challenge in fashion retail, where limited replenishment and evolving customer preferences amplify lost sales risk. In this work, we leverage a novel dataset from a leading footwear retailer, combining transaction records, daily inventory, and real-time session data from an in-store tracking tool. This tool logs customer product requests and associate interactions, providing a clickstream-like view of the offline shopping journey.

We use these data to: (1) estimate the rate at which customers accept cross-store fulfillment when their desired product is unavailable; (2) identify the product, customer, and store-level factors that drive substitution decisions; (3) quantify the incremental value of enabling cross-store substitutions on sales and margins; and (4) explore how substitution patterns can inform optimal inventory allocation across stores. Our analysis reveals significant heterogeneity in substitution likelihood and demonstrates that incorporating these patterns into allocation decisions can substantially improve performance.

Our findings offer new insights into consumer behavior under stockouts and provide actionable guidance for inventory and assortment planning in fashion retail, bridging the gap between online and offline behavioral data.

2 - Optimal Replenishment Policies for Industrial Vending Machines

Esma Gel, University of Nebraska-Lincoln, Lincoln, NE, United States, Karina Sindermann, Nesim Erkip

Our paper introduces and analyzes optimal replenishment strategies for Industrial Vending Machines (IVMs) used by industrial supply distributors managing customer's inventory of maintenance, repair and operational supplies. IVMs have emerged as an important technology, offering real-time inventory tracking and enhanced supply chain visibility in vendor-managed inventory settings. We formulate this novel replenishment control problem where multiple items with stochastic demand face a joint fixed replenishment cost and item-specific stockout costs. We develop two approaches: (1) a state-dependent trigger set control policy and (2) a fixed cycle replenishment policy. For the trigger set policy, we address the previously intractable challenge of determining which inventory states should optimally trigger replenishment by reformulating the problem as an optimal stopping rule and proving key monotonicity properties. This innovation enables us to characterize the optimal policy and develop computationally efficient approximations that achieve near-optimal performance. For fixed cycle replenishment, we derive closed-form expressions for the optimal cycle length. Our numerical studies demonstrate that our approximate online trigger set policy remains within 1% of optimality while computing thousands of times faster. A case study using real transaction data from 316 item-device combinations shows that optimal fixed cycle replenishments could reduce costs by 61.7 to 78.6% compared to current daily replenishment practices, while the trigger set control policy provides additional savings of 4.1 to 22.9%. These results provide industrial distributors with theoretically sound, practical tools for optimizing IVM operations.

3 - Data Driven Assortment Optimization with Product Returns

Recep Yusuf Bekci, University of Waterloo, Waterloo, ON, Canada, Mehmet Gumus, Sentao Miao

The rise of online shopping and lenient return policies has led to a significant increase in product returns, posing economic and environmental challenges. In collaboration with a European fast fashion retailer, this study addresses how to leverage returns data in product assortment decisions. We tackle two main challenges: dynamically learning customer preferences and estimating return rates amid delayed returns. We formulate an assortment optimization problem considering customer and return uncertainties and propose an algorithm to optimize decisions. Our performance guarantee and analyses with synthetic and real data provide insights for retailers on managing returns and improving assortment decisions.

4 - Distributionally Robust Multi-Purchase Choice Modeling and Assortment Optimization

Joline Uichanco, University of Michigan, Ross School of Business, Ann Arbor, MI, United States, Jiawei Zhang, Zhuoxin Chen

In many retail environments, consumers often purchase multiple products in a single transaction, yet most existing choice models focus solely on single-purchase behavior. This talk introduces a new *Marginal Distribution Multi-Purchase* (MDM-MP) choice model that extends traditional choice frameworks by accommodating multiple purchases under uncertainty in random utility correlations. Leveraging a distributionally robust optimization approach, our model assumes known marginal distributions of random utility while remaining agnostic about their joint distribution.

We derive tractable formulations for choice probabilities under this framework and explore their implications for assortment optimization. Notably, we show that the optimal assortments under the MDM-MP model are not necessarily revenue-ordered, challenging a key result from the multinomial logit (MNL) model literature. We also provide closed-form solutions under exponential noise assumptions, enabling efficient implementation and estimation.

Our results yield actionable insights for retailers designing assortments in contexts where customers often buy more than one item—such as flash sales or e-commerce platforms—highlighting the strategic value of "anchor" products that consistently drive multi-item purchases. This work contributes to the growing literature on robust and multi-choice consumer models with practical relevance for revenue management and operations strategy.

Empirical and Analytical Research on Sustainable Operations

Invited Session

MSOM: Sustainable Operations

Chair: Mirel Yavuz, IESE Business School, BARCELONA, Spain

Co-Chair: Anna Saez de Tejada Cuenca, IESE Business School, BARCELONA, 08034, Spain

1 - Interactive Preference-Based Optimization with Unknown Value Function: Application to Sustainable Sourcing In the Apparel Supply Chain

Mirel Yavuz, IESE Business School, BARCELONA, Spain, Charles Corbett

Optimization problems often inherently include multiple criteria, and the underlying value function of the decision maker is often unknown and difficult to elicit. This is particularly true in sustainable operations, when some of the criteria are environmental or social in nature, and frequently in conflict with one another. Firms seeking to incorporate sustainability in their decisions face difficult choices, with no well-defined guidelines on how to make trade-offs between different environmental and social impact categories. In this work, we consider a multi-objective linear optimization problem, and assume the preferences of the decision maker are based on an unknown implicit linear value function. We propose an interactive optimization approach that asks pairwise comparison questions to the decision maker to determine the solution that is most aligned with her preferences. The method is guaranteed to yield the decision maker's optimal solution, without needing to elicit the weights defining their value function. To illustrate the method, we use the context of sustainable sourcing in the apparel industry. We numerically test our approach using realistic data based on the Higg Material Sustainability Index (MSI) with three to four criteria: cost, global warming potential, water use and fossil fuel use. Preliminary interactions with

practitioners suggest they find this approach promising, and that it can help them better understand and articulate their preferences. We hope that this work will draw attention to this type of interactive method for solving multi-objective optimization problems with unknown or implicit value functions in sustainable operations.

2 - Is (Climate) Adversity the Mother of Invention? Evidence from Billion Dollar Weather Disasters

Suvrat Dhanorkar, The Pennsylvania State University, University Park, PA, United States, Suresh Muthulingam, Max Ji

We examine the impact of extreme weather events on firm-level innovation.

3 - An Empirical Investigation of Establishment-Level Operations and Occupational Hazards in Underserved Communities

Abhinav Shubham, Georgia Institute of Technology, Atlanta, GA, United States, Ravi Subramanian

Socioeconomic factors and differing establishment-level operational characteristics may contribute to disparities in exposure to occupational safety hazards. We investigate whether similar establishments pose disparate occupational injury risks when operating in underserved communities. Additionally, we consider the moderating role of random inspections by regulators and successful unionization efforts by employees in mitigating disparities in occupational injury risks.

4 - Specialize OR Balance? Sales Agent Allocation in the Presence of Low-Resilience Firms at the Base of the Pyramid

Olumurejiwa Fatunde, Georgetown University, Washington, DC, United States, Gonzalo Romero, Andre Calmon, Joann de Zegher

This paper explores whether distributors should assign some sales agents to “specialize” in serving informal firms in settings where such firms are particularly vulnerable. We propose a novel hypothesis for why distributors struggle to scale last-mile distribution of durable, life-improving goods to customers at the Base of the Pyramid (BoP): the relatively lower supply chain relationship resilience of informal retailers, which are the primary source of retail purchases for BoP customers. We measure this concept as the ratio of post-disruption revenue to pre-disruption revenue. Informal retailers are often embedded within communities where local, long-term relationships are essential to business transactions. We build an analytical model to demonstrate how supply chain relationship resilience can shape a distributor’s allocation of retailers to sales agents. We show that if resilience levels are uniform across informal and formal retailers, the distributor’s optimal assignment to sales agents is fully unbalanced (i.e., the majority of sales agents handle only one of the two retailer types). We then show how accounting for differences in supply chain relationship resilience can dramatically change the firm’s optimal sales agent assignment strategy. We provide empirical evidence for this hypothesis by analyzing data from a distributor selling to 319 formal retailers and 505 informal retailers in India from April 2016 to December 2019. Our results demonstrate the importance of supply chain relationship resilience when designing BoP operations. In particular, informal retailers’ resilience levels should be considered when making resource allocation decisions and designing BoP operations strategy.

Co-Chair: Titing Cui

1 - Employees OR on-Demand Workers? Rethinking Workforce Strategy in a Productivity-Driven Tech Era

Tolga Dizdärer, Boston College, Carroll School of Management, Chestnut Hill, MA, United States, Dmitry Mitrofanov

This paper examines optimal workforce design strategies in environments where firms can choose between permanent employees and on demand independent contractors. We consider a setting where the same workload can be distributed across different types of workers, each with distinct cost structures. Although both worker types can perform similar tasks, their effectiveness varies in subtle but important ways. It is not obvious how firms should determine the optimal mix of workers—or how recent advances in automation and AI may shift this balance. We show that as worker productivity changes, both the optimal staffing levels and the composition of the workforce can shift dramatically. In particular, we characterize conditions under which firms rely entirely on one worker type, split work across both, or adjust their strategy in response to workload intensity. The results offer insights for workforce design in service operations, platform businesses, and environments facing uncertainty due to technological change.

2 - Optimal Design for Revenue-Based Financing

Eryn Juan He, University of Utah, Salt Lake City, UT, United States, Joel Goh

Small businesses play a crucial role in emerging markets, despite facing various challenges that impede their growth and success. One primary challenge is the limited access to affordable financing. Revenue-based financing (RBF) has emerged as an alternative, enabling small businesses to secure funding without sacrificing part of its equity (compared with equity-based financing) or the burden of inflexible debt conditions (compared with debt-based financing). Under RBF, repayments are structured as a percentage of future revenues, aligning the interests of lenders and borrowers.

In this paper, we develop a stochastic model to examine the conditions under which a lending platform can achieve higher profitability through revenue-based financing compared to classical debt financing. Our analysis yields two key insights. First, we identify the conditions that make RBF advantageous for platforms, highlighting the roles of revenue mean and volatility, as well as the variability of operating costs. Second, building on this analysis, we design an optimal contract framework that allows platforms to effectively screen different types of retailers, thereby maximizing their expected utility.

3 - Competing with Genai: a Two-Period Game-Theoretic Model

Guoxing He, Faculty of Business and Economics, HKU, Hong Kong, Hong Kong, Chunghan Kang, Feng Tian

Two heterogeneous firms compete using AI in high- and low-margin markets over two periods. First-period AI usage influences second-period productivity gains, with spillover effects on the competitor. Depending on the spillover rate and initial lead in the high-margin market, these spillover effects can undermine the leading firm’s competitive advantage.

Recent Advances in Online Resource Allocation Problems

Invited Session

Revenue Management

Chair: Murray Lei, Queen's University, Kingston, ON, Canada

1 - Privacy Preserving Dynamic Assortment Selection

Young Hyun Cho, Purdue University, West Lafayette, IN, United States, Will Wei Sun

This presentation introduces a novel framework for privacy-preserving dynamic assortment selection using the multinomial logit (MNL) bandits model. Our approach employs a perturbed upper confidence bound method that satisfies Joint Differential Privacy (JDP), a robust privacy guarantee well-suited for dynamic environments. We will present the theoretical analysis of our framework, which includes a near-optimal regret bound that quantifies the trade-off between privacy and performance. Finally, we demonstrate the superiority of our method over the benchmark through extensive simulations and a case study on the Expedia hotel dataset.

2 - Privacy-Aware Online Resource Allocation with Privacy Preference Heterogeneity

Geoffrey Chua, Nanyang Technological University, Singapore, Singapore, Du Chen, Frank Chen

Online resource allocation is a central problem in revenue management that has been perplexed recently by growing privacy concerns, as decisions often rely on customers' sensitive data. The question of how to efficiently allocate resources while protecting customer privacy has become imperative, yet remains largely unexplored. In this paper, we study online allocation problems with privacy considerations, where customers arrive sequentially, each submitting a service request containing sensitive data along with a privacy request specifying a desired protection level. For each customer, after receiving both requests, the decision maker must determine an allocation immediately and irrevocably, while meeting the requested privacy level under the joint differential privacy framework. The objective is to maximize total revenue subject to limited resources. To address this, we develop a generalized algorithm based on the primal-dual paradigm, incorporating a noisy shadow price to coordinate allocations. The algorithm employs a tree-based mechanism for privately tracking resource consumption and uses mirror descent to update shadow prices. The tree-based mechanism is further customized to accommodate heterogeneous privacy preferences. We prove that the algorithm achieves sublinear regret and satisfies the requested privacy guarantees across a broad class of settings, including both stationary and nonstationary arrivals. Moreover, we identify a spillover effect in which protecting one customer's privacy may inadvertently degrade the utility for others. We show that collecting privacy preferences in advance and adjusting the algorithm accordingly can substantially mitigate this negative impact. Numerical experiments confirm our theoretical findings and demonstrate the effectiveness of the proposed algorithm.

3 - Near-Optimal Pricing and Resource Allocation in a Large-Scale Service System

Sun Xu, Miami Herbert Business School, Coral Gables, FL, United States

We study dynamic pricing and capacity allocation in large-scale service systems where multiple service units serve customers who are both price- and delay-sensitive. Customers are segmented into classes, each characterized by class-specific service rates and demand functions shaped by posted prices and perceived delays. To jointly optimize revenue and delay performance, we propose a family of state-dependent greedy heuristics. These heuristics (i) assign dedicated service capacities to each customer class and (ii) dynamically set prices by solving a tractable one-step optimization problem at each decision epoch. Despite their simplicity, the proposed policies achieve provably strong performance: in large-market regimes where demand scales with the number of servers n , they attain a relative optimality gap of $O(n^{-(2/3)} \log n)$. Moreover, we show that this performance guarantee extends to any work-conserving allocation, not just the dedicated-capacity rule. This robustness highlights the practicality of our approach in settings where centralized control over service units is limited. Extensive numerical experiments validate the theoretical results and offer further managerial insights. In particular, we observe that queue-based wait-time estimates can lead to non-monotonic congestion pricing behavior—i.e., optimal prices may decrease with increasing congestion—a counterintuitive yet rational response under certain demand sensitivities.

4 - Diffusion Approximation in Restless Bandits

Chen YAN, University of Michigan, Ann Arbor, MI, United States

We study finite-horizon restless multi-armed bandits (RMAB) with homogeneous arms, focusing on degenerate cases where LP-based policies suffer a suboptimal gap. We introduce a novel diffusion approximation that captures both mean and variance, achieving significantly tighter performance guarantees and showing that standard fluid approximations are loose in degenerate settings.

5 - Capacitated Multi-Echelon Batch Inventory Networks

Maximiliano Stock, The University of Chicago Booth School of Business, Chicago, IL, United States, Levi DeValve

We study the Capacitated Multi-echelon Batch Inventory problem, which models batch inventory ordering in a two-echelon fulfillment network with capacity constraints at the lower echelon, as often seen in e-retailing. A centralized upper echelon places batch orders from a supplier and allocates units to the lower echelon to minimize total costs, including ordering, allocation, and expected fulfillment costs.

The hard capacity constraints make the problem structurally similar to capacitated facility location, which is well known to be challenging to approximate using linear relaxations. We address these challenges by exploiting key features of our setting: the allocation and fulfillment costs are metric, and the upper echelon is uncapacitated.

Leveraging these features, we develop a new clustering technique that uses information from the dual program to group nearby distribution centers in the lower echelon with enough inventory. This clustering enables us to round the LP solution while satisfying the capacity constraints and leads to a constant-factor approximation algorithm for the offline two-stage version of the problem.

We further extend our approach to an online setting in which demand arrives sequentially over a finite time horizon. To address this, we develop a framework that integrates our approximation algorithm with tools from the online decision-making literature to decide on the ordering, allocation, and online fulfillment. Our framework achieves an additive regret bound that decreases with the time horizon, which makes the theoretical guarantee of the online solution to converge to that of the offline two-stage problem as the horizon grows.

1 - Randomized Policy Optimization for Optimal Stopping

Xinyi Guan, The Hong Kong Polytechnic University, Hong Kong, China, People's Republic of, Velibor Misic

Optimal stopping is the problem of determining when to stop a stochastic system in order to maximize reward, which is of practical importance in domains such as finance, operations management and healthcare. Existing methods for high-dimensional optimal stopping that are popular in practice produce deterministic linear policies – policies that deterministically stop based on the sign of a weighted sum of basis functions – but are not guaranteed to find the optimal policy within this policy class given a fixed basis function architecture. In this paper, we propose a new methodology for optimal stopping based on randomized linear policies, which choose to stop with a probability that is determined by a weighted sum of basis functions. We motivate these policies by establishing that under mild conditions, given a fixed basis function architecture, optimizing over randomized linear policies is equivalent to optimizing over deterministic linear policies. We formulate the problem of learning randomized linear policies from data as a smooth non-convex sample average approximation (SAA) problem. We theoretically prove the almost sure convergence of our randomized policy SAA problem and establish bounds on the out-of-sample performance of randomized policies obtained from our SAA problem based on Rademacher complexity. We also show that the SAA problem is in general NP-Hard, and consequently develop a practical heuristic for solving our randomized policy problem. Through numerical experiments on a benchmark family of option pricing problem instances, we show that our approach can substantially outperform state-of-the-art methods.

2 - Incentive-Aware Dynamic Resource Allocation Under Long-Term Cost Constraints

Yan Dai, Massachusetts Institute of Technology, Cambridge, MA, United States, Negin Golrezaei, Patrick Jaillet

Motivated by public and societal challenges such as governments allocating mobile health units across underserved regions, we study the dynamic allocation of a reusable public resource to self-interested agents -- who may strategize based on their private valuations for the resource -- under long-term cost constraints. Our objective is to simultaneously (i) maximize social welfare, i.e., yielding efficient utilization of the public resource, (ii) satisfy multi-dimensional long-term cost constraints, and (iii)

incentivize truthful reporting. We begin by numerically evaluating primal-dual methods widely used in non-strategic online resource allocation, and find them to be highly fragile in strategic settings. Indeed, agents easily manipulate their reports to distort future dual updates for future gain.

To address this vulnerability, we develop an incentive-aware framework that makes primal-dual methods robust to strategic behavior. Our design combines epoch-based lazy updates -- where dual variables remain fixed within each epoch -- with randomized exploration rounds that extract approximately truthful signals for learning. Leveraging carefully designed novel online learning techniques that can be of independent interest for dual updates, our mechanism achieves $\sim O(\sqrt{T})$ social welfare regret, satisfies all cost constraints, and ensures incentive alignment. This matches the performance of non-strategic allocation approaches while being robust to strategic agents.

3 - On the Sample Bias of Bandit Algorithms

Yilun Chen, the Chinese University of Hong Kong (Shenzhen) , Shenzhen, China, People's Republic of, Jiaqi Lu

Many real-world datasets are collected adaptively through the use of learning algorithms, resulting in data that is inherently non-i.i.d. and often lacks desirable statistical properties—such as unbiasedness of simple estimators. A prominent example arises in the stochastic multi-armed bandit setting, where the sample average reward of each arm, when computed naively, is known to exhibit negative bias. Despite this, a precise characterization of such bias under different bandit algorithms has remained elusive.

In this work, we show that data collected by any minimax-optimal bandit algorithm necessarily exhibits non-negligible sample bias. Specifically, we prove that the worst-case bias of the Z-statistic constructed from naive sample means is non-vanishing in the large sample limit. This provides rigorous theoretical justification for the use of debiasing procedures in adaptive data analysis. Furthermore, focusing on the class of UCB-type algorithms, we derive the exact asymptotic leading term of the sample bias and uncover a fundamental trade-off between regret minimization and statistical bias. In particular, we find that despite guarantees of asymptotic normality and unbiasedness in the literature, the bias under standard UCB algorithms (e.g. UCB1) vanishes at an extremely slow rate and remains substantial in practical, finite-time regimes.

4 - Policy Evaluation in Distributional Reinforcement Learning

Lan Wang, University of Miami, Coral Gables, FL, United States

Motivated by the recent success of distributional RL in many practical applications, we study the distributional off-policy evaluation problem in the batch setting when the reward is multi-variate. We propose an offline Wasserstein-based approach to simultaneously estimate the joint distribution of a multivariate discounted cumulative reward given any initial state-action pair in the setting of an infinite-horizon Markov decision process. Finite sample error bound for the proposed estimator with respect to a modified Wasserstein metric is established in terms of both the number of trajectories and the number of decision points on each trajectory in the batch data. I will also discuss non-asymptotic error bounds for online distributional RL. (Joint work with Zhengling Qi, Chenjia Bai, and Zhaoran Wang)

Information in Auctions

Invited Session

Auctions and Market Design

Chair: Yingkai Li, National University of Singapore, Singapore, N/A, Singapore

Co-Chair: Jinzhao Wu, Yale University, 123 York Street, New Haven, CT, 06511, United States

1 - The Role of Prescreening in Auctions with Predictions

Yanwei Sun, Imperial College Business School, London, United Kingdom, Fupeng Sun, Chiwei Yan, Jiahua Wu

Sellers often use closed auctions to create scarcity and prestige, aiming to intensify competition among a select group of high-status bidders. Advances in machine learning and AI make this strategy increasingly viable, enabling cost-effective identification of capable participants. In this paper, we develop a theoretical model to assess whether such practice can be justified from an economic perspective. We consider a setting in which bidders have i.i.d. private valuations, and the auction seller observes a noisy predictor of each bidder's valuation, which is assumed to be fully informative with some probability. Based on this noisy predictor, the seller determines how many bidders to admit -- a process we refer to as *prescreening*. We show that an auction with prescreening is equivalent to a standard auction (i.e., without prescreening) in which bidder valuations are *correlated*. Notably, the standard notion of *affiliation* commonly assumed in the auction literature does not generally hold in this equivalent formulation. We characterize conditions for the existence of symmetric and strictly monotone equilibrium strategies across three classic auction formats: all-pay, first-price, and second-price auctions. Our results demonstrate that prescreening with noisy predictors can significantly enhance revenue in all-pay auctions; in fact, with a perfect predictor, admitting only two bidders is optimal. By contrast, in both first-price and second-price auctions, admitting all bidders remains revenue-maximizing.

2 - Algorithmic Cheap Talk

Konstantin Zabarnyi, Yale University, New Haven, CT, United States, Yakov Babichenko, Inbal Talgam-Cohen, Haifeng Xu

The literature on strategic communication originated with the influential cheap talk model, which precedes the Bayesian persuasion model by three decades. This model describes an interaction between two agents: sender and receiver. The sender knows some state of the world which the receiver does not know, and tries to influence the receiver's action by communicating a cheap talk message to the receiver.

This paper initiates the systematic algorithmic study of cheap talk in a finite environment (i.e., a finite number of states and receiver's possible actions). We first prove that approximating the sender-optimal or the welfare-maximizing cheap talk equilibrium up to a certain additive constant or multiplicative factor is NP-complete. We further prove that deciding whether there exists an equilibrium in which the receiver gets utility higher than the trivial utility he can guarantee is NP-complete. Fortunately, we identify two naturally-restricted cases that admit efficient algorithms for finding a sender-optimal equilibrium - a constant number of states or a receiver having only two actions.

3 - Information Disclosure Makes Simple Mechanisms Competitive

Jinzhao Wu, Yale University, New Haven, CT, United States

In classical mechanism design, the prevailing assumption is that the information structure about agents' types is *exogenous*. This assumption introduces complexity, especially with multi-dimensional agent types, leading to mechanisms that, while optimal, may appear complex and unnatural. Furthermore, Hart and Nisan (2019) show that the gap between the performance of any simple mechanism and the optimal solution could be potentially unbounded. We challenge this conventional view by showing that *simple mechanisms can be highly competitive* if the information structure is *endogenous* and can be influenced by the designer.

We study a multi-dimensional generalization of a single-dimensional model proposed by Bergemann and Pesendorfer (2007), where the designer can shape the information structure via *information disclosure*. Specifically, we consider a fundamental multi-dimensional mechanism design problem, where a seller is selling m items to a single *unit-demand* buyer to maximize her revenue. The buyer's values can be arbitrarily correlated across the items.

Our main result shows that, following an appropriately chosen information disclosure scheme, *item pricing*, i.e., set a take-it-or-leave-it price on each item is highly competitive and guarantees to attain at least 50.1% of the optimal revenue. To our knowledge, this is the first result demonstrating the (approximate) optimality of simple mechanisms in this extensively studied multi-dimensional setting, without making any assumptions about the buyer's value distribution. We believe our result not only demonstrates the power of information disclosure in enhancing the performance of simple mechanisms but also suggests a new framework for reevaluating their efficacy in multi-dimensional settings.

4 - The Simplicity of Optimal Dynamic Mechanisms

Andres Cristi, EPFL, Lausanne, Switzerland, Jose Correa, Laura Vargas Koch

A fundamental economic question is that of designing revenue-maximizing mechanisms in dynamic environments. This paper considers a simple yet compelling market model to tackle this question, where forward-looking buyers arrive at the market over discrete time periods, and a monopolistic seller is endowed with a limited supply of a single good. In the case of i.i.d. and regular valuations for the buyers, Board and Skrzypacz (2016) characterized the optimal mechanism and proved the optimality of posted prices in the continuous-time limit. Our main result considers the limit case of a continuum of buyers, establishing that for arbitrary independent buyers' valuations, posted prices and capacity rationing can implement the optimal anonymous mechanism. Our result departs from the literature in three ways: It does not make any regularity assumptions, it considers the case of general, not necessarily i.i.d., arrivals, and finally, not only posted prices but also capacity rationing takes part in the optimal mechanism. Additionally, if supply is unlimited, we show that the rationing effect vanishes, and the optimal mechanism can be implemented using only posted prices.

Real-World Experimentation: Bridging Academic Insights and Industry Practice

Invited Session

Revenue Management

Chair: Ramesh Johari, Stanford University, Stanford, CA, United States

Co-Chair: Chao Qin, Stanford University, Palo Alto, CA, United States

1 - Shortlisting Using Adaptive Experimentation

Kuang Xu, Stanford Graduate School of Business, Stanford, CA, United States, Chao Qin

Shortlisting involves narrowing a large pool of candidates to a small, high-quality subset likely to include the best option. This challenge appears in domains like experimental design, where cost limits restrict testing to a few treatments from a vast design space. We explore adaptive experimentation to optimize shortlisting and introduce A1 Sampling, a streamlined variant of Thompson Sampling. A1 Sampling offers both robust theoretical guarantees and strong performance in finite-sample simulation experiments.

2 - Best-Arm Identification in a 2 Times 2 Landscape: Frequentist Vs Bayesian Under Fixed-Confidence & Fixed-Budget

Junpei Komiya, NYU Stern, New York, NY, United States

Best-arm identification is the problem of finding which of several arms (options) has the highest expected reward when each arm's reward distribution is unknown and can only be learned through noisy samples. Depending on whether you face a strict sampling budget or aim for a target confidence level and whether you take a frequentist or Bayesian viewpoint, the optimal algorithmic strategy changes. In this talk, we will show how algorithm design is tailored to each of these scenarios.

3 - Pure Exploration via Frank-Wolfe Self-Play

Wei You, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Chao Qin

We study pure exploration in structured stochastic multi-armed bandits, aiming to efficiently identify the correct hypothesis from a finite set of alternatives. For a broad class of tasks, asymptotic analyses reduce to a maximin optimization that admits a two-player zero-sum game interpretation between an experimenter and a skeptic: the experimenter allocates measurements to rule out alternatives while the skeptic proposes alternatives. We reformulate the game by allowing the skeptic to adopt a mixed strategy, yielding a concave-convex saddle-point problem. This viewpoint leads to Frank-Wolfe Self-Play (FWSP): a projection-free, regularization-free, tuning-free method whose one-hot updates on both sides match the bandit sampling paradigm. However, structural constraints introduce sharp pathologies that complicate algorithm design and analysis: our linear-bandit case study exhibits nonunique optima, optimal designs with zero mass on the best arm, bilinear objectives, and nonsmoothness at the boundary. We address these challenges via a continuous-time limit: a differential inclusion with a Lyapunov function that decays exponentially, implying a vanishing duality gap and convergence to the optimal value. Although Lyapunov analysis requires differentiability of the objective, which is not guaranteed on the boundary, we show that along continuous trajectories the algorithm steers away from pathological nonsmooth points and achieves uniform global convergence to the optimal game value. We then embed the discrete-time updates into a perturbed flow and show that the discrete game value also converges. Building on FWSP, we further propose a learning algorithm based on posterior sampling.

4 - Seeing Beyond the Experiment Window: Impacts of Long-Term Ranker Changes

Lo-Hua Yuan, Airbnb, San Francisco, CA, United States, Lei Shi, Peng Ding, Navin Sivanandam

Online randomized experiments are critical for evaluating updates to Airbnb's search ranking algorithm, but short experiment windows limit visibility into longitudinal dynamics: seasonality, evolving user/listing characteristics, and feedback loops between ranker outputs and marketplace evolution. Moreover, past experiment results may not hold in future contexts. To better align ranker deployment decisions with long-term goals, we propose a causal framework to estimate *prospective long-term average treatment effects*: the average effect that a long-term ranker change has on future long-term outcomes. Our approach consists of three components:

1. **Structural nested mean models** (SNMMs) to estimate effects of sustained ranker changes while adjusting for time-varying confounders (e.g., booking intent) and dependencies between past and future ranker exposure;
2. **Surrogate index modeling** using *search result sets* as mediators to impute long-term outcomes (e.g., annual bookings);
3. **Causal transfer learning** to generalize effects from historical data to future ranker evaluation, across temporal shifts (via SNMMs and seasonality patterns) and ranker iterations (via the *result set* surrogate)

Together, these three components offer a way to translate results from short ranker experiments to estimates of future business impacts beyond timescales of any single experiment. This in turn allows decision-makers to better trade off immediate and downstream objectives during ranker iteration, while balancing experimentation constraints. We demonstrate the efficacy of our approach through real-world-based simulation studies, and summarize conditions in which it outperforms alternative estimation strategies.

5 - Beyond Multi-Arm Bandits: Tackling Challenges in Adaptive Experiments at Airbnb

Yicheng Li, Airbnb, San Francisco, CA, United States, Yan Wang, Jiayun Dong

The adoption of adaptive experiments in the tech industry has gained more attention recently. However, current adaptive experiment literature focuses more on improving efficiency of decision-making and less on impact estimation and error control of decision-making. Additionally, adaptive methods explored in research literature usually leverage simplified setups to achieve optimal results even though experiments with real-world impact involve non-stationarity, repeated measure, and infrequent updates, which are often overlooked in literature. Given the complex nature of adaptive experimentation setup for real-world scenarios, classic bandit algorithms are often subject to additional tweaks to improve decision-making, provide impact estimation and provide error control for decision-making - key outcomes of experimentation. At Airbnb, we developed adaptive experiment techniques to tackle these challenges from pre-experiment design and backtesting to post-experiment analysis. In this talk, we will showcase the current practices of adaptive experiments at Airbnb to enhance the efficiency of large-scale online experiments, and share insights for future research and development.

1 - The Role of Saliva-Based Testing Programs in Reducing COVID-19 ICU Admissions in Disadvantaged Communities**Alireza Kasaie, Loyola University Chicago, Chicago, IL, United States, Samie Tootooni, Sina Ansari**

The COVID-19 pandemic exposed disparities in severe case management, particularly in disadvantaged communities during the Alpha, Delta, and Omicron waves. This study evaluates the impact of SHIELD Illinois test centers, a saliva-based testing initiative, on COVID-19 ICU admissions in greater Chicago, focusing on socioeconomic factors. We conducted a secondary analysis using data from a medical center's Electronic Health Record (EHR) system and the SHIELD Illinois Testing Program, covering the Alpha, Delta, and Omicron waves. Using linear mixed-effects regression models, we examined the relationship between SHIELD center availability, ICU admissions, center density, and area deprivation index scores. Findings revealed that increased SHIELD center availability during the Omicron wave significantly reduced ICU admissions in disadvantaged zip codes. Each additional SHIELD center reduced ICU admission rates by 0.6% (IRR = 0.994, 95% CI: 0.990–0.998), equating to 0.38 fewer admissions per 1,000 population. Lag analyses indicated further reductions over time, with the incidence rate ratio dropping by 0.7% in underserved areas (IRR = 0.993; 95% CI: 0.989–0.997), translating to 0.45 fewer ICU admissions per 1,000 population. These results underscore the importance of strategically deploying SHIELD test centers to mitigate severe outcomes and promote healthcare equity. This approach offers valuable insights for improving responses to future pandemics in underserved communities.

2 - Mapping Multimorbidity in Neurodegenerative Diseases Through Temporal Network Analysis**Mostafa Amini, California State University Long Beach, Long Beach, CA, United States, Ali Bagheri, Dursun Delen**

Millions of people suffer from neurodegenerative diseases (NDDs) with Alzheimer's alone being the sixth leading cause of death in the US. We study the multimorbidities (i.e., co-occurring diseases) network of NDDs to enhance descriptive and predictive models. These co-occurring conditions may arise independently or from a common biological, social, or environmental antecedent. We use the Cerner data warehouse to study over 25 million encounters of more than 800 thousand patients diagnosed with NDDs. We transform the data into multimorbidity networks, where the nodes are the diseases, and the edges show the existence of a patient diagnosed with both disorders. We construct a series of evolving networks based on patient data from periods before, during, and after the diagnosis of NDDs. These networks grow progressively over time, with increasing numbers of nodes and edges. The pre-diagnosis networks help identify early patterns leading to disease onset, while the post-diagnosis networks capture the development and progression of subsequent comorbidities. This study uses evolutionary multimorbidity networks to explore several predictive tasks: forecasting the appearance of new disease co-occurrences over time, predicting which diseases are likely to emerge in patients or patient groups, estimating the future strength of connections between disease pairs, and analyzing changes in comorbidity clusters. These tasks aim to deepen our understanding of how multimorbidity evolves in the context of NDDs.

3 - Predictive Analysis of Acute Care use Among People with Diabetes**Jinha Lee, Temple University, Philadelphia, PA, United States, Daniel Rubin, Hardik Sharma, Zoran Obradovic**

An estimated 30.2 million Americans have diabetes, and this number is projected to rise. Hospitalizations related to diabetes are common and costly, with approximately one-quarter of adult hospitalizations in the U.S. having a listed diabetes code in recent years. Acute care use, including hospital readmissions and post-discharge Emergency Department (ED) visits, among people with diabetes is a significant driver of healthcare costs and a quality marker. Therefore, focusing acute care use preventive interventions for people at the highest risk would be more efficient and potentially more effective in improving healthcare service outcomes and quality. However, prior research has generally focused on hospital readmissions within 30 days of discharge. While this is an important endpoint, it excludes hospitalizations that occur more than 30 days after discharge, all ED visits, and people who have not been hospitalized.

This research focuses on a way to predict the risk of hospitalizations and ED visits over a longer period (1 year) of individuals with diabetes. Using electronic health records of 22,666 patients with encounters, demographic factors, vital records, diagnosis records, prescribing history, and lab test results, this research predicts the acute care use over a 1-year period and identifies its relevant importance features. The result of this study could provide a better understanding of risk factors for and preventive factors against acute care use, and eventually guide the selection of the best interventions for individuals according to their risk profile.

4 - Predicting Long Length of Hospital Stays from Clinical Notes and Electronic Health Records**Shahrazad Khanizadeh, University at Buffalo, Buffalo, NY, NY, United States, Justin Kwok, Haimonti Dutta**

Accurate prediction of Length of Stay (LoS) can enhance hospital resource management, reduce readmissions, and improve patient care. In recent years, there has been a widespread adoption of electronic health records resulting in the availability of clinical notes from patients. In addition, significant advances in machine learning (including deep and reinforcement learning), natural language processing, and related statistical methods have facilitated accurate predictions of LoS. Surprisingly, the distribution of LoS in hospitals tends to have a very high variance -- some patients stay for less than one day while others can be in the hospital for several months. In this research, we take a closer look at what drives Long Length of Stay (LLOS) by examining clinical notes and extracting from them factors that can extend stays in the hospital. In doing so, we closely observe managerial aspects of the stay such as hospital course and acute, chronic and transitional issues related to it, need to be transferred between departments or ICU for treatment, types of service required (surgery, medicine, neurology, orthopedics, etc.), discharge condition and disposition, etc. After extracting these features from the clinical notes, we integrate them with multimodal data extracted from EHRs and build models to effectively predict LLOS.

5 - Comorbidity Patterns in Jia-Diagnosed Patients**Kazi Arman Ahmed, Oklahoma State University, Stillwater, OK, United States, Hamid Hadidi, Mohammad Fili, Dursun Delen, Guiping Hu, Lizhi Wang**

Juvenile idiopathic arthritis (JIA) is a chronic pediatric inflammatory disease often accompanied by other health conditions. However, the timing of these comorbidities and variations across patient subgroups require more in-depth investigation. JIA is relatively uncommon but significant, affecting approximately 1 to 2 in every 1,000 U.S. children and resulting in an estimated 7,000–10,000 new diagnoses each year. In this study, we leverage Oracle Real-World Data, a large-scale electronic health record database from diverse U.S. healthcare settings, to analyze comorbidity patterns among pediatric JIA patients both before and after diagnosis. Key objectives include: 1) identifying the demographic characteristics of children diagnosed with JIA; 2) characterizing common pre-diagnostic comorbid conditions that might serve as early clinical indicators; and 3) profiling post-diagnostic comorbidities to understand how the disease's burden evolves over time. Understanding these temporal comorbidity trends and demographic differences may inform improved early screening protocols and comprehensive long-term care strategies for JIA patients.

1 - Mixed-Integer Programming and Constraint Programming Approaches for Precast Concrete Flowshop Scheduling with Multiple Production Lines

Siyan Wang, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Nanfang Cui

Timely production scheduling and delivery of precast concrete components are critical for prefabricated building projects. This study addresses a precast flowshop scheduling problem that involves customized molds and common production pallets across multiple lines. A mixed-integer programming (MIP) model is developed, which effectively solves small-scale problems to optimality. To tackle the inherent complexity, this paper introduces a constraint programming (CP) model leveraging interval decision variables and constraint propagation algorithms. Experimental results demonstrate that the CP model outperforms both the MIP model and existing algorithms in small-scale instances and real-world case studies. Notably, the MIP and CP models have proved the optimality of solutions for 38 out of 60 small-scale instances. The findings highlight the potential of the CP model as a powerful tool for solving scheduling problems efficiently and underscore the importance of adopting exact algorithms for scheduling in precast production.

2 - Analyzing Makespan-Sojourn Time Trade-Offs for Open Shop Schedule with Unit-Time Operations

Gwanhee Lee, Pohang University of Science and Technology, Pohang, Korea, Republic of, Kangbok Lee, Michael Pinedo

We consider the open shop scheduling problem under a maximum makespan constraint, where each job consists of unit-time operations, each processed on a different machine. The problem is structurally similar to other combinatorial optimization problems, such as timetabling and edge coloring of complete bipartite graphs. To evaluate schedule performance, we focus on the sojourn time of a job, defined as the elapsed time between a job's start time and completion time. Minimizing sojourn time enhances system efficiency and reduces operational costs associated with prolonged job processing. However, there is an inherent trade-off between sojourn time and makespan, since allowing a longer makespan can decrease job sojourn times. In this study, we analyze the trade-off relationship between makespan and sojourn time.

3 - Deep Nonnegative Matrix Factorization with Beta Divergences

Akwum Onwunta, Lehigh University, Bethlehem, PA, United States

Deep Nonnegative Matrix Factorization (deep NMF) has recently emerged as a valuable technique for extracting multiple layers of features across different scales. However, all existing deep NMF models and algorithms have primarily centered their evaluation on the least squares error, which may not be the most appropriate metric for assessing the quality of approximations on diverse datasets. For instance, when dealing with data types such as audio signals and documents, it is widely acknowledged that beta-divergences offer a more suitable alternative. In this talk, we present new models and algorithms for deep NMF using some beta-divergences, with a focus on the Kullback-Leibler divergence. Subsequently, we apply these techniques to the extraction of facial features, the identification of topics within document collections, and the identification of materials within hyperspectral images.

4 - Neglecting Initial Population Uncertainty Leads to Biased Distributional Flood Risk Outcomes

Parin Bhaduri, Cornell University, Ithaca, NY, United States, Adam Pollack, Vivek Srikrishnan

Efforts to improve urban resilience rely on understanding population-level impacts and responses to environmental shocks. These analyses are subject to a number of critical uncertainties, which have the potential to greatly influence coupled natural-human system outcomes. For example, assumptions around population demographics can influence the capacity for adaptation and the distribution of risk and damages. One approach to explore the impact of demographic assumptions is the use of synthetically-generated populations. However, synthetic population generation often relies on sampled survey data, such as from the U.S. Census, which yield highly uncertain estimates of household demographic characteristics. Neglecting such uncertainties could result in biased projections of future environmental impacts, but studies that utilize synthetic populations are typically silent on the sensitivity of model outcomes to these initial population conditions. Here, we quantify the impact of initial population uncertainty along with other key uncertainties, such as model parameters and exogenous forcings, on simulations of agent-based urban-scale flooding with an agent-based model. After calibrating our model to openly available data, we identify how uncertainties influence a variety of model outputs over the course of a multi-decadal simulation.

5 - Uncovering the Drivers of Centenarian Lifespans: a Data Analytical Approach

Samaneh Rezaeimanesh, Oklahoma State University, Stillwater, OK, United States, Mohammad Fili, Guiping Hu, Alex Bishop

As the global population ages, exceptional longevity, defined as living to 100 years or more, is becoming an increasingly important subject in demographic and aging research. Understanding the factors that contribute to such extended lifespans is essential not only for addressing the evolving needs of aging populations, but also for uncovering the mechanisms that enable some individuals to reach such old age. This study employs analytical methods to uncover the pathways to exceptional longevity. This form of longevity can be influenced by a range of factors, including demographic, familial, social, occupational, and lifestyle characteristics. This study investigates the effects of these elements using a dataset of 1858 centenarians. Our findings may offer valuable insights into the life course experiences that could shape extended lifespans, informing strategies to support aging populations and enhance healthy aging.

6 - Explainable AI Signal Diagnosis for AI-Based Statistical Process Monitoring

Jiaqi Qiu, University of Amsterdam, Amsterdam, Netherlands, Rob Goedhart, Jannis Kurtz, Inez Maria Zwetsloot

AI techniques have excelled in many fields, including statistical process monitoring (SPM). Although existing AI-based SPM methods show a promising detection ability in high-dimensional scenarios, post-signal diagnosis for black-box models is often ignored. The lack of explainability makes it difficult to make an out-of-control action plan and take appropriate actions after the signal. Explainable AI (XAI) techniques, like feature attribution and counterfactual explanations, can help decision-makers investigate these signals. Feature attribution helps explain which features contribute to the output most, and counterfactual explanations provide insights into which minimal changes to features (perturbations) make the difference between an in-control or out-of-control observation. This paper proposes a framework integrating XAI signal diagnosis with AI monitoring methods. The applicability of the proposed framework is validated by the experiments generating explanations on simulated and real data.

1 - Machine Learning in the Mortgage Industry: a Literature Review

Sajede Farahani, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Wilkistar Otieno

Credit risk refers to the potential financial loss incurred when a borrower fails to meet their contractual repayment obligations. Effectively managing credit risk is a fundamental component of risk management for financial institutions. In recent decades, credit risk assessment—particularly in consumer lending—has become increasingly data- and model-driven. Financial institutions now rely heavily on credit scoring models to predict the likelihood of delinquency or default across a range of consumer credit products, including mortgages, auto loans, credit cards, and personal loans.

In this study, we present a literature review of existing research methods and machine learning (ML) techniques applied specifically to mortgage credit scoring models, with a focus on how Explainable Artificial Intelligence (XAI) can enhance the robustness and transparency of predictive modeling. We find that only a limited number of studies have incorporated XAI methods into mortgage credit scoring, highlighting a significant gap in the current literature. Moreover, although many individual studies include macroeconomic indicators—such as interest rates, unemployment rates, and inflation—as well as climate-related variables, there is a notable absence of any comprehensive framework that organizes and classifies these variables. To address this shortcoming, we propose a structured categorization intended to serve as a practical reference for researchers and practitioners seeking to incorporate these factors more systematically into future credit risk models.

2 - Interpretable Electrode-Band Optimization for Affective Emotion Decoding

Jorge Fresneda Fernandez, New Jersey Institute of Technology, Newark, NJ, United States, Sumya Akter, Simon Bin Akter, Md Mohit Hasan, Tanmoy Sarkar Pias, David Eisenberg, Chelsea Hill, Jerry Fjermestad

Emotion decoding is pivotal for advancing neurotechnology and affective computing. Prior electrode selection methods often relied on statistical or spatial heuristics, limiting interpretability and cross-dataset scalability. This study incorporates an explainable AI framework employing SHapley Additive exPlanations (SHAP) to identify the most informative electrodes and frequency bands for emotion decoding. Signals were first converted from time to frequency domain using Fourier Transform. A residual CNN trained on the DEAP dataset with 32 brain electrodes and 8 additional physiological signals outperformed 16 popular models across Valence, Arousal, Dominance, and Liking (precision: 0.97, specificity: 0.96, sensitivity: 0.98, F1-score: 0.97), exceeding baselines by 32.54%. SHAP-based feature selection (threshold ≥ 0.02) identified an optimal 25-electrodes (61 features), retaining 98.78% of full-model (200 features) performance while reducing input parameters by 23.93%. Cross-dataset generalization on SEED-V and AMIGO showed strong consistency, with 21-mapped electrodes (52 features) and 11-mapped electrodes (32 features) reaching 96.25% and 98.04% similarity to the full 64-electrode (320 features) and Emotive 17-electrode (85 features) setups for detecting six (Happiness, Sadness, Fear, Anger, Disgust, Neutral) and four (Valence, Arousal, Dominance, Liking) emotions, while reducing parameters by 35.86% and 9.79%, respectively. Key insights reveal a dominant role of fronto-central and parieto-occipital brain regions in Delta and High Beta bands. Additionally, non-brain signals—especially from eye activity, facial muscle engagement, and respiration—emerged as influential under Delta band analysis, underscoring their often-overlooked value in emotional decoding. This interpretable, optimized, and scalable approach reduces computational complexity, offering an efficient solution for real-time emotion recognition in neurotechnology applications.

3 - Machine Unlearning via Information Theoretic Regularization

Shizhou Xu, University of California Davis, Davis, CA, United States, Thomas Strohmer

How can we effectively remove or “unlearn” undesirable information, such as specific features or individual data points, from a learning outcome while minimizing utility loss and ensuring rigorous guarantees? We introduce a mathematical framework based on information-theoretic regularization to address both feature and data point unlearning. For feature unlearning, we derive a unified solution that simultaneously optimizes diverse learning objectives, including entropy, conditional entropy, KL-divergence, and the energy of conditional probability. For data point unlearning, we first propose a novel definition that serves as a practical condition for unlearning via retraining, is easy to verify, and aligns with the principles of differential privacy from an inference perspective. Then, we provide provable guarantees for our framework on data point unlearning. By combining flexibility in learning objectives with simplicity in regularization design, our approach is highly adaptable and practical for a wide range of machine learning and AI applications. We demonstrate its effectiveness across diverse data modalities, including tabular data, images, and large language models, through comprehensive numerical experiments.

4 - Modular and Adaptive Conformal Prediction for Two-Stage Models via Residual Decomposition

William Zhang, MIT Operations Research Center, Cambridge, MA, United States, Saurabh Amin, Georgia Perakis

Conformal prediction offers finite-sample coverage guarantees under minimal assumptions. However, existing methods treat the entire modeling process as a blackbox, overlooking opportunities to exploit modular structure. While model-aware conformal techniques have been proposed for specialized architectures, conformal prediction for modular two-stage blackbox pipelines remains underexplored. We introduce a conformal prediction framework for two-stage models, where an upstream predictor generates intermediate representations for a downstream model. Such pipelines are common in domains like macroeconomic forecasting and supply chain modeling, where interpretability and retrainability are crucial for downstream decision-makers. By decomposing the overall residual into stage-specific components, our method enables interpretable uncertainty attribution and modular risk control, facilitating more informed and accountable decisions. To ensure valid coverage, we calibrate stage-wise scaling parameters using a risk-controlling selection procedure based on family-wise error rate (FWER), and extend this to an adaptive variant for online settings. Our method provides long-run coverage guarantees and improves robustness to distribution shifts. Experiments on synthetic upstream, downstream, and pipeline-wide shifts, as well as real-world economic indicator forecasting, show that our approach maintains coverage over Adaptive Conformal Inference (ACI) and proportional-integral-derivative control (PID) and provide stage-aware, interpretable prediction intervals support that robust decision-making.

5 - Nonparallel Support Vector Ordinal Regression for Imbalanced Data

Chi-Chun Chien, Department of Information Management, National Chi Nan University, Nantou, Taiwan, Puli, Taiwan, Jing-Rung Yu, Stephan Jao, Donald Lien, Pi-Hsia Hung, Hou-shen Chen

Support Vector Ordinal Regression (SVOR) is a multiclass classification method designed for ordered categories by constructing parallel discriminant hyperplanes. However, conventional SVOR struggles with imbalanced datasets, often exhibiting bias toward majority classes and resulting in poor classification accuracy for minority classes. To address this limitation, we propose an enhanced approach that integrates accuracy sensitivity into a nonparallel SVOR framework, referred to as NSVORA. This method employs an ℓ_1 -norm support vector machine with accuracy-sensitive mechanism to construct class-specific hyperplanes independently, allowing each class to have its own decision boundary. Additionally, the model incorporates constraints that maximize the lower bounds of the true positive rate (TPR) and true negative rate (TNR) for each class, thereby improving classification performance across all classes. By removing the restriction of parallel hyperplanes, NSVORA effectively addresses the shortcomings of conventional SVOR in handling class imbalance. The model was evaluated with datasets from the UCI Machine Learning Repository as well as other sources, including data on Taiwanese companies to predict financial distress. Empirical results demonstrate that the proposed model significantly enhances classification performance, particularly for minority classes.

1 - Surrogate Active Subspaces for Jump-Discontinuous Functions

Nathan Wycoff, University of Massachusetts Amherst, Amherst, MA, United States

Surrogate modeling and active subspaces have emerged as powerful paradigms in computational science and engineering. Porting such techniques to computational models in the social sciences brings into sharp relief their limitations in dealing with discontinuous simulators, such as Agent-Based Models, which have discrete outputs. Nevertheless, prior applied work has shown that surrogate estimates of active subspaces for such estimators can yield interesting results. But given that active subspaces are defined by way of gradients, it is not clear what quantity is being estimated when this methodology is applied to a discontinuous simulator. We begin this article by showing some pathologies that can arise when conducting such an analysis. This motivates an extension of active subspaces to discontinuous functions, clarifying what is actually being estimated in such analyses. We also conduct numerical experiments on synthetic test functions to compare Gaussian process estimates of active subspaces on continuous and discontinuous functions. Finally, we deploy our methodology on Flee, an agent-based model of refugee movement, yielding novel insights into which parameters of the simulation are most important across 8 displacement crises in Africa and the Middle East.

2 - Efficient Gaussian Process Modeling for Replicated and Censored Data in Manufacturing Applications

Emily Kang, University of Cincinnati, Cincinnati, OH, United States, Ying Zhang, Shuo Li

Gaussian process (GP) regression is widely used for modeling responses in both physical and computer experiments. In practice, data from physical experiments may include replications and be subject to censoring due to equipment limitations or contextual constraints. Motivated by real-world manufacturing data, we develop a GP modeling framework that efficiently analyzes replicated and potentially censored data. Our approach leverages recent advances in likelihood-based inference and latent-

variable methods for GPs, effectively exploiting replication while rigorously incorporating censoring information—analogue to exact simulation techniques for truncated distributions. We demonstrate the effectiveness of our method on synthetic manufacturing data, showing that it provides enhanced prediction, uncertainty quantification, and computational scalability, making it well-suited for large-scale applications with structured replication and incomplete data.

3 - Bayesian Bridge Gaussian Process Regression

Lulu Kang, University of Massachusetts Amherst, Amherst, MA, United States

Gaussian Process (GP) regression is a widely used surrogate modeling approach for both computer and physical experiments, especially when modeling complex and highly nonlinear input-output relationships. However, like many supervised learning methods, GP regression can suffer from the "curse of dimensionality." The goal of this project is to perform shrinkage regularization to both the regression coefficients of the mean part of the GP and the length-scale of the correlation function. Under the Bayesian framework, it is similar to the Bayesian bridge regression, which leads to constrained posterior distribution of the parameters. We propose using the Spherical Hamiltonian Monte Carlo method to solve the constrained sampling problem. Through several examples, we have shown the proposed method outperforms other alternative in prediction accuracy and variable selection.

4 - Probabilistic Reduced Order Models

Naichen Shi, Northwestern University, Evanston, IL, United States, Yuheng Wang, Wenxi Cai

As computer simulation models grow increasingly sophisticated, they also become more computationally expensive. Reduced-order models (ROMs) offer a computational feasible solution by simplifying high-dimensional simulation problems and operating in a reduced latent space, with results later mapped back to the physical domain. Traditional ROMs rely on dimension reduction techniques such as Singular Value Decomposition (SVD) and variational autoencoders (VAEs) to establish this latent-physical correspondence. However, these methods often suffer from limited expressiveness and struggle to reproduce complex stochastic dynamics in the original physical space.

In this work, we propose a novel framework that leverages diffusion models to more effectively bridge the latent and physical spaces. Diffusion models offer a powerful generative capability, allowing us to capture rich, multi-modal distributions and reconstruct physically realistic dynamics. By integrating simple physical mechanisms with the learning of denoising neural networks, our approach produces predictions that are both statistically plausible and consistent with governing physical principles. We demonstrate the effectiveness of our method using two case studies: fluid flow simulation and laser-based additive manufacturing.

1 - An Adaptive Sampling Strategy for Real-Time Anomaly Detection with Unmanned Sensing Vehicles

Yue Jiang, Purdue University, West Lafayette, IN, United States, Ana Maria Estrada Gomez

Unmanned sensing vehicles (USVs) have been widely used for real-time anomaly detection in various applications, including environmental monitoring, precision agriculture, and military surveillance. The USVs collecting data can only provide partial information about the space being monitored. Thus, it is critical to decide where to deploy the USVs at each point in time to maximize the change detection capability, while minimizing deployment costs. This article proposes an adaptive sampling strategy for real-time anomaly detection with USVs. First, a novel spatio-temporal sequential tensor decomposition algorithm is developed to decompose the high-dimensional data collected by the USVs into three components, a spatial component, a temporal component, and a sparse component, that captures the locations suspicious of change. The spatial and temporal components are used for one-step prediction to guide the adaptive sampling strategy. The strategy is designed to maximize the detection power and control the deployment costs. The main idea is to balance exploration and exploitation by designing a sampling distribution function to decide where to collect data at each acquisition time. The movement of the USVs is controlled by using Voronoi tessellations on the sampling distribution function. The performance of the proposed framework is demonstrated through simulations and case studies.

2 - Personalized Tucker Decomposition: Modeling Commonality and Peculiarity on Tensor Data

Hao Yan, Arizona State University, Chandler, AZ, United States, Kamran Paynabar, Jiuyun Hu, Naichen Shi, Raed Al Kontar

We propose a personalized Tucker decomposition (perTucker) to address the limitations of traditional tensor decomposition methods in capturing heterogeneity across different datasets. perTucker decomposes tensor data into shared global components and personalized local components. We introduce an order orthogonality assumption and develop a proximal gradient regularized block coordinate descent algorithm guaranteed to converge to a stationary point. The unique and common representations learned by perTucker reveal intrinsic statistical patterns in data and provide valuable information for a wide range of downstream analytics, including anomaly detection, source classification, and clustering. We demonstrate perTucker's effectiveness through a simulation study and two case studies on solar flare detection and tonnage signal classification.

3 - Convolutional Non-Homogeneous Poisson Process and Its Application to Wildfire Ignition Risk Quantification for Power Delivery Networks

Xiao Liu, Georgia Institute of Technology, Atlanta, GA, United States

This article proposes a spatio-temporal point process model, known as the Convolutional Non-homogeneous Poisson Process (cNHPP), and applies the model to quantify wildfire ignition risks for power delivery networks. The proposed model captures both the current (i.e., instantaneous) and cumulative (i.e., historical) effects of key environmental processes (i.e., covariates) on wildfire risks, as well as the spatio-temporal dependency among different segments of the power delivery network. The computation and interpretation of the intensity function are thoroughly investigated. We apply the proposed approach to estimate wildfire ignition risks on major transmission lines in California, using historical fire data, meteorological and vegetation data obtained from the National Oceanic and Atmospheric Administration and National Aeronautics and Space Administration.

4 - Targeted Variance Reduction: Effective Bayesian Optimization of Black-Box Simulators with Noise Parameters

Simon Mak, Duke University, Durham, NC, United States

The optimization of a black-box simulator over control parameters arises in broad scientific applications. Here, the simulator often takes the form $f(x, \theta)$, where θ are parameters that are uncertain in practice. Stochastic optimization aims to optimize the objective $E[f(x, \theta)]$, where $\theta \sim P$ is a random variable that models uncertainty on θ . For this, existing black-box methods typically employ a two-stage approach for selecting the next point (x, θ) , where x and θ are optimized separately via different acquisition functions. As such, these approaches do not employ a joint acquisition over (x, θ) , and thus may fail to fully exploit control-to-noise interactions for effective stochastic optimization. We propose a new Bayesian optimization method called Targeted Variance Reduction (TVR). The TVR leverages a novel joint acquisition function over (x, θ) , which targets variance reduction on the objective within the desired region of improvement. Under a Gaussian process surrogate on f , the TVR acquisition can be evaluated in closed form, and reveals an insightful exploration-exploitation-precision trade-off for stochastic black-box optimization. The TVR can further accommodate a broad class of non-Gaussian distributions on P via a careful integration of normalizing flows. We demonstrate the improved performance of TVR over the state-of-the-art in a suite of numerical experiments and an application to the robust design of automobile brake discs under operational uncertainty.

1 - Sparse Plus Low-Rank Decomposition of Large Language Models

Mehdi Makni, MIT, Cambridge, MA, United States, Xiang Meng, Rahul Mazumder

Sparse plus Low-Rank (S+LR) decomposition of Large Language Models (LLMs) is emerging as a promising approach in model compression (reducing the size of neural networks), where one aims to decompose pre-trained model weights into a sum of sparse and low-rank matrices ($W \sim S + LR$). This decomposition can be an appealing alternative to pure sparsification of models (setting parameters to zero) under the same compression ratio. It is also Hardware-aware as it can result in inference acceleration on modern GPUs (compared to the dense model). Despite recent progress, existing methods suffer from substantial performance degradation relative to dense models. In this work, we introduce 3BASiL, a highly efficient one-shot post-training method for (S + LR) decomposition of LLMs that addresses this gap. Our approach first leverages a novel 3-Block Alternating Direction Method of Multipliers (ADMM) approach, termed 3BASiL, to minimize the layer-wise reconstruction error with convergence guarantees. Our numerical experiments show that 3BASiL reduces the WikiText2 perplexity gap to dense model by over 35% compared to prior methods for a Llama3.2-3B model under a 50%-Sparse plus 128-low-rank configuration. Moreover, our method achieves faster compression runtime than current state-of-the-art (S + LR) decomposition techniques. The compression of a Llama3.2-3B model under a 50%-Sparse plus 128-low-rank configuration takes ~1.5 hours on a single L40 48GB GPU.

2 - Learning to Price Rentals Under Unknown Degradation and Demand

Joo Seung Lee, UC Berkeley, Berkeley, CA, United States, Anil Aswani

We study a dynamic pricing problem in equipment rental where equipment degrades with use and incurs a cost upon failure. The renter receives only binary feedback after each use as to whether the equipment fails or survives, along with contextual information about rental usage-intensity and cumulative past usage. The goal is to estimate the latent degradation dynamics from interaction data and use this knowledge to inform pricing decisions. This work also lays the foundation for learning demand-side behavior, specifically the distribution of customer willingness-to-pay, toward designing an optimal rental pricing policy that balances revenue and risk over the equipment's lifetime.

3 - Flow-Based Conformal Prediction for Multi-Dimensional Time Series

Junghwan Lee, Georgia Institute of Technology, Atlanta, GA, United States, Chen Xu, Yao Xie

Conformal prediction for time series presents two key challenges: (1) leveraging sequential correlations in features and non-conformity scores and (2) handling multi-dimensional outcomes. To address these challenges, we propose a novel conformal prediction method for time series using Flow with classifier-free guidance. Specifically, we use a flow to model the distribution of prediction residuals and their transformations conditioned on historical context, which is encoded using Transformer. Non-conformity scores are defined as the Euclidean distance between transformed prediction residuals and the mean of a Gaussian source distribution, enabling the construction of prediction sets directly in the source distribution space at a target confidence level. We provide theoretical guarantees that our method satisfies marginal coverage and derive finite-sample bounds for conditional coverage under stationary features. Experiment results on real-world multi-dimensional time series datasets demonstrate that our method constructs smaller prediction sets while satisfying a target coverage, outperforming existing baselines.

4 - Data to Dose: Personalized Dosing with Data Generation and Expert Feedback

Hansraj Satyam Verma, Carnegie Mellon University, Pittsburgh, PA, United States, Holly Wiberg, Woody Zhu, Sridhar Tayur

Personalized treatment optimization is often constrained by data scarcity, particularly in settings involving heterogeneous or rare patient profiles. We introduce **GenEx**, a hybrid framework that integrates preference-based Bayesian optimization with a generative model that is fine-tuned online using expert feedback. Expert-provided pairwise rankings are used to update both the surrogate model and the generative component, which proposes synthetic labels in uncertain regions when agreement with expert preferences is high. The expert is selectively queried in regions of high model uncertainty. Our model accommodates imperfect expert feedback and variation in source data quality. Theoretical analysis establishes sublinear regret bounds that account for bias introduced by synthetic augmentation. In a numerical study simulating a development environment, GenEx achieves faster convergence and improved decision quality compared to preference-only and purely generative baselines with a smaller starting data set. This demonstrates the promise of combining generative modeling with expert feedback for principled decision-making in low-data regimes.

1 - Integrating Heterogeneous Suffering In Disaster Response: a Robust Estimation and Optimization Framework

Yuxin Hong, Tianjin University, Tianjin, China, People's Republic of, Ning Zhu

The increasing frequency and severity of natural disasters present significant challenges for effective humanitarian logistics, particularly in the aftermath of the disaster. In this paper, we propose a joint vehicle routing and supply allocation model that integrates an extended area-level Deprivation Cost Function (DCF) to mitigate human suffering. The DCF is estimated using survey data, and we incorporate regression residuals to capture the heterogeneous suffering among affected populations, thereby formulating the problem as a stochastic program. To address estimation uncertainties inherent in survey data and the potential ambiguity in residual distribution, we propose a robust satisficing model that accounts for these uncertainties and approximates it as a finite-dimensional program. Exploiting the finite-valued and maximization-based structure of our cost function, we devise an L-shaped method with a tailored algorithm to solve the subproblem, and we further introduce a conservative approximation to enhance computational scalability. Extensive numerical experiments validate the algorithm's efficiency and demonstrate the model's robustness in mitigating estimation errors and distribution ambiguities. The comparison of different strategies reveals that accounting for heterogeneous suffering leads to more balanced and effective relief operations. Additionally, strategically prioritizing aid to less resilient areas, even at the cost of moderate distribution imbalances, significantly reduces extreme suffering without compromising overall fairness.

2 - Operationalizing Spatial Food Insecurity Using Cell Phone Mobility Data: a Network-Based Alternative to Usda's Food Access Research Atlas

Dwight Lewis Jr, The University of Alabama, Tuscaloosa, AL, United States, Irem Sengul Orgut, Lauren Davis, Shonna Morgan

Food insecurity—limited or uncertain access to nutritious food—affects millions across the U.S., with accessibility as a key determinant. Spatial access to grocery stores offering fresh, healthy ingredients supports health-protective behaviors. Traditional tools like the USDA's Food Access Research Atlas (FARA) rely on uniform, distance-based measures between supply and demand points, which often fail to reflect actual consumer behavior. Without a full picture of communities' food environments, this limitation can undermine the ability of public health and hunger relief organizations to develop targeted and effective food access interventions.

This research introduces a network-based alternative to FARA using 2022–2024 cell phone mobility data from Dewey Data's SafeGraph dataset. Our methodology employs two key innovations: (1) network analysis of consumer movement patterns to delineate empirically derived grocery service areas, and (2) spatial accessibility measurement within those areas.

We analyze mobility data across all 50 states and Washington, D.C., focusing on supermarkets (NAICS 445110), meat/farmers markets (445210, 445230), and warehouse clubs/supercenters (445231). Using network analysis grounded in information theory, we delineate grocery service areas and apply floating catchment methods to examine accessibility within these zones—enabling the identification of potential grocery deserts in context of the local food environment.

As a next step, we will simulate optimal grocery market placements by targeting high-traffic convenience stores (NAICS 445120) and dollar stores (452319) as potential sites to qualify for a hypothetical fresh food financing policy. While ongoing work remains, this framework offers stakeholders a behavior-based understanding of food access that complements and enhances FARA's traditional, distance-based approach.

3 - A People-Centric Approach to Model Risks in Post-Wildfire Recovery and Resource Allocation Using A Two-Stage Machine Learning Modeling

Poulomee Roy, State University of New York at Buffalo, Buffalo, NY, United States, Sayanti Mukherjee

In recent years, the frequency and severity of wildfires have increased across the United States due to anthropogenic interferences, poor land management, and Wildland-Urban Interface (WUI) expansion. Although predicting wildfires has improved, challenges remain in wildfire suppression and resource allocation meeting people's needs. This project aims to develop a people-centric approach that accounts for socio-economic characteristics, demographics, living conditions of WUI residents, and wildfire impact to identify risks to post-wildfire recovery and guide resource allocation for wildfire mitigation.

We categorized the high- and low-risk cohorts based on the wildfire impacts in the first stage of the proposed two-stage machine learning (ML) modeling framework. We implemented ML classifiers (e.g., random forest (RF), boosting) and selected CatBoost as the most effective classifier, achieving a predictive accuracy of 95%. In the second stage, we investigated each risk cohort separately to understand how the risk of scarce resource allocation is associated with the wildfire severity, socioeconomic characteristics, and the demographic composition of the affected population, leveraging multivariate linear regression, ridge and lasso regression, RF, decision tree, XGBoost, and Gradient Boosting, achieving 90% accuracy across the cohorts.

Our research shows that lower-income individuals, those residing in congested housing, the disabled, the educationally disadvantaged, and the elderly individuals are most affected, lacking adequate resources to cope with wildfire impacts. The insights from our analysis will help policymakers design an efficient people-centric rescue plan that addresses supply and targeted resource allocation while considering people's needs and reducing delays in rescue operations.

4 - Bi-Level Optimization Integrating Socioeconomic and Geospatial Analysis for Disaster Response Facility Allocation

Vinayaka Gude, Elon University, Elon, NC, United States

This study presents a multi-level analytical framework for optimizing the placement of disaster recovery centers integrating socio-economic vulnerability, physical accessibility, and storm damage severity. The initial model employs a population-based greedy algorithm to select facility locations that maximize risk-weighted coverage and minimize access disparity. In the second phase, a road network analysis is performed to assess the spatial accessibility of each facility. The model accounts for connectivity within the drivable network and elevation impacts, identifying the top three locations with the highest reachability and least terrain impediments. A damage-weighted efficiency metric is introduced to capture how well each facility serves the most affected counties. Results from Western North Carolina after Hurricane Helene show that the model-selected locations consistently outperform the real deployed disaster recovery locations across all metrics, offering broader and more equitable service to high-risk populations. By combining socio-demographic, infrastructural, and geographic considerations, this approach supports more just and operationally feasible disaster response planning.

5 - Building Capacity Function with Dynamic Categorization of Food Agencies in Hunger-Relief Networks

Naimur Rahman Chowdhury, North Carolina State University, Raleigh, NC, United States, Julie Ivy, Osman Ozaltin

Estimating the capacity for receiving donations (CRD) in a geographic region is a crucial step in effective and equitable donation allocation in food bank networks. The CRD in a geographic region is influenced by the operational performance of food agencies within the region, which changes over time. Therefore, estimating CRD requires a dynamic approach instead of exploring the empirical distribution over all temporal periods. In this study, we develop a dynamic approach to estimate CRD by categorizing agencies into different groups with dynamic features. To choose the best lookback window for dynamic agency feature extraction, we use multiple recurrent neural networks (RNNs). Then, we use partitional and hierarchical unsupervised learning for agency categorization. Furthermore, we use a non-parametric approach to obtain the probability density function (PDF) of donations received in each agency category. Finally, we develop an aggregated sampling method to develop a capacity function for a region with multiple agencies. We illustrate results from Food Bank of Central and Eastern North Carolina (FBCENC) data and show significant statistical differences in the capacity function for regions with different compositions of agencies.

1 - Winner's Curse in Data-Driven Decision-Making: Evidence and Solutions

Sikun Xu, Washington University in St. Louis, St. Louis, MO, United States, Raphael Thomadsen, Dennis Zhang

Data-driven decision-making involves estimating the value associated with each possible decision and selecting the optimal estimated choice. This type of decision making is at the heart of a huge number of modern marketing applications, including ad creative choice, algorithm optimization, personalized targeting, A/B testing, pricing, and assortment optimization. In practice, it is crucial not only to estimate the optimal policy but also to accurately measure the incremental value or lift of that policy. In this paper, we first demonstrate theoretically that selecting the optimal policy based on estimated effects from data leads, on average, to overly optimistic evaluations of the policy value, a phenomenon known as the winner's curse. This is true no matter what best methodology is used to estimate the policy's effectiveness. We then empirically illustrate that the winner's curse arises in a wide range of key marketing applications, including A/B testing, personalized targeting, and counterfactual estimation using structural models, and that its magnitude can be substantial even within realistic parameter ranges commonly seen in the literature. Given the generality of this problem across diverse settings, we propose a correction method based on a non-continuous bootstrap approach designed to effectively mitigate the winner's curse in nearly all scenarios. Finally, we benchmark our proposed method against several existing context-specific solutions, demonstrating that our bootstrap-based correction consistently performs well and frequently outperforms alternative methods across important marketing contexts.

2 - Learning to Cooperate Without Using Non-Public Information

Shukai Li, Northwestern, Evanston, IL, United States, Cong Shi

We consider price competition among multiple sellers over a selling horizon of T periods. In each period, sellers simultaneously offer their prices and subsequently observe their respective demand that is unobservable to competitors. The realized demand of each seller depends on the prices of all sellers following a private unknown linear model. We propose a manipulatable pricing algorithm, which does not require sellers to communicate demand information or coordinate prices once the selling horizon starts. With property algorithm inputs, our algorithm leads to competitive prices, while with manipulated algorithm inputs, our algorithm leads to cooperative prices. We show that our algorithm, when employed by all sellers, leads at a fast convergence rate $O(1/\sqrt{T})$ to the competitive/cooperative prices that sellers would reach if they were fully informed. Particularly, in the manipulated case, sellers achieve an optimal order-of- $\sqrt{T}$ regret relative to the static benchmark policy of cooperative prices as well as a linear revenue increment relative to the static benchmark policy of competitive prices.

3 - Data-Driven Knowledge Transfer in Batch Q^* Learning

Wenbo Jing, New York University, New York, NY, United States, Elynn Chen, Xi Chen

In data-driven decision-making across marketing, healthcare, and education, leveraging large datasets from existing ventures is crucial for navigating high-dimensional feature spaces and addressing data scarcity in new ventures. We investigate knowledge transfer in dynamic decision-making by focusing on batch stationary environments and formally defining task discrepancies through the framework of Markov decision processes (MDPs). We propose the Transfer Fitted Q -Iteration algorithm with general function approximation, which enables direct estimation of the optimal action-state function Q^* using both target and source data. Under sieve approximation, we establish the relationship between statistical performance and the MDP task discrepancy, highlighting the influence of source and target sample sizes and task discrepancy on the effectiveness of knowledge transfer. Our theoretical and empirical results demonstrate that the final learning error of the function is significantly reduced compared to the single-task learning rate.

4 - Robustness Versus Statistical Efficiency: Superiority of Naive Optimization via Worst-Case Stochastic Dominance

Arindam Roy Chowdhury, Columbia University, New York City, NY, United States, Henry Lam

Many decision-making tasks give rise to optimization problems with uncertainty in the underlying parameter or probability distribution. This uncertainty can arise from statistical noises due to limited data, or non-stationary parameter shifts that are not predictable from the past. In the literature, various approaches ranging from (distributionally) robust optimization to regularization have been proposed, as attempts to obtain solutions that perform well statistically or robustly against model shifts. Contrary to common belief, we show that, in terms of the behavior of regret or optimality gap, a naive optimization formulation based on empirical or simple point estimate of the uncertain parameter is in a sense optimal, regardless of whether the uncertainty comes from statistical noises, unpredictable shifts, or both. Our superiority assertion for naive optimization is based on a new notion of worst-case stochastic dominance for the asymptotic regret, and is argued via what we call the "symmetry" of uncertainty that applies universally over statistical errors, adversarial errors, and their interactions. We show how our results apply to the comparisons among a wide range of existing data-driven and robust optimization formulations.

5 - Scalable Data-Driven TIME Series Analytics with Applications in the Energy Sector

Ali Eshragh, Johns Hopkins Carey Business School, Washington, DC, United States, Yuexing Li, Luke Yerbury, Fred Roosta, Michael Mahoney

We develop a new scalable algorithm for approximating leverage scores in large datasets using techniques from randomized numerical linear algebra. Leverage scores play a central role in tasks such as data sampling, outlier detection, and dimensionality reduction, making their efficient estimation critical for modern analytics applications.

Building on this, we introduce a fast and interpretable algorithm for modeling large-scale time series data. Together, these methods enable data-driven modeling and decision-making in resource-intensive settings.

We demonstrate the effectiveness of our approach through extensive experiments, including applications in the energy market, where large volumes of high-frequency data demand scalable and accurate forecasting tools. Our methods achieve up to 800x speedups over exact approaches while maintaining high accuracy, offering practical solutions for time series analytics in energy systems and beyond.

1 - Clustering Us Metro Areas by Per-Capita Mobile Greenhouse Gas Emissions: Targeted Mitigation Strategies

Peiyao Zhao, University of Massachusetts, Amherst, MA, United States, Jimi Oke

We present a novel typology of 349 metropolitan statistical areas (MSAs) in the United States and demonstrate its implication for understanding and mitigating per-capita mobile greenhouse gas emissions (PMGE). Via factor analysis of 55 indicators across 7 categories of road network, buildings, socioeconomic, car ownership, commute mode share, transit energy, and climate, we identified eight key drivers of mobile emissions: Auto + Scale, Transit Propensity, Density, Sustainable Transit, Warm Weather, Remote + Active, Network Connectivity, Network Sprawl. Based on these, we clustered the metro areas via Gaussian mixture modeling to obtain seven metro types, namely Auto Large, Auto Small, Dense Active, Heavyweight Eco-Transit, Heavyweight Transit, Sparse Active, and Sparse Auto. We used an Extreme Gradient Boosting regression model to predict PMGE based on all the indicators, excluding population. By using SHapley Additive exPlanations (SHAP) values, we identified the most significant indicators for all MSAs and for each cluster type.

The model reveals that density and transit mitigate PMGE, while car use and climate exacerbate it. The typology provides further insights into how these effects vary across network, mode share and development patterns. Ultimately, the typology can serve as a framework to inform and initialize type-specific mitigation strategies.

2 - How to Get the Most Accurate Results for Your Data Using Ensembles for Numeric, Classification, Logistic and TIME Series Data

Russ Conte, ensembles1.com, Forest Park, IL, United States

Ensembles are well established as a way to get the most accurate results for data. This presentation will highlight four new packages that automatically produce a wide range of individual models and ensembles of models for numeric data, classification data, logistic data, and time series data.

If you want to see how to get the best possible results for your data, this session is for you!

The session will begin with an introduction to building ensembles, so everyone starts from the same point. It is NOT necessary to have prior ensemble building experience, that's what the packages will do for you automatically.

A very important point will be demonstrating how the packages address the issue of reproducibility of results. Each of the four packages have built-in methods to produce results on untrained data that are testable, falsifiable, and fully reproducible with very high accuracy.

The packages contain many other features which can be used to provide the most accurate results.

This is a technical session, and will cover the steps used to get optimal solutions, such as how the NumericEnsembles package can be used to eliminate correlated predictors, how the ClassificationEnsembles package automatically produces 20 confusion matrices, how the LogisticEnsembles package can be used for sports and HR analytics, and how the ForecastingEnsembles package can be used to predict labor market data.

Many examples will be demonstrated in real time to allow you to see how you can use the power of ensembles in your work.

3 - Estimating Motif Counts via Generalized Intersection Local Times

Qinghua Ding, UC Berkeley, Berkeley, CA, United States, Venkat Anantharam

We study the problem of estimating structural properties of graphs using local random walk observations. Quantities such as triangle density and motif counts are fundamental in network analysis, but computing them exactly is often infeasible for large graphs due to memory and computational constraints. Prior work has explored random-walk-based estimators for specific statistics, but these are often limited to simple cases like vertex or triangle counts and may lack theoretical guarantees on sample complexity.

A general framework is proposed based on generalized intersection local times, which measure how often multiple independent random walks simultaneously visit the vertices of a target subgraph pattern. This formulation allows us to construct estimators for a broad class of subgraph counts in a unified and principled way.

We analyze the variance and sample complexity of these estimators under standard assumptions. For many random graph models, our approach achieves sublinear sample complexity in the graph size. Importantly, our estimators require only local neighborhood access, making them practical for massive graphs such as social networks.

This work establishes a scalable, general-purpose, and theoretically grounded framework for subgraph count estimation. We also outline ongoing extensions to other local graph statistics and to sample-efficient machine learning based on data gathered via random walks on large networks.

This work is supported in part by NSF grants CCF-1901004 and CIF-2007965.

4 - Comparison of Clustering Analysis Methods on Behavioral Supply Chain Data

Souri Sasanfar, Northeastern University, Boston,, MA, United States, Jacqueline Griffin

This study explores whether different clustering methodologies yield distinct insights into behavioral patterns observed in pharmaceutical supply chain simulations. We applied both single-phase (Longest Common Prefix (LCP) and Dynamic Time Warping (DTW)) and two-phase clustering approaches (LCP-LCP and DTW-DTW, segmented into pre- and post-disruption periods) to gameplay data from 169 participants. Analysis of cluster compositions revealed notable discrepancies: behaviors classified distinctly by LCP—such as 'Followers,' 'Reactors,' and 'Hoarders'—mapped differently onto DTW clusters, indicating complex behavioral distinctions between methods. Statistical validation using Chi-Square tests, Cramér's V, and Cohen's Kappa confirmed significant associations and differences across clustering methods. Our findings support hypotheses that clustering methods substantially influence the interpretation of behavioral data. Specifically, disruptions and information availability significantly alter ordering behaviors, underscoring the importance of methodological choice in behavioral analysis. These results highlight how leveraging multiple clustering techniques can provide comprehensive behavioral insights critical for improving decision-making frameworks in complex, disrupted environments

5 - A Theory-Informed Text Mining Approach to Identifying and Classifying Strategic Paradoxes in Organizational and Sectoral Contexts

Gulce Cuhaci Tasdelen, Istanbul Bilgi University, STAMFORD, CT, United States

Conceptualized as “contradictory yet interrelated elements that exist simultaneously and persist over time” (Smith & Lewis, 2011), paradoxes are especially salient in decision-making contexts where leaders must navigate competing demands and dual transformation pressures (Smith, Binns & Tushman, 2010). Strategic paradoxes, persistent and interdependent tensions such as exploration vs. exploitation or control vs. flexibility, are increasingly recognized as central to contemporary organizational complexity. However, identifying and classifying such tensions within large-scale organizational and sectoral texts remains a methodological challenge. This paper introduces a theory-informed text mining approach that detects and classifies paradoxical expressions in strategic documents through rule-based regular expressions (regex), dynamic paradox typologies, and natural language processing (NLP) techniques. The framework is grounded in paradox theory, drawing on foundational models by Smith and Lewis (2011) and extended by research on paradoxical leadership (Lavine, 2014; Zhang et al., 2015), mindset and cognition (Miron-Spektor et al., 2017; Boemelburg et al., 2023), and institutional and processual perspectives (Jarzabkowski et al., 2013; Besharov & Smith, 2014; Schad et al., 2016). We operationalize paradox detection through a curated inventory of “seed expressions” and regex patterns, applied to the U.S. healthcare and insurance sector reports, and aim to integrate sectoral and transformational tagging via rule-based and semantic similarity models. Findings demonstrate the framework’s potential for sectoral benchmarking, longitudinal text analysis, and future integration into leadership analytics. We also discuss its applicability for studying paradoxical leadership behaviors and paradoxical mindset development, offering scalable pathways to support both academic research and practical decision-making in complex environments.

6 - Towards Robust Time Series Modeling via Motif Discovery

Li Zhang, University of Texas Rio Grande Valley, Edinburg, TX, United States, Salomon Ibarra

Deep learning models have achieved remarkable progress in recent years and have the potential to make a transformative impact on critical applications such as renewable energy and disaster response. However, current deep learning methods mostly rely on average loss -- which often excels in average performance and fails to deliver reliable predictions in critical tasks — the samples occurs less yet important and difficult to predict. Such discrepancy in performance greatly hurts the reliability and usability of deep learning models in the real world. To address this problem, we propose we propose a new framework incorporates time series motif behavior into training framework. We will demonstrate the effectiveness and efficiency through our experiment results.

Recent Advances in Tensor Decomposition and Completion Algorithms and Their Applications

Invited Session

Data Mining

Chair: Mehrdad Ghadiri, MIT, Cambridge, United States

Co-Chair: Xinyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Approximately Optimal Core Shapes for Tensor Decompositions

Matthew Fahrbach, Google Research, Atlanta, GA, United States, Mehrdad Ghadiri, Gang Fu, Vahab Mirrokni

This work studies the combinatorial optimization problem of finding an optimal core tensor shape, also called multilinear rank, for a size-constrained Tucker decomposition. We give an algorithm with provable approximation guarantees for its reconstruction error via connections to higher-order singular values. Specifically, we introduce a novel Tucker packing problem, which we prove is NP-hard, and give a polynomial-time approximation scheme based on a reduction to the 2-dimensional knapsack problem with a matroid constraint. We also generalize our techniques to tree tensor network decompositions. We implement our algorithm using an integer programming solver, and show that its solution quality is competitive with (and sometimes better than) the greedy algorithm that uses the true Tucker decomposition loss at each step, while also running up to 1000x faster.

2 - Quantifying Time Series Periodicity with Interpretable Machine Learning

Xinyu Chen, Massachusetts Institute of Technology, Cambridge, MA, United States

Time series autoregression is a classical statistical model for capturing auto-correlations and identifying temporal patterns such as periodicity and seasonality. In this work, we propose a novel sparse autoregression framework from an interpretable machine learning perspective and the model interpretability for periodicity quantification is reinforced by L0-norm induced sparsity constraints. On the multidimensional time series that involves complicated spatial and temporal dimensions, we propose a spatially- and time-varying sparse autoregression model and resolve the mixed-integer programming problem by developing a two-stage optimization scheme. In particular, the proposed scheme makes the model scalable to large problems even with millions of decision variables. Empirically, we conduct extensive experiments to evaluate the proposed model on real-world time series data. First, we apply our framework to real-world human mobility data in NYC and Chicago, and our analysis of ridesharing data from 2019 to 2024 demonstrates the disruptive impact of the COVID-19 pandemic on mobility regularity and the subsequent recovery trends. Second, we demonstrate the spatial patterns of yearly seasonality in climate variable time series across the past four decades, and our model allows to discover dynamic climate patterns and identify climate phenomena such as El Nino in sea surface temperature. Thus, our framework lays an insightful foundation for understanding periodicity in real-world time series.

3 - Matrix Completion with Cross-Concentrated Sampling: Bridging Uniform Sampling and Cur Sampling

HanQin Cai, University of Central Florida, Orlando, FL, United States

While uniform sampling has been widely studied in the matrix completion literature, CUR sampling approximates a low-rank matrix via row and column samples. Unfortunately, both sampling models lack flexibility for various circumstances in real-world applications. In this work, we propose a novel and easy-to-implement sampling strategy, coined Cross-Concentrated Sampling (CCS). By bridging uniform sampling and CUR sampling, CCS provides extra flexibility that can potentially save sampling costs in applications. In addition, we also provide a sufficient condition for CCS-based matrix completion. Moreover, we propose a highly efficient non-convex algorithm, termed Iterative CUR Completion (ICURC), for the proposed CCS model. Numerical experiments verify the empirical advantages of CCS and ICURC against uniform sampling and its baseline algorithms, on both synthetic and real-world datasets.

4 - Understanding the Challenges of Entry-Wise Matrix Completion Under Arbitrary Observation Patterns

Ruijia Cao, Cornell University, Ithaca, NY, United States

Matrices are fundamental units for representing and organizing data: estimating missing entries from the often noisy and incomplete observed ones therefore comprises a crucial task in modern data science. While the field of matrix completion has been well-studied, most existing techniques rely on strong distributional or structural assumptions on the observation pattern. In many real world applications, however, the observation patterns may be highly non-uniform, thus limiting the applicability of existing approaches.

In this work, we consider the special case where the ground-truth matrix is a rank-1 sign matrix and the observed entries are random flips of the true ones. Given a specific target entry to estimate, we show that the min-max optimal estimator of any missing entry is given by the Bayes estimator under a uniform prior, which can also be expressed as a function of an appropriate Eulerian flow on the observation graph. We then illustrate how non-uniformity in the observations could result in the failure of existing matrix completion algorithms such as the spectral method. These insights lead to improved algorithms that explicitly account for the non-uniformity in observations.

AI and RL for Robust and Adaptive Decision-Making in Business

Invited Session

Data Mining

Chair: Elynn Chen, New York University, New York, NY, United States

1 - Transfer Reinforcement Learning: Value-Based Methods for Non-Stationary Mdp

Elynn Chen, New York University, New York, NY, United States

In dynamic decision-making scenarios across business, healthcare, and education, leveraging data from diverse populations can significantly enhance reinforcement learning (RL) performance for specific target populations, especially when target samples are limited. We develop comprehensive frameworks for transfer learning in RL, addressing both stationary Markov decision processes (MDPs) with iterative Q*-learning and non-stationary finite-horizon MDPs with backward inductive Q*-learning. For stationary MDPs, we propose an iterative Q*-learning algorithm with knowledge transfer, establishing theoretical justifications through faster convergence rates under similarity assumptions. For non-stationary finite-horizon MDPs, we introduce two key innovations: (1) a novel "re-weighted targeting procedure" that enables cross-satege transfer along multiple temporal steps, and (2) transfer deep Q*-learning that leverages neural networks as function approximators. We demonstrate that while naive sample pooling strategies may succeed in regression settings, they fail in MDPs, necessitating our more sophisticated approach. We establish theoretical guarantees for both settings, revealing the relationship between statistical performance and MDP task discrepancy. Our analysis illuminates how source and target sample sizes impact transfer effectiveness. The framework accommodates both transferable and non-transferable transition density ratios while assuming reward function transferability. Our analytical techniques have broader implications, extending to supervised transfer learning with neural networks and domain shift scenarios. Empirical evidence from both synthetic and real datasets validates our theoretical results, demonstrating significant improvements over single-task learning rates and highlighting the practical value of strategically constructed transferable RL samples in both stationary and non-stationary contexts.

2 - Doubly high-dimensional contextual bandits: An interpretable model for joint assortment-pricing

Linda Zhao, University of Pennsylvania, Philadelphia, PA, United States

3 - Online Estimation and Inference for Robust Policy Evaluation in Reinforcement Learning

Yichen Zhang, Purdue University, West Lafayette, IN, United States

Reinforcement learning has emerged as one of the prominent topics attracting attention in modern statistical learning, with policy evaluation being a key component. Unlike the traditional machine learning literature on this topic, our work emphasizes statistical inference for the model parameters and value functions of reinforcement learning algorithms. While most existing analyses assume random rewards to follow standard distributions, we embrace the concept of robust statistics in reinforcement learning by simultaneously addressing issues of outlier contamination and heavy-tailed rewards within a unified framework. In this paper, we develop a fully online robust policy evaluation procedure, and establish the Bahadur-type representation of our estimator. Furthermore, we develop an online procedure to efficiently conduct statistical inference based on the asymptotic distribution. This paper connects robust statistics and statistical inference in reinforcement learning, offering a more versatile and

reliable approach to online policy evaluation. Finally, we validate the efficacy of our algorithm through numerical experiments conducted in simulations and real-world reinforcement learning experiments.

4 - A Customer-Aware Recommender System for Influencer Marketing

Xuan Bi, University of Minnesota, Minneapolis, MN, United States

Influencer marketing is transforming digital retail by leveraging social media influencers to promote products. However, matching the right influencers with right products remains challenging. This is because influencers act as intermediaries, and a proper matching should reflect not only influencers' own tastes, but also the underlying preferences of their following customers. To address this, we take a design science approach and propose a Customer-Aware Recommender system for Influencer marketing (CARI), an AI-powered recommender framework that integrates customer behavior into influencer-product matching. CARI combines graph neural networks and self-attention mechanisms, enhanced with customer-aware embeddings, to capture the multifaceted preferences and interactions among influencers, products, and customers. An online field experiment on a leading influencer platform in Asia showed that CARI significantly improves upstream influencer endorsement engagement by 105% and downstream customer spending by 19.8 times.

Preference Learning in Large Language Models

Invited Session

Data Mining

Chair: Chong Liu, State University of New York at Albany, Albany, NY, United States

Co-Chair: Fan Yao, University of North Carolina at Chapel Hill, Chapel Hill, United States

1 - Statistical Impossibility and Possibility of Aligning LLMs with Human Preferences: from Condorcet Paradox to Nash Equilibrium

Weijie Su, Wharton School, University of Pennsylvania, Philadelphia, PA, United States

Aligning large language models (LLMs) with diverse human preferences is critical for ensuring fairness and informed outcomes when deploying these models for decision-making. We seek to uncover fundamental statistical limits concerning aligning LLMs with human preferences, with a focus on the probabilistic representation of human preferences and the preservation of diverse preferences in aligned LLMs. We first show that human preferences can be represented by a reward model if and only if the preference among LLM-generated responses is free of any Condorcet-cycle. Moreover, we prove that Condorcet cycles exist with probability converging to one exponentially fast under a probabilistic preference model, thereby demonstrating the impossibility of fully aligning human preferences using reward-based approaches such as reinforcement learning from human feedback. Next, we explore the conditions under which LLMs would employ mixed strategies--meaning they do not collapse to a single response--when aligned in the limit using a non-reward-based approach, such as Nash learning from human feedback (NLHF). We identify a necessary and sufficient condition for mixed strategies: the absence of response that is preferred over all others by a majority. We prove that this condition holds with high probability under the probabilistic preference model, thereby highlighting the statistical possibility of preserving minority preferences without explicit regularization in aligning LLMs. Finally, we leverage insights from our statistical results to design a novel, computationally efficient algorithm for finding Nash equilibria in aligning LLMs with NLHF. Our experiments show that Llama-3.2-1B, aligned with our algorithm, achieves a win rate of 60.55% against the base model.

2 - Competition and Diversity in Generative AI

Manish Raghavan, Massachusetts Institute of Technology, Cambridge, MA, United States

Recent evidence suggests that the use of generative artificial intelligence reduces the diversity of content produced. In this work, we develop a game-theoretic model to explore the downstream consequences of content homogeneity when producers use generative AI to compete with one another. At equilibrium, players indeed produce content that is less diverse than optimal. However, stronger competition mitigates homogeneity and induces more diverse production. Perhaps more surprisingly, we show that a generative AI model that performs well in isolation (i.e., according to a benchmark) may fail to do so when faced with competition, and vice versa. We validate our results empirically by using language models to play Scattergories, a word game in which players are rewarded for producing answers that are both correct and unique. We discuss how the interplay between competition and homogeneity has implications for the development, evaluation, and use of generative AI.

3 - Understanding the Preferences of Large Language Models Under Interdisciplinary Contexts

Yushun Dong, Florida State University, Tampa, FL, United States

This presentation explores the preferences and behaviors of large language models (LLMs) when applied to interdisciplinary tasks. We first introduce Political-LLM, a structured framework for integrating LLMs into political science research, bridging positive and normative traditions via taxonomy-guided alignment. Through a voting simulation case study, we uncover ideological preferences in LLM outputs, emphasizing the need for domain adaptation and ethical safeguards. Complementing this, we present CEB, a compositional evaluation benchmark that systematically assesses bias in LLMs across multiple social dimensions and tasks. By combining the two studies, we reveal how LLMs encode and express context-dependent preferences, highlighting risks such as ideological skew and social stereotyping. This interdisciplinary investigation provides new insights into value alignment and responsible deployment of LLMs.

4 - Faster Wind: Accelerating Iterative Best-of-N Distillation for LLM Alignment

Bo Dai, Georgia Tech, Atlanta, GA, United States

Recent advances in aligning large language models with human preferences have corroborated the growing importance of best-of-N distillation (BOND). However, the iterative BOND algorithm is prohibitively expensive in practice due to the sample and computation inefficiency. In this talk, we address the problem by revealing a unified game-theoretic connection between iterative BOND and self-play alignment, which unifies seemingly disparate algorithmic paradigms. Based on the connection, we establish a novel framework, WIN rate Dominance (WIND), with a series of efficient algorithms for regularized win rate dominance optimization that approximates iterative BOND in the parameter space. We provide provable sample efficiency guarantee for one of the WIND variants with the square loss objective. The experimental results confirm that our algorithm not only accelerates the computation, but also achieves superior sample efficiency compared to existing methods.

5 - Coactive Learning for Large Language Models Using Implicit User Feedback

Kianté Brantley, Harvard University, Allston, MA, United States

We propose coactive learning as a model and feedback mechanism for training large language models (LLMs). The key insight is that users provide implicit feedback whenever they edit the text y proposed by an LLM. While the edited text $\bar{y}$ is typically not a gold-standard example for supervised training, coactive learning merely requires that the edited text $\bar{y}$ is an improvement over the proposed text y . Note that such weak implicit preference feedback $\bar{y} \succcurlyeq y$ is available in many application settings on a per-user basis, thus enabling the personalization of LLMs. In this paper, we develop the theoretical basis for coactive training of non-linear models, and we derive CoRLL as the first coactive learning algorithm for LLMs. Empirical results indicate that CoRLL is effective even for weak and noisy coactive preference feedback, making it a promising algorithm for training and personalization of LLMs from feedback that is naturally collected in many use cases.

Omega-Rho Lecture

Plenary Keynote

Keynote

Chair: Tao Hong

1 - AI and OR in Action: Enhancing Decision-Making for Forest Fire Risk Mitigation

Andres Weintraub, Universidad de Chile, Santiago, Chile

Climate change has made forest fires more frequent and destructive. Increasingly preventive measures, taken before fires start, are becoming essential. In particular, fuel management, like fire breaks, where areas that allow fire to spread are cleared out to stop or delay the advance of fires. This Omega Rho Distinguished Lecture will describe AI and OR tools we have developed to support fire prevention decisions. The extremely high uncertainty in fire ignitions and spread require complex approaches. Particularly challenging problems are how to detect and prevent intentional fires and how simulation and optimization models support decisions on where firebreaks are more effective in stopping the growth of megafires.

Keynote - The Irrational Decision How We Gave Computers the Power to Choose for Us

Plenary Keynote

Keynote

1 - The Irrational Decision How We Gave Computers The Power to Choose for US

Benjamin Recht, University of California Berkeley, Berkeley, CA, United States

This talk traces the intellectual history of automated decision-making to its origins in the post-World War II development of computers. Mathematicians of the 1940s set out to design machines that could act as ideal rational agents in the face of uncertainty. In this pursuit, a cluster of foundational mathematical technologies—including linear programming, game theory, and neural networks—emerged as a foundation for a mathematical rationality, which changed how we think about human decision-making itself.

As the operations research community knows, these seminal computational methods have grown into a robust discipline and industry with countless success stories. I'll describe several such successes in accelerating computers, regulating pharmaceuticals, and deploying electronic commerce. These examples will highlight how automated decision systems excel in specific sweet spots with clear rules, well-defined goals, and well-constrained contexts.

However, most of life, for better or for worse, doesn't fit into neat mathematical models. Even in our data-driven world, we make decisions based on values, emotions, and incomplete information that can't be reduced to optimization problems. I will thus close by exploring how to best harness eighty years of unfathomable computational progress while preserving human agency and judgment.

Edelman Reprise

Plenary Keynote

Keynote

Chair: Irv Lustig, Princeton Consultants, Coral Gables, FL, 33146, United States

1 - Edelman Reprise: Usa Cycling

Ryan Cooper, USA Cycling, Georgetown, TX, United States, Jim Miller

In Olympic cycling, the difference between gold and missing the podium is measured in fractions of a second. For USA Cycling's Women's Team Pursuit squad, the 2023 World Championships in Glasgow highlighted a stark reality: a 6th-place finish with a time of 4:12.684 and missing the qualification round for the bronze medal final by 0.159 seconds. With the Paris 2024 Olympics approaching and the team falling to an 8th-place World Ranking, the challenge was clear: reduce nearly seven seconds off their performance in just one year, an improvement considered nearly impossible in elite sports. With limited funding compared to powerhouse nations like Great Britain and Germany, USA Cycling relied on Operations Research (OR), Machine Learning (ML), data analytics, race simulation, and targeted athlete development to bridge the gap. Armed with cutting-edge analytics and modeling, real-time performance tracking, and aerodynamic innovations, this initiative aimed at optimizing every aspect of the team's race strategy. Through the power of data-driven decision-making, USA Cycling achieved what few thought was possible: a stunning eight-second reduction in time to capture Olympic gold, with a time of 4:04.32.

From Data to Decision: Intelligent Decision-Making with Applications in Manufacturing and Healthcare

Invited Session

Quality, Statistics and Reliability

Chair: Jihoon Chung, Hanyang University, Seoul, N/A, Korea, Republic of

Co-Chair: Ziyang Zhang, Oklahoma State University, Stillwater, OK, 74078, United States

1 - Development of a Rubber Property Prediction Model Based on Integrated use of Mixing Process Sensor and Recipe Data

Jung-Hwan Hong, Pusan National University, Geumjeong-Gu, Korea, Republic of, Sa-Eun Park, Ho-Jin Cho, Chie-Hyeon Lim, Hye-Mee Kim, Hyeong-Woo Choi, Jik-Hyun Yoon, Ki-Hun Kim

The rubber mixing process is a critical stage in rubber manufacturing, where multiple raw materials are combined according to a predefined recipe to achieve desired material properties. However, product quality is assessed through physical and chemical tests conducted only after the mixing is complete, and the results are typically available several hours later. Consequently, any quality issues in the compounded rubber are identified only after the fact, limiting timely intervention. To address this challenge, we propose a predictive model that estimates key quality characteristics of rubber at the completion of the mixing process. The model integrates heterogeneous data sources — real-time process sensor data and recipe data — both of which are essential for accurate prediction. Experiments conducted on real-world industrial data demonstrate that the proposed model significantly outperforms state-of-the-art benchmarks in terms of prediction accuracy. By enabling real-time estimation of rubber properties, the model offers potential for early defect detection and enhanced process reliability in rubber manufacturing.

2 - TestImputer: Neural Imputation to Mitigate Information Loss in Reduced Semiconductor Wafer Probe Test

Min-Kun Shin, Pusan National University, Pusan, Korea, Republic of, Sa-Eun Park, Young-Mok Bae, Seung-Hyun Choi, Ki-Hun Kim

Semiconductor Wafer Probe Test (WPT) verifies each chip's electrical integrity, but running thousands of subtests per chip greatly increases test costs. Test Reduction (TR) based on chip sampling alleviates this burden but introduces Unsampled Chip Measurements (UCMs) that undermine multivariate quality analytics and elevate test escape risk. This study proposes TestImputer, a graph neural imputation network that imputes UCMs accurately while mitigating information loss due to TR. TestImputer first transforms tabular WPT data into a graph structure by representing chips and subtests as nodes and assigning their measurements as attributes of the edges connecting chip and subtest nodes. Simultaneously, TestImputer connects each chip to its adjacent chips to utilize Adjacent Chip Correlation (ACC), where spatially adjacent chips exhibit similar electrical measurements due to locally shared process conditions and gradual variations across the wafer surface. A attention mechanism then weights each neighboring chip, propagating information to impute the UCMs of the target chip. Experiments on real-world WPT data under different TR scenarios, characterized by unsampled chip ratios of 25%, 50%, and 75%, demonstrate that TestImputer consistently outperforms state-of-the-art baselines, achieving average improvements of 3.7% in root mean squared error, 3.0% in mean absolute error, and 4.8% in Wasserstein distance. TestImputer enables manufacturers to reduce WPT costs while mitigating the information loss.

3 - A Machine Learning-Based Reduced Order Model for Predicting Aerosol Dynamics in Dry Powder Inhalers

Ziyang Zhang, Oklahoma State University, Stillwater, OK, United States, Chenang Liu, Yu Feng

Accurately modeling aerosol transport in dry powder inhalers (DPIs) is critical for understanding and improving drug delivery efficiency. Traditional high-fidelity Computational Fluid Dynamics-Discrete Element Method (CFD-DEM) simulations provide detailed insights into particle-flow interactions and emitted particle size distributions. However, CFD-DEM simulations are computationally intensive and impractical for real-time or patient-specific optimization.

This work presents a data-driven Reduced Order Model (ROM) that leverages machine learning (ML) to fast predict emitted aerodynamic particle size distributions (APSDs), dosage metrics and patient usage conditions. A CFD-DEM simulation framework is used to generate training data, incorporating parametric sweeps across inhaler geometries, drug formulations, and patient-specific inhalation profiles.

The ROM architecture integrates autoencoders with regression networks and attention mechanisms to capture both global aerosol dynamics and localized particle interactions. Data augmentation strategies, including parametric perturbation and symmetry-based transformations, are employed to enrich training diversity and improve model generalizability.

Preliminary validation shows that the ROM achieves agreement with CFD-DEM simulations on key aerosol metrics, including emitted APSDs and spatial dose distributions. By significantly reducing simulation time while maintaining predictive accuracy, the proposed ROM provides a promising framework for real-time DPI design evaluation and personalized respiratory drug delivery modeling.

4 - Diffusion Model-Enhanced Integrative Approach for Adaptive Tumor Segmentation in Ultrasound Imaging

Emmanuel Yangué, Oklahoma State University, Stillwater, OK, United States, Chenang Liu, Yuxuan Li, Ashish Ranjan

Accurate identification of tumor regions, referred to as regions of interest (ROIs), in ultrasound imaging is critical for advancing image-guided drug delivery (IGDD). However, segmentation remains challenging due to high levels of interference and noise. To address these challenges, this study introduces IC-DREAM, an adaptive framework that integrates intensity-based centroid estimation for improved ROI center identification and employs a diffusion-based model to enhance boundary delineation, thereby improving segmentation accuracy and quality. The algorithm was validated on both simulated and real-world ultrasound image datasets, showing superior accuracy and reliability over conventional methods, all without the need for labeled data or training. While IC-DREAM effectively segments ROIs from ultrasound images, its performance remains highly dependent on the accurate identification of ROI centers and contours. These findings underscore the potential of IC-DREAM to tackle complex challenges in ultrasound-based tumor segmentation.

Optimization and Scheduling in Complex Logistics Systems

Contributed Session

Contributed

Chair: Tzvika Geft, Rutgers University, New Brunswick, NJ, United States

1 - Improving Picking Efficiency in E-Commerce Warehouses: a Correlation-Aware Scattered and Commingled Storage Optimization

TAO HE, University of Science and Technology of China, Hefei, China, People's Republic of

With the rapid expansion of e-commerce, warehouse picking efficiency has become a decisive competitive factor. Responding to the “small-batch, high-frequency, and SKU-diverse” nature of e-commerce orders, this study focuses on the **Scattered & Commingled Storage Assignment (SCSA)** strategy and, for the first time, systematically incorporates SKU demand correlations into this framework. We define groups of SKUs that frequently co-occur in the same order as **Demand Correlation Patterns (DCPs)** and formulate a mixed-integer programming model that maximizes the spatial proximity of correlated SKUs while preserving SKU dispersion constraints. To tackle the resulting NP-hard problem, we develop a two-stage heuristic algorithm based on fix-and-optimize framework that achieves tight alignment with a theoretical lower bound, thereby ensuring computational efficiency. Computational experiments and simulation studies show that our correlation-aware approach outperforms traditional scattered storage schemes, and that commingled storage configurations offer additional operational advantages. The analysis yields actionable insights into dynamic replenishment policies and slot-capacity settings, striking an optimal balance between inventory availability and accessibility. By resolving the inherent conflict between SKU dispersion and correlation clustering, this research advances warehouse optimization for modern e-commerce operations and provides a practical solution for picker-to-part systems handling complex order profiles.

2 - Ilp-Based Preemption Decisions in Twin Yard Crane Scheduling with Bidirectional Flows

Kim Jeong Heon, Pusan National University, Busan, Korea, Republic of

As global maritime container volumes continue to rise, efficient container handling at ports is becoming increasingly vital. Yard cranes—particularly in Twin Yard Crane Systems (TYCS), where two cranes operate on a shared rail—are crucial for improving terminal throughput. However, the non-crossing constraint between cranes adds significant scheduling complexity. This study focuses on the preemption decision problem in TYCS, where the goal is to determine whether and where to preempt container transport tasks to reduce interference and enhance efficiency. Unlike previous studies that assume unidirectional flows or fixes preemption points, we address a more realistic setting of bidirectional container flows. We propose a novel approach that approximates a single-crane schedule using an Eulerian path-based method and formulates the preemption decision as an Integer Linear Programming (ILP) model. The model features a fixed number of variables, proving the problem to be Fixed-Parameter Tractable (FPT). A genetic algorithm is then applied to optimize task sequences and interference handling priorities. We evaluate our approach across 72 diverse scenarios (with 20 instances each), showing that it consistently outperforms existing methods in minimizing makespan. A secondary analysis on waiting times further confirms the operational benefits. To the best of our knowledge, this is the first study to address preemption decisions in TYCS under bidirectional flows. Our results demonstrate that the proposed method is both robust and scalable, with strong potential for improving real-world container terminal efficiency.

3 - A Preprocessing Framework for Narrowing Objective Domains in Challenging Integer Programs: Application to the Traveling Salesman Problem

Aadya Bhattarai, University of south florida, Tampa, FL, United States, Hadi Gard, LAGNAJITA BASU

We study how the set of possible optimal objective values in integer programs can be narrowed to a significantly smaller subset. To achieve this, we propose a branch-and-bound technique integrated with a constraint programming solver, applied to the binary-encoded reformulation of challenging integer programs. The primary goal of this approach is to significantly reduce the set of feasible optimal objective values, which in turn can lead to modified integer programming models that can potentially enhance the overall performance of solvers on difficult instances. We provide initial numerical results that support the efficacy of this approach. Specifically, we apply the proposed techniques to hard instances of the Traveling Salesman Problem and provide insights into its performance. Additionally, we demonstrate that the embedded bounding mechanisms within the proposed branch-and-bound framework, when warm-started, can significantly boost the performance of the overall approach.

4 - Stochastic Fleet Mix Optimization for Robot-Aided Intralogistics

Arghadeep Mitra, University of Missouri, Columbia, MO, United States, Sharan Srinivas

Intralogistics operations, a critical component of the supply chain, are among the most labor-intensive and time-consuming processes that directly impact overall efficiency and responsiveness. In recent years, the growing supply chain challenges, including labor shortages, cost constraints, rising turnover, and increased customer demands, have intensified the need for resilient solutions. The effective integration of autonomous mobile robots (AMRs) has the potential to address these challenges through collaborative automation, where AMRs handle labor-intensive order transport tasks, allowing human workers, who are adept at item retrieval, to focus on this more specialized task. While existing studies have investigated the operational impacts of AMRs in intralogistics, strategic decisions concerning optimal AMR fleet

composition remain unaddressed. This research proposes a two-stage stochastic model to minimize both operational and acquisition costs. The first stage addresses the strategic decisions regarding fleet mixing and sizing, while the second stage optimizes operational decisions, specifically order batching, batch assignment to AMRs, and sequencing. A sample average approximation approach is used to solve the model and estimate the expected total cost. Due to the NP-hard nature of the problem, a hybrid metaheuristic approach is developed to efficiently solve realistic instances. The applicability and effectiveness of the proposed method are demonstrated through extensive numerical analysis. In addition, several practical implications on AMR fleet sizing and mixing are also established based on the experiments.

Keywords: intralogistics, autonomous mobile robots, fleet mix, stochastic optimization, sample average approximation, metaheuristic

5 - A Column Generation Algorithm with Hybrid MILP+CP Decomposition for Irregular 3D Bin Packing in Maritime Block Transportation wonjun choi, Pusan National University, Pusan, Korea, Republic of

The Irregular-shaped Three-Dimensional Bin Packing Problem (I3DBPP) for maritime block transportation involves efficiently loading shipbuilding blocks into self-propelled barges while ensuring collision-free placement in discretized 3D space. The objective is to minimize the number of barges used, thereby reducing transportation cost and improving operational efficiency. This problem is NP-hard due to the combination of irregular 3D geometries, complex geometric constraints, and combinatorial assignment decisions. To address this challenge, we propose a column generation algorithm based on a hybrid MILP+CP decomposition. The master problem adopts a set covering formulation to select packing patterns, while the pricing problem generates feasible patterns via a two-stage subproblem: MILP-based 2D placement generation followed by CP-based 3D feasibility checking using no-overlap constraints. This hybrid approach leverages the modeling strengths of MILP and the constraint-handling capabilities of CP to efficiently tackle the spatial complexity of I3DBPP. Computational experiments on realistic shipyard datasets demonstrate the effectiveness of the proposed method in terms of solution quality and computational efficiency. This work contributes to advanced decision-support tools for shipbuilding logistics and highlights the potential of integrating MILP and CP in column generation frameworks.

6 - Fully Packed and Ready to GO: High-Density, Rearrangement-Free, Grid-Based Storage and Retrieval Tzvika Geft, Rutgers University, New Brunswick, NJ, United States, Kostas Bekris, Jingjin Yu

Grid-based storage systems with uniformly shaped loads (e.g., containers, pallets, totes) are commonplace in logistics, industrial, and transportation domains. A key performance metric for such systems is the maximization of space utilization, which requires some loads to be placed behind or below others, preventing direct access to them. Consequently, dense storage settings bring up the challenge of determining how to place loads while minimizing costly rearrangement efforts necessary during retrieval. This paper considers the setting involving an inbound phase, during which loads arrive, followed by an outbound phase, during which loads depart. The setting is prevalent in distribution centers, automated parking garages, and container ports. In both phases, minimizing the number of rearrangement actions results in more optimal (e.g., fast, energy-efficient, etc.) operations. In contrast to previous work focusing on stack-based systems, this effort examines the case where loads can be freely moved along the grid, e.g., by a mobile robot, expanding the range of possible motions. We establish that for a range of scenarios, such as having limited prior knowledge of the loads' arrival sequences or grids with a narrow opening, a (best possible) rearrangement-free solution always exists, including when the loads fill the grid to its capacity. In particular, when the sequences are fully known, we establish an intriguing characterization showing that rearrangement can always be avoided if and only if the open side of the grid (used to access the storage) is at least 3 cells wide. We further discuss useful practical implications of our solutions.

2 - Portfolio Selection Models with Weight Constraints Derived from a Nonlinear Shrinkage Method Reflecting Macroeconomic Variables: Macroaugmented Portfolio Models

Jihye Yang, Yonsei University, Seoul, Korea, Republic of, Seongmoon Kim

We propose portfolio selection models with weight constraints reflecting four important macroeconomic variables: the Baltic Dry Index, interest rates, money supply, and inflation rates. We design two types of macroaugmented portfolio models (MAPs): MAPs with a linear shrinking factor (MAPsL) and MAPs with a nonlinear shrinking factor (MAPsN). Furthermore, we incorporate four nonlinear shrinking factors into MAP construction with a combination level derived from a tracking signal (MAPcN). We assess the performance of MAPs compared to the benchmarks in 12 different stock markets, finding that MAPs outperforms the benchmarks. MAPsN outperforms MAPsL, and MAPcN outperforms MAPsN in terms of the Sharpe, Sortino, and Rachev ratios. Additionally, we compare the performance of MAPs. In terms of individual and collective measures, each MAPsN outperforms the corresponding constituent of MAPsL. The effectiveness of the nonlinear shrinkage method measured by the ratio of the Sharpe ratio (RS) is differentiated by the stock market's characteristics. The RS for each macroeconomic variable is closely related to trade dependence, financial market openness, money supply stability, and market concentration.

3 - Quantification of International Trade Network Performance Under Disruptions to Supply, Transportation, and Demand Capacity, and Exchange Rates in Disasters

Dana Hassani, University of Massachusetts Amherst, Amherst, MA, United States, Anna Nagurney, Oleg Nivievskiy, Pavlo Martyshev

Both sudden-onset and slow-onset disasters are causing disruptions to global trade, impacting the availability and affordability of commodities from agricultural to mineral ones. We develop a multicommodity international trade network equilibrium model under disaster scenarios with distinct probabilities of the occurrence of the disasters and their impacts on the capacities associated with production, transportation, and consumption. The disaster scenarios can also affect the exchange rates. We state the governing equilibrium conditions and derive the variational inequality formulation in commodity path flow variables and Lagrange multipliers associated with the capacity constraints. For each disaster scenario, we construct an international trade network performance measure, followed by a unified performance measure that includes all the disasters and their probabilities. Robustness is then quantified as the difference between the network performance under no disruptions and the unified performance

measure. An international trade network component performance indicator is also given to assess the impacts of the complete removal of trade network supply markets, demand markets, and/or transportation routes. The modeling framework is then illustrated through a series of numerical examples, motivated by Russia's war on Ukraine. The work is of relevance to decision-makers and policy-makers.

4 - Sustainable Administrative Management from the Perspective of Balanced Contraction

Yuji Sato, Chukyo University, Nagoya, Aichi, Japan

This study considered the state of sustainable administrative management from the perspective of balanced contraction of its scope of responsibility. Countries like Japan that have entered aged societies with low birthrate can no longer expect the increase of administrative resources. Therefore, efficient administrative management has become an urgent issue for local governments in Japan. This situation gives rise to the discussion of scaling back the current range of administrative services. However, the discussion is not straight forward due to vested interests of citizens or bureaucratic conflict within a government. Specifically, it is difficult to reach a consensus on the downsizing of services or the delegation of authority from a government to substitutable business operators. Public administration in such countries thus need to explore practical ways to show specific and logical grounds for the retrenchment. Theoretical approaches based on the New Public Management to this issue exist, while concrete ways of administration have not been presented to date. Focusing on the properties of publicness, this study proposed how to outsource public services to substitutable operators by evaluating the degree of matching between services and operators. In the evaluation, we applied the Analytic Hierarchy Process and the Principal Component Analysis to measure the properties of publicness and explored the combination of services and operators with the highest compatibility. A case study in a local government in Japan suggests the feasibility of the approach proposed in this study.

5 - Welfare vs. Revenue: Optimal Government Loan Design for Green Production

Minjeong An, Yonsei University, Seoul, Korea, Republic of, Jiyoung han, Seung Hwan Jung, Yunzhe Qiu

We explore government loan contract designs aimed at supporting green production while balancing environmental objectives and fiscal prudence. Traditionally, government finance has relied on subsidies that prioritize social welfare. However, increasing demand for substantial investments in green production has led to the emergence of government loans. Such loans uniquely combine aspects of traditional government subsidies—emphasizing social welfare—and supply chain finance—prioritizing revenue maximization and risk mitigation. Employing a Stackelberg game framework, this study systematically compares these two distinct policy approaches: social welfare maximization versus government revenue maximization subject to minimum green production constraints. Our analytical model demonstrates significant divergence in optimal interest rate policies and production outcomes under these contrasting objectives. Specifically, welfare-oriented governments typically adopt zero interest rates to enhance environmental outputs, whereas revenue-oriented policies impose positive interest rates to mitigate fiscal risks and ensure repayment. Furthermore, we introduce an innovative two-part financing contract capable of reconciling these conflicting goals. This contract structure decouples marginal borrowing costs from fixed fees, enabling governments to achieve socially optimal production levels without necessitating negative interest rates. Our findings contribute valuable insights for policymakers designing green loan programs, highlighting essential trade-offs between ecological benefits and fiscal accountability in sustainable financing initiatives.

6 - Linking Global Supply Pressures to Business Cycle Dynamics: a Framework for Enhancing the Gscpi

Sein Kim, School of Business Administration, Kyungpook National University, Daegu, Korea, Republic of, Sungsu Kim

The Global Supply Chain Pressure Index (GSCPI), developed by the Federal Reserve Bank of New York, provides a valuable benchmark for quantifying global supply disruptions. However, its current formulation faces limitations in capturing the evolving, nonlinear nature of supply shocks. In particular, the index does not incorporate commodity price movements, which play a critical role in signaling upstream supply stress and in the transmission of input costs across production networks. Moreover, its reliance on static principal component analysis (PCA) limits the model's responsiveness to structural shifts and time-varying transmission mechanisms. This study explores the development of an enhanced GSCPI that addresses these limitations by incorporating additional price-based indicators and adopting a dynamic PCA framework. To evaluate its macroeconomic relevance, we apply standard business cycle moment diagnostics volatility, cyclical with output, persistence, and lead/lag relationships widely used in empirical validation of macroeconomic models. By bridging high-frequency supply-side indicators with low-frequency macroeconomic fluctuations, this approach contributes to a more adaptive and interpretable assessment of global supply pressures and offers a framework for more timely macroeconomic assessment.

Chair: Raziye Aghapour, University of Texas at Arlington, Arlington, TX, United States

1 - Paying for Drawdown: the Value of Commitment on the Cost of Ending Global Warming

John F Raffensperger, Simon Business School, University of Rochester, NY, Rochester, NY, United States

This paper investigates the costs of ending global warming under different levels of commitment. To estimate the costs, the paper contributes “smart market” models simulating auctions for emissions and carbon removal to reach net zero or base zero (pre-industrial temperature) by a particular date.

The models constrain warming robustly under different discount rates. The paper shows that Hotelling's rule does not apply to carbon policy with a deadline.

The paper contributes a mechanism to pay for drawdown of warming beyond net zero, avoiding third party payments. The mechanism converts a revenue negative auction to revenue neutral. The paper shows that drawdown costs less when emitters pay for it than when a third party pays for it.

The paper contributes a quantitative method to model and price carbon removal contracts, and gives estimates of the value of commitment to strong versus weak contracts.

The least cost trajectory requires long commitments to emissions reductions and carbon removal. The paper gives estimates of the value of long-run versus short-run commitments and the value of the ability to manage revenue across decades.

The paper provides a method to calibrate the models to a climate simulator while accounting for all greenhouse gasses.

For reducing global temperature 1.4°C by 2125, estimates range from \$20.4 trillion to \$10.8 trillion (total over 100 years present value at 3%) depending on commitment. This is much lower than other researchers' estimates simply for keeping global temperature to 1.5°C. The models could be used in actual trading.

2 - Climate and Water Risk Across the Bulk Power System Under Various Future Climate and Infrastructure Buildout Scenarios

Jonathan Lala, EPRI, Palo Alto, CA, United States, Erik Smith, Nalini Rao

The bulk power system in the U.S. faces substantial changes in the coming decades stemming from both climate change and the shift of the generation mix towards renewables. These changes present a challenge for both system planners and operators, who need a solid understanding of how changes will manifest as risks across uncertain climates and system configurations. Here we present a standardized and consistent process to identify relevant climate hazard metrics, connect them to vulnerabilities, and measure impacts across thermoelectric, hydropower, wind, solar, and transmission assets. We then simulate this process across various future climate models, emissions scenarios, and power system infrastructure buildouts to characterize uncertainty across the risk space. Results demonstrate unique regional risk profiles

depending on the climate hazard, climate scenario, and generation mix, although risks from high temperatures are measurable across all assets and regions. Stakeholders can use this risk-based approach to identify and monitor the effects of capacity losses and potential resulting consequences as climate and infrastructure change.

3 - Environmental Flows and the Hidden Costs of Hydropower: Evidence from Glen Canyon Dam

Ao Yu, Argonne National Laboratory, Lemont, IL, United States, Matija Pavicevic, Quentin Ploussard

Hydropower production in the U.S. operates within a complex regulatory framework that balances power system reliability, resource allocation, and environmental regulation. Because power plants are interconnected through the grid, policies affecting hydropower can have spillover effects on the broader generation fleet. This paper evaluates the economic impact of a 2024 environmental flow experiment that required dam operators to bypass water rather than use it for electricity generation. Leveraging quasi-random variation in the bypass schedule and an econometric model of hourly unit-level generation data, we estimate that the experiment increased system-level generation costs substantially. The implied economic value of the foregone water was about \$20 to \$50 per acre-foot. In addition, the policy resulted in significant environmental costs in increased pollutant emissions due to substitution toward fossil-fuel generation. These findings have important implications for designing environmental flow regulations and electricity market policy, particularly in the context of growing water scarcity and increased variable renewable energy penetration.

4 - Designing a Resilient Renewable Energy System for Zero-Energy Buildings Using a Simulation-Based Stochastic Program

Ricardo Lima, King Abdullah University of Science and Technology, Thuwal, Saudi Arabia, Farah Souayfane, Raju Pathak, Hayssam Dahrouj, Ibrahim Hoteit, Omar Knio

This work presents a methodology for designing resilient renewable energy systems for zero-energy buildings that accounts for the uncertainty of climate change over the next 75 years. Zero-energy buildings are poised to be energy-efficient and feature on-site generation and storage to meet their power demand. It becomes, therefore, a fundamental quest to properly design a resilient renewable energy system and storage capacities to meet the building's electricity demand while minimizing the life-cycle cost. The proposed methodology consists of 1) generation of long-term high-resolution atmospheric data by downscaling global climate projections, 2) a building simulation to estimate cooling electricity demand as a function of the atmospheric input fields, 3) a renewable energy system simulation integrated alongside the load-demand forecast, 4) a stochastic program based on climate projection scenarios; 5) adaptation of the stochastic programming for implementation within a simulation-based optimization framework, 6) a multi-objective optimization using a simulation-based algorithm to determine the best system configuration balancing resilience and cost, and 7) a rolling-horizon approach applying the reformulated stochastic program over 25-year horizons at hourly resolution, and 8) integration of extreme weather events from multiple climate models into the optimization framework to ensure robustness. Our optimization results emphasize the first-stage decision variables, and their associated 25-year expected life cycle cost of the renewable energy system. In particular, we quantify how incorporating extreme weather events from multiple climate model scenarios alters both the system design and its life-cycle cost.

5 - A Design of Experiments Approach to Assessing State-Level Decarbonization Strategies in Texas Using GCAM-Usa

Raziye Aghapour, University of Texas at Arlington, Arlington, TX, United States, Erick Jones

Effective state-level decarbonization planning requires an understanding of how different policy levers interact across the energy, industrial, and transportation sectors. This study presents a structured Design of Experiments (DoE) approach for systematically evaluating key policy pathways using GCAM-USA, a state-resolved integrated assessment model. The analysis focuses on Texas as a case study and investigates the influence of five continuous policy variables: adjustments to natural gas prices, subsidies for rooftop solar adoption, constraints on electric vehicle (EV) market share, production caps in the cement industry, and taxation of oil refining activities.

To efficiently explore the multidimensional policy space, we use a **Sobol sequence**—a quasi-random low-discrepancy sampling method—to generate a balanced and representative set of 35 scenarios. These scenarios are designed to capture a wide range of potential interactions between policy levers. Total CO₂ emissions are tracked as the primary output to assess how policy combinations influence mitigation outcomes.

This work highlights the value of combining integrated assessment modeling with structured experimental design to support subnational climate policy evaluation. By enabling transparent, reproducible, and systematic scenario analysis, this approach helps identify promising decarbonization strategies that account for sectoral interdependencies and policy trade-offs.

Toward Circular and Low-Carbon Transitions: Policies, Incentives, and System Designs

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Ilgin Dogan, INSEAD, Fontainebleau, France

1 - Closing the Loop OR Opening the Market? Deposit-Refund System Design Under Recycling Targets

Donghyun Choi, Georgia Institute of Technology, Atlanta, GA, United States, Andre Calmon, Beril Toktay

Beverage producers increasingly face mandatory recycled-content targets while financing deposit-refund systems (DRS) or broader extended-producer-responsibility schemes. Yet DRS governance differs markedly, reshaping both system costs and material circularity. We build an analytical model that compares (i) open-access, in which DRS-collected material is sold to the competitive commodity market, with (ii) priority-access, in which beverage producers have the right of first refusal (ROFR) on that material. The model embeds supply uncertainty and competition from non-beverage sectors to quantify how each design shifts financial burdens, price risk, and closed-loop (bottle-to-bottle) recycling rates. By illuminating the trade-offs, the study provides actionable guidance for policymakers crafting DRS legislation and for beverage firms shaping sourcing and investment strategies in a circular-economy context.

2 - Diffusion in Circularity: the Missing Link in Circular System Design

Clara Carrera, INSEAD, Fontainebleau, France, Atalay Atas, Dragos Florin Ciocan, Luk Van Wassenhove

Despite growing enthusiasm for circular economy models, implementing profitable circular strategies remains challenging—particularly for new products with short lifecycles and unpredictable return flows. This paper examines the viability of circular business models that combine leasing (servitization) with remanufacturing, focusing on how product diffusion dynamics shape the alignment between return supply and remanufactured demand. Using a dynamic model that captures consumer heterogeneity, arrival patterns, and word-of-mouth effects, the analysis introduces the concept of Circular Potential—a measure of the temporal overlap between returned products and remanufactured demand. The results show that products with slower diffusion and stronger peer influence are better suited for circular models, while products targeting environmentally conscious consumers often exhibit lower Circular Potential due to faster uptake and longer usage times. The study identifies conditions under which managers can ignore or must account for lifecycle effects in pricing and contract design. Calibration with data from the consumer electronics industry highlights the counterintuitive finding that mass-market products may offer more favorable conditions for circularity than sustainability-focused alternatives.

3 - An Empirical Analysis of Sustainable EV Charging: Human vs. Smart Algorithm

Rahul Roy, Kenan-Flagler Business School, The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, Nur Sunar, Jayashankar Swaminathan

The transportation sector is the world's second-largest source of greenhouse gas (GHG) emissions, making its decarbonization essential for global climate goals. Electric vehicles (EVs) offer a promising pathway to sustainable mobility by reducing fossil fuel dependence. However, widespread EV adoption increases electricity demand on

the grid, especially during peak consumption hours, when electricity is costlier and harder to supply. This creates a challenge for both grid operators and consumers. Shifting EV charging to off-peak hours may reduce system strain and lower user costs, benefiting all stakeholders. As such, utilities and grid operators have adopted various charging strategies to foster off-peak charging: some allow fully consumer-controlled charging, while others rely on automated algorithms or hybrid approaches that incorporate both algorithmic control and user feedback. In this context, we study two key questions: (i) How do smart algorithms perform relative to humans in promoting off-peak EV charging? (ii) Building on this comparison, how does incorporating human guidance into smart algorithmic systems affect off-peak charging performance? To answer these questions, we analyze data from a large-scale field experiment on residential EV charging. Our findings offer valuable insights and practical guidelines for grid operators and utilities designing smart charging systems, especially those involving human-algorithm interaction.

4 - Area Conditions and Positive Incentives: Engaging Local Communities to Protect Forests

Xavier Warnes, Indiana University, Bloomington, IN, United States, Joann de Zegher, Dan Iancu, Erica Plambeck

Agricultural production is a dominant driver of tropical deforestation, causing alarming CO₂ emissions and loss of biodiversity and ecosystem services. Complex land tenure systems coupled with low enforcement of conservation laws enable farmers to convert tropical forests into productive land for a better income. We propose positive incentives with area conditions for local communities to prevent this deforestation while increasing farmer welfare. We model the deforestation decisions of the community using a cooperative game in partition correspondence form and show how these area-conditional incentives can leverage the existing social capital in agricultural communities. Finally, we demonstrate the effectiveness of these conditions by using data from the Indonesian context.

1 - Competing Platforms, Competing Sellers: the Strategic Impact of Personalized Recommendations in Two-Tiered Market Competition

Zhe Yang, Tianjin University, Tianjin, China, People's Republic of, Zhaofang Mao, Yuxin Liu, Yunchuan Liu

Personalized recommendations, powered by advanced machine learning techniques, have become a key strategic tool for platforms. We explore the design choices between profit-based and demand-based recommendation systems when competing sellers offer products of varying quality to heterogeneous consumers through online platforms. Our analysis considers both monopolistic and competitive platform settings. Our findings reveal the following: (1) In a monopolistic market, the platform consistently prefers profit-based recommendation systems. However, in a duopoly, a platform may adopt a demand-based system to alleviate the double-layered competition between platforms and sellers. (2) In a duopoly, the pioneering platform always selects a profit-based recommendation system, regardless of the product cost structure or the degree of consumer heterogeneity. (3) In contrast, as consumer heterogeneity increases, the following platform becomes more inclined to adopt a demand-based recommendation system. (4) A profit-based recommendation system does not necessarily promote high-quality products; the recommendation outcome depends on the seller's cost structure and consumer heterogeneity. Our paper also offers managerial implications for policymakers regarding the regulation of recommendation algorithms and the protection of consumer privacy.

2 - Information Disclosure and Efficiency of Dynamic Price Negotiations

Gaoyang Cai, Northwestern University, Kellogg School of Management, Evanston, IL, United States

Negotiation is prevalent in two-sided markets, where users have incomplete information about the other side. Information disclosed by the platform owner or revealed by users critically impacts market outcomes and welfare.

Leveraging a panel experiment on a large on-demand delivery platform that exogenously varies the information disclosed to drivers negotiating with shippers on prices, I find that disclosing information about the lowest counteroffer rejected by a shipper significantly increases shipper rejections on driver counter prices while increasing transactions due to the decreasing driver counter prices.

To evaluate the equilibrium and welfare impacts of different information disclosure policies, I develop a dynamic model incorporating shipper counteroffer acceptance and driver counter strategies under different information sets. I find that disclosing the information benefits low-value shippers by allowing them to signal valuations and decrease subsequent counter prices by rejecting counteroffers and waiting. In contrast, high-value shippers suffer from drivers' more aggressive countering based on their rejection records.

Counterfactual analyses show that a partial information disclosure policy, i.e., no information disclosure above a threshold and full information disclosure below the threshold, protects high-value shippers from price discrimination while keeping the signaling benefits. The platform can restore 91.45% of the social surplus in the infeasible first-best benchmark without incomplete information and driver markups by optimally choosing the partial information disclosure threshold. The optimal partial disclosure policy increases the social welfare by 19.96% compared to the no-information-disclosure benchmark and increases the social welfare by 11.25% compared to the full-information-disclosure benchmark.

3 - Multi-Tier Capacity Planning in Fulfillment Center and Storage Networks at Amazon

Junho Lee, Amazon, New York, NY, United States, Song Song

From the business problem, we develop a science model answering when, how many, where, and what to build, with uncertainty in future demand and economic factors coupled with capacity planning. It supports capacity planning of the fulfillment center (FC) and storage and distribution centers (SDCs) at Amazon. We introduce an approach that decomposes a monolithic model into two parts: topology and economics models. Given how many to build, the topology model generates a build plan, which consists of the best locations of FCs and SDCs. The economics model evaluates economic factors for every build plan from the topology model and recommends the one with the least cost. Our model has been supporting multi-billion dollars' decision making for Amazon's FC and SDC network.

4 - The Steady State of Picking and Packing Throughputs in Fulfillment Centers, with The Optimal Labor Allocation

Jiung Lee, Coupang, Seoul, Korea, Republic of, Zhixin Liu, Ryan Cybulski, Vikram Balaji, Manish Garg, Gowri Krishnan, Paul Stroup, Harshal Wanjari

In the domain of e-commerce fulfillment, optimizing labor allocation within fulfillment centers is critical to ensuring high throughput and meeting stringent service level agreements. This study introduces a novel analytical model that captures the end-to-end dynamics of picking and packing operations for fresh products—a process characterized by multiple SKUs in an order, heterogeneous labor resources, and tight operational constraints. Our model explicitly incorporates the interplay between pickers, item collection walls, and packing stations, all of which must be coordinated to maintain flow balance and avoid bottlenecks.

We develop a mathematical framework that characterizes the steady-state throughput capacity of each resource type and identifies optimal allocation strategies under realistic operational constraints. The model enables decision-makers to evaluate trade-offs and reconfigure resources dynamically to maximize efficiency.

To validate our approach, we calibrate the model using proprietary operational data from a global commerce service provider. Empirical results demonstrate the model's ability to accurately capture system behavior and provide actionable insights for improving fulfillment performance. Our findings offer both theoretical contributions to the modeling of complex logistics systems and practical implications for real-world deployment in high-volume, time-sensitive environments.

5 - Online Supplier Selection for a Drop Shipping E-Retailer

Thomas Bryant Cassidey, University of Colorado Colorado Springs, Denver, CO, United States, Emily Griffin, Burcu Keskin

Firms using drop shipping must choose suppliers to fulfill orders in real time. Suppliers may vary in fulfillment accuracy, fulfillment speed, order acceptance rate, and cost, among other attributes. These trade-offs are difficult to manage due to the difficulty in eliciting coherent preferences from decision makers and due to the uncertainty of important supplier attributes. Further, due to the on-line nature of the problem and suppliers both leaving and joining the network, varying levels of information are available to a firm when an order is received. We devise a system to elicit the preferences of a firm and investigate methods to automate decisions accordingly, considering known factors of the supply options and a prediction of their performance. We test our methods using real transactional data from a large e-retailer of durable goods in the United States. Our case study provides an analysis of the important factors in predicting supplier attributes and demonstrates the trade-offs in outcomes of our methods compared to the incumbent approach.

6 - Auditing the Effectiveness and Impartiality of Pricing Algorithms in Online Grocery Retailing

Rafael Becerril Arreola, USC Darla Moore School of Business, Columbia, SC, United States

Online retailers often use automated software to set product prices that maximize profits by capitalizing on geographic differences of consumer sensitivity to prices. As a result, prices may correlate with consumer demographics. We collect and analyze data to study the variation of algorithmic prices across geographies and to investigate what explains such geographic differences. We compare online prices against brick-and-mortar prices to isolate the algorithmic component of prices and find it to be correlated with some demographics. By reverse-engineering the pricing algorithm, we find that it is not fully consistent with profit maximization. The data shows that the algorithm is suboptimal for products and locations with low product sales, suggesting that the algorithm is ineffective because of weaknesses in the data it uses. As a result, the pricing algorithm can only effectively maximize profits for consumers with specific demographic profiles.

1 - Selecting Industry 4.0 Technologies for Applications in Digital Construction Using Text Mining and Clustering Techniques

Hamid Seifoddini, University of Wisconsin-Milwaukee, Milwaukee, WI, United States, Benyamin Sadeghi

Industry 4.0 technologies—such as Artificial Intelligence (AI), robotics, 3D printing, and the Internet of Things (IoT) are essential for enhancing the efficiency and effectiveness of human endeavors in the 21st century. This is especially relevant in the construction industry, which has lagged manufacturing in adopting these advanced technologies. To address this gap, we have developed a comprehensive framework for identifying and classifying 33 Industry 4.0 technologies based on 106 application attributes specific to construction, using text mining and clustering techniques.

In this paper, we introduce a framework for modeling the alignment of advanced technologies with various construction activities using clustering techniques. To prioritize these technologies, we assign weighting factors to key attributes such as safety, productivity, sustainability, cost, quality, and timeliness. This approach allows users to tailor solutions according to their specific priorities. Moreover, by applying a range of weighting factors, practitioners can conduct sensitivity analyses to identify the most suitable cluster of advanced technologies for a given priority. This study also highlights the power of data mining in transforming large volumes of data into concise, useful, and actionable information.

The framework is grounded in an extensive review of over 500 peer-reviewed publications and additional resources. Its application supports the advancement of Construction 4.0 by promoting the integration of Industry 4.0 technologies into construction practices.

2 - From Experimentation to Impact: Governing Enterprise Innovation Through Crucial use Case Identification

Joseph Ng, NYU, New York, NY, United States, Andres Fortino

Organizations face a critical challenge in translating burgeoning emerging technology experiments into scalable, impactful enterprise solutions. This innovation bottleneck stems from a "portfolio fallacy," prioritizing exploration volume over rigorous, strategically aligned evaluation. Drawing upon the scientific concept of *experimentum crucis* and the "killer uses" framework, we posit that identifying crucial use cases—high-leverage business needs uniquely addressable by new technologies—is paramount for overcoming this challenge. Unlike retrospective "killer apps," crucial use cases are forward-looking and amenable to systematic identification and evaluation.

This paper introduces the Casus Exponentialis Technology Matrix (CETM), a multi-dimensional governance framework designed to operationalize the analytical identification and evaluation of crucial use cases. Leveraging principles from decision theory and innovation diffusion, CETM provides a structured, quantitative scoring mechanism across eight critical dimensions: technology readiness, business impact, ethical implications, regulatory compliance, cybersecurity, workforce impact, sustainability, and market risk. By applying this systematic evaluation, CIOs and innovation leaders can move beyond intuitive decision-making, prioritize initiatives with demonstrable potential for responsible scaling, and align technology investments with strategic objectives. The CETM framework fosters interdisciplinary accountability and supports a repeatable innovation lifecycle from initial discovery through institutionalization. This approach offers a robust methodology rooted in management science for navigating the complexities of the exponential technology landscape, transforming fragmented experimentation into structured, value-driven transformation, and directly contributing to the revolutionizing of decision-making through the effective integration of technology and human collaboration.

3 - A Strategic Framework for Identifying National R&D Investment Opportunities in Energy Transition: An Integrated Analysis of Patent, SCIE, and SSCI Data

Heeseok Moon, Kyung Hee University, Yongin, Korea, Republic of, Hyunhong Choi

This study presents a strategic framework for identifying national R&D investment opportunities in the energy transition sector by integrating patent data with SCIE and SSCI publication records. To address the limitations of existing technology-centered analyses, the study incorporates signals from scientific discovery and societal discourse.

A five-stage analytical process is proposed. First, Structural Topic Modeling (STM) is applied to extract latent topics from patents and academic papers, integrating metadata to estimate context-sensitive topic prevalence. Second, regression analysis is performed to evaluate topic-level characteristics such as growth, novelty, and citation performance, enabling the identification of emerging topics. Correlation analysis is then used to cluster closely related topics, capturing recent trends in technological convergence. Third, the analysis assesses national R&D focus by examining country-specific topic intensities and regression coefficients. Fourth, TF-IDF-based cosine similarity is calculated to evaluate semantic alignment between patents and papers, identifying both shared research-industry trends and academically dominant topics. Fifth, a set of decision-support tools is developed: (1) a Patent Portfolio Matrix that maps technology-level impact and country-level competitiveness, and (2) a commercialization opportunity map derived from emerging academic topics that are weakly aligned with patents but closely related to societal concerns.

By linking scientific, technological, and social dimensions of innovation, this framework offers a data-driven basis for forward-looking R&D strategy development. It supports the identification of underexplored yet impactful investment areas and contributes to national-level planning in complex, demand-sensitive domains such as

energy transition.

4 - Pricing Problems in Adoption of New Technologies

Yijin Wang, University of Illinois Urbana-Champaign, Urbana, IL, United States, Subhonmesh Bose

We propose a generalization of the Bass diffusion model in discrete-time that models the effect of price in adoption. Our model fits well to adoption data for various products and is amenable to mathematical analysis. We utilize this model to study two decision-making problems. First, we provide a series of structural results on optimal pricing strategies to maximize profits from product sales by a monopolist over a finite horizon. We derive a closed-form optimal pricing strategy for the single-period problem. For the multi-period problem, we show that the search for the optimal price can be restricted to a bounded set. Furthermore, for the special case of low peer effects, we analytically establish some desirable properties of the value function and the optimal price function. We also show that the optimal pricing trajectories calculated using our model have a similar structure to those proposed by prior research. Second, we study a Stackelberg game between a policy-maker and a monopolist, where the former seeks to maximize adoption through rebates, while the latter maximizes profits. The firm, which is the follower, must determine its optimal pricing strategy in response to a fixed rebate set by the leader, the policymaker. We analytically characterize the single-period game and show that the presence of rebates does indeed boost adoption. Due to the difficulty in analyzing the multi-period game, we conduct numerical simulations and show that characteristics of the single-period game appear to apply to the multi-period game as well.

5 - Cultivating Future Innovators: a Smart Agriculture Summer Camp for Middle and High School Students

Sara Masoud, Wayne State University, Detroit, MI, United States

This presentation highlights the objectives, structure, and projected outcomes of the Smart Agriculture Summer Camp. Funded by USDA and supported by additional partners, the camp aims to introduce middle school and high school students to the emerging field of smart agriculture through immersive, hands-on learning experiences. Over the two-week period, students are engaged with four interconnected modules: Indoor/Outdoor Farming, Internet of Things (IoT) and Sensor Technologies, Data Analysis, and Artificial Intelligence/Machine Learning in Agriculture. Each module combines experiential learning activities, expert-led workshops, and site visits to local farms and tech labs, offering students a well-rounded understanding of the technologies transforming agriculture. The program is intentionally designed to bridge the gap between traditional agricultural practices and advanced digital tools, while fostering awareness of STEM careers in agri-tech. To measure the program's impact, pre- and post-camp surveys are administered to assess changes in students' knowledge, attitudes, and interest in agricultural technologies and related career pathways. The camp also incorporates leadership development and peer collaboration exercises to build students' confidence and problem-solving skills.

6 - Technology Opportunity Discovery for Incremental Innovation: A Hybrid Framework with Structural Topic Modeling and Generative Topographic Mapping

Junyong Lee, Kyung Hee University, Yongin-si, Gyeonggi-do, Korea, Republic of, Hyunhong Choi

As markets are increasingly shaped by diverse technologies, the identification of technological opportunities has become paramount. This study proposes a novel framework combining Structural Topic Modeling and Generative Topographic Mapping to identify incremental innovation opportunities. While recent analyses of technological opportunities have predominantly focused on identifying radical innovations, the identification of incremental innovations holds comparable significance, as their accumulation can pave the way for radical breakthroughs.

The proposed framework uses patent data to identify latent topics, then constructs data points from principal topic keywords, reducing these to latent points. Using GTM's inverse function, topic models enhance the interpretability of vacant coordinates, offering a robust decision-support tool for unearthing technological opportunities. This approach adopts a semi-automated methodology, minimizing expert intervention during the analysis phase.

An empirical study was conducted on Unmanned Aerial Vehicles (UAVs), analyzing the trend of how technological gaps are filled over time according to patent application dates. From the technology map, 11 vacant points were identified and proposed as promising candidates for incremental innovation. Consequently, this research contributes to the discovery of incremental innovation opportunities by demonstrating that topic models can be employed not only to improve GTM's dimensionality reduction performance but also to simultaneously strengthen its interpretative capabilities.

Furthermore, the effectiveness of the proposed methodology was validated. This was achieved by inputting the generated outputs as prompts to ChatGPT and comparing the results obtained when utilizing comprehensive information from both STM and GTM against those derived solely from GTM-restored keyword information.

Health IT and User Engagement: Patients and Clinicians

Invited Session

Information Systems

Chair: Atiye Cansu Erol, Johns Hopkins University-Carey Business School, Baltimore, United States

1 - Does Premium Version Adoption in Mhealth Improve User Engagement and Health-Related Outcomes?

Yikun Jiang, Purdue University Mitch Daniels School of Business, West Lafayette, IN, United States, Kosuke Uetake, Nathan Yang

This study examines the impact of premium adoption on user engagement and health outcomes in an mHealth setting. Using a staggered Difference-in-Differences (DiD) framework, we estimate the effects of premium adoption on food and exercise tracking, adherence to caloric budgets, and weight loss. Although premium users exhibit an initial spike in engagement, these effects dissipate within weeks, consistent with hedonic decline. Despite increased tracking activity, premium adoption does not translate into sustained improvements in weight loss. We further demonstrate that failing to account for endogeneity and selection in premium adoption leads to an overstatement of its effects on both engagement and health outcomes. Taken together, these findings underscore the transient nature of premium-induced behavior change and highlight the importance of reinforcement mechanisms to sustain long-term engagement.

2 - The Impact of Telehealth Expansion on 'Doctor-Shopping' and Drug Overdose

Byoung-Hyuk Ahn, Boston University, Boston, MA, United States, Meizi Zhou, Gordon Burtch

Telehealth technologies have revolutionized the traditionally fragmented and polarized U.S. healthcare landscape by enabling efficient and cost-effective access to quality healthcare services across state borders. Legislative initiatives at both state and federal levels such as Interstate Medical Licensure Compact (IMLC) and temporary licensure waivers during the COVID-19 pandemic further democratized healthcare access and accelerated telehealth adoption. However, this expansion has simultaneously introduced new pathways for patients to engage in "doctor-shopping" for controlled substances. In this study, we examine the causal relationship between telehealth expansion and patients' attempts in acquiring prescription drugs from multiple providers and related drug overdoses, leveraging the staggered timing of states' entry into the IMLC and national temporary licensure waivers in U.S. as a quasi-natural experiment. Analyzing the patient data from 2012 to 2022, our findings reveal that telehealth expansion increases doctor-shopping activities for controlled substances and associated overdose incidents, with nuanced variations across drug categories. Additionally, we investigate the moderating effects of Prescription Drug Monitoring Programs (PDMPs) and Interstate Data Sharing initiatives, highlighting the monitoring effect in mitigating these adverse outcomes. Finally, we investigate the cross-drug effects by analyzing how change in illicit drug price influences doctor-shopping behavior and overdose rates. Our study illuminates the unintended consequences of telehealth technologies and provides practical regulatory implications for healthcare system designers and policymakers.

3 - The Devil's Advocate: when AI Challenges Human Expertise

Kanghyun Cho, Temple University, Philadelphia, PA, United States, Kihwan Nam, Jin-Woo Park

While artificial intelligence (AI) has the potential to enhance clinical decision-making, much existing research focuses on low-stakes tasks with non-experts, overlooking the complexities of high-stakes environments where decisions involve expert judgment and serious consequences. To address this gap, we examine AI use in a high-stakes medical context through the lens of reflective practice. We conducted a randomized crossover experiment with experienced psychiatrists diagnosing swallowing disorders using video data. Two AI-assisted workflows were tested: a one-step workflow, where AI advice is given during initial diagnosis, and a two-step workflow, where AI input is revealed only after an initial unaided decision. The one-step workflow improved overall accuracy but increased automation bias, particularly in simple cases. The two-step approach improved accuracy for medium-difficulty tasks by promoting reflective engagement but decreased performance in highly difficult cases, likely due to cognitive conflict when AI contradicted prior assessments. Notably, our AI system outperformed human experts in many cases, but both reached a performance ceiling on the most challenging tasks. These findings underscore how expert identity, cognitive complexity, and the consequences of error influence AI effectiveness in clinical settings. We argue that results from low-stakes studies may not generalize to high-stakes environments and call for the development of task-sensitive, context-aware AI systems that complement rather than replace professional judgment.

4 - Offline Privacy Concerns in Mental Health Care Delivery Through Telehealth

Atiye Cansu Erol, Johns Hopkins University - Carey Business School, Baltimore, MD, United States, Lynn Wu

Mental health conditions are responsible for 23% of all pregnancy-related deaths in the US. A significant contributor is postpartum (after birth) mental health issues, primarily depression, which affect 1 in 8 mothers. Yet more than half of new mothers with depression go untreated. Telehealth has the potential to increase access to and utilization of mental health care, but any such benefits may be affected by offline(physical) privacy concerns. On the one hand, telehealth shifts care from a provider office setting to a home setting, which may reduce privacy for individuals using telehealth in crowded households(“privacy at home”). On the other hand, consumption of telehealth services may be less observable than in-person care, alleviating concerns about societal stigma related to the use of mental health services(“privacy in the community”). Using detailed insurance claims data surrounding a period of rapid increase in telehealth use, we find that telehealth availability increases treatment utilization, with lower utilization for individuals in crowded households and higher utilization where there is a high societal stigma to the use of mental services. These insights are potentially actionable as insurers and providers can expand the utilization of maternal mental health services by increasing support for telehealth in environments where there is high societal stigma, and seek alternative delivery mechanisms for individuals who may live in crowded households. Furthermore, our findings are likely to extend beyond maternal mental health setting, as the advantages and disadvantages of telehealth and the associated privacy concerns are not exclusive to mothers or mental health.

People-Centric Operations

Invited Session

Manufacturing and Service Operations Management (MSOM)

Chair: Abhishek Deshmene, Georgia Institute of Technology, Atlanta, GA, United States

1 - Fair Funnels: Bias, Performance, and Interventions in Multistage Hiring Processes

Jordan Tong, University of Wisconsin-Madison, Madison, WI, United States, Eunjee Kim, Xiaoyang Long

How does the multistage funnel structure interact with discriminatory judgment behaviors to impact hire representation and quality? What is the best way to design regulations and incentives within funnel structures to improve representation and performance, and can they improve both? We develop a stylized mathematical model that captures tasted-based and statistical discrimination in a multistage funnel. We show that three distinct discriminatory judgment behaviors work through the funnel in three distinct ways to cause underrepresentation. We then endogenize the funnel's threshold decisions to study the impact and effective design of regulations and incentives. Whereas common wisdom would suggest targeting regulations and incentives at the stage where underrepresentation appears most severe, our analysis suggests a simple recommendation is surprisingly robust irrespective of where the underrepresentation manifests: *regulate the top, subsidize the bottom*. We identify several distinct asymmetric dynamics that support this prescription: asymmetry in regulation workarounds, asymmetry in regulation win-win opportunity, and asymmetry in subsidy propagation. Our results help organizations better predict how discriminatory judgment behaviors will affect representation and quality at various stages in the funnel. They help guide policymakers seeking to design regulations and incentives on where to target their interventions, and their likely consequences on representation and performance outcomes.

2 - Information Sharing to Optimize the Wait-TIME Experience

Laurens Debo, Dartmouth College, Hanover, NH, United States, Jeunghyun Kim, Robert Shumsky

We develop a behavioral model to optimize the frequency of queue-position updates provided to customers in an unobservable M/G/1 queue. Departing from standard waiting cost functions, the model captures disutility using two psychological constructs: *loss aversion* and *discomfort with uncertainty*. We evaluate a class of information policies in which customers receive position updates every $\$m\$$ service completions.

We first examine two extremes: a full-information policy ($\$m = 1\$$) and an arrival-only policy ($\$m = \infty\$$). Customers who are purely loss-averse prefer minimal information, while those who dislike uncertainty benefit from frequent updates. For customers sensitive to both, we derive a tractable approximation for highly utilized systems to determine the optimal update interval $\$m\$$. The analysis shows that as utilization or service-time variability increases, the optimal strategy is to reduce the frequency of updates (i.e., increase $\$m\$$). However, the *number* of updates experienced by the average customer still rises, as longer queues compensate for the sparser update schedule.

Numerical experiments validate the approximation and demonstrate robustness even under moderate utilization.

This work contributes a behavioral optimization framework to the queueing literature and provides actionable insights for service providers: tailoring the timing of updates can improve customer experience by managing emotional responses to waiting, not just expected wait times.

3 - Dali OR Dall-E? Consumer Perception of Human Versus AI Creative Processes

Abhishek Deshmene, Georgia Institute of Technology, Atlanta, GA, United States, Diwas KC

As AI-generated content proliferates in creative domains, understanding how consumers evaluate the authenticity and value of such works has become increasingly important. This study examines how attribution — human versus AI-assisted — shapes consumer perceptions of visual art, and whether disclosures about creative effort and uniqueness moderate these effects. Drawing on theories of authenticity, creative labor valuation, and algorithmic aversion, we theorize that AI involvement may trigger a perceived deficit in originality or intentionality, lowering perceived value. However, we also propose that transparency about the creative process can restore some of this lost value by reintroducing signals of effort and uniqueness. Using a VR-based mixed within-between subjects experiment, participants viewed artworks with systematically varied attribution and process information before expressing preferences. Our findings show a consistent “AI discount” in perceived value, but also reveal that this discount is significantly reduced — sometimes eliminated — when the AI-assisted creation is accompanied by high-effort disclosures or uniqueness cues. These results advance our understanding of how consumers make sense of creativity in the age of AI, and suggest that attribution and process transparency can meaningfully shape public reception of algorithmically generated content.

4 - Sustainable Procurement Contracts for Infrastructure Networks

Yuri Fonseca, Stanford University, Stanford, CA, United States, Vahideh Manshadi, Daniela Saban

In this work, we focus on the design and analysis of procurement mechanisms in which a set of products must be procured using one auction per product, yet these products have positive/negative synergies. Auctioneers often approach procurement as independent, especially when there is no overlap of bidders. For instance, possibly due to difficulty in coordination efforts, when developing infrastructure projects, the impact of each project for both society and the environment is often analyzed in isolation; however, when executed, synergies may occur, making the combined benefit super- (or sub-)additive of the individual ones. To understand the impact of ignoring the network effects on procurement, we characterize the optimal mechanism for the settings in which auctions are run simultaneously, or sequentially. In the simultaneous setting, each auction's optimal reserve price solves a pair of fixed-point equations reflecting how one project's success probability alters the marginal value of the other; positive externalities relax reserves, while negative ones tighten them. In the sequential setting, we show how reserves can be dynamically updated based on earlier outcomes. Next, we conduct a numerical study based on real infrastructure projects under Brazil's National Logistics Plan (PNL), demonstrating how ignoring these network effects in the design of the procurement auction leads to substantial loss across economic and environmental metrics, underscoring the importance of incorporating network effects into procurement design.

Chair: Luca Binder, Vlerick Business School, Gent, N/A, Belgium

1 - Beyond Zero-Sum Game: Deliberate Competition Building in Fragmented Markets

Abdullahi Babatunde, Africa Business School, Mohammed VI Polytechnic University, Rabat, Morocco, Dirk Boehe

This inductive, multiple-case qualitative study investigates why businesses in fragmented informal markets deliberately foster, rather than suppress, competition. Focusing on Nigeria's Igbo Apprenticeship System (IAS), where established entrepreneurs train apprentices to become future competitors, we introduce and theorize stewarded-competitions, defined as a culturally legitimized and economically motivated practice through which business owners deliberately develop new competitors by mentoring, capitalizing, and embedding them into shared market spaces. This distinct market logic challenges mainstream views on competition, especially the assumption that businesses succeed by protecting their territory or keeping out potential rivals. Based on 40 interviews across four industry sectors, we identify two connected drivers underpinning stewarded-competition: economic drivers, including keeping the market active and stable, sharing business risk across firms, and promoting long-term stability of the trading environment; and social-cultural drivers rooted in norms of reciprocity, communal responsibility, trust-based governance, and intergenerational continuity. Unlike cooperation frameworks, which depict collaboration as limited strategic alliances, stewarded-competition emerges as a culturally mandated yet strategically rational practice that proactively integrates economic sustainability and socio-cultural obligations. Our study contributes to neo-institutional theory by showing how informal institutions such as IAS go beyond filling institutional voids. They actively reconfigure competitive practices by embedding competition within culturally legitimate norms of mentorship, reciprocity, and collective responsibility. By theorizing stewarded-competition as a culturally grounded form of business logic, we extend the understanding of how informal institutions not only show how markets are organized but also how businesses compete and grow together in community-anchored informal economies.

2 - Strategic Focus in Digital Platforms: Capability Alignment for Sustainable Success

Michelle Vanassche, Vlerick Business School, Ghent, Belgium, Amit Basu, Steve Muylle

Digital platform capabilities are often studied in isolation from a platform's broader strategic focus. At the same time, many platforms are expanding their core functionality in an effort to become "super apps"; while this strategy offers opportunities for revenue diversification, it can backfire, as with X (formerly Twitter)'s pivot toward an "everything app". We present a conceptual model that links platform processes and capabilities to three distinct strategic activity types: transaction, engagement, and innovation. In contrast to prior research, our model emphasizes the importance of strategic focus, showing that platforms aligning their capabilities with a clear strategic direction are more likely to achieve sustainable success, whereas overly broad strategies tend to undermine platform performance. The model is validated by an extensive literature review and multiple case study research.

3 - Making It Epic? Demand-Side Reactions to Complementor-Driven Disruption in Platform Ecosystems

Luca Binder, Vlerick Business School, Ghent, Belgium, Ksenia Podoynitsyna

Digital platform ecosystems are increasingly shaped not only by platform owners but by strategic moves of powerful complementors. However, little is known about how end-users respond to such disruptions - particularly in mature platform markets where network effects and high switching costs are assumed to insulate incumbents. This study explores demand-side reactions to ecosystem fragmentation by analyzing end-user discourse surrounding Epic Games' adjacent entry with the Epic Games Store (EGS) into PC game distribution, a market historically dominated by Valve's Steam platform.

Drawing on high-engagement Reddit threads from 2017 to 2024, we employ transformer-based topic modeling (BERTopic) to trace discursive shifts and sentiment patterns across four distinct phases of Epic's ecosystem disruption. Our analysis captures how perceptions of both actors evolved in response to value bundling (e.g., cross-platform features) and value fragmentation (e.g., exclusive content), revealing iterative patterns in legitimacy assessments and multi-homing intentions.

Building on these insights, we develop a process model that traces how complementor disruption sets in motion a dynamic interplay between complementor platformization, incumbent repositioning, and end-user coordination. The model highlights pathways through which disruptive entrants and incumbent platforms jointly reconfigure ecosystem boundaries and how powerful complementors can position themselves as alternative platform gatekeeper.

Theoretically, we contribute to research on platform ecosystem evolution by proposing a process model of complementor disruption that foregrounds end-user mobilization as a key mechanism in shaping the trajectory of fragmented platform markets. Methodologically, we illustrate the value of machine learning-based text analysis for inductive theorizing from large-scale user discussions.

Experiment Design and Causal Inference in Operations

Invited Session

Revenue Management

Chair: Sentao Miao, University of Colorado Boulder, Westminster, United States

Co-Chair: Zhiyuan Tang, The University of Texas at Dallas, Richardson, TX, United States

1 - Experimental Design in Live-Interaction Platforms

Chenran Weng, University of California, Berkeley, Berkeley, CA, United States, Xiao Lei, Nian Si

We investigate experimental design problems in live-interaction platforms, which are commonly found in the online gaming industry and anonymous social networks. These platforms involve users being matched with others for activities such as games or social interactions, resulting in an interdependence of users' metrics on the treatment assignments of their counterparts. We construct a stochastic market model and develop its mean field limit to analyze the experimental dynamics in such platforms. Our focus is on two randomization strategies: user randomization and match randomization. We demonstrate that under Markovian user behavior and

homogeneous treatment effects, match randomization can provide unbiased estimations. However, significant biases may arise when these conditions are not met. On the other hand, user randomization is generally biased but exhibits greater resilience to model inaccuracies. We then propose a simple linear regression estimator under user randomization and demonstrate that this estimator consistently outperforms alternatives in various situations.

2 - Disentangling Interference of Multiple Promotions: a Debiased Machine Learning Approach

zhe wang, Boston University, Allston, MA, United States, Jinglong Zhao

Online platforms send multiple promotions each day, which can lead to complex interference that makes it difficult to understand the impact of each individual promotion. In this paper, we adopt a debiased machine learning approach to study the interference problem arising from the multiple promotions.

3 - Debiased Difference-in-Differences Estimation and Inference of Causal Effects Under Adaptive Controls

Zhiyuan Tang, The University of Texas at Dallas, Richardson, TX, United States, Sentao Miao, Yining Wang

As adaptive experiments and data-driven decision systems become increasingly prevalent in managerial contexts, new challenges emerge regarding the validity of difference-in-differences (DiD) methods when the data collection process is influenced by prior outcomes. For example, panel data may be gathered during a dynamic pricing experiment in which prices are set adaptively based on historical prices and customer responses. In such settings, key covariates—such as price—is governed by an underlying policy that induces dependence across observations. This violates standard DiD assumptions and introduces bias into conventional estimators.

In this paper, we address the problem of estimating and conducting valid inference on causal effects within the DiD framework when data are adaptively collected. Our contributions are three-fold. First, we develop a general debiasing method that converts the bias of standard DiD estimators into variance, enabling valid inference under adaptive data collection. Second, we derive finite-sample bounds on the bias and variance of the proposed estimator and establish the asymptotic validity of the associated confidence intervals. Third, we demonstrate the applicability of our method through a dynamic pricing example, showing that our estimator achieves a minimax-optimal trade-off between estimation accuracy and policy regret. Taken together, our results provide a robust framework for applying DiD method in sequential decision-making environments, extending its applicability to modern adaptive data settings.

4 - Policy-Aware Design of Large-Scale Factorial Experiments

Xin Wen, New York University, New York, NY, United States, Xi Chen, Will Wei Sun, Yichen Zhang

Modern digital platforms and policy evaluations increasingly face “graduated A/B tests,” where dozens of features or interventions—each with multiple dosage levels—must be assessed jointly. Exhaustively testing every combination is prohibitively costly, while ad-hoc pruning risks discarding the best option. We study policy-aware design for such large-scale factorial experiments. Building on the observation that treatment–response tensors are typically low-rank, we develop a two-stage framework that (i) learns a compact latent-factor representation of combinatorial effects from a pilot sample and (ii) adaptively allocates additional units to identify a near-optimal treatment bundle. The resulting algorithm balances exploration and exploitation without presuming additive effects or requiring strong ignorability across concurrent experiments. Simulation evidence shows that, for realistic traffic budgets, our approach attains the same error guarantees as full-factorial designs with an order-of-magnitude fewer observations. An illustrative platform application highlights how the method can shorten experimentation cycles while remaining transparent to decision-makers. Beyond digital products, the framework is applicable to multi-component policy packages and clinical treatment regimens, offering a practical path toward evidence-based implementation when the search space is combinatorially large and ethical or opportunity costs constrain sample size.

Policy-Enabling Models in the Electricity Sector

Invited Session

ENRE: Electricity

Chair: Afzal Siddiqui, Stockholm University, Kista, Sweden

Co-Chair: Ramteen Sioshansi, Carnegie Mellon University, Pittsburgh, PA, United States

1 - Uniqueness of Nash-Cournot Equilibria in Wholesale Electricity Markets with Variable Renewable Energy and Demand Uncertainty

Joseph Duggan, University of Dayton, Dayton, OH, United States

This work explores the uniqueness of Nash-Cournot equilibria in wholesale electricity markets with both thermal and renewable generation in the presence of both uncertain demand and variable renewable generation. In a previous work (Chaiken and Duggan (2024)), the authors expanded upon the uniqueness results proven by Lagerl (2006) to incorporate the presence of renewable generation into the market in the manner of Acemoglu et al. (2017). The model of Acemoglu et al. (2017) incorporates a constant amount of renewable generation, with zero marginal cost, distributed among all firms. The present work extends this model to include uncertainty over the amount of renewable generation available in any given period, and extends the prior uniqueness results to study the effects of variable renewable supply on the multiplicity of equilibria.

2 - Modeling Day Ahead Ancillary Services Initiative (Dasi)

Golbon Zakeri, University of Massachusetts - Amherst, Amherst, MA, United States

Energy imbalance reserve (EIR) product is introduced into the Independent System Operator (ISO) of New England's day-ahead wholesale electricity market to provide a better fuel procurement incentive for generating resources. Different from existing forward reserve products, EIR is a novel real option product, which is settled against real-time energy price rather than reserve prices. In this presentation, we develop a stochastic equilibrium model that incorporates the risk preference of generator and demand agents participating in the energy and reserve market in both day-ahead and real-time time frame.

3 - Sustainable and Reliable Pathways to Electricity Capacity Auctions

Emily Cai, Tepper School of Business, Carnegie Mellon University, Pittsburgh, PA, United States, Alan Scheller-Wolf, Ramteen Sioshansi

This ongoing project studies the joint behavior of regulators, renewable generators, and non-renewable generators in modern electricity markets to identify pathways for securing sustainable and reliable generation resources. Procuring adequate capacity for future electricity demand is a challenging and critical task for independent system operators and regional transmission regulators. Doing so while incentivizing the right balance between green and reliable firm power generation resources is nontrivial. How can regulators secure reliable and cheap capacity, with increasing electricity demand on one hand and public policies incentivizing renewable energy generation on the other? Equally important, how do renewable and non-renewables react to these rules? Why, when and how should renewables participate in capacity auctions? We consider an oligopolistic setting with one representative renewable generation firm, one non-renewable generation firm, a load-serving entity (utility company), a regulator, and a constrained locational deliverability area. These market participants interact with one another in three connecting markets—capacity, spot, and renewable energy credit. We intend to address three fundamental issues: 1) Modeling the capacity planning problem for renewable power generation resources based on the interaction between auction mechanisms and public policies, 2) Aligning the foundational objective of a capacity auction to secure reliable generation capacity with environmental health and sustainability efforts, and 3) Developing operational and business insights that guide power generation stakeholders—consumers, load serving entities, and generation resources—towards a greener, more sustainable, and reliable energy future.

4 - Integrating Floating Offshore Wind In Capacity Expansion Planning: a California Case Study

Jessica Wert, Lawrence Livermore National Laboratory, Livermore, CA, United States, Jean-Paul Watson, Matthew Signorotti, Robert Arthur, Hsiang-He Lee, Jean-Christophe Golaz

Diversifying energy sources supports grid resilience, and California's proximity to strong, relatively uniform winds off the coast presents floating offshore wind as a promising option. This study integrates floating offshore wind into Lawrence Livermore National Laboratory's (LLNL) nodal capacity expansion planning model to evaluate bounded and cost-effective buildouts of generation, storage, and transmission infrastructure under future conditions. Using three cost trajectories and 100 representative days informed by high-resolution climate data from DOE's E3SM climate model, the stochastic mixed-integer optimization model assesses the feasibility and cost-effectiveness of offshore wind in California's grid.

Machine Learning in Optimization

Contributed Session

Contributed

Chair: Yue Lin, The Chinese University of Hong Kong, Hong Kong, Hong Kong

1 - Federated Learning for Stochastic Scenario Generation with Cost-Aware Prediction

Mehrdad Mohammadi, Auburn University, Auburn, AL, United States, Alexander Vinel

This study presents a federated learning framework for generating stochastic scenarios in a decentralized and privacy-preserving manner. The approach captures data heterogeneity without raw data sharing by training models locally across clients and aggregating them globally. The model incorporates prediction accuracy (via MAE and MAPE) and operational cost metrics (holding, backorder, and ordering) to ensure realistic and decision-relevant scenarios. This cost-aware, federated optimization method enhances decision-making under uncertainty and demonstrates strong potential for applications in data-sensitive environments.

2 - Stochastic Qubo Optimization via Bayesian Factorization Machines and Quantum Annealing

Tomah Sogabe, The University of Electro-Communications, Chofu, Japan, Yuya Ito, Taihei Kuroiwa, Daiki Yamazaki, Kiria Yamashita, Daiki Sasaki, Ryosuke Koga

Combinatorial optimization under uncertainty remains a challenging problem across a wide range of domains, including logistics, finance, and energy systems. Traditional deterministic approaches and scenario-based stochastic programming methods often fail to capture deep correlations among uncertain parameters, leading to solutions that are either costly or risk-prone. In this study, we propose a probabilistic optimization framework called BFMQA, which integrates Bayesian Factorization Machines (BFM) with Quantum Annealing (QA). BFM represents costs, demands, and risk factors as a sparse interaction matrix and learns complex probabilistic correlations by estimating the posterior distribution of latent factors. The resulting probabilistic model is directly embedded into a Quadratic Unconstrained Binary Optimization (QUBO) formulation, enabling the integrated expression of economic objectives and risk penalties. QA then explores the high-dimensional optimization landscape in a quantum superposition state, efficiently generating candidate solutions that account for correlated uncertainties while avoiding local optima. Numerical experiments demonstrate that the proposed method achieves high consistency with solutions obtained by conventional deterministic and scenario-based stochastic programming approaches, while significantly reducing computation time and avoiding excessive risk. Thanks to its modular design, this framework can be easily extended to a variety of domains such as supply chain design and risk-aware portfolio management, offering a promising path toward the practical realization of uncertainty-resilient optimization using quantum hardware.

3 - Robust Data-Driven Cara Optimization

Li Chen, The University of Sydney, CHIPPENDALE, Australia, Arjun Ramachandra, Napat Rujeerapaiboon

Problem definition: Inspired by Von Neumann's foundational work on expected utility, this paper extends the data-driven expected utility maximization framework under constant absolute risk aversion (CARA) preferences by incorporating nonlinear payoff functions and enhancing robustness. These improvements aim to broaden the applicability of utility maximization in prescriptive analytics and to improve out-of-sample performance, particularly in data-scarce settings, respectively.

Methodology/results: The combined nonlinearity of exponential utility and payoff functions presents significant computational challenges in ensuring robustness. We show that existing safe tractable approximation techniques are overly conservative, potentially causing unexpected infeasibility. To address this, we define a notion of consistent approximation and propose an augmentation technique that provably retains the consistency in the approximation.

Managerial implications: Theoretical insights are validated through computational experiments in two applications: data-driven portfolio optimization and facility location optimization. Our results demonstrate the effectiveness of incorporating robustness into prescriptive analytics, yielding solutions that significantly outperform traditional empirical and stochastic optimization. Our utility maximization framework is therefore not only robust, but also interpretable, scalable, and adaptable to a wide variety of real-world risk-aware decision-making problems involving nonlinear payoffs.

4 - Faster Global Minimum Cut with Predictions

Helia Niaparast, Carnegie Mellon University, Pittsburgh, PA, United States, Benjamin Moseley, Karan Singh

Global minimum cut is a fundamental combinatorial optimization problem with wide-ranging applications. Often in practice, these problems are solved repeatedly on families of similar or related instances. However, the de facto algorithmic approach is to solve each instance of the problem from scratch discarding information from prior instances.

In this paper, we consider how predictions informed by prior instances can be used to warm-start practical minimum cut algorithms. The paper considers the widely used Karger's algorithm and its counterpart, the Karger-Stein algorithm. Given good predictions, we show these algorithms become near-linear time and have robust performance to erroneous predictions. Both of these algorithms are randomized edge-contraction algorithms. Our natural idea is to probabilistically prioritize the contraction of edges that are unlikely to be in the minimum cut.

5 - Asymptotically Optimal Distributionally Robust Solutions Through Forecasting and Operations Decentralization

Yue Lin, Chinese University of Hong Kong, Hong Kong, Hong Kong, Daniel Zhuoyu Long, Viet Anh Nguyen, Jin Qi

Two-stage risk-averse distributionally robust optimization (DRO) problems are ubiquitous across many engineering and business applications. In these problems, decision-makers commit to capacitated first-stage decisions, anticipating that they can execute second-stage recourse decisions after observing the realization of the uncertain parameters. Despite their promising resilience, two-stage DRO problems are generally computationally intractable. To address this challenge, we propose a simple framework by decentralizing the decision-making process into two specialized teams: forecasting and operations. This decentralization aligns with prevalent organizational practices, in which the operations team uses the information communicated from the forecasting team as input to make decisions. We formalize this decentralized procedure as a bilevel problem to design a communicated distribution that can yield asymptotically optimal solutions to the original two-stage risk-averse DRO problems. We identify an optimal solution that is surprisingly simple: The forecasting team only needs to communicate a two-point distribution to the operations team. Consequently, the operations team can solve a highly tractable and scalable optimization problem to identify asymptotically optimal solutions. Specifically, as the magnitude of the problem parameters (including the uncertain parameters and the first-stage capacity) increases to infinity at an appropriate rate, the cost ratio between our induced solution and the original optimal solution converges to one, indicating that our decentralized approach yields high-quality solutions. We compare our decentralized approach against the truncated linear decision rule approximation, illustrating its broader applicability and superior computational efficiency with competitive performance. The finely tuned solution outperforms traditional sample-average approximation methods in out-of-sample performance, underscoring its practical viability.

1 - The Drone Scheduling Problem in Shore-to-Ship Delivery: A Time Discretization-Based Model with an Exact Solving Approach

Xiaodeng Hao, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Ying Yang, Silong Zhang, Zhou Xu

Amid growing interest in the integration of drones into maritime logistics, this paper addresses the drone scheduling problem in shore-to-ship delivery (DSP-SSD). We introduce a time-discretized mixed-integer programming model incorporating drone-specific constraints and moving targets. For larger instances, we propose a tailored branch-and-price-and-cut (BPC) algorithm, which integrates a specialized backward labeling algorithm, cutting planes, and acceleration methods. Experimental results demonstrate that our BPC algorithm substantially outperforms commercial solvers in both solution quality and computational efficiency. We also conduct sensitivity analyses on key parameters to provide practical insights for real-world DSP-SSD operations.

2 - An Exact Price-and-Enumerate-and-Cut Algorithm for Vehicle Routing Problem with Speed Optimization

Ying Yang, Hong Kong Polytechnic University, Hong Kong, Hong Kong, Silong ZHANG, Shuaian Wang

We study the vehicle routing problem with speed optimization (VRP-SO), in which vehicle routes and travel speeds are jointly optimized to minimize total operational costs. These costs are modeled as a convex function of speed, capturing key trade-offs such as fuel consumption and driver wages. The simultaneous consideration of routing and continuous speed decisions introduces significant computational challenges.

To solve the VRP-SO, we develop an exact price-and-enumerate-and-cut (PEC) algorithm. The PEC algorithm relies on a tailored set-partitioning formulation in which each column represents a complete route with an associated speed profile. We present a novel labeling algorithm for solving the pricing subproblem, which employ closed-form analytical expressions for optimal speeds and efficient dominance rule. These eliminate the need to solve convex optimization problems during label extension and significantly improves computational performance while maintaining exactness. Additionally, we introduce a dedicated route enumeration phase that systematically generates a pool of high-quality, speed-optimized routes. This framework eliminates the need for branching on integer variables and is enhanced by valid inequalities and effective bound-tightening techniques.

We evaluate the PEC algorithm on both pollution routing and maritime transportation benchmark instances. Computational results demonstrate that the algorithm efficiently solves small- and medium-scale instances and consistently outperforms existing methods in terms of both runtime and solution quality.

3 - A Two-Stage Exact Method for the Fair Capacitated Vehicle Routing Problem

Dong Han, University of Florida, Gainesville, FL, United States, Zhengzhong You, Yu Yang

Fairness in optimization has gained increasing attention, with both cost efficiency and equitable outcomes recognized as critical objectives. A common fairness measure is the range, defined as the difference between the largest and smallest values of interest. In this study, we focus on the Fair Capacitated Vehicle Routing Problem (F-CVRP), which aims to find a feasible set of routes that minimizes the range of route distances. To efficiently handle the computational challenges of F-CVRP, we propose a two-stage solution framework. In the first stage, we apply modern techniques designed for CVRP and use RouteOpt, a state-of-the-art solver, to shrink the feasible region of the original problem, keeping only a small number of routes that can be explicitly enumerated while ensuring optimal solution to F-CVRP is kept. In the second stage, we solve a mixed-integer programming (MIP) model using these enumerated routes to find the optimal solution. To improve tractability, we introduce a set of valid inequalities and develop a tailored branching strategy. Our computational results show that the proposed approach can solve F-CVRP instances with up to 60 customers, which is three times larger than the instance sizes solved in the most recent literature, to the best of our knowledge.

4 - An ALNS-Based Framework for the Capacitated Vehicle Routing Problem with A Zone Tariff

Manuel Ostermeier, University of Augsburg, Augsburg, Germany, Niklas Tuma, Alexander Hübner

Cost pressure and fierce competition force companies to focus on their core competencies. Therefore, 90% of Fortune 500 companies in the United States outsource parts of their distribution planning to logistics service providers (LSPs). LSPs help to buffer peak demands and offer cost savings through economies of scale. This trend also applies to the retail industry. Most retailers supply their stores with less-than-truckload shipments from a distribution center. They propose store clusters to the LSPs, which check and execute the tours. The LSPs bill according to a zone tariff where the tour price depends on the farthest zone visited and the carried load, including volume discounts. Zone tariffs reduce the planning complexity for retailers since the clustering and pricing are independent of the delivery sequence.

To minimize costs, retailers must form clusters that respect capacity and detour limits, which are specific distance constraints. We formalize the resulting planning problem as a Capacitated Vehicle Routing Problem with a Zone Tariff (C-VRP-ZT). Zone tariffs are widely applied in practice but mostly neglected in research. Existing C-VRP-ZT approaches focus on exact approaches for small instances and an absolute detour limit. We propose an ALNS-based matheuristic framework using problem-specific operators and multiple adaptive mechanisms to solve realistic (large) problem instances and different detour limitations. The algorithm comprises a heuristic tour generation component and an exact post-optimization component. We provide extensive numerical studies on datasets up to 1000 nodes, including real-world data from an industry partner.

5 - An Exact Algorithm for the Traveling Salesman Problem with Pickup and Delivery Under Time Windows and Ride-Time Constraints

Xinbo Zhang, City University of Hong Kong, Hong Kong, Hong Kong, Roberto Baldacci

Traveling salesman problem with pickup, delivery, and ride-time constraints (TSPPD-RT) requires a depot-based vehicle to visit multiple known requests. Each request specifies a pickup vertex, corresponding delivery vertex, and maximum travel time between them (ride-time). The goal is to find a tour that (i) starts and finishes at the depot, (ii) visits all requests, (iii) satisfies ride-time constraints for each request, and (iv) minimizes the vehicle's total travel cost. Additionally, undelivered requests must remain within the vehicle's capacity limit. The TSPPD-RT is a fundamental optimization problem in logistics and routing. This paper introduces an exact method for solving an extended version of the TSPPD-RT with time window constraints (TSPPD-TWRT), incorporating both soft and hard ride-time constraints (RDCs). RDCs consider only travel times in the soft case, while in the hard case, they also include waiting times. This paper presents two mathematical formulations: an arc-based and path-based, with the latter derived from the U-tour relaxation. Using these formulations, we develop MIP-based and branch-price-and-cut solution approaches. Computational experiments on datasets from the Dial-A-Ride Problem and the Pickup and Delivery Problem with Time Windows demonstrate the effectiveness of the proposed methods. Results indicate that the U-tour formulation is particularly efficient, solving instances with up to 60 requests within reasonable computational times.

Demand Modeling in Urban Network

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Youngseo Kim, UCLA, Santa Monica, CA, United States

1 - Ride-Sourcing Demand Estimation Using Aggregated Public Data

Yuxin Sun, University of Massachusetts, Amherst, Amherst, MA, United States, Song Gao

The study of the ride-sourcing system is inevitably constrained by the availability of data owned by private platforms. With a few exceptions, public ride-sourcing data is highly aggregated. In this paper, we develop a methodology to estimate ride-sourcing demand at a high spatial resolution (e.g., census tract or higher) based on low-resolution public data, such as the town-level dataset from Massachusetts, making use of geographically weighted regression (GWR) that has been shown to produce robust estimation results across various spatial aggregation levels. The approach uses publicly available socioeconomic, demographic, land use, and built environment data to estimate two sets of models: (1) GWR trip origin (production) and destination (attraction) models that account for the spatial heterogeneity in underlying relationships; and (2) a Multinomial Logit model for the distribution of trips to different destination zones for a given origin. Our analysis reveals significant spatial dependence in ride-sourcing trips, highlighting the influence of local travel behavior patterns, such as commuting and job distribution. By incorporating Origin-Destination Employment data, our framework captures both commute and non-commute factors, offering a more comprehensive understanding of various ride-sourcing trip purposes. Our results provide a scalable framework for exploratory and predictive analyses of ride-sourcing demand patterns. The estimated census-tract level demand data will be put in a public data repository for the research community and beyond.

2 - Reduced-Basis Method for Fast Solutions of Traffic Flow Problems

Ali Pirmohammadi, New York University, Brooklyn, NY, United States, Daniel Vignon

A number of situations require repeated and/or real-time solutions of traffic flow equations in a network. Such scenarios include network design problems in which the underlying network is dynamic and the coordination of traveler movement and emergency response teams during a network-wide disruption. In the former case, the choice of an appropriate design requires the computation of link flows for many designs. In the latter case, one requires fast decisions from system managers while historical data is not applicable. In many systems, model order reduction methods exist to reduce the computational burden, but their application to traffic network problems is limited due to the hyperbolic nature of the partial differential equations (PDEs) and the high-dimensional nature of the many inputs (initial, and boundary conditions). In this study, to overcome the inherent reduction challenges posed by hyperbolic PDEs, we apply the reduced-basis method (RB) to reduce the viscosity solution of a parameterized first-order traffic flow PDE. This approach enables us to construct a solution manifold approximated by a small set of linear basis functions, facilitating rapid solutions for specified time horizons, boundary, and initial conditions. Both the offline training stage and the online stage are made computationally efficient by using an effective greedy sampling method and the Discrete Empirical Interpolation Method (DEIM). To allow for fast solutions at the network level, we extend our framework to handle the reduction of coupled PDEs that describe interactions at junction. Finally, we demonstrate how our methodology performs in the context of network design problems.

3 - Modeling Realized Accessibility in Space&TIME Networks: Why Do We Avoid Places We Can Reach?

Hiroyuki Hasada, The University of Tokyo, Meguro-ku, Japan, Yudai Honma, Xuesong Zhou

Realized accessibility, defined as the extent to which individuals actually visit locations, often diverges from what is theoretically accessible within spatial and temporal constraints. For instance, a person may travel 3 kilometers to visit a large shopping mall with diverse stores and amenities, but choose not to visit a smaller commercial street at the same distance. This study aims to explain the persistent gap between theoretical and realized accessibility using a novel modeling framework on a space-time network, where each link corresponds to either travel or stay segments. We formulate an inverse shortest path problem (ISPP), which recovers link costs that make observed travel paths appear optimal. The formulation allows us to infer underlying preferences without explicitly enumerating the choice set, which is especially valuable on space-time networks with many possible paths. When the model is applied to simple out and back trips, its structure naturally aligns with the formulation of a soft margin support vector machine (SVM), offering interpretable decision boundaries in accessibility space. In real-world urban behavior, our approach captures how individuals choose to stop at specific facilities during their daily tours, revealing patterns that depend on the temporal availability and the perceived attractiveness corresponding to each stay link cost. The optimized link costs vary systematically with facility type, time of day, and individual characteristics. Even when theoretical accessibility is identical, realized accessibility differs significantly between individuals or residential locations. Tensor-based computation accelerates estimation and improves clarity, enabling scalable learning from multidimensional behavioral data.

4 - Integrating Qualitative Data into Decision-Making for Transportation and Logistics

Shriya Karam, Massachusetts Institute of Technology, Cambridge, MA, United States, Alexandre Jacquillat

Public transit agencies face challenges in aligning supply levels with evolving passenger demand. To better understand passenger demand patterns and improve service design, some agencies have begun exploring qualitative data — such as social media posts or customer comment cards — to provide insights on passenger experiences. Yet, unstructured feedback is rarely incorporated into tactical or strategic decision-making, leaving a potentially valuable source of demand information underused. To address this gap, we develop a methodology that leverages qualitative data to derive operational value, combining natural language processing, data-driven demand estimation, and stochastic optimization. As a case study, we use Tweets and customer comment cards from the Washington Metropolitan Area Transit Authority to re-optimize rail timetables. Our two-step approach first combines qualitative customer feedback with aggregated numerical demand data to estimate origin-destination demand matrices. In the second step, we use these demand estimates to re-optimize transit frequencies via a two-stage stochastic optimization problem. Ultimately, our results demonstrate that our demand estimation approach outperforms benchmark models and highlight the practical impact of incorporating qualitative data into transportation decision-making.

5 - Estimate Then Predict: Convex Formulation for Travel Demand Forecasting

Youngseo Kim, UCLA, Santa Monica, CA, United States, Gioele Zardini, Samitha Samaranyake

Travel demand forecasting models play crucial roles in evaluating large-scale infrastructure projects, such as the construction of new roads or transit lines. While combined modeling approaches have been explored as a solution to overcome the problem of input/output discrepancies in a sequential four-step modeling process, previous attempts at combined models have encountered challenges in real-world applications, primarily due to their limited behavioral richness or computational tractability. In this study, we propose a novel convex programming approach and present a key theorem demonstrating that the produced optimal solution coincides with the one arising from the hierarchical extended logit model. This model is specifically designed to capture correlations existing in travelers' choices, including similarities among transport modes and route overlaps. The convex property of our model ensures the existence of solutions and naturally offers computational efficiency. The advantages of our proposed model are twofold. First, it provides a single unifying rationale (i.e., utility/entropy maximization) that is valid across all steps. Second, its combined nature allows one to systematically handle observed data, enabling a better representation of reality. Our convex programming approach shows promise in enhancing the accuracy and applicability of travel demand forecasting, thereby aiding in the decision-making processes for infrastructure projects.

AI and Data-Driven Strategies in the Future of Air Mobility

Invited Session

Air Transportation Section

Chair: Soohwan Oh, N/A

1 - Active Risk Mitigation for Unmanned Aerial Systems

Andrew Kendall, University of Texas at Austin, Austin, TX, United States

As Unmanned Aerial Systems (UAS) enter routine cargo operations within the National Airspace System (NAS), quantitative approaches are needed to assess and mitigate operational risk. Because aircraft accidents are rare but high-consequence events, conventional Monte Carlo simulation is often inefficient for estimating their probabilities.

This talk presents a simulation-based optimization framework for active risk mitigation in UAS operations. An agent-based model captures interactions among aircraft systems, environmental disturbances, and decision-making agents during critical flight phases. To estimate accident probabilities efficiently, a Metropolis-Adjusted Langevin Algorithm (MALA) is applied for rare-event sampling, enabling exploration of high-dimensional failure scenarios involving navigation errors, wind shear, and engine failures.

The approach integrates rare-event estimation with adaptive decision policies that allocate computational effort toward high-risk regions of the state space, improving statistical efficiency while supporting real-time safety management. Results demonstrate how the method enables risk-informed decision-making consistent with FAA safety objectives and provides a generalizable framework for agent based autonomous decision-making in safety-critical domains, including air traffic management, logistics, and infrastructure reliability.

2 - He B-737 Max Saga: Cost Implications of Safety Management in Aircraft Production

Dr I Richmond Nettey, College of Aeronautics and Engineering, Kent State University, Kent, OH, United States

The loss of 346 crew and passengers onboard Lion Air Flight 610 (JT610) on 29th October 2018, and Ethiopian Airlines Flight 302 (ET302) on 10th March 2019, resulted in grounding of the Boeing 737 MAX aircraft between March 2019 and December 2020. These two Boeing 737 MAX 8 accidents, “have cost Boeing more than \$20 billion in compensation, production costs, and fines, led to a 20-month grounding for the bestselling plane (Shepardson, [Reuters](#), 28th November 2023).

Alaska Airlines Flight 1282, a Boeing 737 MAX 9, suffered cabin panel blowout after departure from Portland International Airport on 5th January 2024, while climbing through 14,800’ MSL. If the blowout had occurred at a higher altitude, the losses would have been tragic. On 25th March 2024, Boeing’s leadership team of the CEO and head of airplane production, announced their departure.

These tragic losses underscore safety’s importance in the aviation, manufacturing, and service sectors of the economy. “As with every major accident, the lessons learned go far beyond addressing the primary causal factors. With two accidents to learn from, . . . , the MAX story’s influence on aircraft design, certification, and pilot training is only starting to be felt” (Broderick, 2020). This presentation will examine the importance of safety data through the deployment, design, manufacturing, and production of the Boeing 737 MAX. Specifically, it will examine: development of the B-737; competition for market share; safety challenges in the B-737 MAX development; and costs and implications for Boeing and the airlines.

3 - Development of Decision Support Systems for Advanced Air Mobility Operations in South Korea

Junghyun Kim, Sejong University, Seoul, Korea, Republic of

The Korean government has started exploring the implementation of Advanced Air Mobility (AAM) due to its potential to enhance connectivity in both urban and regional areas. The implementation of AAM requires careful decisions to address critical challenges such as vertiport placement and corridor network design. This paper presents the development of decision support systems for policymakers to evaluate various operational strategies for the upcoming AAM operations in South Korea. Three interconnected systems are developed by leveraging a data-driven approach: unsupervised learning-based vertiport placement, dynamic corridor network generation, and flight path planning. Each system uses relevant datasets tailored to its specific purpose and employs algorithms to enable the proposed concepts. The main contributions of this research are to 1) propose an unsupervised learning-based approach that can be utilized for identifying optimal vertiport locations in the Korean peninsula, 2) establish a dynamic corridor network generation system, and 3) develop a multi-objective flight path optimization system customized to AAM operations in South Korea. The authors believe that these systems can be used to assess various operational initiatives, particularly for single flight scenarios; therefore, policymakers can make informed decisions for effective implementations of the upcoming AAM operations in South Korea.

4 - Data-Driven Spatiotemporal Risk Modeling for Advanced Air Mobility

Soohwan Oh, Hanseo University, Chungcheongnam-do, Korea, Republic of

This study presents a data-driven framework for modeling spatiotemporal risks for advanced air mobility operations. By replacing static census data with high-resolution hourly de facto population data for Seoul, we compute a risk index that transforms dynamic restricted airspace zones into acceptable safety levels. The daytime maps show a dense concentration of restricted areas over commercial areas, while residential areas are largely visible, a pattern that is often overlooked when using traditional residential data.

1 - Utilizing AI to Enhance the Claims Audit Process

Samuel Damon, Riverstone, Manchester, NH, United States, Temi Gaudet

The claims audit process is integral to ensuring compliance, operational efficiency, and customer satisfaction within the insurance industry. However, traditional methods often struggle to scale effectively due to the complexity and volume of claims data. This presentation introduces an innovative approach using agents built on large language models (LLMs) to transform the claims audit workflow. These AI-powered agents leverage pre-existing claims audit guides to break down audit questions, determine their query feasibility, locate relevant data sources, analyze results, and assess whether claims were handled satisfactorily. By automating and optimizing key steps in the audit process, this solution significantly reduces manual effort while increasing accuracy and consistency. Focus will highlight the technical implementation, challenges addressed (such as data integration and context understanding), measurable outcomes, including faster audits and improved decision-making as well as multiple business value streams derived from the effort.

2 - The Agility Revolution: Harnessing AI Agents to Turn Market Challenges into Competitive Advantage

Asad Musa, Innova Solutions, Alpharetta, GA, United States

In an era of relentless market volatility and hyper-accelerated competition, organizations face a stark ultimatum: evolve at the speed of disruption or fade into irrelevance. Enter the agility revolution, powered by AI agents—intelligent systems that don’t just react to change but anticipate and shape it. This panel unveils how trailblazing organizations are harnessing AI agents to transform market challenges into bold competitive advantages, redefining the art of strategy in a digital age. With this fast-evolving revolution, it raises provocative questions: How do we craft AI agents that amplify human ingenuity rather than supplant it? What becomes of corporate culture when autonomous systems drive split-second market responses beyond human control? Through vivid case studies from diverse industries, this presentation reveals how leading firms are building “predictive agility”—the capacity to foresee market shifts and act decisively before opportunities vanish.

3 - Discuss Reflections and Thoughts About the Future of Work

Lakshman Kaveti, ProArch Technologies, Suwanee, GA, United States

Discuss reflections and thoughts about the future of work

4 - Humanity in Flux: Navigating Identity, Ethics, and Value in the Age of AI

Beverly Wright, Wavicle Data Solutions, Anderson, SC, United States

As artificial intelligence increasingly influences the ways we live, work, and connect, it is reshaping not just our systems – but our sense of what it means to be human. This panel will explore how rapid technological advancements challenge our long-standing views of identity, creativity, trust, and ethics. How do individuals and organizations preserve humanity in the face of automation? What new skills, mindsets, and ethical frameworks are essential for thriving in this dynamic environment? Join this discussion about the shifting relationship between people and machines. We'll examine real-world examples from business, education, healthcare, and society – highlighting both the risks of dehumanization and the unprecedented opportunities for human flourishing. This conversation will spark ideas and strategies for leading with empathy, designing for trust, and fostering meaningful human connections in a world increasingly shaped by AI.

1 - Using MLP for Capturing Drivers' Preferences for Improving Adherence in a VRP Optimization Setting

Luis Aburto, Universidad Adolfo Ibáñez, Santiago, Chile, Felipe Lagos, Víctor Bucarey, Tomás Rubio

The Vehicle Routing Problem (VRP) is a well-known problem in the operations research literature, traditionally addressed by minimizing transportation costs. However, in practice, cost matrices are often outdated or fail to reflect real-world conditions. Additionally, drivers frequently develop personal routing preferences based on their daily experience, which are typically ignored in standard VRP models. This project aims to bridge that gap by leveraging GPS data to capture driver route preferences. These preferences are then used to train a multilayer perceptron (MLP) to predict preferred routes based on the specific characteristics of a VRP instance, particularly customer locations. The predicted preferences are integrated into a VRP optimization model to adjust route recommendations and customer-to-vehicle assignments accordingly. We apply this methodology in collaboration with a VRP service provider in Latin America. Empirical results show a significant improvement in route adherence, increasing from 33.6% to 52.9%. This work presents a novel integration of machine learning and optimization techniques to enhance solution quality and incorporate user preferences in logistics planning.

2 - Reinforcement Learning Based Framework to Design Behavioral Interventions to Improve Sustainability and Public Health

Viswa Sri Rupa Anne, Georgia Institute of Technology, Atlanta, GA, United States, Yuming Chang, Srinivas Peeta

Transportation systems in the U.S. are a major source of air pollutants and greenhouse gas emissions, resulting in a growing interest to promote sustainability, public health and well-being. Promoting shifts towards sustainable modes (i.e., walking, biking, or transit) or routes can reduce greenhouse gas emissions, improve air quality, and increase physical activity levels. To promote such shifts, behavioral interventions such as monetary rewards, informational messages communicating health benefits, and gamification strategies have emerged as potential solutions to influence travel behavior. Mobile apps enable personalized delivery of such interventions while collecting behavioral feedback from travelers. However, designing interventions personalized to individual travelers becomes increasingly complex when accounting for time-varying network traffic dynamics. For example, the optimal intervention for a traveler may depend not only on their characteristics and preferences but also on the evolving congestion patterns and system-wide travel behavior. To address this, the behavioral intervention design is formulated as a time-varying problem to adapt to varying traffic dynamics. A reinforcement learning (RL) framework integrated with the SUMO traffic simulator is proposed to simulate the interactions of urban traffic environment, traveler heterogeneity, behavioral response, and mode choices over time. The RL agent learns optimal intervention strategies, such as the informational messages to provide to subgroups, or monetary interventions to provide on a network link by learning the traveler preferences and traffic dynamics of the network in real time. The framework offers a scalable tool for traffic operators to design and deploy interventions based on behavioral feedback and traffic dynamics.

3 - A Simulation-Optimization Framework and Web-Based Application for Dynamic Volunteer Routing in Food Banking Systems

Mehr Sadat Salami, North Carolina State University, Raleigh, NC, United States, Kuangying Li, Leila Hajibabai

Efficient and equitable delivery in not-for-profit food logistics is challenged by dynamic customer demand and fluctuating volunteer availability. This study introduces a simulation-optimization framework to support real-time volunteer routing under uncertainty. The objective is to minimize overall delivery costs while maintaining operational feasibility across dynamically evolving scenarios. The model captures decentralized operational constraints and incorporates stochasticity in both customer arrivals and volunteer participation. A Monte Carlo Tree Search (MCTS) algorithm is embedded in a discrete-event simulation to iteratively update delivery routes based on emerging requests, aiming to minimize delivery costs while maintaining operational feasibility.

Comparative analyses show that MCTS outperforms traditional methods such as greedy insertion and fixed-horizon value iteration, offering significant improvements in cost efficiency by anticipating future demand and adapting routes in real time.

To enable real-world deployment, a web-based application is developed and integrated with the optimization engine. The platform connects households, food pantries, and volunteers through a unified interface, supporting request submission, inventory management, volunteer scheduling, and real-time route dispatch. This integrated system ensures coordinated, efficient, and equitable food delivery across the community.

4 - Real-World Exposure to Last-Mile Delivery Externalities: A Novel Approach Using Vehicle and Human Trajectory Data

Franco Basso, Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile, Sara Perotti, Raúl Pezoa, Francisco Fuentes, Julio Covarrubia

Research on last-mile delivery services and their environmental externalities has traditionally focused on emissions at the source, with limited attention to how these effects are distributed across urban populations. However, negative externalities such as pollution and noise do not impact all residents equally, as exposure is shaped by spatial and temporal proximity to the source. This paper proposes a novel framework to measure the heterogeneous impact of last-mile delivery by integrating high-resolution GPS data from vehicles with dynamic demographic information derived from mobile phone traces. Using econometric models—including zero-inflated count and linear regression techniques—we quantify how delivery vehicle activity correlates with population density and sociodemographic characteristics throughout the day in Santiago, Chile. Our findings reveal substantial disparities in exposure across age, gender, and socioeconomic groups, underscoring the uneven burden of urban logistics on public health and environmental justice. This framework enables more targeted and equitable mitigation strategies for urban freight operations by identifying who is most affected and where. The results highlight the need for logistics planning that accounts not only for operational efficiency but also for its differentiated impact on urban communities.

5 - Optimizing Fire Station Placement for Growing Urban Demand: a Case Study in Goldsboro, North Carolina

Sarah Halsey, North Carolina State University, Raleigh, NC, United States, Demetra Protoggyrou, Mallory Padgett, Catherine Reckard, Leila Hajibabai

This study applies facility location models to support fire station planning for the Goldsboro Fire Department (GFD) in North Carolina. Two mathematical models were used to guide decision-making: a set-covering model to determine the minimum number of stations required to cover all demand points, and a maximum coverage model to identify optimal station placement under resource constraints. The models incorporate both current incident data and projected growth patterns, and apply distance-based constraints (e.g., 1.5-mile service radius) as a proxy for time-based response standards.

The set-covering model successfully generated a configuration that met full coverage requirements, including anticipated growth in the city's northern regions. However, the solution required opening more stations than the city's budget could support. To address this, the maximum coverage model was used to optimize coverage given a limited number of stations. This model revealed inefficiencies in the current network—specifically, overlapping service areas among several stations—and recommended relocating the headquarters station to improve spatial coverage without increasing the number of facilities.

Goldsboro has seen significant residential development in its northwest and northeast corridors in recent years, resulting in increased incident call volume and challenges in meeting national fire response standards. These modeling efforts provide GFD with actionable insights on how to restructure its station layout to maintain service quality in the face of growth and limited resources. This case highlights how location modeling can support infrastructure planning and enhance resilience in small and mid-sized urban settings.

6 - A Novel Approach to Two-Way Arterial Traffic Signal Coordination

JinWoo Na, Pohang University of Science and Technology, Nam-Gu, Pohang-Si, Korea, Republic of, Jun Kim, Indrayoga Putra, Byung-In Kim

Traffic signal coordination plays a critical role in managing traffic flow across urban arterial networks under varied traffic conditions. Selecting an appropriate signal coordination strategy suitable for the traffic conditions is essential for minimizing delays and enhancing traffic-flow efficiency. Maximum bandwidth-based forward progression such as MAXBAND, MULTIBAND, and AM-BAND have been devised and applied to coordinate two-way arterial traffic signals in undersaturated, near-saturated, or moderately congested traffic conditions. MAXBAND establishes uniform progression bands across the artery but fails to consider segment-specific traffic conditions. MULTIBAND addresses this limitation by introducing variable-bandwidth progression in each segment. However, its symmetrical bandwidth allocation restricts the full utilization of available green time. By contrast, AM-BAND facilitates asymmetrical bandwidth allocation but exhibits high sensitivity to the Q-value, which governs the relative distribution of the left and right sides of the bandwidth. Determining an optimal Q-value for varying traffic conditions is further complicated by the absence of a well-defined mathematical relationship between Q-value and performance. Therefore, this study proposes a novel approach which integrates the uniform band structure of MAXBAND with segment-specific asymmetrical bandwidth allocation while addressing their respective limitations. The approach maintains progression efficiency across the artery while providing flexibility to accommodate varying traffic demands. The proposed model was formulated as a mixed-integer linear programming model and evaluated through SUMO traffic simulation in a realistic environment, where all arterial intersections are controlled by a pre-timed strategy with a common cycle length. Experimental simulation results demonstrate that the proposed model outperforms existing progression models.

7 - Monotonic Neural Networks for Crash Severity Prediction at Highway-Rail Grade Crossings

Amin Keramati, Widener University, Chester, PA, United States, Pan Lu

Highway-Rail Grade Crossings (HRGCs) are spatial locations where highways and rail tracks intersect at the same grade, posing a risk of collisions between trains and vehicles. Due to (1) the inability of trains to stop promptly after braking and (2) the substantial mass difference between trains and road users, crashes at HRGCs often result in severe outcomes. Consequently, transportation agencies and decision-makers must implement effective safety strategies to reduce crash severity, typically categorized into three levels: Property Damage Only (PDO), Injury, and Fatal.

A widely adopted approach in the literature for supporting safety decision-making at HRGCs involves developing predictive models that assess the influence of various crash factors on the likelihood and severity of incidents. However, most existing models estimate the likelihood of each crash severity level independently, without accounting for potential dependencies among them. Furthermore, few studies have applied advanced machine learning or statistical models to capture the dynamic impact of crash factors on severity and its variation over time.

In this study, we propose a novel deep learning framework—**Monotonic Neural Network (MNN)**—for time-to-severity event analysis at HRGCs. The model captures the interdependence among the three severity levels, aligning with the inherent characteristics of HRGC crashes. We design and evaluate two MNN architectures: **Multi-Head**, and **Single-Head**. Comparative analysis shows that the best-performing architecture improves prediction accuracy by **3% to 30%**, demonstrating the potential of our approach to support proactive safety interventions.

1 - Learning to Defer in Content Moderation: the Human-AI Interplay

Wentao Weng, MIT, Cambridge, MA, United States, Thodoris Lykouris

Successful content moderation in online platforms relies on a human-AI collaboration approach. A typical heuristic predicts the expected harmfulness of a post and uses fixed thresholds to decide whether to remove it and whether to send it for human review. This disregards the prediction uncertainty, the time-varying element of human review capacity and post arrivals, and the selective sampling in the dataset (humans only review posts filtered by the admission algorithm).

We introduce a model to capture this human-AI interplay. Our algorithm observes contextual information for posts, makes classification and admission decisions, and schedules them for human review. Only admitted posts receive human reviews on their harmfulness. These reviews help educate the machine-learning algorithms but are delayed due to congestion in the human review system. We propose a near-optimal learning algorithm that balances the classification loss from a selectively sampled dataset, the idiosyncratic loss of non-reviewed posts, and the delay loss of having congestion in the human review system.

Our results offer concrete insights on how online platforms can harness the power of AI while ensuring system reliability. First, congestion-aware admission rules are necessary to handle the time-varying nature of online requests and human capacity. Second, popular optimism-only online learning heuristics (used in content moderation practice) can fail to learn capable AI models as they disregard label collection that is necessary for future classification decisions. To the best of our knowledge, this is the first result for online learning in contextual queueing systems, which may be of independent interest.

2 - Joint Learning and Pricing in Many-Server Queues: near-Optimal Policies via Fluid Duality

Xu Zheng, University of Miami, Coral Gables, FL, United States

We study the problem of joint learning and dynamic pricing in a large-scale service system modeled as a many-server queue, where customer arrival rates depend on posted prices through an unknown demand function. The system manager seeks to maximize expected profit—defined as revenue minus congestion costs—by learning the demand function and integrating it into pricing decisions. We propose a novel explore-cooling-exploit policy that integrates structured exploration with state-dependent pricing control. Our approach leverages a fluid approximation and dual-based reformulation to design lightweight, closed-loop pricing rules that respond to real-time system conditions. We analyze the regret of this policy under both finite and continuous pricing settings within a many-server asymptotic framework. Our theoretical results establish tight regret bounds, revealing an economy-of-scale effect where learning becomes more efficient as the system size grows. Numerical experiments validate the effectiveness of our policy and highlight the distinct trade-offs between exploration and congestion in large-scale service environments. This work is the first to provide provably near-optimal closed-loop joint learning and pricing policies for many-server queues under demand uncertainty.

3 - Online Learning for Dynamic Service Mode Control

Wenqian Xing, Stanford University, Stanford, CA, United States, Yue Hu, Anand Kalvit, Vahid Sarhangian

Modern service systems are increasingly adopting innovative modalities enabled by emerging technologies, such as AI-assisted services, to achieve a better balance between quality and efficiency. Motivated by these advancements, we study the optimal dynamic control of service modes in systems with unknown parameters, aiming to balance reward accumulation and system congestion. We consider a single-server queueing system with two switchable service modes, each characterized by a distinct

service rate and an unknown distribution of rewards earned upon service completion. The objective is to maximize the long-run average of cumulative rewards minus holding costs. To address this problem, we first characterize the optimal state-dependent policy under full knowledge of model parameters. For the case of unknown reward distributions, we propose an online learning algorithm based on Upper Confidence Bound estimates to adaptively learn the optimal policy. Our algorithm achieves a statistically near-optimal regret bound of the square root of T over a time horizon T and demonstrates strong numerical performance. A key methodological contribution is a novel regret decomposition and a regenerative cycle-based framework, offering broader insights into learning-based optimal control in queueing systems. Finally, we demonstrate the practical relevance of our approach through a case study on optimizing AI-assisted patient message replies in a healthcare setting.

4 - A Planning Framework for Adaptive Labeling

Daksh Mittal, Columbia University, New York, NY, United States, Yuanzhe Ma, Shalmali Joshi, Hongseok Namkoong

Ground truth labels/outcomes are critical for advancing scientific and engineering applications, e.g., evaluating the treatment effect of an intervention or performance of a predictive model. Since randomly sampling inputs for labeling can be prohibitively expensive, we introduce an adaptive labeling framework where measurement effort can be reallocated in batches. We formulate this problem as a Markov decision process where posterior beliefs evolve over time as batches of labels are collected (state transition), and batches (actions) are chosen to minimize uncertainty at the end of data collection. We design a computational framework that is agnostic to different uncertainty quantification approaches including those based on deep learning, and allows a diverse array of policy gradient approaches by relying on continuous policy parameterizations. On real and synthetic datasets, we demonstrate even a one-step lookahead policy can substantially outperform common adaptive labeling heuristics, highlighting the virtue of planning. On the methodological side, we note that standard REINFORCE-style policy gradient estimators can suffer high variance since they rely only on zeroth order information. We propose a direct backpropagation-based approach, Smoothed-Autodiff, based on a carefully smoothed version of the original non-differentiable MDP. Our method enjoys low variance at the price of introducing bias, and we theoretically and empirically show that this trade-off can be favorable.

5 - Optimal Noise Schedules for Diffusion Models

Billy Jin, Purdue University, West Lafayette, IN, United States, Baris Ata, Harsha Honnappa

Diffusion models have emerged as a cornerstone of modern generative AI, achieving state-of-the-art performance in image, audio, and video generation. However, training these models involves numerous design choices and hyperparameters that can significantly impact performance. In this talk, I will present a principled framework for selecting the noise schedule, providing theoretical foundations that justify commonly used heuristics.

Chair: Prakash Chakraborty, The Pennsylvania State University, State College, PA, United States

1 - Optimizing Telemedicine Referrals to Mitigate ED Overcrowding

Sabha Baniyadi, The Pennsylvania State University, State College, PA, United States, Prakash Chakraborty, Paul Griffin

Emergency department (ED) overcrowding in the US has become a critical public health issue leading to increased wait-times. This delay compromises patient care, strains resources, and increases the risk of adverse outcomes. In this research, we mitigate congestion by identifying an optimal threshold policy for telemedicine referrals of non-urgent patients in a hospital emergency department while simultaneously maximizing revenue generation and minimizing waiting and balking costs. We assume a two-class M/M/c priority queueing system, with different service time distributions for urgent and non-urgent patients. Subsequently, we develop a threshold-based policy to reduce patient congestion and waiting times, thereby enhancing overall revenue generation for the hospital. This approach provides hospital administrators with an implementable decision framework for efficient ED management.

2 - Many Server Functional Fluid Limit for Non-Stationary Loss Models

Mingrui Wang, Penn State University, state college, PA, United States, Prakash Chakraborty

Modern service systems often operate under non-stationary demand and non-Markovian dynamics with limited server and buffer capacities. Classical stationary models fail to capture the dynamic and constrained nature of these environments, motivating the analysis of non-stationary, non-Markovian loss queueing systems. In this research, we study such systems in the many-server regime and establish a functional strong law of large numbers (FSLN) for three core performance processes: the fraction of occupied servers, the fraction of occupied buffers, and the departure rate. These coupled processes are shown to converge to the unique solution of a system of Volterra integral equations. Numerical experiments demonstrate the accuracy of the fluid approximation in estimating blocking probabilities, highlighting its potential as a scalable performance analysis tool.

3 - Exponentially Shifted Gaussian Smoothing for Decision-Dependent Optimization Problems

Prakash Chakraborty, The Pennsylvania State University, State College, PA, United States, Mingrui Wang, Uday Shanbhag

Decision-dependent optimization problems—where the objective or constraints are influenced by the decision variables themselves—arise frequently in machine learning, operations research, and other domains. Addressing these challenges without gradient information necessitates efficient zeroth-order (ZO) methods. However, existing ZO techniques often suffer from poor scalability due to unfavorable dependence on problem dimension. To overcome this, we propose an Exponentially-Shifted Gaussian Smoothing (esGS) estimator, developed via a simple change-of-variable approach. The esGS estimator achieves tighter moment bounds and significantly mitigates dimensional sensitivity. When incorporated into a ZO optimization framework, it leads to improved iteration complexity with rigorous convergence guarantees for both convex and strongly convex settings. Preliminary experiments demonstrate its practical effectiveness, particularly in decision-dependent scenarios.

4 - Stochastic Games with Information Cost in Directed Chain Network

Tomoyuki Ichiba, University of California-Santa Barbara, Santa Barbara, CA, United States

We shall consider a class of stochastic differential games of infinitely many players in a directed chain network with partial information. We discuss the convergence of the Nash equilibria from finitely many players to infinitely many players. Some explicit solution is obtained under the linear quadratic problem and then the cost of acquiring additional information is explored.

Advances in Urban and On-Demand Delivery Systems

Invited Session

TSL: Urban Transportation Planning and Modeling

Chair: Xinwei Chen, The University of Tulsa, Tulsa, OK, United States

1 - Analyzing Fulfillment Dynamics in on-Demand Grocery Delivery Systems

Alp Arslan, Lancaster University, Lancaster, United Kingdom, Jelder van der Gaast, Jan Fransoo

The rapid growth of on-demand delivery services (ODS) has transformed customers' online grocery shopping expectations. ODS offer increased convenience and speed through micro-fulfillment centers or partner-retail stores. Determining the most effective ODS fulfillment strategy across market settings, such as the presence or absence

of micro-fulfillment centers, remains an open question. Additionally, the utility of technology acquisition, such as investing in systems that monitor product availability across retail stores to reduce operational uncertainty, requires further investigation. We study this problem by developing a stylized queueing system that allows us to analytically assess an ODS's performance under a variety of configuration strategies. Our model captures crucial ODS characteristics, including stochastic order arrivals, uncertain product availability, stochastic picking times, and tight service level requirements. We provide explicit expressions for calculating the service time and click-to-delivery time, which depend on factors such as assortment and stock-out uncertainties. These expressions facilitate comparisons between various ODS configurations. Our findings suggest that micro-fulfillment centers may outperform models relying on partner-retail stores in scenarios where assortment information is not shared, in-stock availability is relatively low, and average order basket sizes are substantial. However, when a certain level of information sharing is introduced, incorporating assortment and stock-in data from stores, employing partner-retail stores may prove more efficient in terms of factors like service time and courier utilization compared to relying solely on micro-fulfillment centers.

2 - Unlocking Comodal Rural Mobility Through Integrated Passenger and Package Delivery Services

Xinwei Chen, The University of Tulsa, Tulsa, OK, United States, Qi Luo

Rural and suburban communities are largely overlooked in the design of affordable and reliable on-demand mobility solutions due to sparsely distributed populations, the prevalence of long-distance travel needs, and limited access to alternative transit services. In this research, we propose a comodal mobility system that integrates passenger transport and package delivery, ensuring seamless coordination between the two compatible services within a single network. Our research is comprised of (1) analytical insights into the feasibility conditions for integrating on-demand transit with package delivery, and (2) an online optimization framework for real-time order dispatching in comodal scenarios. Case studies demonstrate the potential of comodality strategies to expand access to essential services, particularly for carless households and individuals with mobility limitations.

3 - A General Decomposition Framework for Dynamic Two-Stage Order Fulfillment Problems

Gal Neria, Tel Aviv University, Tel Aviv, Israel, Michal Tzur, Marlin Ulmer

Coordinating fulfillment operations across two interdependent stages is a critical challenge across industries such as logistics, e-commerce, and food services. In this work, we introduce the Dynamic Two-Stage Order Fulfillment Problem (DTS-OFPP), a new class of problems that unifies several logistical challenges in a cohesive manner. The DTS-OFPP captures the complexities of real-world fulfillment systems and emphasizes the need to simultaneously optimize both preparation and delivery stages under dynamic and stochastic conditions.

We model the problem class as Markov Decision Process and introduce a novel theory-driven policy decomposition formulation.

To exploit this decomposition, we propose an innovative solution framework that integrates operations research elements and machine learning.

Our framework advances beyond prior research, which often treats fulfillment stages independently or sequentially, and offers a new approach to handling interdependencies between sequential operations.

Our framework is applied to three real-world DTS-OFPP contexts: warehouse picking operations, production-delivery systems, and food delivery platforms. Numerical experiments using datasets from Meituan, ORTEC, and Iowa City show that our framework consistently outperforms existing methods.

4 - Who Benefits from Drone-Enhanced Food Delivery? An Economic Analysis of the Food Delivery Market

Chaoyu Wu, The Hong Kong University of Science and Technology (Guangzhou), Guangzhou, China, People's Republic of, Xiaotong Sun, chenyang li

Amid growing interest in drone-enhanced food delivery, most studies have focused on operational challenges, leaving the strategic and economic implications understudied. This talk addresses that gap by developing a parsimonious economic model of on-demand instant delivery market that introduces drones alongside human couriers, capturing strategic interactions between consumers, couriers, and the platform. The model employs a linear city framework with spatially distributed consumers with heterogeneous delivery valuations. Key factors are endogenized, including drone efficiency, pricing, and courier supply. We compare outcomes under three market structures (perfect competition, monopoly, and Bertrand duopoly) across three delivery modes: human-only, drone-only, and bi-modal. Analysis reveals that drone adoption expands delivery coverage beyond the baseline human-only mode and is most cost-effective for long-distance orders. In the bi-modal setting, non-overlapping service regions emerge due to rational consumer choice, yielding maximum social welfare across all market structures. Market structure also influences pricing: under duopoly competition, the introduction of drones drives down delivery fees for remote customers. However, increasing drone penetration diminishes the surplus of human couriers, thereby raising equity concerns for the workforce. Numerical simulations with real data validate our findings, demonstrating that integrating drones significantly expands delivery coverage and enhances customer surplus across all market structures, thereby positioning customers as the primary beneficiaries. These findings provide managerial insights for platform strategy and highlight policy interventions, such as drone subsidies or profit redistribution, to ensure the efficiency gains from drone adoption do not come at the expense of equity.

Service and Logistics Operations Interface

Invited Session

Applied Probability Society

Chair: Daisik Nam, Inha University, Michul-gu, N/A, Korea, Republic of

Co-Chair: EunSu Lee, New Jersey City University, Jersey City, NJ, United States

1 - Leveraging Generative AI for Logistics Data Analysis and Decision-Making

Daisik Nam, Inha University, Incheon, Korea, Republic of, Jaeyoung Lee, Minyoung Park

This study presents a practical framework for implementing generative artificial intelligence (GenAI) in logistics operations, focusing on automated reporting and data analysis workflows. As logistics organizations face increasing demands for operational efficiency and data-driven decision making, systematic approaches to GenAI integration become essential for competitive advantage.

We demonstrate a hands-on implementation approach using Cursor AI for logistics workflow automation, specifically targeting automated inventory reporting and shipment analysis. The methodology involves a structured four-step process: data upload, natural language command execution, result analysis, and iterative improvement through prompt refinement. Through practical case studies using real logistics data, we show how organizations can achieve significant time savings in routine reporting tasks while maintaining accuracy and consistency.

The framework addresses key application areas including automated inventory summaries, shipment delay pattern analysis, and operational dashboard generation. Implementation results demonstrate measurable improvements in reporting efficiency, with case studies showing substantial reductions in manual data processing time. The study provides practical guidelines for logistics practitioners to implement GenAI tools effectively while addressing common challenges such as data accuracy verification and workflow integration.

This research contributes actionable implementation strategies for logistics managers seeking to leverage GenAI for operational automation, emphasizing practical deployment approaches rather than theoretical frameworks.

2 - Developing a Screening Methodology for Dedicated Freight Truck Lanes Using Transportation Big Data and Traffic Simulation

Daejin Kim, Inha University, Incheon, Korea, Republic of

This study proposes a methodology for identifying candidate sections for dedicated freight truck lanes by integrating big transportation data with traffic simulation techniques. Utilizing real-world traffic volume data from the Korea Transport Institute's View-T system, the analysis evaluates traffic and environmental factors across the national road network. Thirteen key indicators—including freight vehicle ratio, average speed, congestion intensity, and pollutant emissions—were selected, normalized

using Min-Max scaling, and aggregated into a composite Screening Score. Based on this score, high-priority road segments were systematically identified. The prioritization process was further refined by incorporating road attributes such as road classification, with weighted adjustments reflecting freight traffic volume to better capture freight-dense corridors. To assess the potential impacts of implementing dedicated freight lanes, top-ranked sections underwent microscopic traffic simulation analysis using VISSIM, evaluating metrics such as changes in average speed, congestion relief, emissions reduction, and traffic safety improvements. This study presents a practical and data-driven analytical framework that supports both strategic screening and simulation-based policy assessment for freight infrastructure planning.

3 - Quantifying the Benefits of Cargo Bikes for Last-Mile Delivery: Operational, Environmental, and Social Perspectives

Sungmin Kim, Inha University, Incheon, Korea, Republic of, Gwanyong Gu, Daejin Kim

The rapid growth of e-commerce has substantially increased urban freight traffic, intensifying challenges such as congestion, environmental pollution, and traffic-related safety risks. In South Korea, for instance, parcel volumes have risen at an average annual rate of 12.53%, further worsening these issues. Conventional delivery trucks are often restricted from entering residential complexes, alleyways, and traditional markets, leading to frequent illegal parking and traffic obstruction. As a sustainable and space-efficient alternative, cargo bikes have emerged as a promising last-mile delivery solution in dense urban areas.

This study assesses the operational, environmental, and safety benefits of cargo bikes through a comparative field experiment conducted over a two- to three-week period in a designated regulatory zone in Gimcheon, South Korea. The area includes both dense residential neighborhoods and modern apartment complexes. Two scenarios were compared: the AS-IS scenario, where diesel trucks made individual deliveries, and the TO-BE scenario, where cargo bikes performed consolidated deliveries from a shared depot in a nearby parking facility. GPS tracking and delivery logs were used to evaluate efficiency in terms of delivery volume, travel time, and distance.

Results show that about 3.3 cargo bikes can replace one conventional delivery truck in terms of capacity. This substitution is projected to reduce annual last-mile operating costs by over USD 7,500 and significantly lower accident-related social costs and environmental impacts. These findings support integrating cargo bikes into urban logistics strategies—especially in areas with limited truck access—while enhancing efficiency, safety, and sustainability.

4 - A Unified Framework for Container Drayage Optimization: Integrating Task Selection with Operational Constraints

Dongyun Kim, Graduate School of Logistics, Incheon National University, Incheon, Korea, Republic of, Kwangsup Shin, Yunhong Min

Drayage is the short-haul trucking of containers between intermodal hubs—ports, rail yards, warehouses, and customer sites—covering the first- or last-mile of a container's journey. Its effectiveness depends on precise scheduling and routing of trucks and containers to meet time windows and maximize efficiency. This study proposes an integrated drayage model that enhances the efficiency and practicality of empty container utilization by embedding task selection into the planning process. Each customer request for an empty container can be satisfied by choosing one of several related tasks that reflect operational constraints such as live operations, dual transactions at terminals, and terminal-container compatibility. The model jointly schedules and routes trucks to minimize both the number of unsatisfied requests and individual truck completion times. Computational experiments are performed to demonstrate the effectiveness of the proposed model and solution.

5 - Innovative Process and Strategic Management for Enhancing Shipbuilding Capacity

EunSu Lee, New Jersey City University, Jersey City, NJ, United States, Luis Alberto, Eun Soo Kim

This presentation examines the current status and production capacity of the U.S. shipbuilding industry and identifies the key challenges limiting its competitiveness in the global market. It explores a range of innovative manufacturing processes and advanced strategic management approaches designed to strengthen operational efficiency, optimize resource utilization, and expand overall shipbuilding capacity.

Scalable Optimization for Large Foundation Models and DNNs

Invited Session

OPT: Nonlinear Optimization

Chair: Yuchen Lou, Northwestern University, Evanston, IL, United States

Co-Chair: Minshuo Chen, Northwestern University, Evanston, IL, United States

1 - Modelling Compositionality and Tensor Structure in Neural Network Optimization

Jeremy Bernstein, MIT, Cambridge, MA, United States

An old idea in optimization theory says that since the gradient is a dual vector it may not be subtracted from the weights without first being mapped to the primal space where the weights reside. In this talk, we take this idea seriously and construct a duality map for general neural networks. Our map, which we call modular dualization, forms a unifying theoretical basis for training algorithms that are a) fast and b) scalable. Modular dualization involves first assigning operator norms to layers based on the semantics of each layer, and then using these layerwise norms to recursively induce a duality map on the weight space of the full neural architecture. We conclude by deriving GPU-friendly algorithms for dualizing Embed, Linear and Conv2D layers -- the latter two methods are based on a rectangular Newton-Schulz iteration (Kovarik, 1970; Björck & Bowie, 1971). A variant of our methods was used to set speed records for training NanoGPT. Overall, we hope that our theory of modular duality will yield a next generation of fast and scalable optimizers for general neural architectures.

2 - Reimaging Gradient Descent: Large Stepsize, Oscillation, and Acceleration

Jingfeng Wu, University of California, Berkeley, Berkeley, CA, United States

Gradient descent (GD) and its variants are pivotal in machine learning. Conventional wisdom suggests smaller stepsizes for stability, yet in practice, larger stepsizes often yield faster convergence, despite initial instability. In this talk, I will explain how large stepsizes provably accelerate GD for logistic regression on separable data in three settings.

- We start with logistic regression, a convex but non-strongly convex problem. We show that GD with a large stepsize attains an ϵ -risk in $O(1/\sqrt{\epsilon})$ steps. This matches the accelerated step complexity of Nesterov momentum and improves the classical $O(1/\epsilon)$ step complexity for GD with a small stepsize.
- We then consider ℓ_2 -regularized logistic regression with regularization strength λ , a strongly convex problem with condition number $\Theta(1/\lambda)$. We show GD with a large stepsize attains an ϵ -excess risk in $O(1/\sqrt{\lambda} \ln(1/\epsilon))$ steps. This, again, matches Nesterov momentum and improves the $O(1/\lambda \ln(1/\epsilon))$ step complexity for GD with a small stepsize.
- Finally, we consider the task of finding a linear separator of a linearly separable dataset with margin γ . We show that, with large and adaptive stepsizes, GD solves this task in $1/\gamma^2$ steps by minimizing the logistic risk. We further show this step complexity is minimax optimal for all first-order methods, and cannot be achieved by GD with small stepsizes.

The talk is based on a sequence of papers in collaboration with Peter Bartlett, Matus Telgarsky, Bin Yu, Ruiqi Zhang, Licong Lin, and Pierre Marion.

3 - Purifying Shampoo: Understanding and Improving Shampoo Through An Approximation Perspective

Anna Cai, Meta, San Mateo, CA, United States, Runa Eschenhagen

The recent success of Shampoo in the AlgoPerf contest has sparked renewed interest in Kronecker-factorization-based optimization algorithms for training neural networks. Despite its success, Shampoo relies heavily on several heuristics such as learning rate grafting and stale preconditioning to achieve performance at-scale. These

heuristics increase algorithmic complexity, necessitate further hyperparameter tuning, and lack theoretical justification. This paper investigates these heuristics from the angle of Frobenius norm approximation to full-matrix Adam and decouples the preconditioner's eigenvalues and eigenbasis updates. We show that grafting from Adam mitigates the staleness and mis-scaling of the preconditioner's *eigenvalues* and how correcting the eigenvalues directly can eliminate the need for learning rate grafting. To manage the error induced by infrequent *eigenbasis* computations, we propose an adaptive criterion for determining the eigenbasis computation frequency motivated by terminating a warm-started QR algorithm. This criterion decouples the update frequency of different preconditioner matrices and enables us to investigate the impact of approximation error on convergence. These practical techniques offer a principled angle towards removing Shampoo's heuristics and developing improved Kronecker-factorization-based training algorithms.

4 - Recent Advances in Kronecker-Factored Preconditioned Stochastic Gradient Methods for Large-Scale Training

Hao-Jun Shi, Meta Platforms, Inc., Menlo Park, CA, United States

Kronecker-factored preconditioned stochastic gradient methods, such as Shampoo and Muon, offer a more sample-efficient alternative to diagonal-scaling-based methods like Adam and AdaGrad for training recommendation systems and large language models (LLMs). Notably, Muon, a stochastic version of the steepest descent method under the spectral norm, can be interpreted as a special case of Shampoo. This talk further explores this relationship through a formal decomposition of Shampoo as a covariance-adapted version of Muon. In order to better understand the effect of different terms in the decomposition, we delve into the role of epsilon, pseudo-inverses, and numerics in Shampoo and Muon, and present detailed ablations that systematically incorporate the covariance adaptation term. Furthermore, we address the challenge of scaling these methods to large-scale models that require parameter sharding via Fully Sharded Data Parallel (FSDP) and other parallelisms, presenting both shard-dependent and shard-independent approaches to overcome scalability issues. By shedding light on the connections between Shampoo and Muon, and providing insights into their scalability, this talk aims to contribute to our understanding of both the systems and training efficiency tradeoffs of different non-diagonal optimization techniques when applied to structured large-scale machine learning problems with different noise and curvature properties.

5 - Structured Positive-Definite Curvature Learning

Wu Lin, vector institute, Toronto, ON, Canada

Stochastic positive-definite curvature estimation plays a crucial role in machine learning. For example, Adam(W) estimates a diagonal curvature matrix for neural network training. Other notable applications include covariance estimation in Bayesian deep learning and gradient-free evolutionary optimization. Leveraging the structure of curvature matrices—such as Kronecker-based, non-diagonal structures—is essential for moving beyond diagonal approximations in large-scale settings. However, existing structured curvature estimation methods, such as Shampoo, are often specialized for particular types of curvature information, limiting their adaptability in addressing challenges posed by non-standard applications. To address this, we propose a Riemannian optimization approach to structured curvature estimation that supports flexible forms of curvature information. We demonstrate the efficacy and versatility of our method in positive-definite matrix optimization and covariance adaptation for gradient-free optimization, as well as its efficiency in curvature learning for neural network training.

Chair: Karthyek Murthy, University of Southern California, Los Angeles, CA, 90089, United States

1 - Efficient Gradient Estimation for Overparameterized Stochastic Systems

Shengbo Wang, University of Southern California, Los Angeles, CA, United States, Jose Blanchet, Peter Glynn

Overparameterized dynamic stochastic models have achieved remarkable success in various complex environments, such as stochastic control, reinforcement learning, financial engineering, and machine learning systems. These models often feature system evolution that is parameterized by a high-dimensional vector $\theta \in \mathbb{R}^n$, aiming to optimize a path-dependent expectation such as a value function through stochastic gradient ascent. Consequently, designing efficient gradient estimators for which the computational complexity scales well with n is of significant interest. We introduce a novel unbiased stochastic gradient estimator—the generator gradient estimator—for which the computation time remains stable in n . In addition to establishing the validity of our methodology for stochastic differential equations and Markov jump processes, we also perform numerical experiments, demonstrating a significant improvement in efficiency compared to the widely used pathwise differentiation method: our estimator achieves near-constant computation times and increasingly outperforms its counterpart as n increases. We also generalize our approach to policy optimization in a reinforcement learning environment where the underlying system dynamics are unknown.

2 - Cheap Iterated Bootstrap for Higher-Order-Accurate Uncertainty Quantification

Yunhao Yan, Columbia University, New York, NY, United States, Shengyi He, Henry Lam

The bootstrap is a versatile method for quantifying statistical uncertainty. Among its variants, a popular approach, the studentized bootstrap, provably achieves higher-order coverage error reduction compared to other benchmarks. However, without further structural knowledge, the latter implementation requires iterated resampling which can make the computation expensive, especially for large-scale models such as those arising in stochastic simulation. In this talk, we introduce a "cheap" iterated bootstrap method that substantially thins one of the sampling layers in running the studentized bootstrap, via an integrated view of the uncertainty coming from the resample distribution and the Monte Carlo computation in implementing the resampling. Intriguingly, in building our methodology, we also show the intimate relation of the studentized bootstrap with the studentized t-distribution, presenting a distinct view from the common claim of the informality of "studentization" in the bootstrap literature.

3 - Learning Optimal Solutions to Chance-Constrained Optimization Models from Limited Data

Karthyek Murthy, University of Southern California, Los Angeles, CA, United States

We consider the challenge of provisioning resources to meet high reliability or service level requirements, which are typical in applications such as power distribution, emergency response, and regulatory risk management. With chance-constrained optimization serving as a natural starting point for modeling this class of problems, our main contribution is to characterize how the optimal costs and decisions scale for a generic joint chance-constrained model as the target probability of satisfying the reliability constraints approaches its maximal level. Besides providing insights into the behaviour of optimal costs and decisions based on large-deviations theory, the scaling result carries several algorithmic implications, beginning with the following observation on distributionally robust optimization (DRO) modeling of chance constraints: While widely used DRO approaches based on KL-divergences, Wasserstein distances, and moments distort the scaling properties of optimal decisions and lead to exponentially higher costs, incorporating marginal distributions or employing suitably chosen f -divergence balls preserves the correct scaling and ensures that decisions remain conservative by at most a constant or logarithmic factor. Further, given N data samples, we demonstrate how the scaling can serve as a basis for estimating approximately Pareto-optimal decisions whose constraint violation probabilities can even be smaller than the $\Omega(1/N)$ —estimation barrier that is fundamental in the absence of parametric assumptions.

4 - The Scale Invariance of Portfolio Risk Measurement

Nifei Lin, Laboratory for AI-Powered Financial Technologies Limited, Hong Kong, China, People's Republic of, Jeff Hong

The risk measurement of derivative portfolios is typically formulated as a nested estimation problem. The traditional studies on such problem, including standard nested simulation and smoothing approaches, focus on the convergence rate of the estimator with respect to the sample size of portfolio losses. In practice, however, the core computational burden arises from simulating risk factors and subsequently repricing each instrument in the portfolio, which grows with both the number of instruments and the dimensionality of the risk factors. While the classical analysis framework is adequate for small- and medium-scale portfolios, it becomes increasingly inefficient

for large-scale portfolios, whose computation cost is expensive and performance may suffer from curse of dimensionality. To address the challenges posed by large-scale portfolios, we revisit the standard problem formulation and highlight a key but underutilized structural feature: the additive nature of portfolio losses, which allows us to group multiple instruments in the portfolio with the same underlying risk factors. Leveraging this property, we propose independent sampling and one-hot sampling methods to deal with the repricing for each group of instruments, which are compatible with existing nested estimation frameworks. We prove that, by integrating portfolio scale into the asymptotic analysis, our methods yield a scale-invariant property: the overall computational cost, measured in terms of computation time rather than sample size, remains in the same order of magnitude regardless of portfolio size. In other words, the convergence rate is independent with the scale of the portfolio.

1 - Llms for Instance-Specific Cutting Plane Separator Configuration

Yingxi Li, Stanford University, Stanford, CA, United States, Connor Lawless, Anders Wikum, Madeleine Udell, Ellen Vitercik

Mixed integer linear programming (MILP) solvers come with numerous parameters that are difficult to select a priori for all but expert users, yet they significantly impact solver performance. Current machine learning (ML) methods for configuring solvers require training models on thousands of MILP instances, generalize poorly to new problem sizes, and often demand complex ML pipelines and custom solver interfaces, making integration into existing workflows challenging. In this paper, we introduce an LLM-based framework for configuring cutting plane separators for a given MILP problem with little to no training data. Our pipeline can be applied to MILPs even without prior knowledge of the problem. We augment these LLMs with descriptions of cutting plane separators available in a given solver, grounded by summarizing the existing research literature on separators. While individual solver configurations have a large variance in performance, we present an ensembling strategy that clusters and aggregates configurations to create a small portfolio of high-performing configurations. Our LLM-based methodology requires no custom solver interface, can find high-performing configurations by solving only a few MILPs, and can generate the configuration with simple API calls that run in under a second. Numerical results show our approach is competitive with existing configuration approaches on a suite of classic combinatorial optimization problems and real-world MILPs with only a fraction of the training data and computation time.

2 - Extracting Knowledge Priors with LLMs for Bayesian Optimization

Jacob Gardner, University of Pennsylvania, Philadelphia, PA, United States

Algorithmic advances in the efficiency, scalability, and applicability of Bayesian optimization have made it competitive or even state-of-the-art on some of the most fascinating optimization problems of our time. Recent advances in language modeling have led to an unprecedented ability to retrieve and digest natural language text, and reason about the content of that text. Why not use these models to featurize this text in ways that, for example, a Gaussian process surrogate model can consume during optimization? In this talk, I'll present ongoing work where we are trying to make the knowledge stored in text accessible to Bayesian optimization. As one concrete example, we will consider the problem of augmenting commonly used in silico molecule design benchmarks with a new mandate: the designed molecules must not be toxic or mutagenic. We show that, by fine-tuning LLMs to tag molecules across hundreds of millions of paragraphs found in scientific papers and then by building CLIP embeddings, we can build zero-shot molecular property predictors that, in some cases, achieve more than 90% test precision despite never seeing labeled data. By combining this with Bayesian optimization's relatively newfound ability to handle large numbers of constraints, we achieve a(n early!) prototype of a pretty cool promise: we can simply write down in English properties we'd like a molecule or protein to have, and then optimize a molecule or protein subject to the constraint that it has those properties.

3 - AI and the Future of Optimization Modeling

Madeleine Udell, Stanford University, Stanford, CA, United States, Ali AhmadiTeshnizi, Wenzhi Gao, Connor Lawless

Optimization problems are pervasive in sectors from manufacturing and distribution to healthcare. However, most such problems are still solved heuristically by hand rather than optimally by state-of-the-art solvers, as the expertise required to formulate and solve these problems limits the widespread adoption of optimization tools and techniques.

As a glimpse of the future, this talk will introduce OptiMUS, a Large Language Model (LLM)-based agent designed to formulate and solve MILP problems from natural language descriptions.

OptiMUS can develop mathematical models, write and debug solver code, develop tests, and check the validity of generated solutions.

Experimentally, OptiMUS correctly solves more than 80% of benchmark problems, more than twice as many as a basic LLM prompting strategy.

More broadly, we discuss the potential for LLMs in domains where accuracy and fidelity to real-world data is critical and strategies to augment and safeguard their performance.

4 - Direct Regret Optimization in Bayesian Optimization

Fengxue Zhang, University of Chicago, Chicago, IL, United States, Yuxin Chen

Bayesian optimization (BO) is a powerful paradigm for optimizing expensive black-box functions. Traditional BO methods typically rely on separate hand-crafted acquisition functions and surrogate models for the underlying function, and often operate in a myopic manner. In this paper, we propose a novel **direct regret optimization** approach that jointly learns the optimal model and non-myopic acquisition by distilling from a set of candidate models and acquisitions, and explicitly targets minimizing the multi-step regret. Our framework leverages an **ensemble of Gaussian Processes (GPs)** with varying hyperparameters to generate simulated BO trajectories, each guided by an acquisition function chosen from a pool of conventional choices, until a **Bayesian early stop criterion** is met. These simulated trajectories, capturing multi-step exploration strategies, are used to train an end-to-end decision transformer that directly learns to select next query points aimed at improving the ultimate objective. We further adopt a **dense training--sparse learning** paradigm: The decision transformer is trained offline with abundant simulated data sampled from ensemble GPs and acquisitions, while a limited number of real evaluations refine the GPs online. Experimental results on synthetic and real-world benchmarks suggest that our method consistently outperforms BO baselines, achieving lower simple regret and demonstrating more robust exploration in high-dimensional or noisy settings.

1 - Terminating Pandemics with Smartwatches

Martial Ndeffo, Texas A&M University, College Station, TX, United States, Märt Vesinurm, Dan Yamin, Margaret Brandeau

Studies have demonstrated that wearable devices, such as smartwatches, can accurately detect infections in presymptomatic and asymptomatic individuals. Yet, the extent to which smartwatches can contribute to prevention and control of infectious diseases through a subsequent reduction in social contacts is not fully understood. We developed a multiscale modeling framework that integrates within-host viral dynamics and between-host interactions to estimate the risk of viral disease outbreaks within a given population. We used the model to evaluate the population-level effectiveness of smartwatch detection in reducing the transmission of three COVID-19 variants and seasonal and pandemic influenza. With a 66% reduction in contacts after smartwatch-based disease detection, we estimate that the reproduction number R would drop from 2.55 (interquartile range [IQR]: 2.09–2.97) to 1.37 (IQR: 1.00–1.55) for the ancestral COVID-19 variant; from 1.54 (IQR: 1.41–1.69) to 0.82 (IQR: 0.68–0.85) for the delta variant; from 4.15 (IQR: 3.38–4.91) to 2.20 (IQR: 1.57–2.52) for the omicron variant; from 1.55 (IQR: 1.34–1.74) to 0.81 (IQR: 0.63–0.87) for pandemic influenza; and from 1.28 (IQR: 1.18–1.35) to 0.74 (IQR: 0.64–0.79) for seasonal influenza. With a 75% reduction in contacts, R decreases below 1 for the delta variant and for pandemic and seasonal influenza. Sensitivity analyses across a wide array of parameter values confirm that self-isolation initiated shortly after smartwatch detection could significantly reduce R under diverse epidemiological conditions, different levels of smartwatch detection accuracy, and realistic self-isolation levels. Our study underscores the revolutionary potential of smartwatches to manage seasonal diseases and alter the course of future pandemics.

2 - Multi-Scale Modeling of Periodicity for Missing Data Imputation in TIME Series: a Smartwatch Application

Yuewei Ling, Stanford University, Stanford, CA, United States, Edan Shahmoon, Margaret Brandeau, Dan Yamin

Missing data is a challenge in healthcare time-series analysis. Periodic patterns influence both the observations and missingness mechanism, particularly in wearable technologies that produce rich physiological signals, but most current methods ignore these underlying cycles. We introduce a Periodic Multi-scale Imputation (PMSI) framework to impute missing data, which models multi-scale periodic dependencies for both observations and missingness patterns. The imputation process follows three stages: (1) identify candidate periodicities; (2) transform series into multi-dimensional tensors aligned with selected periodicities; (3) optimize hyperparameters using a two-layer minimization of Akaike information criterion (imputation parameters for each dimension and dimensionality). PMSI is applied first to model the missingness mechanism and generate synthetic masks to observations for their optimizations. We validated PMSI using a large smartwatch-derived heart rate dataset, consisting of 1,674 participant-month series in a high-adherence cohort (smartwatch wearing adherence) and 5,871 series in a low-adherence cohort. Spectral analysis revealed daily and 3.5-day (likely smartwatch charging) periodicities in the missingness mechanism, and daily and weekly periodicities in observations. The optimal case used hourly resolution and daily periodicity to impute missing values for PMSI, and outperformed five standard imputation methods: k-nearest neighbors, autoregressive integrated moving average, convolutional neural networks, piecewise linear interpolation, and last observation carried forward. PMSI yielded the lowest RMSE: 6.92 versus 7.74–9.59 in the high-adherence cohort, and 8.65 versus 9.30–14.54 in the low-adherence cohort (all adjusted $p < 0.01$). Our PMSI framework enhances imputation accuracy effectively by modeling periodic dependencies, and holds great promise to impute any time-series with periodicities in healthcare.

3 - Self-Reported Recovery Versus Smartwatch-Detected Recovery for COVID-19, Influenza and Group A Streptococcus: a Two-Year Prospective Cohort Study

Varun Gande, Stanford University, Stanford, CA, United States, Dan Yamin, Margaret Brandeau, Erez Shmueli

Timely and accurate detection of recovery from infectious diseases is essential for minimizing complications, optimizing care, and preventing long-term health issues. This study analyzes recovery dynamics for COVID-19, influenza, and group A streptococcus (GAS) using data from a two-year prospective cohort of 4,795 participants in Israel. We integrate smartwatch-derived physiological and behavioral data with self-reported symptoms and electronic medical records to assess recovery at three key points: (1) end of moderate-to-severe symptoms, (2) full symptom resolution, and (3) return to physiological baseline—termed “digital recovery.” Results reveal a consistent lag between self-reported recovery and physiological normalization, with longer delays observed in moderate-to-severe cases. For COVID-19, digital recovery occurred a median of 7.1 days post-symptom resolution in mild cases, and 60.2 days in moderate-to-severe cases. Influenza showed lags of 2.5 and 7.9 days, and GAS showed 1.1 and 4.4 days, respectively. Notably, daily step counts and reported activities returned to baseline once symptoms resolved, suggesting behavioral recovery precedes physiological recovery. These findings challenge current public health guidelines that recommend return to normal activities five days post-symptom cessation. Our results indicate longer recovery windows—up to two months for severe COVID-19 cases—may be warranted. This framework highlights the value of integrating wearable sensor data into infectious disease monitoring, offering scalable tools for recovery assessment, intervention planning, and policy optimization.

Equity in Health Policy: Shaping the Future of Fair and Informed Care

Invited Session

Health Applications Society

Chair: Amaya McNealey, Georgia Institute of Technology, Atlanta, GA, United States

1 - Mind the Gap: Methods to Evaluate the Quality of Clinical Care

Divya Shanmugam, Cornell Tech, NYC, NY, United States

The evaluation of clinical care is fundamentally constrained by the need for large, labeled datasets—resources that range from expensive to impossible to obtain. This talk introduces methods to evaluate the quality of clinical care by making use of unlabeled data to evaluate decision-making of both humans and algorithms. In the first part, I focus on retrospective evaluation of past diagnostic decisions, and present a framework to measure the rate of missed diagnoses in the health record. In the second part, I turn to prospective evaluation of algorithmic decision-making in clinical care, and introduce a method to assess the performance of clinical predictive models in the absence of abundant labeled data. Together, these projects highlight a shared challenge in both human and algorithmic decision-making—evaluating decision quality under data constraints—and provide steps towards robust evaluation of both human and algorithmic care.

2 - Modelling the Cost-Effectiveness of a Combined Rsv Prevention Strategy

Leonardo Basso, Instituto Sistemas Complejos de Ingeniería, Santiago, Chile

Recent developments in RSV prevention—including the availability of the RSVpreF maternal vaccine, nirsevimab, and clesrovimab—present an important opportunity to model the potential benefits of combined immunisation strategies. Performing simulation analyses on the integrated national databases that we have been using, we propose to assess the cost-effectiveness and expected health impact of various implementation scenarios that integrate these three Immunoprophylactic agents, considering variations in their mixture within a universal prevention strategy. Our focus will be on estimating reductions in RSV-related hospitalisations, medical leaves, and on computing performance metrics such as the number needed to immunise (NNI). Key parameters of the modelling will be efficacy and/or effectiveness, costs and expected coverage of each monoclonal; these values will be allowed to change within reasonable boundaries. It is possible to create a visual tool to analyze different cases easily. This modelling effort will provide timely and actionable evidence to support strategic planning by health authorities in Chile and other countries with similar demographic and epidemiological profiles

3 - Estimating the Effectiveness of Nirsevimab in High-Risk Infant Populations

Denis Saure, Universidad de Chile, Santiago, Chile, Leonardo Basso, Marcel Goic, Charles Thraves, Miguel O'ryan, Juan Torres, Felipe del Solar, Ignasi Neira, Amal Zgheib

Respiratory syncytial virus (RSV) is a leading cause of infant hospitalization, especially among preterm infants and those with congenital heart disease (CHD). This study evaluates the impact of Chile's nationwide Nirsevimab immunization program on RSV-related hospitalizations in high-risk infant populations.

We conducted a matched case-control study using national administrative and clinical data covering over 145,000 immunized infants. RSV-related hospitalizations were identified by linking ICD-10 discharge codes to confirmed RSV cases through optimization-based calibration using sentinel surveillance data. This approach allowed for precise classification of RSV-related lower respiratory tract disease (LRTD) events in the absence of universal virologic testing.

To control for confounding, we employed a mathematical integer programming model to match each RSV-related case to seven controls based on infant age, hospital admission date, and geographic region. This 1:7 matching scheme optimized statistical power and balance across key covariates.

Effectiveness of the Nirsevimab immunization was estimated using the matched cohort. Further, we applied simulation modeling to estimate the overall reduction in RSV-related hospitalizations attributable to the immunization strategy in the high-risk population.

Findings demonstrate that the targeted Nirsevimab campaign substantially reduced RSV-related LRTD hospitalizations among preterm and CHD infants. This study underscores the value of combining optimization and simulation methods for evaluating public health interventions and informing resource allocation decisions.

Emerging Issues at the Interface of Supply Chain and Finance

Invited Session

MSOM: iForm

Chair: M. Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY, United States

1 - On the Benefits of Supplier Vs Customer Diversification: a Geographical Analysis

Deepak Agrawal, Carnegie Mellon University, Pittsburgh, PA, United States, Nikolay Osadchiy

Diversification is traditionally considered a risk mitigation tool. In our paper, we examine both supplier and customer diversification, geographically, and find that diversification also have first order effect on inventory productivity. We find a nonlinear relationship between geographical diversification and inventory turnover. Further, we examine the varying effects of diversification by firm's upstreamness.

2 - Internal Credit and External Blame: Self-Attribution In Operations and Supply Chain Performance

Yimeng Niu, Tilburg University, Tilburg, Netherlands, Xiao Qiao, Jing Wu, Xingsheng Yang

Problem definition: This paper examines self-attribution tendencies within corporate settings, specifically in the context of operations and supply chain performance. Managers often attribute superior company performance to internal factors, such as product innovation and intra-organizational teamwork ("internal credit"), while attributing poor performance to external factors, such as supply chain partners or macroeconomic conditions ("external blame"). **Methodology/Results:** We fine-tune large language models (LLMs) to analyze extensive question-and-answer transcripts from earnings conference calls, developing a measure of company-level self-attribution. Through empirical investigations, we identify a consistent pattern of self-attribution, characterized by internal credit and external blame, in discussions related to operations and supply chain issues. Our findings indicate that companies with larger sizes and more experienced managers exhibit stronger self-attribution tendencies. Furthermore, firms with lower operational efficiencies and supply chain risks are more likely to display this behavior. This self-attribution, on average, seems healthy and improving. Companies with stronger self-attribution tendencies are more likely to optimize their internal operations, enhance cash flow and production efficiency, as well as make strategic supply chain adjustments. These firms also demonstrate a greater ability to coordinate effectively with customers, replace underperforming suppliers, and retain high-performing ones in the subsequent quarter. **Managerial implications:** Managers can leverage self-attribution tendencies as a cost-effective operational risk-hedging tool to safeguard their reputation and better position their organizations to proactively address operational challenges and adjust to poor performance outcomes

3 - Vintech: Investing in Wine Using Analytics

M. Hakan Hekimoglu, Rensselaer Polytechnic Institute, Troy, NY, United States, Burak Kazaz

This paper examines a comprehensive path regarding how analytics can be employed for automated trading of wine. We coin this as VinTech. The paper highlights the essential components of data analytics necessary for robo-advising. We first develop a pricing algorithm to represent the realistic value of a wine. Using this algorithm, we then compare the price evolution of underpriced wines to overpriced wines. Last, our robo-advising algorithm constructs wine portfolios for different investment goals and risk preferences. We demonstrate the performance of our algorithm using out-ofsample testing. This paper aims to convert an opaque market into a transparent and efficient investment market.

Sustainable Supply Chain Management

Contributed Session

Contributed

Chair: Akshay Mutha, University of Vermont, Burlington, VT, United States

1 - Dual-Channel Supply Chain Contract Design Considering Retailer Greening Cost

Yuan Yuan Deng, Huazhong University of Science and Technology, Wuhan, China, People's Republic of, Haijun Wang

In dual-channel supply chain, the retailer's possession of private cost information gives rise to information asymmetry, which may lower supply chain efficiency and affect supply chain coordination. Based on dual-channel supply chain consisting of a manufacturer and a retailer, this paper analyzes the design of revenue-sharing contract considering the retailer's green investment cost under both full and asymmetric information, and explores the impact of the retailer's green investment level on the decisions in the dual-channel supply chain. The result shows that the impact of the retailer's green investment level on the supply chain members' optimal decisions may be affected by information asymmetry. In addition, we explore the impact of cost information asymmetry on the performance of dual-channel supply chain by comparing the optimal decisions under the two cases and analyze the value of information. We show that the retailer's asymmetric cost information hurts the manufacturer's profit and the efficiency of the whole supply chain, but it weakly benefits the retailer.

2 - A Stochastic Optimization Model for Consumer-Responsive Sustainable Supply Chain Management Under Market Uncertainty

Ikhyun Jo, Yonsei University, Seoul, Korea, Republic of, Soongeol Kwon

As consumer interest in sustainability continues to grow, companies increasingly recognize the importance of integrating consumer preferences into their sustainable supply chain management (SSCM) strategies. These preferences, as reflected in purchasing behavior, are shaped by companies' long-term and consistent sustainability efforts, and their relative importance may vary depending on the specific dimensions of sustainability under consideration. In this study, we propose an optimization model for SSCM that incorporates consumers' long-term and differentiated preferences across various sustainability factors. To quantitatively capture these preferences and analyze their implications, we develop a mixed-integer linear programming (MILP) model. The model features consumer-responsive demand that evolves over time based on the supply chain's sustainability performance. Additionally, the uncertain proportion of green consumers significantly influences SSCM decision-making. To handle this uncertainty, we use a two-stage stochastic programming approach, generating time-series scenarios for the proportion of green consumers. Through numerical experiments, we evaluate the proposed consumer-responsive SSCM model and demonstrate the critical importance of understanding the proportion of green consumers and their purchasing behavior in shaping effective sustainability strategies.

3 - More or Less: Climate Pledges and Supply Chain Flexibility

Jie Lian, The University of Oklahoma, Norman, OK, United States, Keith Skowronski, Yan Dong

Firms increasingly make environmental commitments, including climate pledges, which can significantly influence the operational decisions of their suppliers. For example, suppliers may reduce inventory buffers and supply diversification in response to decreased uncertainty in products and technologies. This study focuses on the supplier decision-making process and examines how climate pledges affect key operational choices that shape supply chain flexibility.

4 - Tracing Influence: ESG Spillovers in Complex Supply Chain Networks

Francis Bilson Darku, University of Notre Dame, Notre Dame, IN, United States, Rick Hardcopf, Sarvanan Devaraj

As environmental, social, and governance (ESG) practices become central to corporate strategy, firms face increasing scrutiny and evaluation from stakeholders and ESG rating agencies. While substantial research exists on the drivers of ESG adoption and abandonment, less is known about how ESG behaviors diffuse across interconnected firms, particularly within complex supply chain networks. This study explores the extent to which a focal firm's ESG ranking is shaped by the ESG performance of its suppliers, customers, and industry peers. Leveraging longitudinal data from Bloomberg's SPLC and ESG datasets, we analyze over 1,600 U.S. manufacturing firms and their supply chain partners over a nine-year period. We identify key actors within these networks and quantify their influence on ESG performance, offering new insights into the dynamics of ESG practices. Our findings aim to inform both scholars and practitioners about the relational drivers of ESG performance in supply chains.

5 - Product Acquisition for Remanufacturing

Akshay Mutha, University of Vermont, Burlington, VT, United States, Zhaolin Li, Daewon Sun, Jennifer Ryan

We develop models to analyze the process of acquiring used products for remanufacturing. We perform numerical analyses to show the applicability of our models.

The Expanding Role of GenAI in Data-Driven Decisions in Digital Society

Invited Session

Decision Analysis Society

Chair: Dongtan Li, Auburn University, Auburn, AL, 36830, United States

1 - Exploring the Impact of Genai Integration on Behavioral Shifts in Multifaceted Online Communities

Dongtan Li, Auburn University, Opelika, AL, United States

With the advent of generative AI (GenAI), online platforms navigate critical decisions regarding its integration, as GenAI has reshaped user experiences and behaviors in digital society. To compete with external GenAI influence, many platforms embed GenAI algorithms into their services to enhance user engagement. This study investigates how GenAI integration affects user behavior within multifaceted online communities (MOC), which facilitate both knowledge exchange and social communication. By leveraging data from Reddit, we examine changes in user information seeking and sharing patterns after implementing Reddit Answers. Additionally, we explore how these behavioral shifts are moderated by forum characteristics, differentiating between social-oriented and knowledge-oriented subreddits. Our analysis employs a Difference-in-Differences estimation with propensity score matching to provide robust results. Findings reveal significant alterations in posting and commenting behaviors that vary by forum type. These insights offer valuable guidance for platform designers and community managers seeking to optimize AI-enhanced interactions.

2 - The Impact of ESG Risks on Product Recalls

Niyanta Sookraj, Auburn University, Auburn, AL, United States, Yen-Yao Wang

The growing prominence of environmental, social, and governance (ESG) concerns has drawn increased attention from investors, regulators, and corporate leaders alike, positioning ESG risk management as a central force in shaping business strategy. This shift toward sustainability is emphasized by substantial financial commitments, with billions of dollars being directed toward ESG-related initiatives. Prior research highlights that firms failing to manage ESG risks are more vulnerable to financial and reputational damage. However, beyond these external consequences, ESG risks may also pose considerable operational threats. While digital tools for sustainability reporting and ESG monitoring are increasingly adopted, empirical research linking ESG risks to operational failures remains scarce.

This study addresses that gap by examining the relationship between ESG risks and product recall events, with a focus on how ESG risks interact with consumer feedback to offer a more holistic view of recall dynamics. Since poor ESG performance would erode consumer trust and increase the likelihood of adverse market reactions, understanding the role consumers play in this dynamic is essential. Leveraging artificial intelligence (AI) to assess consumer sentiment, we demonstrate how advanced information systems can enhance firms' capabilities to detect, assess, and mitigate operational vulnerabilities. Drawing on 2,894 manufacturer-month observations from 22 U.S. automotive firms over a ten-year span, we find that elevated ESG risk ratings significantly increase the likelihood of product recalls. Additionally, consumer complaints amplify this effect, underscoring the interaction between ESG risk exposure and stakeholder responses.

3 - Domino Effects of AI: Spillovers from New App Launches on Developer Portfolio

Yalda Hojjati, Auburn University, Auburn, AL, United States, Niyanta Sookraj, Pankush Kalgotra

Technological innovations often disrupt and reshape digital markets by altering how value is created and consumed. Such disruptions may trigger shifts in the usage of related products and services within the ecosystem. This study explores these intra-platform spillovers through the lens of artificial intelligence (AI)—a highly disruptive and rapidly diffusing technology. Mobile apps represent a key digital platform where AI is increasingly embedded, as they serve as one of the fastest-growing and most direct channels for companies to integrate AI into consumer-facing services. This makes understanding AI's impact on app ecosystems critical. We focus on a key question: How does the launch of a new app—AI or non-AI—affect user engagement with a developer's existing apps? Further, how do these spillover effects differ based on the number of AI and non-AI apps already in the developer's portfolio? To answer these questions, we used data mining techniques to construct a novel longitudinal dataset from the Apple App Store, capturing biweekly observations over six months. Using two-way fixed effects panel regression, we find that new app launches generally boost engagement with existing apps. However, the magnitude and direction of this effect depend on the portfolio's AI composition. Launching a new AI app increases engagement more when the existing portfolio is primarily non-AI, while this effect diminishes in AI-heavy portfolios. Conversely, launching a non-AI app reduces engagement when more AI apps already exist. The findings offer strategic value for AI integration and advance theoretical understanding of demand spillovers and innovation-led disruption in digital platforms.

4 - Impact of Store Openings and Closures on Local Retail Networks: a Community Detection Approach

Amir Mousavi, Auburn University, Auburn, AL, United States, Pankush Kalgotra

This study investigates the impact of store openings and closures on overlapping communities within retail networks. As retail landscapes continuously evolve through dynamic entry and exit patterns, understanding how these changes affect existing market structures becomes crucial for business strategy. We employ the Democratic Estimate of the Modular Organization of a Network (DEMON) algorithm to detect overlapping communities within retail networks, capturing the complex interdependencies that characterize modern retail ecosystems (Coscia et al., 2012).

We examine how opening and closure events affect the structure and performance of retail networks. DEMON's community detection capabilities enable identification of overlapping communities where retail establishments participate in multiple market segments simultaneously. This approach reflects the reality that stores often serve diverse consumer groups across different spatial and commercial boundaries. Our methodology analyzes how retail network topology changes following market disruptions and examines the spillover effects on neighboring competitors.

<p break-words="">Building on literature examining dynamic market evolution and spatial retail interactions (Shen, 2014; Sung, 2022; Fang & Yang, 2024), we explore how competitive dynamics influence retail network resilience. The study contributes to understanding how localized openings and closures impact interconnected retail systems via overlapping communities. This network-based perspective provides insights into the cascading effects of retail transformations, offering valuable implications for stakeholders regarding market stability, competitive positioning, and the sustainability of local retail ecosystems in the face of continuous market changes.

1 - Bilevel Optimization with Non-Convex Lower-Level Problem

Xiaotian Jiang, University of Minnesota, Minneapolis, MN, United States, Ioannis Tsaknakis, Jiaxiang Li, Jiawen Bi, Prashant Khanduri, Mingyi Hong, Shuzhong Zhang

Bilevel optimization (BLO) problem, where two optimization problems (referred to as upper- and lower-level problems) are coupled hierarchically, has wide applications in areas such as machine learning and operations research. We investigate bilevel optimization problems where the lower-level problem is nonconvex. To address the inherent difficulty of such settings, we propose two distinct reformulations. The first method focuses on unconstrained and nonconvex lower-level problems and introduces a new hyperfunction defined via accumulation points induced by a fixed algorithm and initial point for lower-level problem. Since the resulting hyperfunction is typically discontinuous, we apply a smoothing technique and solve its smoothed approximation by sampling the upper-level variable to estimate its gradient. The second method targets constrained and nonconvex lower-level problems by approximating the value function through sampling feasible solutions, leading to a convex surrogate. This surrogate is used to construct a penalized reformulation of the original BLO problem. For both methods, we develop gradient-based algorithms with provable convergence guarantees and validate their effectiveness through numerical experiments.

2 - ODH for FICO® Xpress: Redefining the Limits of Optimization

Robert Ashford, Optimization Direct, Inc., Thurlaston, United Kingdom, Alkiviadis Vazacopoulos

As optimization challenges grow increasingly complex across industries, traditional solvers often fall short when faced with large-scale, multi-constraint decision models. **Optimization Direct Heuristics (ODH) for FICO® Xpress** represents a transformative enhancement in optimization technology—enabling organizations to overcome long-standing performance barriers without replacing existing systems. This paper introduces the breakthrough capabilities of ODH, highlighting its unique ability to complement FICO Xpress by intelligently combining advanced heuristics, structural decomposition, and parallel processing. Rigorous testing demonstrates ODH's impact: faster solve times, significant reductions in optimality gaps, and the ability to find feasible solutions where other methods fail. With demonstrated success in domains such as telecommunications, retail supply chains, energy generation, and healthcare scheduling, ODH is not just a technical innovation—it is a strategic enabler of real-time, high-quality decision-making. This work outlines the technical architecture, implementation strategies, and quantifiable ROI of ODH, establishing it as a pivotal advancement for organizations striving to transform operational complexity into competitive advantage.

3 - Using Knapsack Problems to Motivate Fortified Regression

Hugo Mainguy, University of Maryland, College Park, MD, United States, Bruce Golden, Luca Bertazzi

The knapsack problem can be computationally expensive to solve to optimality. Although it is generally easier to solve than many other NP-Hard problems, there are many instances that remain computationally expensive to solve. In these circumstances, it may be useful to estimate the optimal solution values. In this paper, we develop a simple variant of linear regression and test it by appealing to the knapsack problem literature. We take advantage of well-known knapsack problem datasets in order to illustrate the potential benefits of fortified regression.

4 - A Taxonomy of Control Problems in Boolean Networks

Kyungduk Moon, Pohang University of Science and Technology, Pohang, Korea, Republic of, Céilia Biane, Kangbok Lee, Loïc Paulevé

Boolean networks are discrete dynamical models that use Boolean states and logical transition formulas to capture the dynamic behavior of a system. Identifying a set of controls—defined as modifications of transition formulas—is crucial to ensure that a desired condition is satisfied across all target states. However, existing computational tools often produce inconsistent solutions due to differences in modelling assumptions. We propose a taxonomy that explains these inconsistencies and clarifies relationships among the tools. This framework is demonstrated with Python code that systematically compares them.

5 - Multi-Timescale Distributed Communication Sliding for Distributed Optimization

Junhui Zhang, MIT, Cambridge, MA, United States, Patrick Jaillet

We present first-order methods for convex non-smooth distributed optimization problems with the special structure that the saddle point formulation is dual-block-decomposable. Such structure arises when the consensus constraints are decomposed into blocks, which are penalized separately. We propose a set of conditions for these penalty functions under which duality gaps for the saddle point problem provide upper bounds on objective value suboptimality and consensus constraint violation for the original distributed optimization problem.

Taking advantage of the block structure, we propose the multi-timescale distributed communication sliding algorithms, where dual blocks are updated at different frequencies. We show that the duality gap converges at the rate of $\mathcal{O}(\overline{r}/k)$ for Lipschitz objectives, and $\mathcal{O}(C(\overline{r}, \overline{r^2})/\mu k^2)$ for μ -strongly convex objectives, where $\overline{r}$ and $\overline{r^2}$ measure "average (squared) rate of updates" for dual blocks, and $C(\overline{r}, \overline{r^2})$ depends on $\overline{r}$ and $\overline{r^2}$.

The deterministic block updating rules and the flexibility in picking the updating frequencies allow the design of more efficient algorithms, especially when the costs of updating different duals are different. Moreover, with proper choices of the penalties, the communication round complexities of our MT-DCS achieve optimal dependency on function similarity, a more refined measure of the variation between the local objectives than Lipschitz constants.

6 - Efficient Wave Planning in Omnichannel Retail: Minimizing Sku Repetition with Random Keys Optimizer

Marçal Ferreira, ITA / UNIFESP, São Paulo, Brazil, Luiz Leduino, Antônio Chaves, Guilherme Coelho

In omnichannel retail, repeated SKU picks across production waves inflate labor costs and slow throughput. We address this problem in partnership with Lojas Renner S.A., one of Brazil's largest fashion chains, minimizing SKU repetition while respecting capacity and homogeneity constraints. We cast it as a graph-partitioning problem: boxes are vertices, and shared SKUs induce edges whose separation across waves incurs cost. We apply the Random-Key Optimizer (RKO) framework to encode box-to-wave assignments as continuous random keys. Our decoder enforces (i) homogeneity of wave class and stock type; (ii) capacity limits for boxed and hanging stock. Unlike existing greedy heuristics, RKO guarantees both capacity compliance and class homogeneity in large-scale instances. On real instances, RKO reduces SKU repetition versus a best-fit heuristic, while never increasing — and often reducing — the number of waves. The results demonstrate that RKO delivers a scalable, high-quality decision-support tool for improving picking efficiency and operational throughput in large-scale, multi-wave production systems.

Machine Learning for Better Healthcare Decisions

Invited Session

Health Applications Society

Chair: Yifang Yan, The Pennsylvania State University, University Park, PA, United States

Co-Chair: Qiushi Chen, The Pennsylvania State University, University Park, PA, United States

1 - Robust AI-Assisted Radiation Therapy Planning

Arka Roy, The University of Texas at San Antonio, San Antonio, TX, United States, Ruiqi Li, Nikos Papanikolaou

Artificial intelligence (AI)-based radiation therapy planning offers the potential to enhance treatment efficiency and expand access to care, particularly in underserved and rural communities facing workforce shortages. However, the inherent errors in AI-generated treatment plans can compromise clinical effectiveness. As the adoption of AI in clinical practice accelerates, there is a critical need for methods that can quantify and mitigate model-related errors. In response, we propose an integrated predictive-prescriptive modeling framework that fuses the contouring and treatment planning stages of radiation therapy. This approach is designed to produce treatment plans that are robust to segmentation inaccuracies, ultimately improving the reliability and safety of AI-driven care.

2 - A Machine Learning Approach to Facilitate Optimal Allocation of Hard-to-Place Kidneys

Sait Tunc, Virginia Tech, Blacksburg, VA, United States, Sean Berry, Berk Gorgulu, Mucabit Cevik

The growing concerns surrounding the organ allocation systems, particularly in light of persistently high nonuse rates for kidneys, has intensified calls for more transparent, data-driven methods. Public concern over ad hoc, opaque decision-making has highlighted the limitations of existing policies, especially when it comes to allocating hard-to-place kidneys (e.g., from older donors, with prolonged ischemia, or donor comorbidities). We present a unified machine learning framework designed to improve the placement of such kidneys. We develop interpretable models to predict transplant center acceptance behavior and propose a ranking-based intervention system that prioritizes centers most likely to utilize the offered organ. Our results demonstrate a significant reduction in delays and nonuse rates. We will also discuss ongoing work on optimizing the batch size of simultaneously expiring organ offers. This effort balances the risks of sequential offers, leading to delays and nonuse, against the inefficiencies of overly large batches, which can overwhelm transplant centers and diminish future offer credibility. Throughout this work, interpretability remains central: our aim is not to replace decision-makers but to support them with robust, transparent tools that adapt to evolving clinical practices.

3 - Neural Index Policies for Restless Multi-Action Bandits with Heterogeneous Budgets

Himadri Pandey, Georgia Institute of Technology, Atlanta, GA, United States, Gian Garcia, Kai Wang

Restless multi-armed bandits (RMABs) with multiple actions and heterogeneous budget constraints pose a major challenge for sequential decision-making under uncertainty, with broad applications in areas such as healthcare and resource allocation. Existing RMAB approaches, including Whittle index policies, are typically restricted to binary actions and struggle to adapt to complex budget constraints. We propose a novel `neural index policy` that assigns learnable indices to multiple actions and uses a knapsack formulation to translate these indices into a feasible action policy under multiple constraints. To enable end-to-end training, we reformulate the knapsack selection step as a differentiable optimal transport (OT) problem and solve it using the Sinkhorn algorithm, allowing gradients to propagate through the selection process. The neural network is trained by minimizing the discrepancy between its induced occupancy measure and the optimal occupancy measure obtained from a linear programming relaxation. Our approach enables scalable and effective policy learning for multi-action RMABs under complex constraints, with experimental results demonstrating strong approximation.

4 - Learning from Simulated Patient Trajectories: A Sequential Decision-Making Agent for Heart Transplantation

Yingtao Luo, Carnegie Mellon University, Pittsburgh, PA, United States, Reza Skandari, Carlos Martinez, Arman Kilic, Rema Padman

Decisions about managing patients on the heart transplant waitlist are currently made by committees of doctors who consider multiple factors, but the process remains largely ad-hoc. With the growing volume of longitudinal patient, donor, and organ data collected by the United Network for Organ Sharing (UNOS) since 2018, there is increasing interest in analytical approaches to support clinical decision-making at the time of organ availability.

We introduce an agentic decision-making framework based on model-based reinforcement learning (MBRL) for optimizing long-horizon, sequential decisions in heart transplantation. Our approach leverages time-to-event models for waitlist mortality, transplant mortality, and donor offer arrival to simulate full patient trajectories. These predictive models serve as environment dynamics, enabling the agent to learn policies that make timely, personalized decisions to maximize patient outcomes.

By capturing temporal dependencies and clinical trade-offs across the transplant process, our framework supports decision-making beyond static risk models or myopic heuristics. The learned policy identifies key predictors aligned with known clinical risk factors while surfacing novel insights, offering a foundation for urgency assessment and policy refinement in heart transplant care. The agent supports realistic counterfactual reasoning, allowing us to evaluate what might happen under alternative action sequences for individual patients. It also captures the temporal dependencies, uncertainty, and trade-offs inherent in the transplant process—such as urgency, donor-recipient matching, and long-term outcomes—through full patient trajectory simulation. This work illustrates the potential of agentic AI systems to support transparent, consistent, and patient-centered clinical decision-making in high-stakes settings.

5 - Making Multi-Class Prediction Actionable: An Application to Reduce Missed Primary Care Appointments

Yifang Yan, The Pennsylvania State University, University Park, PA, United States, Qiushi Chen

Missed primary-care appointments disrupt continuity of care, leading to poorer health outcomes, higher healthcare costs, and wasted clinical resources. Previous studies have developed risk prediction models for missed appointments to understand the patients' no-show behavior and to guide patient outreach strategies. However, most studies focus on predicting binary outcomes, rarely distinguishing late cancellations from no shows, despite their different impacts on clinical workflow in practice. For multi-class prediction problems, prediction results are typically presented as a set of predicted probabilities, making it difficult to inform actions directly. To bridge these gaps, we present a novel classification with inconclusiveness framework based on a disjunctive optimization model, which translates predicted probabilities into deterministic classes and can also identify inconclusive cases with low predictive confidence. The optimization model minimizes the misclassification loss weighted by potential impact on patients' health outcomes. We demonstrate this approach in the context of primary care appointments for adults with type 2 diabetes. We use real-world patient health records from 15 family medicine clinics at a regional academic health center to predict three classes (no-show, late cancellation, and completed visit) and solve for the optimal classification rule to determine confident and inconclusive cases. In our case study, we develop a simulation model of a patient navigation center with limited patient outreach resources to evaluate the potential health impact of various patient classification rules. Our optimal classification rule yields fewer QALYs lost attributed to misclassifications compared with strategies that prioritize by no-show risk alone or by potential health impact alone.

Financial Adaptation and Resource Allocation under Climate Risk

Invited Session

ENRE: Energy-Climate

Chair: Felipe Verastegui, Columbia University, New York, NY, United States

Co-Chair: Agostino Capponi, Columbia University, New York, NY, United States

1 - Market Mechanisms to Improve Efficiency with Green Energy Resources

John Birge, University of Chicago, Chicago, IL, United States

Adapting to changing climate conditions will require integration of extensive renewable resources. Current energy markets have innate inefficiencies that can lead to significant increases in costs of adaptation. This talk will discuss the use of expanded markets with contingent claims to reduce or eliminate these inefficiencies and to enable a smooth energy transition.

2 - Innovator's Edge In Supply Chain Transparency and Food Waste Reduction

Chenghuai Li, University of Alberta, Edmonton, AB, Canada, Bora Keskin, Jing-Sheng Jeannette Song

New digital technologies are transforming fresh produce retail, enabling real-time freshness tracking and allowing retailers to share valuable information—like sustainability certifications—directly with consumers. These innovations promise not only to streamline supply chains and reduce food waste but also to redefine competitive advantage. In a duopoly with freshness-sensitive demand, we explore whether an innovator—the unique adopter of supply transparency technology—gains a competitive advantage over a follower who adopts the technology when her competitor has adopted it. Our analysis reveals that the innovator can achieve higher profits, reduce food waste, enhance consumer satisfaction, and increase demand fulfillment. When consumers value transparency, the innovator's advantage grows, reshaping the market in her favor. Notably, the innovator curbs more food waste through a "market shrinkage" effect, where the competitor's market share contracts, easing supply-demand imbalances and mitigating the risk of excess inventory. Meanwhile, the follower's gains are limited, as the non-adopter passively benefits from the innovator's proactive choices. We also find that markets with fewer competitors are more inclined toward industry-wide adoption, suggesting that mergers in grocery retail could further amplify food waste reduction and consumer demand satisfaction. Finally, we extend our findings to cases involving freshness-based discounts and sequential technology adoption.

3 - Integrating AI, Remote Sensing, and Optimization for Urban Flood Resilience

Yuki Miura, New York University, Brooklyn, NY, United States

As climate-driven flood hazards worsen, both public and private institutions must make high-stakes investment decisions under deep uncertainty. We introduce an optimization framework for resilient flood risk management that integrates dynamic flood simulations with structural and socioeconomic exposure data to support financially sound resource allocation informed by stakeholders' inputs. A key contribution is the development of a novel global rooftop material dataset, derived from satellite imagery using machine learning, which serves as a scalable proxy for structural vulnerability. Together, the framework and dataset enable robust scenario-based planning: we simulate millions of plausible flood events and various strategies to identify interventions that remain effective across diverse futures. New York City has served as a testbed through collaborations with multiple agencies spanning administration, utility, transportation, and public safety. This work offers a new paradigm for operationalizing climate resilience at scale and guides actionable solutions.

4 - Electric Infrastructure Investment Under Uncertainty

Christoph Graf, New York University, New York, NY, United States, David Wozabal

Electric infrastructure investment decisions are increasingly challenged by deep uncertainty arising from climate change and extreme weather events, which impact both electricity demand and the supply from weather-dependent renewable energy sources. Enabling electric infrastructure, such as storage and transmission, can enhance the value of renewables by mitigating their variability across time and space. We present a stochastic electricity investment model for the U.S. that is highly granular in time and space. Our approach incorporates classical optimization methods alongside preliminary applications of deep learning techniques to explore investment decisions under a range of uncertain futures.

5 - Sustainable Investment Strategies with Real Asset Trades

Felipe Verastegui, Columbia University, New York, NY, United States, Agostino Capponi, Jay Sethuraman

What strategy should sustainable investors adopt to reduce emissions without inducing firms to excessively engage in the reallocation of industrial pollution? We study this question in a matching model in which entrepreneurs choose attributes for their businesses and then form stable matchings with investors. The presence of environmentally minded investors in the matching market affects the attribute choice creating regimes with pooling and separating equilibria, which depends on the strength of the sustainable preferences. When we account for real asset trades, there is a misalignment between value-based and impact-based preferences: entrepreneurs can achieve warm-glow in a separating equilibrium without reducing emissions, by efficiently reallocating their productive assets. Trades prove efficient for value-based investors, but limit the scope and attractiveness of impact investing strategies.

Customer Behavior in Service Systems

Invited Session

MSOM: Service Operations

Chair: Jimmy Qin, University of Texas in Dallas, Richardson, United States

Co-Chair: Andrew Frazelle, The University of Texas at Dallas, Richardson, TX, United States

1 - Mitigating Service Incompletion via Sunk Costs: a Queueing Approach

Jimmy Qin, The University of Texas at Dallas, Richardson, TX, United States, Carri Chan, Jing Dong

Sunk-cost bias occurs when decisions are influenced by the time, energy, and money already invested, rather than considering the future costs necessary to achieve success. This phenomenon of "irrational behavior" is well-documented in decision-making studies and is generally recognized as a factor that can lead to suboptimal decisions. In this work, we investigate how sunk cost (and the behavioral bias associated with it) can be used as an operational lever to increase service completion rates in a congested service system. We run a controlled online experiment and find that the abandonment rate is significantly reduced for the group of participants who incur a larger sunk cost. To better capture the dynamics of service systems and their impact on customers' behavior, we study a queueing model with sunk cost and strategic customers, where customers experience a disutility of balking that is proportional to the sunk cost they incur. We characterize the equilibrium behavior of the customers, from which we further derive the optimal strategy for the service provider in terms of whether to provide real-time queue length information to customers as well as the optimal level of sunk cost to impose. Our results show that the sunk cost strategy is effective only when waiting information is provided and that using a non-zero sunk cost is optimal when the queueing system is moderately congested. Through a comprehensive numerical study, we demonstrate that implementing a non-zero sunk cost can substantially improve the throughput of the system.

2 - Bayesian Pricing for Impatient Customers with Unknown Valuation

Zhenghang Xu, Rotman School of Management, University of Toronto, Toronto, ON, Canada, Philipp Afeche, Opher Baron, Dmitry Krass

We study a Bayesian dynamic pricing problem for a revenue-maximizing, capacity-constrained service provider that learns unknown customer valuations through sequential pricing. Customers arrive sequentially, accept or reject the prevailing price, and those who accept occupy the server; arrivals are lost if the server is busy. Our contributions include: (1) A novel recursive algorithm to compute optimal prices that balance demand learning and revenue maximization; (2) theoretical identification of an *adaptive explore-then-commit* structure: when uncertainty resolves sufficiently, the firm prices at the valuation's lower bound to guarantee sales; (3) a practical heuristic for delay-free settings, inspired by the Bayesian optimal policy, that numerically outperforms existing benchmarks and achieves the optimal regret order. By unifying Bayesian learning with pricing dynamics, we show how firms adaptively transition from exploration to exploitation. Results demonstrate how customer impatience and server constraints shape pricing strategies, offering actionable methods with provable guarantees for revenue management under uncertainty.

3 - Information Avoidance In Diagnostic Testing

Zack Zhu, University of British Columbia, Surrey, BC, Canada, Steven Shechter, Woonghee Huh

In formalizing information acquisition decisions as combined instrumental and hedonic utility maximization problems, we develop insights on the degree to which individuals seek vs. avoid diagnostic tests. By explicitly incorporating a psychological positive utility for a good test outcome and a negative utility for a bad test outcome, we provide a decision-analytic model that rigorously explains why for some people, "ignorance is bliss." We apply this model to the context of COVID-19, examining individuals' decisions related to testing. The model sheds light on willful ignorance during the pandemic, and offers policy-relevant insights into how public health interventions can help mitigate the societal costs due to information avoidance.

Security and Resilience of Critical Systems: Advances in Optimization Under Strategic and Stochastic Uncertainty

Invited Session

OPT: Optimization Under Uncertainty

Chair: Mathieu Dahan, Georgia Institute of Technology, Atlanta, GA, United States

1 - Adaptive Sampling and Partition-Based Methods for Stochastic Shortest Path Interdiction Problems

Di Nguyen, University College Dublin, Dublin, Ireland

We investigate the computational performance of two solution approaches and various enhancements in a two-stage shortest-path network interdiction game. This game involves an interdicator and an evader. The evader seeks to traverse the network using a source-sink path that is shortest, while the interdicator seeks to maximize this cost by interdicting a subset of arcs given a budget. In the first stage, the interdicator determines an interdiction solution while only being able to anticipate the range of arc costs. In contrast, the evader can observe the exact arc cost realizations at the time of their operation, as well as the impact due to the interdicator's decision in the second stage. In this problem, we act as the interdicator and find an interdiction solution that maximizes the evader's expected shortest-path cost. Our research evaluates two main approaches to solving this problem, one leveraging the adaptive sampling framework and one utilizing partition-based methods. Several enhancements that exploit the problem's structure are explored. The computational results, along with their advantages and disadvantages, are discussed and compared against the existing benchmark from the work of Nguyen and Smith (2022).

2 - A Game-Theoretic and McdA Framework for Sustainable Arctic Development: Balancing Economic Interests, Security, and Indigenous Rights

Yiqi Zhao, University at Buffalo, SUNY, Buffalo, NY, United States, Jun Zhuang

The rapid economic development in the Arctic, driven by its natural resources and strategic significance, poses substantial challenges. This study integrates game theory and multi-criteria decision analysis (MCDA) to scientifically examine the interplay between economic growth and indigenous interests, enhancing the robustness and analytical rigor of decision-making. The research employs sequential and non-cooperative game theory to model strategic interactions among governments, corporations, and indigenous communities, while MCDA evaluates and prioritizes diverse criteria to assess policy impacts comprehensively. This combined approach aids policymakers in balancing economic objectives with the protection of indigenous rights, sustainability, and regional stability. Indigenous concerns regarding cultural heritage, traditional lifestyle disruption, resource overexploitation, and environmental risks are addressed through MCDA-driven, data-informed analysis. Recommendations include promoting indigenous participation in policy-making, ensuring fair distribution of economic benefits, enforcing strict environmental safeguards, and supporting long-term community development. The findings demonstrate strategies that respect indigenous sovereignty and promote sustainable development. Integrating game theory with MCDA equips policymakers with scientifically grounded tools for informed, collaborative decision-making, balancing economic goals with indigenous rights and environmental stewardship.

3 - Learn to Optimize: Self-Supervised Progressive Hedging and Adaptive Penalties for Multistage Stochastic Network Recovery Planning

Graham Hulsey, George Mason University, Fairfax, VA, United States, Shima Mohebbi

This work explores using self-supervised machine learning (ML) to solve large and computationally difficult multi-stage stochastic programs (MSSPs). Recent work integrating machine learning into existing algorithms to solve MSSPs has shown promise in reducing computational time with minimal reduction in solution quality. In the Learn-to-Optimize framework, ML models are used to either predict solutions or algorithm parameters directly, or to improve algorithm structure or model formulation via classification, prediction, or clustering models. Typically, these methods are supervised methods and so require generating training data, which can be computationally expensive. The self-supervised approach proposed in this work builds on the progressive hedging (PH) algorithm, a stochastic programming algorithm with well-known properties, and because it is self-supervised does not require training data. Moreover, the approach can seamlessly handle binary variables, which is a major bottleneck for classical solver-based algorithms. Computational experiments over random networks of different sizes demonstrate the self-supervised approach yields near-optimal solutions in substantially less time than PH with binary variables, though the self-supervised approach is sensitive to the choice of hyper-parameters. A real-world case study of Tampa, FL infrastructure networks is also presented.

4 - Wisdom: Wisconsin Intelligent System for the Detection of and Optimization Against Marine Threats

Vanessa Sawkmie, University of Wisconsin-Madison, Madison, WI, United States, Jeff Linderoth

The underwater domain presents significant challenges for surveillance and defense due to the inherent uncertainty in target behavior and detection outcomes. Effective detection depends on successful encounters between adversarial targets and search assets, each with distinct capabilities and operational constraints. Central to our approach is the concept of a search pattern, defined by a spatial region and time interval, to which different asset types can be assigned. To address uncertainty in both target motion and detection outcomes, we formulate a two-stage stochastic integer programming model that strategically allocates search assets across a decision theater over a finite planning horizon to maximize the expected number of targets detected. We extend this framework to a three-stage stochastic model by incorporating fixed bottom sensors that provide probabilistic observations of target movement, thereby informing more effective pattern assignments for the search assets.

Computer-aided Design and Verification for First-order Optimization Algorithms

Invited Session

OPT: Computational Optimization and Software

Chair: Jisun Park, Princeton University, Princeton, NJ, 08540, United States

1 - Data-Driven Analysis of First-Order Methods via Distributionally Robust Optimization

Jisun Park, Princeton University, Princeton, NJ, United States, Vinit Ranjan, Bartolomeo Stellato

We consider the problem of analyzing the probabilistic performance first-order methods, when solving a distribution of parametric convex optimization problems. By combining performance estimation (PEP) and Wasserstein distributionally robust optimization (DRO), we formulate the analysis as a tractable semidefinite program. Our approach unifies worst-case and average-case analyses by incorporating data-driven information from the observed convergence of first-order methods on a limited number of problem instances. This yields probabilistic, data-driven performance guarantees—specifically, in terms of the expectation or conditional value-at-risk of the selected performance metric. Experiments on convex quadratic and smooth convex minimization show that our method significantly reduces the conservatism of classical worst-case bounds and narrows the gap between theoretical and empirical performance.

2 - Exact Verification of First-Order Methods via Mixed-Integer Linear Programming

Bartolomeo Stellato, Princeton University, Princeton, NJ, United States

We present exact mixed-integer linear programming formulations for verifying the performance of first-order methods for parametric quadratic optimization. We formulate the verification problem as a mixed-integer linear program where the objective is to maximize the infinity norm of the fixed-point residual after a given number of iterations. Our approach captures a wide range of gradient, projection, proximal iterations through affine or piecewise affine constraints. We derive tight polyhedral convex hull formulations of the constraints representing the algorithm iterations. To improve the scalability, we develop a custom bound tightening technique combining interval propagation, operator theory, and optimization-based bound tightening. Numerical examples, including linear and quadratic programs from network optimization, sparse coding, and optimal control, show that our method provides several orders of magnitude reductions in the worst-case fixed-point residuals, closely matching the true worst-case performance.

3 - Composing Optimized Stepsize Schedules for Gradient Descent

Benjamin Grimmer, Johns Hopkins University, Baltimore, MD, United States, Kevin Shu, Alex Wang

Recent works by Altschuler and Parrilo and the authors have shown that it is possible to accelerate the convergence of gradient descent on smooth convex functions, even without momentum, just by picking special stepsizes. In this talk, we will provide a general theory for composing stepsize schedules capturing all recent advances in this area and more. We propose three notions of "composable" stepsize schedules with elementary associated composition operations for combining them. From these operations, in addition to recovering recent works, we construct three highly optimized sequences of stepsize schedules. We first construct optimized stepsize schedules of every length generalizing the exponentially spaced silver stepsizes. We then construct highly optimized stepsizes schedules for minimizing final objective gap or gradient norm, improving on prior rates by constants and, more importantly, matching or beating the numerically computed minimax optimal schedules. We conjecture these schedules are in fact minimax (information theoretic) optimal. Several novel tertiary results follow from our theory including recovery of the recent dynamic gradient norm minimizing short stepsizes and extending them to objective gap minimization.

4 - Optimization Algorithm Design via Electric Circuits

Tetiana Parshakova, Amazon, New Haven, CT, United States, Stephen Boyd, Ernest Ryu, Jaewook Suh

We present a novel methodology for convex optimization algorithm design using ideas from electric RLC circuits. Given an optimization problem, the first stage of the methodology is to design an appropriate electric circuit whose continuous-time dynamics converge to the solution of the optimization problem at hand. Then, the second stage is an automated, computer-assisted discretization of the continuous-time dynamics, yielding a provably convergent discrete-time algorithm. Our methodology recovers many classical (distributed) optimization algorithms and enables users to quickly design and explore a wide range of new algorithms with convergence guarantees.

2 - Sequential Choice Model with Representative Products: Modeling and Optimization

Yu SUN, The Chinese University of Hong Kong, Hong Kong, Hong Kong, Daniel Zhuoyu Long, Ruxian Wang

Modeling decision behavior among multiple choice options has been an active research area for several decades. Typically, classic discrete choice models consider that customers observe all available products simultaneously and select the one with the highest utility (e.g., the widely used MNL and NL models). In this paper, we propose a novel sequential choice model with representative products to describe customers' purchase behaviors, in which the products are grouped in multiple nests, and each nest has a representative product that is viewed in the first stage and other products that are viewed in the second stage. Customers make their purchase decision sequentially following the product information disclosure process in two stages: in the first stage, customers only observe incomplete information about the product set (i.e., limited information of all representative products) and choose a nest with the most attractive representative or leave without purchasing; in the second stage, customers unlock full information about all products in the selected nest and purchase the product in this nest with the highest utility. We employ the widely used MNL choice model in each stage to formulate the sequential choice process. Under this sequential choice model, we first investigate the problem on the selection of representative products and product information display management. We then investigate the assortment optimization, nest planning and pricing problem, and establish the structural properties of optimal solutions. We finally present effective estimation techniques and comparative statics to demonstrate its application to real-world issues.

3 - Tax Relief OR Public Belief: CSR-Induced Consumer Segmentation with Tax Incentives

Xinyi ZHOU, The Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Lijian Lu, Ruxian Wang

We study a retail firm selling quality-differentiated products to both low- and high-expertise consumers and analyze how its level of Corporate Social Responsibility (CSR) investment influences consumer preferences and purchase behavior. CSR efforts enhance low-expertise consumers' confidence in the firm but have no impact on high-expertise consumers, leading to market segmentation. When high quality is relatively inexpensive, high-expertise consumers purchase only the high-quality product, while low-expertise consumers are split across product types. CSR and pricing strategy together can drive market-level quality upgrading by shifting demand from low- to high-quality products. We further examine how government tax deduction policies interact with CSR investment and affect the welfare of the firm, consumers, and society. We find that the benefit of charity-related tax deductions depends critically on who holds decision power and how the charitable tax relief scheme is designed.

4 - Product Information Display Optimization with Quality Uncertainty and Returns

Yang Lu, University of Science and Technology of China, Hefei, China, People's Republic of, Ruxian Wang, Xiaoming Yan, Yugang Yu

Display quality refers to product information such as the images and textual descriptions of product quality presented to consumers shopping online, and can directly influence market demand during the sales phase and product returns during the after-sales phase. In this paper, we investigate the product display optimization problems on display quality, pricing, and assortment planning, taking into account the uncertainty of product quality and consumer returns. We employ the widely used multinomial logit (MNL) model to investigate the impact of display quality on consumer choices. In particular, we incorporate display quality into the utility function regarding consumers' purchase and return behavior, which is largely affected by display quality. We then conduct a joint optimization analysis on assortment planning, display quality and pricing, and characterize the optimal solution and propose an efficient method that involves assessing whether the conservative retention rate of a product is positive. Moreover, we investigate the estimation problem and conduct a comprehensive empirical validation with real data. Our results reveal that model misspecification and optimization on display quality could result in substantial losses. Because of its high impact on both market demand and subsequent returns, display quality alters the structure of the optimal pricing and assortment decisions. In addition, we find that optimizing display quality creates another opportunity to achieve a win-win outcome for both the retailer and consumers, which could serve as a reference for market regulation.

Smart Charging and Clean Mobility Systems

Contributed Session

Contributed

Chair: Sandjai Bhulai, Vrije Universiteit Amsterdam, De Boelelaan 1111, Amsterdam, 1081 HV, Netherlands

1 - Energy-Aware Resource Allocation for Industry 4.0 Using Evolutionary Game Theory**Ka Shuen Ho, Purdue University, West Lafayette, IN, United States, Nga Hin Ben Fong**

In the context of Industry 4.0, smart factories operate in highly dynamic environments with fluctuating workloads and energy constraints. This requires real-time, adaptive resource allocation strategies. At the same time, energy-aware operations have become essential for minimizing environmental footprint, reducing costs, and meeting strict energy regulations. Traditional centralized approaches often lack the scalability and responsiveness needed under such conditions, prompting a shift toward decentralized, autonomous decision-making systems. To address these challenges, this study proposes an evolutionary game theory (EGT) framework for energy-aware resource allocation in smart factories to achieve greater efficiency, flexibility, and sustainability. In this framework, each machine is modelled as an autonomous agent that iteratively evolves its task selection and operation strategies through game-theoretic dynamics. Payoffs incorporate multiple factors including energy consumption, task priorities, and resource requirements. Through local interactions and strategic adaptation, the system converges to equilibria at evolutionarily stable strategies (ESS) that balance competing objectives such as throughput and energy efficiency. The research demonstrates the potential of EGT-based approach for supporting sustainability and operational performance in smart manufacturing systems.

2 - Coordinated Load Shifting Through Storage-Enabled Demand Response in Smart Grids**Ahmed Ali, University of Miami, Miami, FL, United States, Murat Erkoç**

With growing emphasis on demand-side flexibility and the increasing availability of behind-the-meter storage, effective demand management through dynamic pricing has become essential for ensuring the reliability and efficiency of modern electricity systems. This study investigates the impact of consumer-level electricity storage on improving load shifting strategies within a demand-side management framework. A Stackelberg game is established between a single electricity provider and a large number of heterogeneous consumers. In this model, the provider implements time-varying price discounts to encourage consumers to shift their usage from peak to off-peak periods. Consumers, in turn, independently optimize their electricity consumption, considering their individual demand preferences and inconvenience costs. Two control paradigms are analyzed: provider-controlled storage and consumer-controlled storage. Through analytical characterization and simulation outcomes, the study reveals how the integration and management of storage influence load shifting behavior, peak to average demand ratio reduction, and overall economic performance. The findings suggest that consumer diversity regarding inconvenience levels significantly affects the equilibrium outcomes. Additionally, the incorporation of storage enhances the efficacy of price-based load shifting strategies, with provider control enabling more coordinated peak management, while consumer control provides greater flexibility and welfare benefits. These insights contribute to the formulation of effective storage deployment strategies and dynamic pricing policies in smart grid systems.

3 - Scheduling Charging of Electric Vehicles at Airport Rental Car Centers**Devon Sigler, National Renewable Energy Laboratory, Longmont, CO, United States, Gustavo Campos, Juliette Ugirumurera, Yanbo Ge, Monte Lunacek, Caleb Phillips, Roberto Vercellino, Margaret Mann, Yi He**

Airports and rental car companies are currently grappling with the infrastructure and operational challenges of fleet electrification. Full electrification of an airport rental car fleet requires charging to be integrating into their operational model. Charging vehicles using DC fast charging allows rental car companies to minimally alter their operational paradigm. However, plugging vehicles into DC fast charging infrastructure immediately upon arrival will create new electrical loads in the tens of Megawatts at major airports, which the current power grid infrastructure is not equipped to support. In this work we investigate the potential of smart charge scheduling to the reduce peak loads at airport rental car centers from vehicle charging. Towards this end we present two scalable smart charge scheduling algorithms and demonstrate their impact through simulation of real-world scale vehicle fleets.

4 - Optimizing Power Grid Topologies with Reinforcement Learning: a Survey of Methods and Challenges**Sandjai Bhulai, Vrije Universiteit Amsterdam, Amsterdam, Netherlands, Erica van der Sar, Alessandro Zocca**

Power grid operation is becoming increasingly challenging due to the growing integration of renewable energy sources and the demand for more adaptive control strategies. Reinforcement Learning (RL) offers a promising solution for Power Network Control (PNC), with its ability to support effective decision-making under dynamic and uncertain conditions. The Learning to Run a Power Network (L2RPN) competitions have significantly contributed to the field by offering standardized benchmarks and well-defined problem settings, thereby accelerating research progress. This survey presents a structured and comprehensive review of RL applications in power grid topology optimization. It categorizes current methodologies, examines critical algorithmic design decisions, and identifies key research gaps. Furthermore, it includes a comparative numerical analysis of frequently used RL approaches, evaluating their practical performance and limitations. By synthesizing the current state of the field and outlining unresolved challenges, this survey provides a valuable reference for guiding future developments in RL-based power grid optimization.

Online Decision Making for RM Problems

Invited Session

Revenue Management

Chair: Zizhuo Wang, CUHK Shenzhen, Shenzhen, N/A

1 - Wait-Less Offline Tuning and Re-Solving for Online Decision Making**Jingruo Sun, Stanford University, Stanford, CA, United States, Wenzhi Gao, Ellen Vitercik, Yinyu Ye**

Online linear programming (OLP) has found broad applications in revenue management and resource allocation. State-of-the-art OLP algorithms achieve low regret by repeatedly solving linear programming (LP) subproblems that incorporate updated resource information. However, LP-based methods are computationally expensive and often inefficient for large-scale applications. In contrast, recent first-order OLP algorithms are more computationally efficient but typically suffer from worse regret guarantees. To address these shortcomings, we propose a new algorithm that combines the strengths of LP-based and first-order OLP methods. The algorithm re-solves the LP subproblems periodically at a predefined frequency f and uses the latest dual prices to guide online decision-making. In addition, a first-order method runs in parallel during each interval between LP re-solves, smoothing resource consumption. Our algorithm achieves $O(\log(T/f) + \sqrt{\log T})$ regret, delivering a "wait-less" online decision-making process that balances the computational efficiency of first-order methods and the superior regret guarantee of LP-based methods.

2 - Beyond Regularity: Simple Versus Optimal Mechanisms, Revisited**Yiding Feng, Hong Kong University of Science and Technology, Hong Kong, Hong Kong, Yaonan Jin**

A large proportion of the Bayesian mechanism design literature is restricted to the family of regular distributions [Mye81] or the family of monotone hazard rate (MHR) distributions [BMP63], which has overshadowed this rich and well-developed theory. We (re-)introduce two generalized families: quasi-regular distributions and quasi-MHR distributions. Likewise, the parameterized families of λ -regular (a.k.a. α -strongly regular) distributions [CR14,SS19], which smoothly interpolate regular distributions and MHR distributions, generalize to λ -quasi-regular distributions.

The significance of our new families is manifold. Firstly, their defining conditions are immediate “economic” relaxations of the original defining conditions (e.g., regularity as monotonicity of the virtual value functions), capturing key economic intuitions. Secondly, they satisfy natural mathematical properties (about order statistics) failed for the original families, thus technically more tractable. Thirdly, numerous results (by [BK96, HR09, CD15, DRY15, HR14, AHNPY19, JLTx20, JLQTX19, FLR19, GHZ19, JX23, LM24] etc) known merely for the original families now can extend to our new families. Many of these extensions incur no quantitative loss, or even improve the state of the art for the original families. Finally, beyond the third point, our new families guide us to entirely new perspectives and thus entirely unknown

results. For example, regarding revenue maximization for symmetric versus asymmetric regular buyers, we acquire 0.5- versus 0.1908-approximations for the (less-than-)one-sample prophet inequalities, respectively. To the best of our knowledge, such results are blank in the literature, despite their widely-studied welfare maximization counterparts [CDFS19, RWW20, CCES20, CDFS21, CCES24].

3 - Instance-Dependent Sample Complexity for Bilinear Saddle-Point Optimization with Noisy Feedback: An Lp-Based Approach

Jiashuo Jiang, HKUST, Hong Kong, Hong Kong

Abstract: In this work, we study the sample complexity of finding a Nash Equilibrium (NE) of two-player zero-sum matrix games with noisy feedback. We propose a novel algorithm based on resolving linear programs (LP), achieving an ϵ -approximate NE with an instance-dependent sample complexity for general m_1 times m_2 game matrices, while being robust by enjoying a worst-case sample complexity at the same time. To our knowledge, this result provides the first instance-dependent sample complexity for general-dimension matrix games under noisy feedback and non-unique NE. Our algorithm is inspired by recent advances in online resource allocation and includes two key components: first, identifying a support set of the NE, and second, determining the unique NE within this support. Both steps rely on a careful analysis of the performance of solving the LP constructed by noisy samples. This is a joint work with Mengxiao Zhang

4 - Llm Serving with Variable Prefill & Decode Lengths

Meixuan Wang, Tsinghua University, Beijing, China, People's Republic of, Zijie Zhou

We study the problem of serving LLM (Large Language Model) requests where each request has heterogeneous prefill and decode lengths. In LLM serving, the prefill length corresponds to the input prompt length, which determines the initial memory usage in the KV cache. The decode length refers to the number of output tokens generated sequentially, with each additional token increasing the KV cache memory usage by one unit. Given a set of n requests, our goal is to schedule and process them to minimize the total completion time. We show that this problem is NP-hard due to the interplay of batching, placement constraints, precedence relationships, and linearly increasing memory usage. We then analyze commonly used scheduling strategies in practice, such as First-Come-First-Serve (FCFS) and Shortest-First (SF), and prove that their competitive ratios scale up with the memory limit—a significant drawback in real-world settings where memory is large. To address this, we propose a novel algorithm based on a new selection metric that efficiently forms batches over time. We prove that this algorithm achieves a constant competitive ratio of 48. Finally, we develop heuristic algorithms inspired by this approach and demonstrate through simulations that they outperform standard baselines.

5 - Online Linear Programming with Batching

Haoran Xu, Stanford University, Palo Alto, CA, United States

We study Online Linear Programming (OLP) with batching. The planning horizon is cut into K batches, and the decisions on orders arriving within a batch are permitted to be delayed to the end of their associated batch. Compared with OLP without batching, the ability to delay decisions improves operational performance, as measured by regret. We are interested in (1) What is a lower bound on the regret as a function of K ? (2) What algorithms achieve the regret lower bound? We analyze these questions when the distribution of the reward has a continuous support. With a single resource and a known total number of orders, we show a $\Omega(\log K)$ regret lower bound and propose an algorithm achieving this lower bound. We also propose algorithms with regret $O(\log K)$ for the setting with multiple types of resources and the setting with a Poisson order arrival process. All these regret bounds are independent of the length of the planning horizon, and all the proposed algorithms delay decisions on orders arriving in only the first and the last batch. We also take customer impatience into account and establish an appropriate batch size.

6 - Infrequent Resolving Algorithm for Online Linear Programming

Zizhuo Wang, CUHK Shenzhen, Shenzhen, China, People's Republic of

Online linear programming (OLP) has gained significant attention from both researchers and practitioners due to its extensive applications, such as online auction, network revenue management, order fulfillment and advertising. Existing OLP algorithms fall into two categories: LP-based algorithms and LP-free algorithms. The former one typically guarantees better performance, even offering a constant regret, but requires solving a large number of LPs, which could be computationally expensive. In contrast, LP-free algorithm only requires first-order computations but induces a worse performance, lacking a constant regret bound. We bridge-the-gap between these two extremes by proposing well-performing algorithm, that solves LPs at a few selected time points and conducts first-order computations at other time points. Specifically, for the case where the inputs are drawn from an unknown finite-support distribution, the proposed algorithm achieves a constant regret (even for the hard “degenerate” case) while solving LPs only $O(\log \log T)$ times over the time horizon T . Moreover, when we are allowed to solve LPs only M times, we design the corresponding schedule such that the proposed algorithm can guarantee a nearly $O(T^{\frac{1}{2}(M-1)})$ regret. Our work highlights the value of resolving both at the beginning and the end of the selling horizon, and provides a novel framework to prove the performance guarantee of the proposed policy under different infrequent resolving schedules. Furthermore, when the arrival probabilities are known at the beginning, our algorithm can guarantee a constant regret by solving LPs $O(\log \log T)$ times, and a nearly $O(T^{\frac{1}{2}M})$ regret by solving LPs only M times.

AI, Information, and Algorithmic Market Design for Platforms

Invited Session

Auctions and Market Design

Chair: Rad Niazadeh, Chicago Booth School of Business, Chicago, IL, United States

Co-Chair: Jiaqi Lu, the Chinese University of Hong Kong (Shenzhen), Shenzhen, N/A

1 - Information Design and Pricing In Lead-Selling Platforms with Supply Competition

Jiahua Wu, Imperial College London, London, United Kingdom, Yanwei Sun, Niloofar Zamani Foroushani, Zhe Liu

We analyze a type of platform common in the service sector, where customers can freely post tasks, and service providers pay a fee to purchase job leads and unlock the ability to communicate with these customers. We adopt a Bayesian persuasion framework to explore how the platform can leverage its informational advantage about the provider base and pricing to strategically influence the decisions of service providers, aiming to maximize its revenue. We begin the analysis by assuming that prices are exogenously given and characterize the structure of the optimal signaling mechanism. Specifically, the platform recommends that all service providers participate when the pool size is below a certain threshold. When the pool size exceeds this threshold, the platform randomizes its recommendations between two consecutive numbers, independent of the pool size. This behavior is driven by a unique feature of our model, where the beliefs of the platform and service providers are non-identical: a provider's knowledge of their own participation inflates their belief about the total number of service providers. Next, we endogenize the platform's pricing decision and consider the policy space where the signaling mechanism and (possibly randomized) state-dependent pricing are jointly optimized. Notably, within this space, we find that the optimal signaling mechanism with fixed pricing is optimal. This result implies the superiority of the optimal signaling mechanism over the commonly adopted contingent pricing policy. We show that the performance discrepancy between these two policies is particularly pronounced when supply competition is intense.

2 - Optimizing Pilot Mentorship Through Algorithmic Matching: Evidence from a Randomized Controlled Trial

Meixi Wu, National University of Singapore, Singapore, Singapore, Jussi Keppo, Hong Ming Tan

This study evaluates the effectiveness of mentoring workshops and algorithmic matching in enhancing pilot performance and mentoring quality through a randomized controlled trial (RCT). Drawing on historical data, we first identify key features correlated with improved performance, then design and implement an integer programming-based algorithm that optimizes mentor-mentee pairings using a weighted combination of these features while satisfying operational constraints. Compared to conventional matching, algorithmic pairing leads to higher post-workshop competency scores, as shown by an analysis of covariance (ANCOVA) that controls for pre-workshop performance and a Difference-in-Differences (DID) model with mentee fixed effects to account for time-invariant individual heterogeneity. Survey evidence further shows that algorithmic matching enhances mentees' perceived mentoring quality (as measured by the LMX framework) and strengthens perceptions of legitimate power. These findings demonstrate that data-driven matching can enhance mentorship effectiveness in aviation training.

3 - AI Agents Can Enable Superior Market Designs

Gili Rusak, Harvard University, Cambridge, MA, United States, Benjamin Manning, John Horton

Many theoretically appealing market designs are under-utilized because they demand preference data that humans find costly to provide. This paper demonstrates how large language models (LLMs) can effectively elicit such data from natural language descriptions. In our experiment, human subjects provide free-text descriptions of their tastes over potential roles they could be assigned. An LLM converts these descriptions into cardinal utilities that capture participants' preferences. We use these utilities and participants' stated preferences to facilitate three allocation mechanisms---random serial dictatorship, Hylland-Zeckhauser, and a conventional job application type game. A follow-up experiment confirms that participants themselves prefer LLM-generated matches over simpler alternatives outside their top choices---exactly the choices market participants face under high congestion. These findings suggest that LLM-proxied preference elicitation can enable superior market designs where they would otherwise be impractical to implement.

4 - Strategic Supply-Demand Mismatch through Lead Time and Pricing Autonomy: Evidence from a Car-Sharing Platform

Asif Nazrul, University of Cambridge, Cambridge, United Kingdom, Stylianos Kavadias

This paper examines supply-demand mismatch on hybrid peer-to-peer (P2P) car-sharing platforms, where decentralized hosts make strategic decisions about asset availability. Using booking-level data from one of largest online marketplace and exploiting a quasi-experimental policy shift in February 2023 that granted pricing autonomy to hosts, this study investigates how self-pricing affects listing behavior and utilization. A Triple Difference-in-Differences (DDD) framework identifies heterogeneous treatment effects moderated by host experience.

The results show that experienced hosts with self-pricing privileges strategically delay their listings, reducing lead times by an additional 0.92 days compared to other host groups. This temporal shift contributes to a 6.9 percentage point decline in utilization, reflecting lower booked hours relative to availability. Inexperienced self-pricing hosts also experience diminished performance, likely due to suboptimal pricing decisions. Together, these findings suggest that pricing autonomy encourages strategic but inefficient supply behavior, particularly among experienced providers.

This study contributes to the literature on marketplace design and decentralized operations by offering causal evidence on the behavioral consequences of pricing flexibility. It highlights how autonomy can exacerbate service availability gaps, particularly in advance-booking settings where supply timing is a critical decision that is overlooked in current literature. The findings underscore the need for experience-sensitive interventions, such as feedback-based incentives or dynamic listing nudges, to maintain platform efficiency while preserving host flexibility. Future work can extend this analysis using unsupervised clustering to uncover latent experience profiles and improve behavioral targeting in two-sided digital markets.

5 - Optimizing Mixed Workforce in Delivery Platforms

Xinyuan Wu, The Chinese University of Hong Kong, Shenzhen, Shenzhen, China, People's Republic of, Yunpeng Li, Costas Courcoubetis

Delivery platforms rely on full-time couriers in low-demand periods, but during peak times, they supplement their workforce with crowdsourcing couriers. We study a platform operating both courier types during peak periods. While full-time couriers are centrally dispatched, crowdsourcers strategically choose the number of orders to deliver simultaneously to maximize their average rewards, where the job waiting time is endogenously determined by their collective behavior. The crowdsourcer interaction corresponds to a mean-field game where agents compete for sequentially consumable resources. We show that their behavior forms a submodular game and the equilibrium is characterized by a convex problem. To optimize platform profit, we formulate a Stackelberg game where the platform acts first to decide on the demand allocated to full-time and crowdsourcers, then crowdsourcers respond by reaching equilibrium. To avoid directly solving this bilevel problem, we analytically derive and compare the marginal profit of serving additional demand via full-time couriers and crowdsourcers, proposing an efficient heuristic for optimal demand allocation. On a longer time scale, crowdsourcers observe the demand assigned to them and make their participation decisions. Crowdsourcers require both sufficient allocated demand and adequate per-job payment to engage. The platform can strategically adjust payment to expand participation when profitable. We extend our heuristic to jointly optimize demand allocation and crowdsourcer payment. Our results provide insights into the strategic behavior of crowdsourcers, offering scalable solutions for demand allocation and balancing operational efficiency with crowdsourcing incentives.

1 - Context-Driven Sustainability Metrics for Smes: Smart Decision Frameworks in Resource-Constrained Manufacturing

Akshay Gajanan Khanzode, Indian Institute of Management Visakhapatnam, Visakhapatnam, India

In emerging markets, small and medium-sized manufacturing enterprises (SMEs) are critical nodes in global supply chains, yet they face acute challenges in adopting sustainability practices due to limited resources, technical expertise, and data infrastructure. Traditional ESG frameworks (e.g., GRI, SASB) often overwhelm SMEs with their complexity and misalignment with ground-level realities.

This study proposes a decision-analytic approach tailored to resource-constrained firms by integrating Context-Based Sustainability (CBS) and the MultiCapital Scorecard (MCS)—frameworks that assess environmental and social performance against ecological thresholds and stakeholder expectations. Through detailed case studies from Indian SMEs we demonstrate how SMEs translate abstract sustainability goals into actionable, localized metrics that improved both performance and resilience.

The presentation highlights a five-step playbook to help SME leaders identify material issues, apply open-source metrics, and embed sustainability into operational decision-making. This pragmatic framework bridges the gap between aspirational sustainability and data-informed strategy, offering a scalable model for other emerging market firms.

2 - Carbon Trading and Offsetting with Eco-Conscious Consumer

Lingchunzi Li, Huazhong Agricultural University, Wuhan, China, People's Republic of

This study evaluates the effectiveness of carbon trading and offsetting mechanisms in a market with ecologically conscious consumers, which is vital for informing policy-making and enhancing social welfare. We analyze the interaction between these mechanisms and the impact of consumer environmental awareness on firms' low-carbon investments and pricing strategies in a duopoly market. Using a game-theory model that includes two producers with different emission reduction costs and eco-conscious consumers, we find that both carbon trading and offsetting encourage producers to invest more in emission reduction, with carbon trading leading to higher product prices. However, the integration of carbon offsetting can mitigate this price increase. Our findings challenge the conventional view by showing that in markets with high initial carbon emissions, increasing consumer environmental awareness may actually decrease total social welfare, including both economic and environmental benefits. Conversely, in markets with low initial carbon emissions, a combination of carbon trading and heightened consumer awareness can significantly enhance social welfare. This research addresses critical gaps in understanding the combined effects of carbon trading and offsetting, providing a comprehensive framework for more effective policy design in high energy-consuming industries.

3 - Identifying Trends in Logistics Facilities in Chicago and Their Impact on the Surrounding Communities

Otgondulam Boldbaatar, University of Illinois at Chicago, Chicago, IL, United States, Carla Tejada

The increasing demands of e-commerce and consumer expectations for rapid delivery have led to the growing importance of proximity logistics, prompting companies to position warehouses closer to city centers. While this strategic placement improves logistical efficiency by reducing transportation costs and delivery times, it also brings challenges such as proximity to vulnerable populations, increased exposure to noise and emissions, heightened health risks like asthma, and greater traffic congestion near logistics facilities.

This study examines e-commerce logistics facilities in the Chicago MSA, spanning Illinois, Indiana, and Wisconsin, with data from MWPVL International. To assess societal and environmental impacts, this study follows the methodology developed by Tejada and Conway (2024), identifying vulnerable populations near logistics facilities using variables such as minority status, poverty, unemployment, as well as added factors like car and housing access. The environmental analysis also follows this framework, using three transportation-related indicators: particulate matter 2.5 (PM_{2.5}), diesel particulate matter (DSL_M), and ozone (O₃) with data sourced from the EPA's Office of Environmental Justice. Traffic data was additionally obtained from the Chicago Open Data, which provides historical records for vehicle and truck volumes in the Chicago area.

Preliminary results indicate that in urban areas, e-commerce warehouses and logistics facilities are often located near vulnerable populations. Areas permitting such developments tend to show greater vulnerability than those that do not. Additionally, emissions are higher in low-income, minority communities and decrease in predominantly white, wealthier areas.

4 - Heart for Hearts: Pricing and Donation Strategies in the BoP Market with Prosocial Consumers

Xinyue Cai, Tsinghua University, Beijing, China, People's Republic of, Yongbo Xiao, Tony Cui, Chen Hu

With the growing emphasis on common prosperity and poverty alleviation, the affordability and availability of products in the underserved "Bottom of the Pyramid (BoP)" markets have emerged as a critical public concern. This research explores how firms strategically make optimal decisions by addressing this challenge, with socially responsible initiatives like price markdowns and product donations in the BoP market. In this paper, we examine a firm operating across two markets: the economically developed mainstream market and the less developed BoP market. By implementing markdowns and donations, the firm benefits from the increased willingness-to-pay of consumers in the mainstream market due to their prosocial nature. We analyze how mainstream market consumers' prosociality affects the firm's pricing decisions in both markets and the donation strategy in the BoP market. We uncover an intricate interplay between pricing and donation strategies, where donation can either complement or substitute for price markdown. With moderate consumer prosociality, the firm even charges a lower price together with donations. Surprisingly, our findings reveal that mainstream consumers' prosociality may inadvertently hurt consumers in both markets. We also extend the base model to capture BoP consumers' strategic behavior and examine how it may influence the firm's decision-making and stakeholders' payoffs.

5 - Global Agricultural Trade Under Seasonal and Policy Asymmetries: a Perspective from India's Pulse Imports

Shivam Sharma, Department of Management Sciences, IIT Kanpur, Kanpur, India, Sobhan Arisian, Vipin Balakrishnan, Raghu SENGUPTA

India's rising demand for pulses, driven by a projected population increase of 300 million between 2030 and 2050, shifting dietary preferences toward plant-based protein, and a predominantly vegetarian population, continues to outpace domestic production. Despite being the world's largest producer and consumer of pulses, India remains heavily reliant on imports—particularly lentils from countries such as Australia and Canada. This dependence is exacerbated by seasonal variability in global pulse production, inconsistent domestic yields, and reactive, often asymmetric, trade policy adjustments. These dynamics create significant uncertainty for exporters and introduce inefficiencies into the global agricultural supply chain.

This study examines the interaction between production seasonality and trade policy design in shaping import volumes and domestic market behavior, using India's pulse sector as a focal lens. We develop a sequential game-theoretic model capturing the strategic decisions of profit-maximizing importers and domestic producers under symmetric and asymmetric trade policy scenarios. In particular, we consider key policy mechanisms including simple tariff rate systems, tariff-rate quota (TRQ) systems, and their implementation via licensing and first come-first-serve (FCFS) allocation. These mechanisms introduce differentiated treatment across exporters, shaped by geopolitical factors, bilateral relationships, and domestic supply needs.

The analysis highlights how seasonality in global harvesting schedules and policy asymmetries jointly influence sourcing, production timing, and market outcomes. The framework provides actionable insights for policymakers seeking to balance domestic supply objectives with stable import flows, and for market participants navigating seasonal production asymmetries and evolving policy environments in global agricultural trade.

6 - Socially Responsible Operations for Medical Devices

Zhongxin Hu, Eindhoven University of Technology, Eindhoven, Netherlands, Yeqing Zhou, Christina Imdahl, Zumbul Atan

Access to essential medical devices (MDs) remains a persistent challenge for underserved communities. The World Health Organization estimates that up to 70% of donated equipment in low-resource countries is non-functional or underutilized due to high acquisition costs, inadequate infrastructure, and maintenance barriers. In response to these challenges, we propose a business model in which manufacturers refurbish and rent MDs to resource-limited communities using a pay-per-use (PPU) scheme. Each device has a finite lifetime, and manufacturers must decide when to refurbish in the developed community and how to price usage post-refurbishment in the underserved community. We formulate this decision-making problem as a Markov Decision Process (MDP) under dynamic refurbishment costs. We find structural properties of the optimal refurbishment timing and pay-per-use price. Numerical experiments show that optimal decisions are highly sensitive to the refurbishment cost. The results highlight that strategic timing and pricing in MDs transfer can extend asset utility, reduce waste, and foster a sustainable ecosystem that benefits both communities. Our work offers actionable insights for healthcare authorities and manufacturers seeking scalable solutions to address medical device shortages in resource-limited settings.

1 - Data Envelopment Analysis to Measure the Hospitals Efficiency: a Brazilian Case Study

REINALDO GARCIA, University of Brasilia, Brasilia, Brazil, Raphael Akira Hirata Iwamoto, Sofia André Pereira, Carlos Augusto de Mello Ferraz, Leonardo Gomes Ferreira, Luis Eduardo Weaver

The Brazilian universal public health system (SUS – *Sistema Único de Saúde*, Unified Healthcare System) has not only a budget shortcut but also a continuous growth in demand for healthcare services. It is essential then to identify ways to improve the program's performance without requiring additional investments, prioritizing a more efficient management of available resources. Therefore, the Brazilian Federal Accounting Office (TCU – *Tribunal de Contas da União*) has developed tools to promote efficiency and equity gains in hospital care. This study evaluates the implementation of these tools in Brazilian public hospitals applying the Data Envelopment Analysis (DEA) approach. The data set includes parameters of the number of beds and hours worked by healthcare professionals, geographical location, size, and the management level, among other parameters. The data was collected for about 2,941 hospitals from January 2019 to March 2024. A clustering technique based on Euclidean distance was applied to group hospitals with similar procedures, enabling comparisons among healthcare facilities. The preliminary results show that large hospitals having more than 300 ward beds are more efficient ones when compared with hospitals having less than 50 ward beds.

2 - Multi-Task Learning with Hybrid Feature Selection for Joint Prediction of Nafld and Fibrosis Staging Using Nhanes Data

Elmira Ahmadinedamani, Oklahoma State University, Stillwater, OK, United States, Tieming Liu

Nonalcoholic Fatty Liver Disease (NAFLD) is a major public health concern that can progress to advanced fibrosis if left undetected. We propose a novel machine learning framework that jointly predicts NAFLD status (binary classification) and fibrosis stage (ordinal regression) using data from the National Health and Nutrition Examination Survey (NHANES). Our model employs a Multi-Task Learning (MTL) architecture with CORAL loss to simultaneously optimize both tasks. To enhance interpretability and generalizability, we develop a hybrid feature selection pipeline that combines statistical, information-theoretic, and model-based approaches. This model-agnostic pipeline identifies a compact, clinically meaningful set of predictors by filtering redundant and non-informative features. Across 5-fold cross-validation, the model achieved an average AUC-ROC of 0.944, F1 score of 0.933, and Recall of 0.97 for NAFLD classification. For fibrosis staging, the model obtained a mean squared error of 0.283 and consistent class-wise performance. These results demonstrate strong predictive performance while maintaining interpretability, supporting early screening and risk stratification of liver disease in real-world, imbalanced population datasets.

3 - Using Mathematical Modeling to Understand Spatial Dynamics of Cortical Oxygen Consumption from fNIRS Data

Jun Hu, University of Michigan, Ann Arbor, MI, United States

Functional near-infrared spectroscopy (fNIRS) is a low-cost, portable, and user-friendly neuroimaging tool for detecting hemodynamic responses linked to brain activation via neurovascular coupling. It can be a great tool for building a digital twin of the dynamic brain functions and energy consumption in real-world settings. We introduce a novel methodology based on the laws of conservation of mass to estimate spatially and temporally dynamic oxygen consumption and distribution patterns of the cortical areas of the brain. We first use deep learning to automate motion artifact removal from the resting-state data. We then apply stochastic differential equations and Ito's Lemma to derive geometry-dependent correction factors to estimate concentrations of oxygenated and deoxygenated hemoglobin. We then use the temporal dynamics of the fNIRS data and law of conservation of mass to obtain point estimates of oxygen consumption and flow, and then finally use tessellation techniques and statistical modelling to obtain the spatial dynamics of this data from the point estimates. This data will finally be used to build a deep learning neural networks model to predict hemodynamic activity of the cortical brain. We believe that our work will produce a powerful diagnostic tool for identifying abnormalities in hemodynamic functions. Our early findings show that the estimated oxygen consumption and flow is synchronous with background physiological activity (e.g., heart rate, Meyer waves, etc.), supporting the physiological validity of our model. These results suggest the method successfully captures underlying blood flow dynamics driven by cardiac cycles.

4 - Survival Models for Children with Severe Acute Malnutrition: A Nigerian Case Study

Paul Rubin, Michigan State University, East Lansing, MI, United States, Ricardo Casonatto, Reinaldo C. Garcia, Jennifer Ostrowski, Brianna Eales, Tiago Teixeira, BRIAN CHAPLIN

Adequate nutrition is a critical determinant of health and development being vital for the survival of children under 5 years of age. Globally, an estimated 49 million (7.3%) children had acute malnutrition, with 16 million children being victims of severe acute malnutrition (SAM), accounting for estimated three million child deaths. In particular, it is estimated that 4.4 million children younger than 59 months suffered from acute malnutrition from May 2023 to April 2024 in northeast Nigeria. The SAM cases show failure to receive adequate nutrition due to episodes of diarrhea and other acute illnesses. It is then important to increase the numbers of Community Management of Acute Malnutrition (CMAM) centers in countries having a high prevalence of SAM. The CMAM centers allows to reduce the number of children who develop SAM and death complications. In order to aid the CMAN centers, this work implements statistical methods for survival data analysis including the models of Cox Proportional Hazard (CPH) and the Support Survival Vector Machine (SSVM). This work applies the CPH and the SSVM models to a sample of not only more than 5,000 Nigerian children but also with more than 1,400 initial parameters. These children take part in the Taimaka Program. The models results look very promising having an accuracy rate of over 0.83 and the implemented approaches do not have more than 27 final parameters showing their simplicity and robustness. This project is part of the Informs Pro-Bono Analytics initiative.

5 - A Study of Accessibility to Community Pharmacy Using Mobile Data and Machine Learning Models

Ilker Guven, University of Louisville, Louisville, KY, United States, Lihui Bai, Sumei Zhang

The COVID-19 pandemic exposed significant healthcare disparities, particularly in access to care. On the other hand, pharmacies as accessible healthcare points are known to be visited twice as often as primary care offices. This study aims to identify determinants in access to community pharmacy, thus helping to reduce health disparity. We employ machine learning models (e.g., linear regression, random forest, support vector machines, and multilayer perceptron) to predict annual visits and distance traveled to community pharmacies. Predictors include demographic, socioeconomic and geographic factors, as well as built environment and business features (e.g., distance to highway exits, % of service establishments, total number of establishments, crime rate). Diversity subsampling is used to improve model performance and computational efficiency. We report computational results using 2022 mobile phone data from placer.ai with 37 residential zip codes and 149 community pharmacies in Louisville, KY. Future work will extend the study with block group data in ArcGIS.

1 - A Game-Theoretic Framework for Multi-Player Global Lithium Supply Chain

Sarasadat Alavi, University of Texas at Arlington, Arlington, TX, United States

Lithium, a critical mineral essential for clean energy technologies, has prompted numerous nations and stakeholders to invest in domestic supply chain development to achieve resource independence. However, the complex interplay of tariffs, policies, production costs, and pricing strategies across global markets creates interdependencies that significantly impact individual national optimization efforts. While previous studies have explored optimization models for the global lithium supply chain, limited attention has been given to the strategic interactions among countries and their mutual influence on supply chain design and performance.

This study introduces a novel multi-level optimization framework that captures both strategic and operational interactions within and between multiple decision-making entities (i.e., countries). The proposed framework employs a game-theoretic approach to model the hierarchical nature of decision-making, where each country seeks to optimize its own lithium supply chain while anticipating the responses of others. The focus of this presentation is on formulating a multi-level optimization model and implementing exact solution approaches based on decomposition methods to illustrate causal relationships between nations and quantify their mutual effects on supply chain performance and economic outcomes. Our findings provide valuable insights for policymakers seeking to navigate the complex trade-offs between national resource security and economic efficiency in the global lithium market.

2 - Vector-Valued Games: Characterization of Equilibria in Matrix Games

Giovanni Crespi, Università Cattaneo LIUC, Castellanza, Italy, Daishi Kuroiwa, Matteo Rocca

In this work, we investigate equilibrium concepts for games with vector-valued payoffs, focusing on Nash, weak Nash, and proper Nash equilibria. We provide a general framework for defining these equilibria using cone-based vector orderings, and we explore the relationships among them. Existence results are established through fixed-point theorems and scalarization techniques, allowing us to represent vector preferences via weight vectors and scalar-valued functions.

In the special case of vector-valued matrix games, we show that proper and classical Nash equilibria coincide, and we provide existence results for both Nash and weak Nash equilibria. We further characterize best response correspondences by constructing functions from the payoff matrices and the players' preference cones, showing how these can be used to identify all equilibrium points.

For two-player, two-strategy, two-objective matrix games, we develop a complete classification of best correspondence sets using convex analysis and scalarization. This leads to an explicit description of all possible equilibrium regions in the mixed strategy space.

Our approach provides a systematic method for analyzing multi-objective strategic interactions, with applications ranging from environmental management to negotiation and public policy. The results offer theoretical insight and computational tools for identifying equilibrium behavior in settings where players face multiple, possibly conflicting, objectives.

3 - Solving Markov Games with Coupled Local Constraints via Dual Gradient Descent

Ceyhun Eksin, Texas A&M University, College Station, TX, United States, Soham Das, Santiago Paternain, Luiz Chamon

We introduce a dual gradient descent method to solve Markov games subject to local but coupled constraints. These constrained Markov games (CMGs) model multiagent systems operating in dynamic environments where each agent seeks to maximize its individual utility while respecting specific local constraints. These constraints, which capture real-world limitations such as resource budgets or safety requirements, are local in the sense that they pertain to individual agents but are coupled through dependencies on other agents' actions and the shared environment state. Our approach builds on the concept of the unconstrained Lagrangian game, which agents repeatedly solve based on the current values of their own local Lagrange multipliers. Agents simulate trajectories to estimate cumulative rewards and constraint violations, then adjust the multipliers using a dual gradient step grounded in their local observations. This primal-dual process produces a sequence of policy profiles that converge to a nonstationary and feasible Nash equilibrium of the original constrained game. This work extends previous frameworks for solving Markov games with global constraints, providing a principled approach to safe multiagent learning under localized, interdependent feasibility conditions.

1 - A Similarity Based Method Against ChatGPT Based Plagiarism

Petros Xanthopoulos, Stetson University, DeLand, FL, United States, Konstantinos Xylogiannopoulos, Panagiotis Karampelas, Georgios Bakamitsos

Large language models (LLMs) have found many profound applications and for many are necessary tool that boosts productivity. At the same time they enable several malicious applications with plagiarism and copyright infringement being one of them. In this presentation we show examples of ChatGPT paraphrased news articles, we capture the inability of AI detectors to detect these paraphrases and we propose a similarity based approach for tackling this emerging problem. We demonstrate our method with a database of real news articles from a major international news vendor. Our proposed method achieves performance of over a set of characteristic classification performance metrics such as accuracy, sensitivity, specificity and F1 statistic.

2 - Collaboration and Knowledge Sharing in Teams: a Graph-Based Deep Learning Approach

Qianyin Xia, Georgia State University, Atlanta, GA, United States, Yi Zhao, Sarang Sunder

Collaboration and knowledge sharing are foundational to modern organizations, especially in environments where teamwork drives performance. However, understanding how individuals contribute to and learn from multiple teams remains empirically and methodologically challenging. This paper introduces a Two-Stage Hypergraph Neural Network (TSHyGNN) framework to model agent behavior in multi-agent, multi-team settings. Leveraging hypergraph structures, the model captures both within-team collaboration and cross-team knowledge transfer. To address endogeneity in team formation, we adopt a two-stage estimation approach: the first-stage hypergraph model predicts team formation and produces a correction term, which is incorporated into the second-stage performance model to account for selection bias. Using salesforce data from a large financial services firm, we show that TSHyGNN outperforms traditional econometric and network-based models in predicting team outcomes. Simulation results suggest that replacing a novice with an experienced salesperson can generate approximately \$10K in direct team collaboration gains and \$16K from knowledge spillovers across teams, with sales increasing by 1-3%. The deep learning architecture is designed to be interpretable by aligning its components with collaboration and knowledge-sharing processes. This approach offers a scalable and flexible tool for team design, with broad applicability to settings characterized by overlapping team structures and dynamic collaboration networks.

3 - Syngene: a Knowledge Graph Framework for Root Cause Analysis in Regulated Life Sciences Manufacturing

Darshan Desai, Quantic School of Business and Technology, Washington DC, DC, United States, Manashri P. Vyas, Ashish Desai

Timely and accurate root cause analysis (RCA) is essential in life sciences-related manufacturing industries such as pharmaceuticals and medical devices, where quality deviations can lead to costly recalls, regulatory scrutiny, and public health risks. Yet RCA processes remain largely manual, relying on siloed systems and time-intensive expert investigations, making it difficult to maintain traceability, audit readiness, and fast decision-making when it matters most.

To help close this gap, we introduce a data-centric framework that combines knowledge graph traversal and rule-guided reasoning to automate RCA. The system, called SynGene, constructs a process graph based on ISA-88/95 principles, linking batches, materials, equipment, operators, lab tests, and deviations into a cohesive structure. SynGene's traversal agent identifies causal pathways through multi-hop queries, surfacing contamination risks and compliance issues with high interpretability. Unlike black-box approaches, it builds on logic-driven methods and domain-specific ontologies to provide transparent, auditable insights.

Evaluation on a synthetic benchmark designed to reflect common batch genealogy structures and deviation types in life sciences manufacturing showed that SynGene significantly reduced RCA effort and response time in simulated quality incident scenarios. The traversal agent identified failure pathways in under 10 minutes, compared to manual trace-style queries that required substantially more time and domain knowledge. The system accurately identified affected batches across multi-hop failure chains, and its visual outputs including failure propagation paths and node clusters enhanced interpretability and supported audit readiness. This work illustrates how graph-based, domain-aligned representations can advance decision automation in regulated industries, with broad applicability across life sciences manufacturing.

4 - Inducing Interpretability In Deep Learning via Scalable, Kernel-Based Density Estimation

Ayyuce Begum Bektas, Sloan Kettering Institute, New York, NY, United States, Mithat Gonen

Interpretability remains a central concern in deep learning applications across healthcare, finance, and autonomous systems where transparency is essential. We introduce a scalable method that incorporates random Fourier features with softmax-weighted kernel density estimation into a unified learning objective. This construction enables efficient approximation of kernel evaluations while emphasizing structured density modeling. We conduct a sensitivity analysis on the dimensionality of the mapped space to characterize its effect on computational cost. The framework also allows the integration of multiple kernels within a single model, enabling distinct treatment of heterogeneous feature sets such as gene groups or modality-specific inputs. The method is evaluated in a conditional density estimation setting using real world data, demonstrating competitive predictive performance alongside interpretable behavior.

5 - An AI Approach for Learning the Spectrum of the Laplace-Beltrami Operator

Yulin An, Penn State University, State College, PA, United States, Enrique Del Castillo

The spectrum of the Laplace-Beltrami (LB) operator is central in geometric deep learning tasks, capturing intrinsic properties of the shape of the object under consideration. The best established method for its estimation, from a triangulated mesh of the object, is based on the Finite Element Method (FEM), and computes the top k LB eigenvalues with a complexity of $O(Nk)$, where N is the number of points. This can render the FEM method inefficient when repeatedly applied to databases of CAD mechanical parts, or in quality control applications where part metrology is acquired as large meshes and decisions about the quality of each part are needed quickly and frequently. As a solution to this problem, we present a geometric deep learning framework to predict the LB spectrum efficiently given the CAD mesh of a part, achieving significant computational savings without sacrificing accuracy, demonstrating that the LB spectrum is learnable. The proposed Graph Neural Network architecture uses a rich set of part mesh features —including Gaussian curvature, mean curvature, and principal curvatures. In addition to our trained network, we make available, for repeatability, a large curated dataset of real-world mechanical CAD models derived from the ABC dataset (Koch et al., 2019) used for training and testing. Experimental results show that our method reduces computation time of the LB spectrum by approximately 5 times over linear FEM while delivering competitive accuracy.

6 - Toward Precise Sleep Apnea Screening: a Sound-Based Approach via Temporal Anchor Contrastive Learning and Synergistic Distillation

Fulin Cai, Arizona State University, Tempe, AZ, United States

Obstructive sleep apnea (OSA) is a common sleep disorder associated with serious cardiovascular and metabolic risks, yet it remains widely underdiagnosed due to the cost and inconvenience of in-lab polysomnography. Recent studies have explored deep learning (DL)-based screening using ambient audio recordings as a contactless and scalable alternative. However, existing segment-based detection models struggle to precisely delineate apnea event boundaries, which is essential for estimating apnea duration—an increasingly recognized clinical biomarker.

Accurate delineation of OSA events requires models that can address two core challenges: temporal variation in respiration patterns and ambiguous transitions between respiratory states, where changes occur gradually rather than abruptly. To address these issues, we propose TACO-SynD (Temporal Anchor Contrastive learning with Synergistic Distillation), an auxiliary DL module for second-level OSA detection using sleep sound recordings. Built on a second-level classification model, TACO-SynD introduces: (1) temporal anchor contrastive learning, which aligns latent representations to context-specific breathing patterns, and (2) synergistic distillation, which transfers localized relational knowledge to enhance the global classifier.

A comprehensive evaluation is conducted on the real-world PSG-Audio dataset across both OSA screening and event detection tasks. TACO-SynD achieves state-of-the-art screening performance with mean absolute errors of 6.41 for AHI and 1.33 for MAD, along with superior event-level alignment and boundary localization. These results demonstrate the framework's robustness and potential as a scalable solution for in-home OSA monitoring.

7 - An Image-Based Deep Learning Approach for Precise Sorting of Knitted and Woven Textiles

Md Abdul Quddus, North Carolina State University, Raleigh, NC, United States, Yihan Huang, Karen Leonas

The rapid growth of the textile industry has led to a significant increase in textile waste, posing serious environmental and resource challenges. Traditional sorting methods are often labor-intensive, slow, inaccurate, and difficult to scale sustainably. In contrast, computer vision and deep learning techniques offer a promising alternative by enabling automatic feature extraction from complex data, achieving high classification accuracy and supporting scalable, real-time sorting using spectral and visual inputs. Our research aims to develop a practical, production-ready solution for textile recycling facilities by leveraging real-world image data collected from both high-resolution scanners and mobile phone cameras. To enhance generalization across these heterogeneous data sources, we will develop an advanced deep learning architecture customized for fabric structure classification. This approach allows models to be trained collaboratively across decentralized devices without the need to pool sensitive or device-specific data, making the system more robust to variations in lighting, resolution, and device quality. By combining advanced AI algorithms, textile domain expertise, and a diverse image dataset, we will create a reliable and efficient system to classify fabric structures such as Plain Weave, Jersey Knit, Rib Knit, Tricot Knit, and related variants with high accuracy. The outcome will be a scalable, intelligent fabric-sorting system that addresses a critical bottleneck in textile recycling, improves material recovery quality, and promotes a more sustainable circular economy.

Innovation, Incentives, and Behavior in Platform Ecosystems

Contributed Session

Contributed

Chair: Lahiru Gunasekara, Lincoln University, Lincoln, 7647, New Zealand

1 - Strategic Data Acquisition and Pricing Decisions in Platform Competition with Data Broker Collaboration

Jingjing Li, Tianjin University, Tianjin, China, People's Republic of, Haiyang Feng

As a tradable and strategic asset in the digital economy, data has driven the rapid development of a thriving data brokerage industry. The rapid emergence of the data brokerage market has fundamentally reshaped how firms compete and create value. Data brokers aggregate and analyze vast datasets, which are then distributed to client firms for targeted advertising and personalized pricing. Collaborating with data brokers has become a strategic lever for firms seeking competitive advantages in the advertising market. However, this practice also raises significant privacy concerns while simultaneously intensifying market competition among firms. To investigate firms' decisions regarding data acquisition and service pricing, this study develops a game-theoretic model that considers two horizontally differentiated firms. The results demonstrate that the firm with superior data analytics capability reduces data acquisitions as the unit price of data increases, while the firm with weaker capability exhibit a non-monotonic purchasing behavior—initially decreasing and then increasing their data demand as data price escalates. A counterintuitive finding reveals that when advertising revenue per user is high and unit price of data is relatively low, the firm with weaker analytics capability tends to set a higher price. Furthermore, under higher data purchasing price, the firm with stronger analytics capability purchase larger volumes of data, attract more users, and achieve higher profits compared to its less analytically capable counterpart. Conversely, in instances of low data price, a scenario of market dominance by stronger analytics capability company emerges, leading to a winner-takes-all outcome.

2 - A Framework for Identifying Causal Structures of AI Service Failures Using Text Mining and Network Analysis

Su-Yeon Kim, Incheon National University, Incheon, Korea, Republic of, Do-Hyeon Ryu

Artificial intelligence-based services (AIS) use autonomous learning and adaptive capabilities to predict user behavior and deliver personalized experiences. The increasing use of AIS coincides with heightened awareness of unintended social, ethical, and operational risks. These risks often materialize as service failures, such as biased outputs, or security breaches. Prior research has focused on categorizing failure types, providing limited understanding of the causal structures underlying the emergence and propagation of such failures. Without this causal insight, organizations are unable to trace causes, resulting in repeated failures or inefficient resource allocation.

This study presents a framework to identify causal elements and their interrelations underlying AIS failures. Based on the Failure Mode and Effects Analysis (FMEA), a three-step structure cause – failure – effect was adopted to guide the extraction process. Failure types were defined from prior literature into four categories: function, security, information, and interaction. Over 15,000 news articles were embedded using Sentence-BERT and classified accordingly. For each failure type, a multi-turn Question Answering model was applied to sequentially extract failures, causes, and effects using tailored queries designed in accordance. The extracted elements were assembled into a causal network, where analysis identified high-centrality nodes, major propagation paths, and clustered failure patterns.

The analysis revealed that AIS failures commonly result from complex interactions among multiple factors rather than singular causes. The proposed framework reveals latent causal structures and identifies high impact paths and key triggers. This insight enables organizations to anticipate how failures propagate, prioritize points of

intervention, and develop targeted mitigation strategies.

3 - Digital Consumption and Self Control

Zheng Wu, Purdue University, West Lafayette, IN, United States, Jiong Sun

The rise of digital vice goods—such as social media, streaming platforms, and video games—has heightened concerns over consumer self-control, as these services often promote impulsive and habitual use. Excessive engagement is linked to negative mental health outcomes, prompting policymakers to advocate for pre-consumption planning as a behavioral intervention. Our study develops a theoretical model to examine how firms price digital vice goods using subscription versus pay-per-use schemes, accounting for consumers with present-biased preferences. We analyze how these pricing strategies interact with product harm and consumer self-control to shape firm profit, consumer welfare, and public health outcomes. Our findings show that pricing digital vice goods differs markedly from standard goods due to behavioral frictions. Without pre-planning, firm profits decline with rising harm. However, when consumers engage in pre-planning, firms can benefit from market segmentation. Interestingly, while pre-planning is often seen as consumer-friendly, we find that some adopting pre-planning may reduce consumer surplus and worsen public health. These results offer practical insights for firms, consumers, and policymakers seeking to design effective pricing strategies and interventions in digital markets.

4 - Gig OR Employee? Platform's Joint Staffing and Pricing Decisions Under Hybrid-Staffing Mode

Xuyan Xin, University of California, Los Angeles, Los Angeles, CA, United States

In the rapidly evolving landscape of on-demand services, platforms are increasingly adopting a hybrid-staffing mode that combines full-time employees with part-time gig workers. This approach leverages the stability of full-time staff and the flexibility of gig workers, enabling platforms to efficiently meet fluctuating consumer demands. To identify optimal staffing and pricing strategies, we develop a two-period model analyzing these joint decisions. Our findings highlight several key insights. First, the platform's staffing choice is influenced by employee salary costs and the labor pool size of gig workers. When both factors are moderate, a hybrid-staffing mode is optimal. Additionally, as the frequency and intensity of demand surges increase, platforms are more inclined to adopt a hybrid staffing approach. Second, within the hybrid staffing framework, gig workers can fulfill multiple roles. They not only act as supplementary resources during peak hours but also maintain operational flexibility in both high and low demand states in some cases. This dual role necessitates adaptive hiring and pricing strategies, which may exhibit non-monotonic patterns in response to market changes. Third, platforms consistently benefit from hybrid-staffing, achieving higher profits compared to single-staffing mode. Moreover, this mode enhances labor and consumer welfare, consistently outperforming gig-only approach. Our study offers valuable insights for platforms to optimize hybrid staffing and pricing strategies, emphasizing the impact on stakeholder welfare within the ecosystem.

5 - Do Subsidies Shape Channels? the Role of Differentiated Incentives in New Energy Vehicle Channel Design

HELI ZHANG, Institute of Operations Research and Analytics, National University of Singapore, Singapore, Singapore, Yexia Zhang, Cejun Cao, Zhongzhu Chu, Mabel C. Chou

Given the global popularity of new energy vehicles (NEVs), a paramount problem for the NEV manufacturer is to consider the selling format and decide whether to encroach on the reseller by setting up a direct channel under differentiated government subsidies. In this paper, we first empirically examine the relationship between government subsidies and NEV manufacturers' channel strategies based on data from the Chinese NEV market. Then, a game-theoretical model is established to investigate these interactions between different channel structures and three types of government subsidies: no subsidy program (NSP), sale-price subsidy program (SSP), and technology subsidy program (TSP), considering heterogeneous consumer preferences. Empirical results reveal that the TSP significantly reduces the number of direct-selling stores but has no significant impact on the number of resellers, whereas the SSP significantly reduces the number of resellers without impacting direct-selling stores. Theoretical findings indicate that prices under the SSP are higher than those under the NSP and TSP, and SSP enhances profits for both manufacturers and retailers when only reselling channels exist. In the TSP, encroachment is favorable for manufacturer only when cross-price competition degree is low, and the TSP proves more effective in increasing social welfare when only a direct channel exists. Both SSP and TSP can stimulate consumer demand to an equal extent but operate through different mechanisms. Our study provides useful insights for the NEV manufacturer to make channel distribution choices and for the government to design subsidy schemes.

6 - Kick Out Innovation: Explore the Conditions Where Innovation Cannot Invade in Competitive Market

Songhan Wu, University of Illinois Urbana-Champaign, Urbana, IL, United States

The introduction of radical innovations frequently disrupts existing markets, yet the mechanisms governing their adoption remain complex and multifaceted. While prior research has primarily focused on binary adoption decisions within monopolistic settings, this study extends the framework by examining how social comparison influences the diffusion of radical innovations in competitive markets with multiple incumbents. Drawing on evolutionary game theory, we model consumer decision-making under ahead-seeking and behind-averse behaviors, revealing the conditions under which innovations succeed or fail. Unlike findings in monopolistic contexts, our results reveal that excessive ahead-seeking behavior can suppress innovation, whereas moderate behind-averse behavior can drive convergence toward a particular product (probably the compromise one). These insights challenge conventional wisdom on social pressure and innovation diffusion, offering a fresh perspective on how competitive structure and psychological effects shape market dynamics.

7 - Optimising Retailer-Level Take-Back Systems for Low- and Medium-Value Used Products for a Circular Economy

Lahiru Gunasekara, Lincoln University, Lincoln, New Zealand, David Robb

Used product take-back plays a significant role in the transition to a Circular Economy. Many businesses are introducing retailer-level take-back schemes for low and medium-value products by deploying collection bins for customers to drop off used products. However, the literature has not given much attention to these schemes compared to those with high recovery value products. The viability of such schemes depends on several factors, including the volume of returns and the contamination in the collection bins. We consider a two-echelon reverse supply chain consisting of a retailer taking back low and medium-value used products and delivering them to a recycler for value recovery. We mathematically model the optimal retailer decisions, including the return incentive paid to customers, investment in contamination reduction, the number and capacity of bins, their product assignment, and time between shipments from the retailer to the recycler, and apply the optimisation model to a case study. In addition, our numerical experiments with globally representative parameter value combinations provide generalisable insights for theory and practice. For example, recycling low-value products like plastic containers is economically infeasible for retailers under all conditions. However, including at least one medium-value product, such as apparel, in a take-back programme aids in offsetting its costs. Investing in reducing contamination for any product type is financially unwarranted unless the costs of separation and disposal exceed that of contamination reduction investment. Furthermore, combining multiple product streams into fewer bins could improve financial results, but keeping bins separate may offer psychological benefits to users.

AI-Driven Innovation in Supply Chain and Business Process

Invited Session

Artificial Intelligence

Chair: Huihui Chi, NEOMA business school, Mont-Saint-Aignan, France

Co-Chair: Jaecheol Park, Nanyang Technological University, Singapore, N/A, Singapore

1 - A Framework for Human-AI Collaboration for Theory Building

Ke Li, INSEAD, Fontainebleau, France, Philip Parker, Phanish Puranam, Eric Uhlmann, Spyros Zoumpoulis

We propose a novel human-AI collaborative framework for theory building. Human researchers are adept at generating creative hypotheses but are prone to biases. Machine learning (ML) models can identify robust empirical patterns but lack explanatory reasoning. Recent advances in generative AI (GenAI) offer a third capability:

the ability to simulate abductive reasoning and generate hypotheses—though they risk producing hallucinations.

Our framework integrates the strengths of human judgment, ML-driven pattern discovery, and GenAI-generated explanation through a structured process. Focusing on inequality discourses (e.g., gender, race, and socioeconomic disparities), we leverage both human intelligence and AI to examine how these inequality discourses spread across different historical periods, societies, and social sectors.

We address two core research questions: (1) How accurately can humans, compared with GenAI models, generate hypotheses about empirical patterns? and (2) How can collaboration between humans, ML, and GenAI improve theory building?

We present results from a pilot forecasting survey comparing the accuracy of individual and aggregated human forecasts to the accuracy of state-of-the-art GenAI models, drawing insights into the value of GenAI and collective human intelligence for theory building. We argue that human–AI collaboration offers a potential solution to challenges in science, including theory fragmentation and the replicability crisis.

2 - Designing for Designers: a Multimodal Hypergraph Rag System to Enhance Automotive Design

Xiaoke Zhang, University of British Columbia, Vancouver, BC, Canada, Mi Zhou, Gene Moo Lee, Angela Kwon

The growing adoption of large language models (LLMs) across industries highlights the need for domain-specific systems that leverage an organization's proprietary knowledge. In the automotive sector, general-purpose LLMs often lack specialized expertise and may produce irrelevant or misleading outputs, hindering vehicle designers' creative processes. To address these challenges, we partner with Kia, a leading automotive manufacturer in South Korea, to develop a designer-oriented, multimodal hypergraph retrieval-augmented generation framework for vehicle concept ideation. Our framework consists of two core components. First, we construct a custom hypergraph knowledge base that captures complex relationships between customer feedback (text modality) and design assets (visual modality). Second, we design an interactive chatbot interface that accepts both free-form text and image inputs, retrieves relevant subgraphs from the knowledge base, and generates contextually grounded responses. We plan to evaluate the prototype through randomized online experiments and user studies involving Kia's design teams. This work will contribute to design science by proposing a scalable method for multimodal knowledge representation and demonstrating how interactive AI tools can support domain-specific creative exploration.

3 - How Does AI Change Drug Development? Evidence from Clinical Trial Phases and Drug Types

Angela Kwon, University of British Columbia, Vancouver, BC, Canada, Jaecheol Park, Gene Moo Lee

We examine how the AI capabilities of pharmaceutical firms affect their drug development processes, with a focus on clinical trials. Clinical trials test the safety and efficacy of drug candidates on human subjects across three phases. While the first two phases (Phases I & II) assess preliminary safety and efficacy in smaller populations, the last phase (Phase III) investigates thorough effectiveness in larger populations prior to post-market surveillance. To examine the effect of the AI capabilities of firms on clinical trial outcomes, we leverage job postings data and clinical trial records provided by the U.S. National Library of Medicine. Our findings suggest that AI capabilities have significant effects on the quantity of clinical trial outcomes (total trials, new trials, and retrials). To further explore underlying mechanisms, we delve into detailed trial process outcomes: (1) trial duration as a proxy for the pace of clinical progress; (2) inter-phase transition time for the preparation between phases; and (3) success rate for the probability that a drug candidate progresses to the next phase. Moreover, we find the heterogeneous effects across drug types and trial phases. This study contributes to the healthcare IS literature by empirically demonstrating the business value of AI in enhancing drug development processes. It also provides practical guidance on AI investment and implementation for pharmaceutical firms, regulatory agencies, and policymakers.

1 - Magic: a Multi-Task Gaussian Process for Joint Imputation and Classification in Healthcare TIME Series

Dohyun Ku, Georgia Institute of Technology, Atlanta, GA, United States, Catherine Chong, Visar Berisha, Todd Schwedt, Jing Li

Time series analysis in healthcare has become instrumental in improving both care quality and predictive analytics. The ability to forecast disease progression and mortality risks can offer substantial life-saving benefits to patients. However, healthcare time series data often presents two critical challenges: time misalignment and data sparsity. Traditional approaches address these challenges through a two-step process: first imputing missing values, then predicting the response variable. The primary limitation lies in its inability to leverage class label information during imputation and its independent parameter optimization. We present the **Multi-task Gaussian Process for joint Imputation and Classification (MAGIC)**, a novel framework that simultaneously performs missing value imputation and class label prediction. Our innovative approach leverages class label information to enhance imputation accuracy through Multi-task Gaussian Process model, which in turn improves the reliability of subsequent predictions. By integrating imputation and classification within a single framework, MAGIC enables real-time predictions of both future variable trajectories and disease progression patterns. This capability facilitates early disease detection and proactive strategies that can significantly impact patient care decisions and treatment outcomes. We validate the model through two healthcare applications: 1) prediction of post-traumatic headache after mild traumatic brain injury, and 2) prediction of in-hospital mortality within 48 hours of ICU admission. In both applications, MAGIC demonstrated superior predictive accuracy compared to existing methods.

2 - Constructing Optimal Patent Datasets for An Effective Patent Analysis: a Multi-Objective Optimization Framework

Doyoung Park, Seoul National University, Seoul, Korea, Republic of, Sungjoo Lee

As data-driven technology management is getting increasing attention, patent data has been recognized as a critical source of technological knowledge. While the effectiveness of patent analysis largely depends on how well the dataset is constructed prior to use, little attention has been paid to validating the quality of the collected datasets in terms of the objective of analysis. In this study, we focus on technology trend analysis, technology opportunity analysis, and patent quality analysis as the objectives of patent analysis. Then, we aim to propose a dataset construction framework with the aim of evaluating and filtering patent data based on different objectives of analysis. To achieve the aim, a domain-specific filtering process is first applied to eliminate noise to ensure alignment between the collected patents and the intended analysis domain. Second, key components that shape the objectives of each patent analysis are identified. Third, a multi-objective optimization process is employed to maximize or minimize the identified components based on different analysis objectives. The optimization problem leverages patent metadata including citation counts, assignee information, and family size, and identifies efficient frontiers among the different objectives. By evaluating and refining patent datasets, the proposed approach can enhance the relevance, reliability, and strategic value of patent analysis.

3 - Considering Overdiagnosis in Cancer During Computer-Aided Diagnosis Decision Making

William Brown, Louisiana State University, Baton Rouge, LA, United States, Evangelos Triantaphyllou

Overdiagnosis is an emerging area of concern within healthcare. Overdiagnosis is when an individual is diagnosed with a disease, but they will never be harmed or have symptoms of it, which causes unnecessary stress. Such a disease is detected through asymptomatic screening, which is becoming increasingly popular with the use of Computer-Aided Diagnosis (CAD), especially for cancers such as breast, prostate, and lung cancer. Overdiagnosed cases are not false-positives because the affected

patients have the disease, but it may be an indolent or slow-growing disease. It is not possible to distinguish between overdiagnosis and successful treatment currently, thus the prevalence of overdiagnosis inflates the success rate of treatments. Overdiagnosis can be observed in a population screened for cancer because cancer is usually fatal if untreated. Therefore, if a cancer screening program is introduced to a population and there is a large increase in the incidence rate, but a relatively stable or slightly reduced mortality rate over an extended time, then it indicates that overdiagnosis has occurred. This phenomenon is often mentioned in medical literature along with CAD. However, although CAD is frequently mentioned in computer science and engineering literature, overdiagnosis is scarcely mentioned. This is concerning because CAD is increasingly used for asymptomatic screening. CAD developers need to begin to implement data mining approaches to offer prognostic information for detected cancers, along with the binary classification of cancer. Such prognostic information can help healthcare professionals and patients make better decisions about treatment options, which can reduce the harm of overdiagnosis.

4 - Advancing Heart Failure Readmission Prediction Through Feature Augmentation and Stratified Machine Learning

Sonia Jahangiri, Rochester Institute of Technology, Rochester, NY, United States, Nasibeh Azadeh-Fard

Reducing hospital readmissions for heart failure (HF) remains a national healthcare priority. While machine learning (ML) models have demonstrated promise in predicting HF readmissions, challenges persist in enhancing model accuracy and ensuring equity across patient subgroups. This study aims to improve HF readmission prediction by incorporating additional clinically relevant features and conducting stratified analyses. We extend an existing ML framework by engineering new features, such as procedure codes and other underutilized variables, to capture more nuanced aspects of patient care. Statistical methods will be employed to identify significant predictors, which will then inform a heuristic feature selection process. A range of ML algorithms will be applied to evaluate the impact of the expanded feature set on prediction performance. To further explore disparities, stratified models will be developed for key subgroups, including HF subtypes and gender. These subgroup analyses are designed to uncover distinct risk profiles and improve the personalization of readmission prediction. The anticipated outcome is a more robust, generalizable, and equitable prediction framework that supports data-driven interventions for at risk patients.

5 - Incremental Learning with Multi-Group Data Stream for Diabetic Retinopathy Prediction

Enrico Laoh, Oklahoma State University, Stillwater, OK, United States, Tieming Liu

Diabetic retinopathy (DR), a leading cause of blindness, disproportionately affects rural U.S. populations due to limited access and low compliance with annual eye exams. Many patients remain undiagnosed as DR shows no early symptoms, despite underlying damage. While AI-based image screening aids early detection, it remains costly and inaccessible for many. This highlights the need for a non-image-based DR screening model using routine clinical data—already available at no extra cost—to enable wider, earlier, and more equitable detection. The Incremental Learning with Multi-Group Data (IL-MGD) framework is proposed in this study to lower the computational burden and completely retrain the model when new data becomes available. The IL-MGD dynamically integrates continuous data updates, enhancing its robustness and relevance. IL-MGD robustness was tested in this study, and a thousand data subsets were generated nationwide from hospitals in the Cerner Real World Data (CRWD) Warehouse. The result demonstrated high accuracy and robust performance of the Gaussian naïve Bayes model, tested under a thousand model-building trials including different dataset variations, with mean accuracy rates of 97.08% and F1-scores around 97.98%, reduced only around 2% from the best offline neural-based model could achieve. With the performance metrics standard deviation below 1%, the framework shows consistency in the prediction. In addition, the framework allows the model to build in under 90 seconds on average, which is around a 94% time reduction compared to the fastest online neural-based model could achieve. These notable potentials make the IL-MGD potentially a scalable and sustainable tool for early DR detection.

6 - Profiling Depression Risk Groups Among Students Using Pca and Cluster Analysis: Identifying Hidden Risk Patterns in Lifestyle and Academic Stress Factors

Neda Amirirad, Binghamton University, Binghamton, NY, United States, Suxia Lu

Depression among university students is a complex issue that demands systematic, data-driven methods to uncover underlying risk groups. In this study, we analyzed survey data from 12,690 students using Principal Component Analysis (PCA) for dimensionality reduction, followed by K-Means clustering to identify distinct subpopulations. Nine psychosocial and behavioral variables were included, such as academic pressure, satisfaction, financial stress, sleep duration, and dietary habits. PCA reduced the data to six principal components, capturing approximately 88% of the total variance. Cluster validation through silhouette scores and the Elbow method indicated that a three-cluster solution was optimal. The identified groups were: (1) a *High-Risk* cluster, characterized by high academic and financial stress and low satisfaction; (2) a *Low-Risk* cluster, with balanced lifestyle behaviors and positive mental health indicators; and (3) a *Hidden Risk* cluster—students with strong academic performance but poor sleep and dietary habits. These results highlight that academic success does not necessarily equate to psychological well-being. Our findings demonstrate the utility of unsupervised learning techniques in revealing latent risk profiles and can inform targeted mental health interventions for student populations.

Real-World Data Analytics and Optimization for Improving Power Grid Operation, Planning, and Resilience

Invited Session

Data Mining

Chair: Zhaoyu Wang, Iowa State University, 2520 Osborn Drive, Ames, IA, 50011, United States

1 - Data-Driven Methods for Improving Distribution System Planning and Operations

Joe Azzolini, Sandia National Labs, Albuquerque, NM, United States

Electric power distribution grids are undergoing significant changes due to increased electrification and the deployment of distributed generation. Conventional analysis methods require distribution system planners and operators to conduct time-consuming simulations on detailed grid models, which are often created and maintained manually. Fortunately, there has been a steady increase in the number of measurement devices on the grid—from residential smart meters to intelligent switches on the medium-voltage system—that generate data at much finer temporal and spatial resolutions. This presentation will discuss how we leverage this data to provide distribution engineers with data-driven alternatives to conventional model-based analyses.

2 - TBD

Rui Yang, National Renewable Energy Lab, Denver, CO, United States

3 - Proactive Planning for Distribution System Resilience Under Uncertainty

Shixiang Woody Zhu, Carnegie Mellon University, Pittsburgh, PA, United States

Distribution systems face growing threats from extreme events such as wildfires, requiring decision frameworks that balance risk mitigation with operational costs. In this talk, I present two recent projects. The first analyzes wildfire resilience interventions—Public Safety Power Shutoffs (PSPS) and Enhanced Powerline Safety Settings (EPSS)—quantifying their effectiveness in reducing ignition risks and their social and operational trade-offs. The second develops an adaptive robust optimization framework that jointly considers proactive measures (e.g., hardening, de-energization) and reactive actions (e.g., restoration), adapting uncertainty sets to evolving conditions. Together, these approaches highlight how robust, adaptive, and socially responsible strategies can enhance grid resilience under deep uncertainty.

4 - Revenue Adequacy-Constrained Optimal Transmission Switching: a Non-Iterative Milp Formulation

Bai Cui, Iowa State University, Ames, IA, United States

Optimal Transmission Switching (OTS) provides a promising approach to enhancing grid efficiency and mitigating congestion while challenging revenue adequacy (RA) in Financial Transmission Rights (FTR) markets, as traditional Simultaneous Feasibility Tests (SFT) rely on static network topology assumptions. To address the optimization of the original model incorporating line-switching variables and its dual variables under RA constraints, a RA-constrained optimal power flow model, referred to the OTS-based optimal price flow formulation (OTS-OPrF), is developed to enable the co-optimization of network topology and generation. By integrating binary transmission variables into the Karush-Kuhn-Tucker (KKT) conditions, the model reformulates Locational Marginal Prices (LMPs) and converts the problem into a

unified Mixed-Integer Linear Programming (MILP) formulation. The behavior of LMPs parallels DC circuit laws, and differences in LMPs can be captured through information on network topology, line susceptance, and the identification of congested lines. This approach eliminates the need for the iterative-based method, significantly reducing computational burden while maintaining solution precision. Case studies on IEEE 39-bus, 118-bus, and 300-bus systems demonstrate the effectiveness of the model, with computational efficiency improvements ranging from 45.33% to 93.80% compared to iterative methods.

1 - Web-Based User Interfaces for Mathematical Models to Support Decisions: the Fuel Distribution Network Optimizer

Walid Matar, King Abdullah Petroleum Studies and Research Center, Riyadh, Saudi Arabia, Pavithra Shetty, Abeer Aghamdi, Nourah Alhosain, Jaidaa Alidrisi, Amr Alruthai, Abdelrahman Muhsen, Lama Yaseen

Mathematical models provide quantitative analyses that can inform policy decisions. We argue that two attributes can support models' adoption by policymakers: an intuitive graphical interface and active engagement between modelers and policymakers. Graphical interfaces make models accessible to non-specialists. Web-based implementations of such interfaces are preferred because they simplify the deployment of updates to the underlying software. Likewise, they minimize disruptions to the end-users when model updates are deployed. Also, active engagement between modelers and policymakers is essential to build trust. End-users may be involved in different stages of model and interface development. We exemplify these attributes in an optimization model and web-based interface framework we developed to support decisions pertaining to the refined fuels' distribution in Saudi Arabia. The model's end-users were involved during model parameterization, advised on model constraints, and helped with developing the inputs and outputs screens of the interface. They were also crucial during the model validation process.

2 - Optimal Equipment Layout Strategy for Small Modular Reactors Using Mixed-Integer Programming

HyungJu Kim, Korea University, Seoul, Korea, Republic of, Taesu Cheong

This study aims to analyze and optimize the efficient layout of small modular reactors (SMRs) and micro modular reactors (MMRs) from an industrial engineering perspective. As the demand for carbon-neutral and decentralized energy supply systems grows, SMRs and MMRs, which are flexible and small-scale nuclear power generation methods, are gaining attention. However, to ensure the practical operational efficiency and economic viability of these modular reactors, a comprehensive layout strategy considering various factors such as geographical conditions, demand patterns, power grid connectivity, and maintenance accessibility is necessary. This study models this problem from a multi-criteria decision-making and mathematical optimization perspective and proposes an optimal deployment model based on mixed integer linear programming (MILP). This study provides practical decision-making support tools for energy supply planning, power infrastructure expansion, and nuclear energy policy formulation, and can serve as foundational data for integrating future smart grids and renewable energy systems.

3 - Optimal Resource Allocation for Hyperscale Data Centers in Texas: a Deterministic Milp Approach

Ryan Callahan, University of California, Davis, Davis, CA, United States, Jiadong Zhao, Thanakorn Piyayothin, Aaron Rabinowitz

We develop a deterministic Mixed-Integer Linear Programming (MILP) model to determine the optimal energy infrastructure investment for projected hyperscale data centers while minimizing costs. The model combines long-term capital investment and short-term operational decisions with hourly dispatch dynamics for an entire year (8,760 time steps). Decision variables include binary capacity selection, continuous generation dispatch, and market participation in real-time and day-ahead wholesale energy markets. The model objective is to reduce total system costs, defined by a Levelized Cost of Energy (LCOE) framework, that includes fixed capital costs, operating and maintenance expenses, market energy prices, and fuel inputs.

Assuming collocation of these generation sources, our findings indicate that the optimal portfolio includes 54.4% natural gas, 36.1% solar, wind 9.5%, and no capacity for nuclear. The model installs 43.9 GW of on-site capacity but fails to meet the full 62.8 TWh demand and necessitates a grid import of 8.7 TWh. The annualized LCOE is \$0.8674/kWh, which is about 8x higher than regional wholesale market rates. Total infrastructure investment exceeds \$1.5 trillion.

Even with optimal co-location strategies, our analysis shows that grid purchases from legacy assets, whose capital costs have already been amortized, using existing Locational Marginal Prices (LMPs) remain more cost-effective than new-build supply. This formulation offers a decision-support framework for assessing the viability of vertically integrated power systems in data centers. Additionally, our model suggests hyperscale data centers may not be economically viable without significant policy intervention, cost innovation, or externalized cost bearing.

4 - Optimization of Energy Transition System Based on Process Linkage Modeling

Hao Ding, Nanjing University of Aeronautics & Astronautics, Nanjing, China, People's Republic of, Dequn Zhou

With the increasing penetration of variable renewable energy in electricity system, multiple uncertain risk factors, ranging from internal technology costs to external policies and markets, introduce significant revenue risks. This work constructed an optimization model by introducing various uncertainties to reach an optimal transition pathway toward carbon neutrality in electricity system considering multi-risks. The results indicate that risks associated with VRE penetration will increase the transition cost, but decision-makers' risk averse will actually reduce the cost. Based on the above findings, we emphasize the importance of risk-averse modelling in power system transition planning and support the future achievement of ambitious high VRE penetration goals. We suggest further reduction in technology costs and deployment of diverse flexible options. Various technologies' utilization is important to deal with the risks in electricity transition toward carbon neutrality.

5 - Optimization of Distribution Grid Restoration with Job Scheduling, Resource Dispatching, and Transportation Network Disruptions

Brent Austgen, Sandia National Laboratories, Albuquerque, NM, United States, Ross Guttromson

The restoration of distribution grids following disruptions is a complex challenge that spans multiple decision domains, including grid operation, job scheduling, and resource dispatching. We present an optimization model that incorporates decisions and constraints from these domains. The grid is represented as a graph, with isolable sections as nodes and switches as edges, allowing for effective management of power flow and topology configurations. The resource dispatching model accounts for crew capabilities, work site accessibility, site-to-site travel times, and disruptions in the transportation network. The job scheduling model, which links resource dispatching and grid operation, incorporates resource and time requirements, job dependencies, and work site safety. The model's objective function is to maximize criticality-weighted load served and crew safety. We intend for the model's job scheduling and resource allocation solutions to inform restoration planning, enabling utilities to respond more effectively to disruptions and minimize downtime for customers. We demonstrate the model using a case study featuring a small distribution feeder, a road network, and a simulated wildfire contingency. We discuss key aspects of the model solution, how the model fits in a rolling horizon optimization framework, worthwhile modeling extensions, and value to utilities.

1 - Strategic Supply-Demand Mismatch Through Lead Time and Pricing Autonomy: Evidence from a Car-Sharing Platform

Asif Nazrul, University of Cambridge, Cambridge, United Kingdom, Stylianos Kavadias

This paper examines supply-demand mismatch on hybrid peer-to-peer (P2P) car-sharing platforms, where decentralized hosts make strategic decisions about asset availability. Using booking-level data from one of the largest online marketplaces and exploiting a quasi-experimental policy shift in February 2023 that granted pricing autonomy to hosts, this study investigates how self-pricing affects listing behavior and utilization. A Triple Difference-in-Differences (DDD) framework identifies heterogeneous treatment effects moderated by host experience. The results show that experienced hosts with self-pricing privileges strategically delay their listings, reducing lead times by an additional 0.92 days compared to other host groups. This temporal shift contributes to a 6.9 percentage point decline in utilization, reflecting lower booked hours relative to availability. Inexperienced self-pricing hosts also experience diminished performance, likely due to suboptimal pricing decisions. Together, these findings suggest that pricing autonomy encourages strategic but inefficient supply behavior, particularly among experienced providers. This study contributes to the literature on marketplace design and decentralized operations by offering causal evidence on the behavioral consequences of pricing flexibility. It highlights how autonomy can exacerbate service availability gaps, particularly in advance-booking settings where supply timing is a critical decision that is overlooked in current literature. The findings underscore the need for experience-sensitive interventions, such as feedback-based incentives or dynamic listing nudges, to maintain platform efficiency while preserving host flexibility. Future work can extend this analysis using unsupervised clustering to uncover latent experience profiles and improve behavioral targeting in two-sided digital markets.

2 - Managing Multi-Component Projects: Task Prioritization and Optimal Stopping

Sasa Zorc, University of Virginia, Charlottesville, VA, United States, Vladimir Smirnov, Ilia Tsetlin

This paper examines a class of multi-component projects in which all components need to be successfully completed in order to realize the reward. Each component evolves stochastically over time and carries the risk of failure. We model this as a dynamic optimal control problem with endogenous decisions over how to distribute effort between components and when to abandon the project. We derive optimal component prioritization and stopping strategies. Since some of the optimal prioritization strategies are computationally demanding and with no clear managerial insight, we put additional focus on (a) specific cases where insight is clear (b) simple index policies that approximate the optimal ones, while being easy to interpret and compute. Our framework applies to a wide range of real-world problems, including research and development, software engineering, and academic research planning, where progress is uncertain, sequential, and interdependent.

3 - The Role of Discussions in Information-Gathering and Decision-Making

Panos Markou, UVA Darden School of Business, Charlottesville, VA, United States, Chan Tian, Hui Sun

We study how discussions among a panel of individuals aids in information gathering and making decisions. Leveraging verbatim transcripts from expert committees, we apply natural language processing techniques to analyze how discussion patterns inform influence and judgment.

4 - The AI Will See You Now: How Healthcare's Digital Revolution Rewrites Power

Emisa Nategh, Georgetown University, Washington, DC, United States

This paper reveals how healthcare AI's boom-bust cycles are not mere technological transitions but profound socio technical dramas that redistribute power between tech giants, healthcare systems, patients, and democratic institutions. Through the lens of "agency loops"—five-phase recursive patterns where humans and AI continuously renegotiate control—we expose how healthcare organizations navigate an impossible trilemma: achieving AI-mandated Medicare compliance, preserving patient agency, and maintaining democratic accountability. Our research unmasks the hidden choreography behind healthcare AI adoption, moving beyond deterministic views of technology to highlight how algorithms are shaped by, and in turn, shape everyday work practices. Each innovation "spring" creates unstable sociomaterial assemblages dominated by tech oligopolies (Google Health, Epic, Microsoft) that control crucial "choke points" in the AI ecosystem. These cycles inevitably collapse into "winters" when attributing life-and-death decisions to opaque algorithms proves ethically unsustainable.

1 - Business Value of AI Governance Frameworks

Nicole Janeway Bills, Data Strategy Professionals, Alpharetta, GA, United States

The talk addresses critical knowledge gaps that many data practitioners face in navigating AI Governance. The presentation will provide insights into the strengths and weaknesses of various AI Governance frameworks from organizations such as NIST and OECD and companies such as Microsoft, AWS, and Google. Moreover, we'll discuss practical recommendations for the application of these frameworks to mitigate risk and enhance business value.

2 - VRP: When Research Meets Reality

Geoffrey De Smet, Timefold BV, Gent, Belgium

It's one thing to solve a VRPTW (Vehicle Routing Problem with Time Windows). It's another to put it in production for a fleet of 50,000 technicians and save hundreds of millions of dollars per year. It's not just more constraints/objectives and more data. In this session, we will talk about the business and technical challenges of transforming an academic VRP into a solution that works well in production.

Resilience and Disruption Management in Transportation Systems

Contributed Session

Contributed

Chair: Nazli Demir, University of Waterloo, Waterloo, ON, Canada

1 - Travel Behavior Modeling Under Network Disruption: a Computational Graph Approach

JINGYAN LI, Carnegie Mellon University, Pittsburgh, PA, United States, Sean Qian

Large-scale disruptions have significant and lasting impacts on transportation systems. Understanding the day-to-day evolution of traffic patterns from the perspective of individual traveler behavior provides essential insights into how traffic systems respond to disruptions over time. Although recent research has explored day-to-day traffic modeling under network disruptions, a comprehensive, end-to-end calibration using real-world data remains largely unexplored.

In this study, we address this gap by proposing a computational graph-based approach to model travelers' day-to-day behavior under network disruptions. Specifically, we construct an integrated framework comprising a travel behavior model, a route choice model, and a dynamic network loading component. This framework captures daily

traffic dynamics as a discrete-time Markov chain process.

Our approach offers notable advantages compared to existing studies. Firstly, the computational graph methodology enables an end-to-end calibration of the entire traffic assignment model, directly learning traveler disutility functions from observed data. Secondly, our design of disutility functions emphasizes generalizability, allowing the model to effectively predict traffic responses to out-of-sample disruptions within the same transportation network.

We have successfully trained and validated the proposed model using a synthetic network, where the model empirically shows the capability of returning to the equilibrium. Future work will involve applying our methodology to real-world data sets, thereby validating its practical effectiveness and predictive capability.

The outcomes of this research hold significant potential for enhancing resilience planning and decision-making processes in transportation management.

2 - Understanding Day-to-Day Evolution of Traffic Patterns During Disruption: An Incremental Non-Negative Matrix Factorization Approach

Jingyan Li, Canegie Mellon University, Pittsburgh, PA, United States, Sean Qian

Recent major infrastructure failures have resulted in significant socio-economic losses and sudden disruptions to transportation networks. Traffic patterns are altered profoundly after the disruption, ultimately reaching a new equilibrium as travelers adjust to the changed infrastructure. However, accurately modeling this disruption-to-equilibrium transition is challenging due to concurrent disturbances from commuting peaks, weather conditions, special events, and accidents. Removing these noise factors, particularly from high-resolution spatiotemporal data, is critical for understanding true disruption impacts.

To address this challenge, this study proposes an incremental non-negative matrix factorization (NMF) approach to capture daily spatiotemporal traffic features during disruption periods. Unlike traditional static NMF methods, our approach dynamically preserves critical features from previous days while simultaneously incorporating emergent patterns resulting from disruptions. This incremental learning and memory-refreshing mechanism facilitates an interpretable understanding of how traffic patterns evolve over time.

The method is validated with data from the 2023 I-95 highway collapse in Philadelphia, Pennsylvania. Results indicate that equilibrium was restored within one week following each disruption event. During the recovery, new features reflecting increased congestion around closure points and along alternative routes emerged, while pre-disruption bottleneck features gained greater significance. Conversely, previously dominant features indicating lighter traffic conditions along alternative routes diminished or disappeared altogether.

This incremental NMF method enables real-time adaptation immediately following disruptions, making it a valuable tool for proactive traffic management. Furthermore, the interpretable low-rank features identified by this method can serve as representative scenarios for conducting what-if analyses, enhancing preparedness, and minimizing adverse impacts in future disruption events.

3 - Adaptive Framework for Flood Relief Using Drones and Floating Mini Depots for Equitable Aid Distribution

Fateme Hafizi, Illinois Institute of Technology, Chicago, IL, United States, Mohammad Miralinaghi

Floods pose significant logistical challenges in delivering essential goods such as food, water, and medicine to affected populations, especially in underserved and isolated areas where transportation infrastructure is damaged or completely submerged. This study presents an innovative disaster relief strategy employing drones and floating mini depots to ensure equitable and efficient distribution of essential supplies during flooding disasters. Mini depots, deployed on boats, serve as mobile hubs that store and dispatch emergency goods to affected communities. Drones launched from mobile depots can rapidly reach affected regions, reducing aid delivery time and improving the overall system's responsiveness. By removing dependence on road-based infrastructure, this system enables access to areas that would otherwise remain isolated during severe flooding. Historical flood and population data guide the identification of high-demand regions, enabling strategic preparedness to minimize delays during disaster response. Predictive analytics and machine learning are employed to anticipate demand surges and optimize routing, ensuring minimal delays and effective resource utilization. This strategy enhances the effectiveness of emergency logistics during flood events while promoting equity by prioritizing access for marginalized populations. This strategy improves the capacity to maintain supply chains during disruptions to conventional delivery routes, making it particularly advantageous for regions susceptible to recurrent flooding. The integration of drone technology with adaptable, aquatic distribution centers constitutes an approach to addressing significant logistical challenges encountered in disaster relief efforts. The system provides a flexible framework that can be adapted to diverse geographical contexts and enhances resilient and participatory emergency response strategies during climate-related disasters.

4 - Navigating Network Availability: a Shortest Path Approach to Uav Traffic Routing

Nazli Demir, University of Waterloo, Waterloo, ON, Canada, Fatma Gzara

The use of unmanned aerial vehicles (UAVs), commonly known as drones, is rapidly increasing across both commercial and recreational domains. This growth highlights a significant challenge: the lack of a drone traffic management system with a well-defined airspace traffic network and, routing and flight path planning. As drone operations expand, airspace becomes increasingly crowded, increasing the risk of aerial conflicts and emphasizing the need for effective regulatory and operational frameworks. This research aims to address these challenges by developing tools to be integrated into UAV Traffic Management (UTM) systems, enabling efficient flight planning for UAVs within an airspace structured as a network in consideration of ongoing traffic. A novel mathematical model is proposed to find a flight plan that specifies the flight path as well as a time schedule of traversing arcs on the path. A network transformation method is developed to reformulate the problem on an auxiliary network that allows solution by a novel labeling algorithm. Computational experiments demonstrate that our proposed solution approach outperforms a commercial solver by efficiently solving large-scale problems in under one second, making it highly suitable for seamless integration into UTM systems. Our findings offer valuable insights into determining the optimal flight paths of UAVs across various problem settings, such as the distance between origin and destination, the duration of the operation horizon, and network traffic. These insights may guide UTM providers in designing UTM systems that facilitate efficient airspace management.

1 - Stochastic Optimization of Hurricane Relief Logistics with Scenario-Based Planning and Rolling Horizon Updates

Ali Tolooie, Mercer University, Macon, GA, United States, Marzieh Soltanolkottabi

This study proposes a stochastic optimization framework for managing FEMA's multi-tiered humanitarian logistics network in response to hurricanes. The model integrates strategic preparedness and operational responsiveness using a rolling-horizon, two-stage stochastic programming approach. In the preparedness phase, optimal inventory pre-positioning at Major Distribution Centers (MDCs) is determined, and candidate locations for Pre-Staging Areas (PSAs) are identified prior to hurricane season. Once a hurricane forms, operational decisions are revised every six hours based on updated forecasts of the storm's trajectory, intensity, and potential impact.

Scenario generation is based on historical hurricane data and ensemble forecasting, with spatial impact assessments derived using FEMA's Hazus-MH platform. These scenarios incorporate uncertainties in infrastructure accessibility, facility operability, and time-dependent regional demand. The model also addresses perishability of items, penalties for unmet demand, return logistics, and disposal of expired supplies, while minimizing transportation and holding costs.

By dynamically integrating real-time data into decision-making, the proposed framework supports more responsive and cost-effective disaster logistics. It offers a practical tool to enhance FEMA's ability to deliver critical supplies under uncertainty, improving both preparedness and post-disaster outcomes.

2 - A Data-Informed Optimization Approach for Dynamic Fire Unit Relocation

Michael Vieira, California Polytechnic State University, San Luis Obispo, Livermore, CA, United States, Zhiyuan Wei

Fire departments face critical challenges when responding to major incidents that require mass deployment of resources, leaving large areas with insufficient coverage for subsequent incidents. Traditional strategies are usually reactive, responding to events that have already occurred. As a result, they overlook future incidents that could occur in the service area of unavailable stations, leading to delayed response and uncovered demand. A common way to address this issue is through a proactive strategy that temporally redistributes units during resource-intensive events. However, this proactive strategy is often based on the prior experience of dispatchers, which is subjective. To address this research gap, we aim to develop a data-driven approach for dynamically relocating fire units to ensure efficient coverage. Specifically, we propose an optimization model that determines optimal relocations to improve coverage. The methodology integrates big data on fire unit availability with geographic coverage requirements to maximize weighted coverage of demand nodes while respecting operational constraints. Our model accounts for various factors including station capacity, travel times between stations, and high-risk areas based on expected demand patterns. The performance of relocation strategies is evaluated in terms of both efficiency and equity. To enable fire departments to maintain the most effective coverage possible, the proposed data-driven optimization framework reallocates emergency service resources under uncertainty to enhance operational resilience and public safety.

3 - Optimal Initial Dispatch of Aerial Firefighting Resources in the Republic of Korea Under Wildfire Spread Simulation

Chanjung Lee, Seoul National University, Seoul, Korea, Republic of, Seung-Jae Joo, Junyeong Choi, Yohan Lee

Wildfires in the Republic of Korea have intensified in frequency, scale, and simultaneity, creating complex challenges for rapid aerial response. We propose an integrated framework that combines (i) an integer-linear optimization for the initial dispatch of helicopters—minimizing immediate suppression and damage costs while enforcing travel-time, refueling, and “golden-hour” response constraints—with (ii) a mixed-integer module that refines fleet composition to reduce the present value of operational and damage expenses over a planning horizon. While prior research typically treats dispatch and fleet sizing separately, our unified formulation captures their interdependencies under realistic operational constraints. To capture fire dynamics, we integrate a quasi-physical wildfire-spread model calibrated on nationwide historical fire data (2022–2024). Numerical experiments demonstrate that our approach improves average response times and reduces expected burned area compared with heuristic rules, all within computation times suited for operational use. Our results also illustrate how relaxing night-flight limits or adding heavy-lift helicopters influences both short-term effectiveness and long-term cost efficiency. Designed for Korea's operational context, our framework delivers a scalable decision-support tool capable of interfacing with advanced wildfire-spread models and incorporating state-of-the-art approaches such as reinforcement learning. Its modular design also supports future extensions to coordinate ground resources, enabling more integrated emergency-response planning.

4 - Designing Resilient Firefighting Systems: Strategic and Tactical Planning for Wildfire Suppression Using a Tri-Level Optimization Framework

Payam Khazaelpour, Florida International University, Maimi, FL, United States, Shabnam Rezapour Behnagh, Ania San Roman

In the face of escalating wildfire threats driven by climate change and human encroachment into fire-prone regions, strategic planning for firefighting has become a critical component of disaster preparedness and response. This study presents a comprehensive tri-level optimization framework to address the complex challenges of resource allocation and operations in wildfire suppression. The proposed model integrates three interdependent decision-making layers: (1) a pre-disaster planning stage, in which a regional authority (the “defender”) determines the optimal number and locations of fire stations and water reservoirs; (2) a worst-case scenario simulation, where a hypothetical “attacker” models the spread of wildfire across zones over a time horizon to challenge the defender's decisions by maximizing disruption; and (3) a post-disaster response phase, where tactical decisions are made regarding the dispatch and routing of firefighting vehicles to extinguish the fire quickly and efficiently. The outer level minimizes total response costs and fire suppression time, balancing economic efficiency with rapid containment. The middle level simulates an adversarial fire pattern to capture risk-averse planning under uncertainty. The inner level coordinates vehicle movements and firefighting actions to reduce logistical costs and accelerate fire termination during emergency response.

By bridging infrastructure planning with dynamic emergency operations, this framework offers a robust and adaptable approach to wildfire preparedness. It provides valuable insights for policymakers, emergency managers, and urban planners engaged in regional disaster risk management.

5 - Commit-OR-Defer Shortest Path Interdiction

Shuai Shao, University of South Florida, Tampa, FL, United States, Juan Borrero, Oleg Prokopyev

We study a sequential shortest path interdiction problem where an interdicator, with initially uncertain knowledge of arc costs, aims to maximize an evader's cumulative travel costs over several time periods. The evader possesses complete cost information. The interdicator has a limited budget for permanent arc removals and refines her cost estimates by observing the evader's path choices. We analyze different strategies for resource deployment.

Our analysis reveals that when adopting worst-case or best-case cost outlooks, a fully-committing strategy is optimal for the interdicator. When performance is evaluated across multiple potential cost scenarios, a fully committing strategy is optimal if considering up to two such scenarios; however, for a larger and more diverse set of potential costs, a fully deferring approach yields better results. We further introduce and analyze ‘risk-free’ policies, which aim to guarantee a specific performance threshold against any realization of uncertain costs, and develop mixed-integer programming formulations for these policies over short time horizons. Computational experiments evaluate the performance of 1-time-step and 2-time-step risk-free strategies, alongside fully-committing (optimistic and pessimistic) and fully-deferring policies, highlighting their practical tractability and comparative effectiveness.

Chair: Kenneth Bruninx, TU Delft, Delft, Netherlands

1 - Combining Benders Decomposition and Stochastic Dual Dynamic Programming: Novel Approaches for Enhanced Performance

Anil Kaya, Karlsruhe Institute of Technology, Karlsruhe, Germany, Alexander Shapiro, Steffen Rebennack

We propose novel algorithmic ideas for combining Benders decomposition and Stochastic Dual Dynamic Programming (SDDP). These algorithms are suitable to solve multi-stage stochastic mixed-integer programming problems of special structure. Here, the first-stage decisions are mixed-integer while other stages are linear programming problems (e.g. power expansion planning models). Benders decomposition is an efficient solution technique for two-stage optimization problems with a block-angular structure, where the so-called subproblems are linear programming problems. SDDP can efficiently solve multi-stage stochastic linear programming problems. Thus, combining these two methods leverages the two-stage nature of the problem as well as its multi-stage structure. However, when combining Benders decomposition with SDDP, the optimality cut for the master problem is not guaranteed to be tight or valid. To this end, we present novel algorithmic ideas to obtain exact optimality cuts. Then, we apply the proposed approaches to power expansion planning problem (as part of the ARTESIS project) to compare their performance and demonstrate their efficacy in addressing large-scale multi-stage stochastic mixed-integer problems.

2 - Game-Theoretic Analysis of Risk-Averse Behaviors in Power Battery Recycling: Closed-Loop Supply Chains with Government Subsidies

Dengke Bai, Ningbo University of Technology, Ningbo, China, People's Republic of, Li Hou

Abstract: The rapid growth of electric vehicles has led to a surge in end-of-life power batteries, posing significant environmental and resource challenges. Efficient recycling is critical not only for sustainable development but also for securing strategic raw materials like lithium and cobalt. While government subsidies are widely used

to promote battery recycling, their interaction with the risk-averse behaviors of supply chain members remains poorly understood. This study develops a tripartite Stackelberg game model incorporating stochastic demand and cost uncertainty, with the manufacturer as the leader and the retailer as the follower. The model examines how risk aversion and subsidies interact through nonlinear pricing dynamics under stochastic demand. We analyze four policy scenarios combining manufacturer and retailer risk aversion with subsidized and unsubsidized conditions. Using mean-variance analysis and backward induction, we derive equilibrium pricing strategies and quantify their impacts on recycling efficiency and supply chain performance. Key findings reveal that (i) government subsidies effectively mitigate risk-averse behaviors while optimizing pricing strategies, with subsidy effectiveness contingent on market uncertainty levels; (ii) risk aversion creates a dual effect on pricing—increasing prices in high-cost scenarios while promoting market expansion through lower prices when production costs are favorable; (iii) consumer recycling sensitivity and voluntary return rates nonlinearly influence optimal subsidy design, with subsidies showing greater impact in high-uncertainty markets. Based on these insights, we propose a tiered subsidy allocation framework: (i) higher subsidies to recyclers in early stages to break risk cascading effects, (ii) manufacturer subsidies tied to recycling rate thresholds.

3 - Modeling Robust Energy Systems Considering Weather Uncertainty and Nuclear Power Failures: a Case Study in Northern Europe

Lina Reichenberg, Chalmers University, Göteborg, Sweden, Kamran Forghani, Xiaoming Kan, Fredrik Hedenus

Capacity expansion models used for policy support have increasingly represented both the variability and uncertainty of weather-dependent generation (wind and solar). However, although also uncertain, as demonstrated by the performance of the French nuclear power fleet in 2022, uncertainty arising from nuclear power outages has been largely neglected in the literature. This paper presents the first capacity expansion model that considers uncertainty in nuclear power availability caused by unplanned outages. We propose a mathematical model that combines a scenario-based stochastic optimization approach (to deal with weather-related uncertainties) with a data-driven adjustable robust optimization approach (to deal with nuclear failure-related uncertainties). The robust model represents the bulky behavior of nuclear power plants, with large (1 GW) units that are either on or off, while at the same time letting the model decide on the optimal amount of nuclear capacity. We tested the model in a case for Northern Europe (seven nodes) with a time resolution of 1250 time steps. Our findings show that nuclear power outages do, in fact, impose a vulnerability on the energy system if not considered in the planning phase. Our proposed model performs well and finds solutions that prevent Loss-of-Load (at a price of robustness of 0.6%), even in more extreme weather conditions. Robust solutions are characterized by a higher capacity of gas plants, but, perhaps surprisingly, nuclear power capacity is barely affected.

4 - Transmission Expansion Planning Under Wildfire Risk Uncertainty: A Two-Stage Stochastic Optimization Approach

Easha Rajalaxmi Vivesh, The George Washington University, Washington DC, DC, United States, Ekundayo Shittu, Miguel Lejeune

This research presents a novel approach to transmission expansion planning (TEP) that incorporates wildfire risk uncertainty using a two-stage stochastic optimization framework. As climate change increases wildfire frequency and severity, power utilities face growing challenges in maintaining grid reliability while minimizing fire risks. The proposed methodology integrates probabilistic wildfire modeling with TEP to determine optimal investment strategies balancing costs against resilience. The optimization model is a two stage stochastic model: first-stage "here-and-now" transmission line investment decisions made before wildfire scenarios are realized, and second-stage "wait-and-see" operational decisions (generation dispatch, load shedding, etc.) implemented after wildfire conditions materialize. The objective function minimizes investment costs plus expected operational costs across all scenarios, subject to power flow physics and risk-based constraints. Using Monte Carlo simulation to generate realistic wildfire scenarios based on temperature, humidity, and wind speed distributions, the model captures the complex relationship between environmental conditions and wildfire probability. A case study using the Garver 6-bus test system demonstrates the model's applicability, with sensitivity analysis exploring the impact of varying risk thresholds on investment decisions, operational costs, and load shedding. Results indicate a significant trade-off between wildfire risk tolerance and system costs, with optimal solutions found in the 0.4–0.6 risk threshold range. This work provides power system planners with a quantitative framework to develop transmission networks resilient to increasing wildfire threats.

5 - Penalty-Free SDDP: Incorporating Benders Feasibility Cuts for Robust Multi-Stage Operational Planning

Guilherme Freitas, PSR, Rio de Janeiro, Brazil, Alexandre Street, Luiz Carlos Costa Junior, Tiago Andrade

The increasing complexity of energy systems stems from the global energy transition, integration of intermittent renewable sources, and the need to ensure supply security and reliability. In Brazil, with its predominantly hydroelectric matrix, incorporating large-scale solar and wind sources presents additional challenges.

Brazilian electrical system operation requires constant balance between economic efficiency and meeting various constraints such as water resource management, environmental preservation, and supply security. This conflict manifests in discussions between different regulatory agencies with distinct and often difficult-to-reconcile objectives. There is a growing need for methodologies that bring rationality to decision-making processes, enabling adequate quantification of each restriction's impact.

The Stochastic Dual Dynamic Programming (SDDP) algorithm has established itself as the primary tool for multi-stage operational planning under uncertainty. The traditional approach involves introducing penalties for constraint feasibility, but this presents significant challenges. Penalty calibration is subjective since there is often no directly associated economic value, making definitions arbitrary and potentially distorting economic signals and algorithm convergence.

This work proposes an SDDP formulation enhancement without artificial penalties, adding Benders feasibility cuts within the algorithm's recursive process. Analogous to the Future Cost Function, the approach introduces a Future Feasibility Function, indicating the benefit of anticipating storage for future constraint compliance.

Results from the Brazilian case study demonstrate significant improvements over the traditional approach, eliminating artificial penalties while improving marginal cost precision and convergence, ensuring optimization based on operational costs aligned with physical and economic constraints. The approach successfully maintains hydraulic constraint compliance while providing more realistic operational decisions.

6 - AI-Augmented Monte Carlo Simulation for Capital Investment Decisions in Innovation Project Portfolios

Gustavo Vinueza, Ferryfield Group, London, United Kingdom

Capital investment decisions in innovation project portfolios are characterized by high uncertainty—ranging from technical feasibility and development timelines to market adoption and regulatory approval. Traditional deterministic models often fail to capture these uncertainties, leading to suboptimal capital allocation and increased risk exposure. This paper introduces a decision-support framework that combines Monte Carlo Simulation (MCS) with artificial intelligence (AI) to support more robust, data-informed investment strategies.

Monte Carlo Simulation is used to model uncertainty across financial and scheduling dimensions, producing probabilistic estimates for key metrics such as Net Present Value (NPV), Internal Rate of Return (IRR), and the likelihood of cost and time overruns. To improve simulation fidelity, AI techniques—particularly machine learning—are applied to historical and contextual project data. These models help refine input distributions, detect interdependencies between projects, and dynamically adjust assumptions in response to new evidence.

Beyond input calibration, AI is used to support optimization efforts by analyzing simulated outcomes and identifying portfolio strategies that maximize expected value under defined risk constraints. This enables decision-makers to explore trade-offs between risk and return, better allocate limited capital, and gain visibility into the impact of uncertainty drivers.

The proposed framework is demonstrated through a fictitious innovation portfolio composed of diverse early-stage projects. Results show improved transparency, better risk-adjusted returns, and actionable insights for capital allocation under uncertainty. The methodology is applicable to industries where innovation drives value, such as pharmaceuticals, energy, and technology.

7 - Risk-Aversion and Capacity Remuneration Mechanisms in Electricity-Hydrogen Markets

Kenneth Bruninx, TU Delft, Delft, Netherlands, Alessio Berdin, Laurens de Vries, Aad Correljé

Hydrogen and derived fuels may act as long-term energy storage in climate-neutral energy systems. However, risk-averse investors will not invest in sufficient renewable electricity, back-up, electrolyzer and storage capacity if they are only remunerated for the hydrogen or electricity produced. We develop a stochastic equilibrium model to study whether capacity markets can restore investments to their risk-neutral levels. Our results show that the efficacy of capacity markets depends on complementary instruments to ensure the availability of renewables. If risk-averse investors build less renewables than what is societally optimal, capacity markets in the electricity and hydrogen sectors are needed to restore the overall capacity mix and limit consumer costs. If complementary instruments lift investments in renewables to their societally optimal level, a capacity market in the electricity sector suffices. In this situation, an additional capacity market in the hydrogen sector may trigger a bias toward hydrogen-fired backup capacity. This illustrates that an integrated systems' perspective is required to design future energy markets.

1 - A Scalable Deterministic Global Optimization Algorithm for Constraint Clustering Problems

Pedro Chumtipatz, University of South Florida, Tampa, FL, United States, My Duong, Cristobal Heredia, Kaixun Hua

Constrained clustering leverages limited domain knowledge to improve clustering performance and interpretability, but incorporating pairwise \emph{must-link} and \emph{cannot-link} constraints is an NP-hard challenge, making global optimization intractable. Existing mixed-integer optimization methods are confined to small-scale datasets, limiting their utility. We propose Sample-Driven Constrained Group-Based Branch-and-Bound (SDC-GBB), a decomposable branch-and-bound (BB) framework that collapses must-linked samples into centroid-based pseudo-samples and prunes cannot-link through geometric rules, while preserving convergence and guaranteeing global optimality. By integrating grouped-sample Lagrangian decomposition and geometric elimination rules for efficient lower and upper bounds, the algorithm attains scalability via embarrassingly simple parallelism. Experimental results show that our approach handles datasets with 200,000 samples for cannot-link constraints and 1,500,000 samples for must-link constraints, which is 200 - 1500 times larger than the current state-of-the-art under comparable constraint settings, while reaching an optimality gap of < 3%. In providing deterministic global guarantees, our method also avoids the search failures that off-the-shelf heuristics often encounter on large datasets.

2 - QOCO: A Quadratic Objective Conic Optimizer with Custom Solver Generation

Govind Chari, University of Washington, Seattle, WA, United States, Behcet Acikmese

Second-order cone programs (SOCPs) with quadratic objective functions are common in optimal control and other fields. Most SOCP solvers which use interior-point methods are designed for linear objectives and convert quadratic objectives into linear ones via slack variables and extra constraints, despite the computational advantages of handling quadratic objectives directly. In applications like model-predictive control and online trajectory optimization, these SOCPs have known sparsity structures and require rapid solutions. When solving these problems, most solvers use sparse linear algebra routines, which introduce computational overhead and hinder performance. In contrast, custom linear algebra routines can exploit the known sparsity structure of problem data and be significantly faster.

This work makes two key contributions: (1) the development of QOCO, an open-source C-based solver for quadratic objective SOCPs, and (2) the introduction of QOCOGEN, an open-source custom solver generator for quadratic objective SOCPs, which generates a solver written in C that leverages custom linear algebra. Both implement a primal-dual interior-point method with Mehrotra's predictor-corrector. Our benchmarks show that QOCO is faster and more robust than many commonly used solvers, and solvers generated by QOCOGEN are significantly faster than QOCO and are free of dynamic memory allocation making them an attractive option for real-time optimization on resource-constrained embedded systems. Both QOCO and QOCOGEN are easy to use and can be called from the modeling language CVXPY.

3 - Modified Eigenvalue Method for Nonconvex Miqucqp and Parallel Local Branching

Yongzheng Dai, The Ohio State University, Columbus, OH, United States

The ability to quickly find feasible solutions is an essential component of modern MIP solvers. A good feasible solution early in the solution process can significantly reduce the size of the branch-and-bound tree. Moreover, for many end users — especially when solving hard problems such as nonconvex MIQCQPs — a good feasible solution can be more valuable than a tight dual bound. Known primal heuristics for MIPs are typically based on projection onto the relaxed feasible regions or local search on reduced problems, which often get into trouble with nonconvex MIQCQPs because of nonconvex constraints. In this work, we propose a modified eigenvalue-based method to approximate nonconvex MIQCQPs, along with two enhanced feasibility pump algorithms designed to rapidly identify feasible solutions. To further improve the quality of these solutions, we develop a parallel local branching approach that efficiently explores large neighborhoods. Computational experiments demonstrate the effectiveness and promise of the proposed methods.

4 - Genlars: An Efficient Path-Seeking Algorithm for Parameterized Quadratic Programs

Roufeng Liu, MIT, Cambridge, MA, United States, Haihao Lu, Rahul Mazumder

We introduce a path-seeking algorithm for efficiently solving parameterized quadratic programs (QPs) with varying parameters where the parameter could appear in regularization terms, constraint right-hand-sides, or linear terms in objectives. Building on the piecewise linearity of solutions in such problems—generalized from LASSO-like settings to constrained QPs with equality and bound constraints—our approach leverages the KKT conditions and dynamic partitioning of variables into different active sets. By tracing linear segments between critical events, the algorithm efficiently updates solutions while maintaining sparsity and scalability, particularly in high-dimensional regimes where the number of constraints and rank of the quadratic term in the objective function is far fewer than the number of decision variables. We also propose a novel gradient screening technique for screening out inactive variables, which provides additional speedups for sparse solutions. In addition, we propose a way to efficiently update the factorization of the coefficient matrix of the KKT system as the active set changes, which allows the system to be solved in quadratic time. Benchmarks demonstrate significant speedups over Gurobi in sparse settings, including box-constrained LASSO and Markowitz portfolio optimization, and SVMs, highlighting its utility in scenarios requiring rapid path exploration or iterative parameter tuning.

5 - A Graph-Based Approach for Representing, Comparing, and Classifying Integer Programs

Tara Schroth, University at Buffalo, Buffalo, NY, United States, Kyle Hunt, Chase Murray

It has long been observed that model structure may play an important role in determining the effectiveness of certain solution techniques to mixed integer linear programs (MILPs). One implication is that solution techniques that work well for one class of MILP are often found to be effective on other “similar” problems. Despite the potential benefits, there is limited research in the area of recognizing similarity among MILPs. This paper seeks to address this gap by presenting a framework for classifying and comparing instances of MILPs, based on their mathematical structure. A new graph-based representation of MILPs is proposed, where decision variables and constraints are described by nodes, and arcs denote the presence of decision variables in certain constraints. Inspired by recent advances in the area of deep learning for graph-structured data, two methods of leveraging the MILP graph representations for classification and comparison are provided. In the first relational approach, a graph convolutional network (GCN) is employed to classify these so-called MILP graphs as having come from one of a known number of problem types. The second approach makes use of latent features learned by the GCN to compare graphs to one another directly. As part of the latter approach, we introduce a formal measure of graph-based structural similarity. Empirical studies indicate that both the classification and comparison procedures perform well on a test set. Additional properties of MILP graphs are also explored through a series of case studies.

6 - On Measuring and Predicting Performance Variability in Mixed Integer Programming (Mip) Solvers

Mourchid Adegbindin, Cornell University, Ithaca, NY, United States, Brenda Dietrich, Jamol Pender

Mixed-Integer Programming (MIP) solvers are widely applied to solve complex optimization problems across a broad range of domains. While these solvers are generally expected to behave consistently, they often exhibit surprising variability. Even under a priori neutral perturbations, a solver may complete the same problem in seconds during one run, yet take significantly longer—or fail to return a high-quality solution—in another.

Although solver variability has been known for decades, systematic investigation remains limited. In this work, we introduce the Weighted Variability Score (WVS), a unified and robust metric that quantifies solver instability across four dimensions: runtime, optimality gap, LP iterations, and branch-and-bound nodes. Unlike traditional runtime-based measures, WVS accounts for partial solutions, search effort, and remains robust to outliers.

We then conduct a large-scale empirical analysis on over 1000 MIPLIB instances. This experiment reveals that variability is neither rare nor restricted to hard instances; in fact, some known “easy” instances behave erratically, while others remain stable despite their complexity. Finally, we build a predictive modeling pipeline that demonstrates that a curated set of static and dynamic features can accurately predict WVS on most instances.

These results underscore the importance of treating solver variability as a first-class property in both algorithmic research and industrial deployment. By revealing that variability is not only systematic but also partially predictable, our findings offer a useful tool for preemptive tuning and solver configuration, lay a foundation for fairer evaluation of new algorithms, and support trust in resource-constrained applications where dependable behavior is essential.

7 - Fedsam: Sharpness-Aware Minimization for Improved Generalization Under FL Settings

Tianjian Haung, University of Southern California, Los Angeles, CA, United States, Maher Nouiehed

While generalization in Federated Learning (FL) has attracted growing attention in the machine learning community, it remains an emerging area of study. A key challenge arises from the inherent heterogeneity of client data and their varying computational capabilities. Recent research has drawn a connection between poor generalization and the sharpness of the optimization landscape.

In this paper, we propose a novel SAM-inspired framework tailored for FL. Unlike existing methods that apply SAM locally at each client, our approach penalizes the sharpness of the global loss function directly. We begin by illustrating a counter-example that highlights a critical limitation: flat minima at local clients do not necessarily aggregate into a flat global solution. This motivates our design of a sharpness-aware algorithm that adaptively estimates gradient similarity across clients and uses this to modulate the sharpness penalty. Specifically, each client receives a distinct penalty term based on the similarity of its gradients to those of other clients, accounting for data heterogeneity.

We provide theoretical analysis establishing the convergence of our proposed algorithm. To validate its effectiveness, we conduct extensive experiments on MNIST, FMNIST, and CIFAR datasets. The results demonstrate that our method achieves notable improvements in generalization performance compared to existing federated optimization techniques.

1 - Demand Forecasting Across Data Silos: Federated Shapley Valuation for Restaurant Supply Chain Collaboration

Yixuan Li, Johns Hopkins University, Baltimore, MD, United States

Demand fluctuations in restaurant supply chains are driven by heterogeneous and distributed data sources, including sales records, lead times, promotional activities, and weather conditions. These data are siloed across suppliers, central kitchens, and storefronts, giving rise to data islands, privacy concerns, and disputes over value attribution. This study proposes a collaborative modeling and data valuation framework that integrates Vertical Federated Learning with Shapley value theory, enabling cross-organizational demand forecasting without exposing raw data. Participating entities exchange only homomorphically encrypted gradients, ensuring commercial confidentiality. A Monte Carlo approximation of the Shapley value is embedded within each training round to quantify the marginal contribution of each party's feature set to model performance. This approach reduces the computational burden of traditional Shapley evaluation from exponential to linear complexity while preserving theoretical unbiasedness. The framework operates under an honest-but-curious threat model and supports game-theoretic mechanisms for revenue sharing based on information value. By unifying privacy-preserving distributed optimization with cooperative game theory, the proposed method offers both a theoretical advance and a practical solution for incentivizing data collaboration in multi-agent supply chains.

2 - Applied Econometric and Machine Learning Approaches for Sales Forecasting: A Case Study from A European Drugstore Chain

Xinyi Lai, Westwood High School, Austin, TX, United States

We analyze sales and related data from a European drugstore chain to develop predictive models for retail performance. After performing extensive feature engineering, we apply a range of econometric and machine learning techniques—including regression analysis, time series models, random forest, and XGBoost—to forecast sales. Our results demonstrate the effectiveness of combining structured data processing with advanced predictive analytics. The study offers a practical and adaptable framework that integrates econometric and machine learning approaches, contributing to data-driven sales and revenue management in retail and related industries.

3 - When Learning Less is More: Embedding Inventory Theories in End-to-End Deep Learning for Perishable Inventory Systems with Random Lead Time

Xuan Liao, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Zhenkang Peng, Ying Rong

Deep learning has shown promise in operations management field. In this paper, we show that training black-box deep neural networks to learn complex inventory state-to-action policies can be ineffective. This paper studies a perishable inventory system with random lead time and unknown demand and lead time processes. We introduce two end-to-end DNN-based policies—E2E-OQ, which directly outputs an order quantity, and E2E-PIL, which predicts a projected inventory level (the target level at the arrival point). Unlike E2E-OQ, the E2E-PIL network embeds a classical “lift-to-level” heuristic for projected inventory, constraining how the current inventory state influences decisions. Through extensive simulations, E2E-PIL consistently outperforms both traditional prediction-then-optimization benchmarks and the unconstrained E2E-OQ policy. We show that embedding a well-specified (though suboptimal) heuristic reduces sample complexity and stabilizes learning, with only marginal loss in approximation capability. This demonstrates the principle that, for complex management problems, “learning less is more”: incorporating domain knowledge into DNN architectures can yield more efficient and robust policies.

4 - Human-Machine Demand Forecasting

Thomas Kretschmar, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd Huchzermeier

Human forecasters and forecasting algorithms perform well in different cases, especially if the human has additional information through private communication or domain knowledge. We propose a method to combine the two forecasts to leverage both of their strengths. A meta-learner selects either the human or the machine forecast based on time-series and product features.

Using data from a beverage manufacturer we show that our method produces more accurate forecasts than either the human or the machine on their own. Additionally, it reduces the human workload by ca. 50%, leaving the human forecasters more time for the cases in which they can add most value.

5 - Too Many Electric Vehicle Brands? Uncovering Market Demand Drivers in Alabama via Sparse Learning

Muting Ma, University of Alabama, Tuscaloosa, AL, United States, Mesut Yavuz, Matthew Hudnall, Qin Wang

We investigate key factors influencing battery electric vehicle (BEV) market demand using a high-dimensional panel dataset from Alabama, U.S. To identify the most significant predictors, we employ an enhanced sparse learning model based on Lasso regularization. Our findings reveal that a greater number of BEV brands in the market is significantly associated with reduced consumer demand. To assess the robustness and generalizability of the improved model, we further test it on two additional domains: GDP and the S&P 500 stock trading market.

6 - Enterprise Assets-Based Revenue Network (EARN) to Tokenize Oil and Gas Assets Through Fractional Ownership

Prasun Singh, Hitachi America, Ltd., R&D Division, Santa Clara, CA, United States, Ravigopal Vennelakanti, Takatoshi Ohara

Tokenizing real-world assets can revolutionize supply chains by linking physical industrial assets to digital ownership models. By converting these assets into non-fungible tokens (NFTs), they can be fractionally owned by a diverse pool of investors. This approach facilitates the creation of a dynamic digital marketplace, enabling greater access to capital and enhancing returns on infrastructure and equipment investments.

We propose an AI-enabled tokenization framework [Enterprise Assets-based Revenue Network (EARN)] to improve allocation visibility, responsiveness, liquidity, and valuation of oil and gas real-world assets (RWA). Fractional (NFT) owners get field operations incentives, such as tradable green energy power production for carbon credits. The framework provides operational AI and valuation insights. The EARN proof-of-concept can demonstrate the monetization of production oil and gas wells and incentivize disposal wells to decarbonize oilfield operations.

The objective function of the oilfield EARN framework is to maximize

$$U = \alpha V_t + \rho G_t + \beta L_t + \gamma S_t - \delta C_t - \epsilon R_t - \lambda n$$

Where:

U : Total Investor fractional possession utility of the oilfield RWA

V_t : Total value of tokenized assets

G_t : Total value added as operational incentives to revenue

L_t : Liquidity of the tokenized RWA (trading scale volume, investor participation, and trading efficiency – exchangeability or convertibility of token value)

S_t : Smart contract transparency

C_t : Costs for solution

R_t : Regulatory and legal risks

λ_n : Constraint or Penalty coefficients

The weights α, β, γ, δ, ε, ρ can be adjusted based on priorities such as maximizing liquidity value, reducing costs, and increase regulatory compliance.

1 - Enhancing Grid Frequency Regulation with Shared Autonomous Electric Vehicles via a Two-Stage Robust Optimization Approach

XiaoFeng Li, Southeast University, China, Nanjing, China, People's Republic of, Xinlian Yu, shunfeng zhang

Shared autonomous electric vehicles (SAEVs) have the potential to provide both mobility services and grid stabilization services, such as frequency regulation, via Vehicle-to-Grid (V2G) technology. This dual functionality can enhance fleet utilization and profitability for operators while facilitating the integration of variable renewable energy sources. To address uncertainties in frequency regulation market prices and trip requests, we propose a data-driven two-stage robust optimization framework for the operation of SAEVs. In the first stage, the operator makes energy and capacity bids in the day-ahead regulation markets, considering uncertain regulation signals and travel demand. The goal is to maximize the platform's expected profit from selling primary frequency regulation to the grid and guarantees that market commitments are met at all times. In particular, the uncertainty market commitment is characterized via data driven deep reinforcement learning approach, which has the benefit of tractability. The second stage focuses on SAV operations, dynamically dispatching EVs to fulfill pre-committed regulation services and real-time trip requests.

Our computational study, based on real-world trip request data and actual frequency regulation prices, demonstrates that enabling SAVs to offer frequency regulation can significantly enhance the platform's expected profits while maintaining trip service quality. We also offer managerial insights into operational efficiency, particularly regarding fleet size, V2G station capacity, and trip request patterns. Our findings provide valuable insights for the design of V2G systems, potentially supporting the sustainable adoption of EVs and complementing renewable power growth by stabilizing the grid.

2 - Embodied AI Customer Service: Mitigating the Negative Impact of AI Identity Disclosure on Cognitive Trustworthiness and Emotional Affinity

Runge Zhu, Central University of Finance and Economics, Beijing, China, People's Republic of, Heyao Ma, Zhidi Shang

With the rapid advancement of artificial intelligence (AI), AI-based customer service is increasingly replacing human agents across various service domains. This research addresses three key questions: Can AI effectively resolve consumer inquiries? How do consumers react when informed the agent is AI rather than human? And, if negative reactions occur, what design strategies can mitigate them? In Study 1, we collected frequently asked questions from a major e-commerce platform and obtained responses from professional human agents and an AI tool. Participants evaluated these responses in a 2 (Response Source: Human vs. AI) × 2 (Label: Human vs. AI) between-subjects design. Results showed AI-generated responses were rated as more cognitively accurate and trustworthy and elicited emotional affinity comparable to human responses. However, when participants were informed the response was from AI, perceived trustworthiness and emotional affinity declined despite recognition of accuracy. In Study 2, we examined whether embodied design could attenuate this "AI label effect." A 2 (Label: Human vs. AI) × 2 (Embodiment: Present vs. Absent) experiment revealed that AI agents presented with visual avatars in immersive virtual reality significantly reduced the negative impact of AI disclosure on trustworthiness and emotional affinity compared to low embodiment (voice only). These findings provide critical insights for designing AI service agents in the evolving AI-driven landscape, guiding practitioners to develop strategies that enhance customer experience.

3 - Assessing the Potential of Drone-Based Stock Record Maintenance to Decrease Oversales in Retail

Toshi Protsch, ETH Zurich, Zurich, Switzerland, Oliver von Dzengelevski, Torbjørn Netland

Effective inventory management is crucial for the economic success of retail businesses. Inaccurate inventory records cause various challenges, one of which is unintentional oversales—selling a product beyond its available inventory. If the replenishment time is longer than the promised lead time, an oversale triggers a customer order that cannot be fulfilled. The ensuing delay or cancellation of orders may lead to increased operational costs, lost sales, and diminished customer satisfaction. This study examines the potential of drone-based systems for autonomous inventory record maintenance and their potential to mitigate oversales.

Based on sales and inventory data of a global retailer, we study the effect of drone implementation by comparing warehouses in which a drone-based autonomous stock counting system was implemented with comparable warehouses which continued to solely rely on manual stock counting. We employ a difference-in-differences methodology to study the effect of drone use on oversales, mediated by inventory record accuracy. Furthermore, we investigate the role of contextual moderators of this mediated relationship, including warehouse size, demand variability, item turnover rates, and customer access to inventory.

We contribute to the inventory management literature by providing empirical evidence on the effectiveness of stock record maintenance enabled by emerging technologies. We expect that drone-based stock record maintenance systems are particularly effective at preventing oversales in large warehouses, for fast-moving items,

with higher demand variability, and in sections inaccessible to customers. Our study provides practical guidance for retailers considering investments in autonomous record maintenance using emerging technologies.

4 - Digital Verification of Experience Certificates, Academic Credentials and Community Service from Source Organizations Using a Blockchain Based System

Sonal Daulatkar, Prin. L.N. Welinkar Institute of Management Development and Research, Mumbai, India, Tanmay Gurav, Jagdish Kharatmol, Nishil Visawadia, Sagar Deshmukh

Every candidate's background verification entails verification from the source organization across the world – corporate bodies for experience certificates, schools/universities for academic credentials and non-profit organizations for community service. This involves multiple stakeholders at different levels in the process including embassies of different countries for international candidates. Existing third-party businesses having liaison with the source organization charge heavily. This also introduces delays in the verification process and may also introduce human error while inserting marks into a database apart from the possibility of fraud. This project proposes a de-centralized block-chain based multi stakeholder platform for verification of documents as a solution. After a blockchain-based tokenized validation from the source organization, the verified document by a candidate is viewable on a web-based platform accessible to all concurrent and future stakeholders. The student community can apply globally to avail quality education while job applicants can apply for work visas with a lower verification cost.

5 - Generative AI in Action: Strategic Adoption and Performance Implications for Firms

Manas Tripathi, XLRI- Xavier School of Management Delhi- NCR Campus India, Jhajjar, India

Generative artificial intelligence (Gen-AI) has the potential to transform how firms create and capture value. Firms deploy Gen-AI technologies in content creation, product development, and customer service. Gen-AI enhances speed and creativity in research and development, promoting product and service innovation. Gen-AI signals innovation leadership to the customers and investors, shaping the competitive positioning of the firm. Prior research has emphasized the role of Gen-AI in enhancing innovation and operational efficiency, but empirical evidence to demonstrate its impact on firm performance remains limited. This study addresses this gap by examining the impact of Gen-AI announcements on firm performance using event study methodology. The event is the announcement of a Gen-AI initiative by a firm, and the event study measures the stock price performance of the firm in a defined event window around the event announcement date. The dataset consists of Gen-AI announcements post-2022 of US firms listed on the NYSE and NASDAQ. The study examines the short-term and long-term impact of Gen-AI announcements on the stock prices of US firms using the market model. Preliminary insights suggest that Gen-AI announcements have a statistically significant positive impact on firm stock prices, indicating investor optimism about the potential of Gen-AI to drive operational efficiency and innovative business models. The study contributes to the literature on artificial intelligence in strategic management by providing empirical evidence of the market impact of Gen-AI announcements. It offers early guidelines for investors, executives, and managers exploring the Gen-AI frontiers.

1 - Navigating the Attention Economy: Content Strategy Trade-Offs for Live Streaming Entrepreneurs

Sung Hyun Kwon, University of Maryland, College Park, MD, United States, Il-Horn Hann

Live streaming entrepreneurs continuously decide whether to explore new content, exploit past successes, learn from competitors, or follow audience feedback. Understanding how content creators make these decisions and how audiences respond is critical as the streaming market intensifies. We examine these content strategy trade-offs among established streamers in a major live streaming platform by developing a framework that combines natural language processing with March's (1991) exploration-exploitation theory to quantify content strategies using streaming titles and game choices. We apply BLP structural demand estimation to analyze how these supplier decisions affect viewer utility and engagement. This study addresses how digital entrepreneurs navigate content strategy decisions when facing ephemeral content value and immediate audience feedback. By quantifying creative strategies in user-generated content markets, we provide insights into entrepreneurial decision-making in attention economies where traditional product development cycles do not apply. The framework offers a systematic approach to measuring content differentiation strategies, with implications for streaming entrepreneurs, platform design, and understanding supplier behavior in digital creative markets.

2 - Playlist-Induced Spillovers: Examining on- and off-Platform Outcomes for Emerging Artists on Spotify

Jose Eduardo Oros Chavarria, Carnegie Mellon University, Pittsburgh, PA, United States

Digitization and streaming platforms-based activities can create opportunities for artists at all stages of their careers. This paper studies the extended multiplier effects of editorial playlisting on both on-platform and off-platform outcomes for emerging, independent artists. Utilizing a unique dataset from Spotify's Playlist pitching tool, a feature that allows artists to pitch their tracks to music editors for playlist consideration, we employ a matched difference-in-differences methodology to compare outcomes between artists who were featured on playlists and those who were not. Our results show that emerging independent artists featured on Spotify's editorial playlists not only experience a significant increase in stream counts but also have a greater likelihood of going on tour. This research emphasizes the role of digital platforms as potent discovery mechanisms that enable fan engagement, in turn driving off-platform career trajectories including live event opportunities.

3 - The Nexus of Embodiment: Digital Agents in Live Streaming Contexts

Peiyan Yu, University of Georgia, Athens, GA, United States

Advances in generative technologies have enabled the rise of digital humans, embodied agents with lifelike appearance and expressive voice, who are increasingly used in advertising and sales. These agents offer a scalable and cost effective alternative to human influencers. Unlike traditional media figures, they can remain available around the clock and convey emotions, personality, and interactive behaviors that foster audience engagement. This study examines whether embodied agents can achieve performance comparable to humans in live streaming commerce and whether their effectiveness depends on how well they align with brand identity. We conduct an online experiment in a live streaming setting, varying agent features in terms of visual style and language use, and compare embodied agents to non embodied ones. We assess how the fit between brand and agent influences viewer engagement, brand perception, and purchase intent. The findings inform how brands can strategically deploy generative agents to enhance consumer connection and marketing effectiveness.

4 - The Impact of Realism and AI Disclosure on Virtual Influencer Effectiveness: a Large Field Experiment

Meixian Wang, Temple University, Philadelphia, PA, United States, Jaehwuen Jung, Ravi Bapna

Influencer marketing has become an essential component for brand strategies, and the adoption of AI-generated virtual influencers is accelerating with advancements in generative AI. However, these emerging practices raise challenges related to transparency and ethical concerns. By conducting a large field experiment involving over 1.8 million consumers, we examine the interplay between virtual influencers' anthropomorphism levels and the disclosure of their AI identity. The results show that virtual influencers with higher anthropomorphism levels enhance engagement metrics, while AI identity disclosure reduces link clicks and three-second video plays, particularly for highly realistic virtual influencers. Our underlying mechanism analysis based on an online experiment reveals that this reduction is driven by "expectation violation effect", where disclosure violates consumers' expectations and evokes negative feelings. Importantly, the negative effects reverse for consumers with prior experience interacting with virtual influencers—among this group, highly realistic virtual influencers with disclosure actually lead to greater engagement than their less anthropomorphic counterparts. Our findings provide theoretical and practical insights into the design and development of AI agents, emphasizing the need to strategically manage anthropomorphism and transparency to optimize consumer engagement.

1 - Causal Product Networks: a Data-Driven Methodology for Modeling Basket-Shopping Consumer Behavior

Ziwei Zhu, Cornell University, Ithaca, NY, United States, Vishal Gaur, Nur Kaynar

The purchase of one product affects the purchases of others in a shopping basket. Discovering and measuring these effects across an exponentially large number of possible interactions among numerous products in different categories is extremely challenging. We propose a new causal discovery approach to learn the underlying causal structure among product purchases from observational shopping basket data, filter out non-causal correlations, and construct a causal product network (CPN) to describe these latent interactions. We validate this approach and demonstrate its value by utilizing a large-scale basket-shopping dataset. Our main results are as follows. (1) We show that CPNs represent interactions among products in a shopping basket much more accurately than other candidate network structures of hypothetical consumer behavior, such as a complete network or a correlations-based network. (2) Our unrestricted CPN model, which allows product-level relationships, more accurately fits basket-shopping data than restricted specifications of product interactions used in the previous literature, such as category-level interactions, without requiring significantly more parameters. (3) Comparing brick-and-mortar and online channels, we discover that the brick-and-mortar channel exhibits denser causal connections among product purchases in a basket. (4) Finally, using the constructed CPNs, we demonstrate their application in a multi-category assortment optimization problem and find that our model outperforms a benchmark multinomial logit model that treats each category independently by 20%-42% in total sales. Our results make a significant advancement towards using large-scale transaction data for modeling shopping behavior, generating new managerial insights, and optimizing decisions.

2 - The Role of Store Brands in Mitigating Operational Disruptions

Yasin Alan, Vanderbilt University, Nashville, TN, United States, Xabier Barriola, William Schmidt

We study the role of store brands on retailers' performance following operational disruptions. We exploit exogenous shocks in a difference-in-difference-in-differences regression specification that estimates the impact on grocery category sales for stores with a high (compared to a low) proportion of store brand market share. Our findings suggest that having strong store brands allows retailers to better manage operational disruptions, as retailers have greater control over the supply and pricing of store brand products.

Chair: Xiang Ji, University of Science and Technology of China, Hefei, N/A, China, People's Republic of

1 - Optimal Subscription Box Design for Online Subscription Service

Renjun Hu, University of Michigan, Ann Arbor, MI, United States, Lennart Baardman, Hyun-Soo Ahn

Subscription services, with their fixed revenue streams per customer, critically depend on minimizing churn. This research introduces a framework for optimal subscription box design aimed at enhancing customer retention. We begin by establishing prior knowledge of customer preferences using machine learning models leveraging rich customer features. These initial beliefs are then dynamically updated through diverse forms of customer feedback, ranging from explicit product ratings to implicit consumption signals and retention decisions.

A key challenge is that learning true customer preferences is costly and ideally achieved within the first few interactions. Our model quantifies the value of different feedback types, recognizing that richer, more granular information significantly accelerates preference identification and allows for more precise box tailoring. This understanding of feedback value is foundational to designing effective mechanisms that incentivize customers to provide more detailed insights. By strategically motivating feedback, we can create a virtuous cycle: improved learning leads to better-personalized boxes, which in turn reduces churn and provides further opportunities for preference refinement.

This research has direct real-world applications and is being developed in collaboration with Hungryroot, a leading online grocery subscription business. The proposed models are validated using real customer data, and we are actively designing experiments to test mechanisms for incentivizing valuable feedback, demonstrating a practical pathway to improving customer satisfaction and lifetime value in subscription services.

2 - Returning Credits Versus Returning Cash in a Competitive Environment

Yiji CAI, Southern University of Science and Technology, Shenzhen, China, People's Republic of, Kanglin CHEN, Xiaoshuai Fan

Consumers often receive either credit or cash refunds for product returns or service cancellations. When receiving the credit, consumers enjoy price deductions in future purchases if they remember to redeem within the expiration term. Receiving cash offers immediate freedom in fund allocation as desired. These refund policies significantly influence consumer behavior and firm profitability. Thus, this study delves into the optimal design of refund policies, specifically examining the choice between refunding credit and refunding cash in a competitive market setting. Our investigation centers on the dynamic interactions between consumers and firms, considering two competing firms offering horizontally differentiated products over time. Employing a model of the repeated interactions across two periods, we analyze the impact of consumers' forgetfulness rates, cash freedom, and exogenous return rates on firms' pricing and refund decisions. Our analysis reveals several noteworthy insights. First, equilibrium choices regarding refunding cash or credit are symmetric, contingent upon consumer perceptions of cash freedom and forgetfulness rates. Notably, a prisoner's dilemma scenario arises when credit refunds dominate due to weak cash freedom and moderate forgetfulness among consumers. Second, cash refunds consistently offer full reimbursement, whereas credit refunds tend to provide partial reimbursements, particularly when forgetfulness rates are low. Finally, despite a decrease in consumer surplus with higher return rates, firms' profits and overall social welfare may increase under cash refund equilibrium.

3 - Selling a Product Line Through a Risk-Averse Platform

Xiang Ji, University of Science and Technology of China, Hefei, China, People's Republic of

This paper analyzes how a manufacturer's product line design interacts with a risk-averse platform's selection of selling mode. The results show that, if the manufacturer's product line extension fee is moderate, the risk-averse platform chooses the agency contract when the commission rate is low, but chooses the wholesale contract when the commission rate is high.

Revenue Management

Chair: Yunzong Xu, University of Illinois, Champaign, IL, United States

1 - Alternating Regret for Online Convex Optimization

Mengxiao Zhang, University of Iowa, IOWA CITY, IA, United States, Soumita Hait, Ping Li, Haipeng Luo

Motivated by alternating learning dynamics in two-player games, a recent work by Cevher et al. (2024) shows that $o(\sqrt{T})$ alternating regret is possible for any T -round adversarial Online Linear Optimization (OLO) problem, and left as an open question whether the same is true for general Online Convex Optimization (OCO). We answer this question in the affirmative by showing that the continuous Hedge algorithm achieves $O(d^{2/3}T^{1/3})$ alternating regret for any adversarial d -dimensional OCO problems. We show that this implies an alternating learning dynamic that finds a Nash equilibrium for any convex-concave zero-sum games or a coarse correlated equilibrium for any convex two-player general-sum games at a rate of $O(d^{2/3}/T^{2/3})$. To further improve the time complexity and/or the dimension dependence, we propose another simple algorithm, Follow-the-Regularized-Leader with a regularizer whose convex conjugate is 3rd-order smooth, for OCO with smooth and self-concordant loss functions (such as linear or quadratic losses). We instantiate our algorithm with different regularizers and show that, for example, when the decision set is the ℓ_2 -ball, our algorithm achieves $O(T^{2/5})$ alternating regret with no dimension dependence (and a better $O(T^{1/3})$ bound for quadratic losses). We complement our results by showing some algorithm specific alternating regret lower bounds, including a somewhat surprising $\Omega(\sqrt{T})$ lower bound for a Regret Matching variant that is widely used in alternating learning dynamics.

2 - Optimal Spatial Matching on a Circle

Hao Liang, University of Illinois, Champaign, IL, United States, Zizhuo Wang, Yunzong Xu

In this study, we investigate spatial matching on a circular road. We derive new analytical results for the expected average matching distance, leading to interesting insights into more general geometric settings. Our findings also provide useful implications for the design of optimal delayed matching strategies for ride-hailing platforms.

3 - Balancing the Optimality-Interpretability Trade-off in Feature-Based Pricing

Jingren Liu, National University of Singapore, Singapore, Singapore, Hanzhang Qin, Mabel C. Chou

We consider a feature-based pricing problem under the predict-then-optimize (PTO) paradigm. In this setting, understanding the impact of features on demand is important for guiding pricing decisions. Although advanced machine learning (ML) models have shown strong predictive power in capturing complex feature effects, their black-box nature often limits interpretability, which is unacceptable in high-stakes decision-making domains. Therefore, it is desirable to harness predictive power while enhancing the interpretability of ML models. In this paper, we propose a Teacher-Student Monotonic Neural Network (TSMNN) to predict feature effects. In this architecture, a standard neural network is trained to balance prediction accuracy with similarity to a monotonic neural network (MNN) that lies in a subspace with lower Rademacher complexity. Such a favorable subspace is found through a theoretical but intuitive analysis of the generalization behavior of MNNs. Our proposed framework is completed by using double machine learning (DML) to estimate the price sensitivity. Theoretically, we show that the proposed framework yields a finite-sample regret bound. The empirical performance on a real-world loan data set further demonstrates both the superiority and practicality of our framework: it produces a monotonic pricing policy at a small cost in optimality.

4 - Data-Driven Diffusion Approximations of Graph Markov Chains

Prem Talwai, MIT, Cambridge, MA, United States, Jose Blanchet, David Simchi-Levi

Diffusion approximations are ubiquitous in the study of optimal control, sequential experimentation, and hypothesis testing, where they have long provided an elegant mechanism to distill Markovian dynamics to their initial moments. However, these approximations are purely asymptotic and largely restricted to the study of one-dimensional dynamics of highly stylized stochastic systems, which often invoke strong parametric assumptions on sequential increments (e.g. Gaussian, multinomial, exponential). However, in many OM settings, these parametric assumptions are too strong, and decision makers are faced with the critical learning problem of building estimators of graph transition kernels using only sample path data. On dense graphs, statistical estimation can be prohibitively expensive, scaling exponentially with the size of the state space. In this paper, we develop a nonparametric Bayesian approach for approximating Markovian dynamics on planar graphs by a special type of two-dimensional time-changed diffusion, known as Brownian motion with darning. Our approaches hinges on the association of the Green's function of the Brownian approximation with the period matrix of a carefully constructed hyperbolic surface. Harnessing the rich theory of Teichmüller dynamics and large genus Weil-Petersson geometry, we study the nonasymptotic posterior contraction of our Bayesian estimator around the Green's kernel of a "darned" projection, and the convergence of the latter to its continuous counterpart in the large-scale limit. We also explore the application of the diffusion approximation to optimal stopping, where we demonstrate that it enables a drastic reduction in the problem's statistical complexity, which now only scales linearly in the number of states.

Stochastic Power System Planning: Modeling and Software Advancements

Invited Session

ENRE: Electricity

Chair: Rachael Alfant, Sandia National Laboratories, Albuquerque, NM, United States

1 - Forestlib: Enabling Performant Optimization of Stochastic Programs For Power Grid Planning

Rachael Alfant, Sandia National Laboratories, Albuquerque, NM, United States

Generation and transmission expansion planning is critical to the operation and maintenance of power grids; however, solutions to these problems can be computationally intractable. This talk introduces ForestLib, an open-source Python package with stochastic programming modeling capabilities, which incorporates solvers that optimize the extensive form and utilizes decomposition via progressive hedging. ForestLib is distinguished by its support for scenario bundling, multi-fidelity modeling, and a rich solution pool manager. Tailored to solve expansion planning problems, it utilizes parallelism and enhancements to the progressive hedging algorithm in order to achieve computational speed ups. We provide an expansion planning exemplar to demonstrate its use and the efficacy of our approach.

2 - Alternative Optima for Resilient Energy Modeling

Matthew Viens, Sandia National Laboratory, Madison, WI, United States

Effective planning for the future of the electricity grid requires improving our ability to treat complex capacity expansion planning problems. We show how generating alternative optimal solutions enhances our understanding of models generally. In capacity expansion planning problems, we use this to explore resilience and robustness characteristics. Our methods decompose cost efficiency modeling and more granular power systems simulation into separate pieces that can apply specialized tools to each component. We also leverage our previous work on alternative solution generation in Benders Decomposition to generate alternatives naturally over investment stage variables rather than the entire variable space.

3 - Using Snoglude, a Parallelized Python Package, to Perform a Priority Branch-and-Bound Global Optimization Algorithm on Stochastic Power Planning Problems

Georgia Stinchfield, Carnegie Mellon University, Pittsburgh, PA, United States, Matthew Viens, William Hart, Carl Laird

Two-stage stochastic programs exhibit a decomposable structure that many stochastic programming algorithms rely on to ensure computational tractability. In this work, we decompose by scenario, building one model for each set of random parameter realizations; each model and parameter set is referred to as a scenario. Aggregating the

optimal objective values after solving each scenario *independently* yields a valid lower bound to the original problem, as we no longer require first-stage variables (that appear in every scenario) to be the same across all scenarios (i.e., dropping constraints to yield a relaxation). We exploit this trivially parallelizable relaxation within the context of a priority branch-and-bound tree, where we branch only on the first-stage variables; by solving all scenarios to global optimality, we implicitly branch on the second-stage variables.

In the application of stochastic power planning problems, offering operators more than one “near-optimal” solution is often valuable to ensure transparency and interpretability of results. Developing a set of alternative solutions within a branch-and-bound tree is logical, as the space can be methodologically explored in a divide-and-conquer manner, naturally traversing the entire space of the optimization problem via tree search. Conventional branching techniques typically aim to close the optimality gap by solving a minimum number of nodes; in this work, we aim to traverse the tree while maximizing the variety of high-quality solutions available at termination. Our Python package, SNoGloDe: Structured Nonlinear Global Decomposition, allows us to employ our algorithm within a flexible software framework, easily adding branching customizations and candidate generators.

4 - Decomposition with Trust Regions for Scalable Stochastic Planning

Leonard Göke, ETH Zurich, Zürich, Switzerland, Giovanni Sansavini

Future power and energy systems are subject to various uncertainties; in particular, renewable sources, namely wind and solar, are characterized by an uncertain supply fluctuating from hour to hour and year to year. Cross- and auto-correlations of weather time series are too complex to describe analytically. Therefore, optimization models planning future systems must deploy a data-driven approach and consider large samples of climatic conditions to give reliable results. However, including a sufficient sample of climate conditions leads to very large linear capacity expansion problems that are computationally intractable for off-the-shelf solvers. Against this background, previous research proposed Benders decomposition for stochastic capacity expansion problems. The first stage of the resulting two-stage problem decides on complicating variables, most importantly capacities. The second stage decides on the operation and adds different scenarios, for instance, for various weather conditions. The original Benders algorithm converges slowly for large linear capacity expansion problems. However, previous research showed significant improvements from stabilization, viz. restricting the solution space for the current iteration to the neighborhood of the current best solution. We investigate synergies of stabilization using a quadratic trust region with other refinements of Benders decomposition. In particular, we leverage the trust region to transfer refinements for small combinatorial mixed integer problems to large but linear stochastic problems. A particular focus is on advanced stabilization, cut management, and cut selection techniques. Preliminary results on advanced stabilization suggest a performance improvement by a factor of five.

1 - Uncovering Key Success Factors in Leading Semiconductor Enterprises: a Hybrid Approach Using Data Envelopment Analysis and Machine Learning

Chen-Hsiang Hong, National Taiwan University, Taipei, Taiwan, Chialin Chen, Ruey-Shan Guo

The semiconductor industry is a critical enabler of technological innovation and economic development, particularly in areas such as wafer foundry, advanced process engineering, and integrated circuit (IC) design. However, the sector is now confronted with unprecedented uncertainty due to the deceleration of Moore's Law, geopolitical tensions, and disruptive supply chain realignments. This research introduces a hybrid methodological framework that integrates Data Envelopment Analysis (DEA) with machine learning to assess firm-level operational efficiency and enhance strategic foresight. In the first phase, network and dynamic DEA models—including the Malmquist productivity index—are applied to evaluate technical and managerial efficiency, identify performance frontiers, and derive actionable insights. The second phase leverages supervised machine learning techniques to forecast market demand and track innovation trajectories. By fusing DEA's diagnostic strengths with the predictive capabilities of machine learning, this study aims to support evidence-based decision-making in areas such as R&D investment, technology adoption, and resource allocation. Key questions addressed include: (1) How can DEA reveal opportunities for improving innovation and operational performance? (2) How can machine learning strengthen strategic forecasting in volatile markets? (3) How can this integrated approach improve organizational agility in the evolving semiconductor ecosystem?

2 - Multi-Objective Trajectory Generation for Offline Model-Based Optimization

Chanho Kim, KAIST, Daejeon, Korea, Republic of, Jong-Seok Lee

In offline model-based optimization (MBO), guided trajectory generation (GTG) methods construct and denoise design trajectories toward high-performing regions. However, existing GTG approaches handle only a single objective, limiting their applicability to problems with multiple conflicting goals. To address this gap, we propose Multi-Objective Trajectory Generation (MOTG), a framework that extends GTG to multi-objective optimization. MOTG first extracts improvement trajectories from an offline dataset, ensuring that each step monotonically improves at least one objective. Each trajectory is annotated with a preference vector that captures the relative trade-offs of its final outcome. Using these labeled trajectories, we train a conditional generative model—either a diffusion model with classifier-free guidance or a continuous GFlowNet—to learn the distribution of multi-objective improvement trajectories. This generator enables us to sample novel trajectories conditioned on desired objective preferences. Finally, we generate a pool of candidate trajectories from the trained model and use a proxy function to select high-fidelity design solutions among them. Experiments on several multi-objective optimization benchmarks show that MOTG discovers diverse, high-quality solutions beyond the support of the original data. It consistently covers more of the Pareto front than existing methods, enabling more flexible exploration of trade-offs in offline settings.

3 - Stochastic Dual Cone Gradient Descent with Adaptive Moments: a Robust Approach to Conflict-Free Multi-Objective Optimization

Dohyun Bu, KAIST, Suwon, Korea, Republic of, Jong-Seok Lee

Multi-objective optimization in deep learning is often complicated by conflicting gradients among tasks and stochastic noise, which can hinder a model's ability to achieve well-balanced performance across objectives. Prior works have attempted to address these issues by either applying deterministic gradient projection techniques to resolve conflicts or introducing stochastic gradient corrections to reduce bias. However, these methods often struggle to simultaneously ensure conflict resolution and maintain robust convergence in the presence of noisy gradients. To overcome these challenges, we propose Stochastic Dual Cone Gradient Descent with Adaptive Moments, a novel optimization algorithm that combines conflict-free update directions with noise-robust gradient estimation. Specifically, our approach projects each stochastic gradient update onto the dual cone spanned by the task-specific gradients, ensuring that every update step is a descent direction for all objectives. In addition, we integrate an Adam-style adaptive moment estimator to track each task's gradient, yielding unbiased estimates of each task's true gradient from noisy samples. As a result, the proposed method guarantees conflict-free update directions in expectation and promotes stable convergence under stochastic conditions. We empirically validate the effectiveness of our approach by training Physics-Informed Neural Networks on representative partial differential equation benchmarks, where it achieves improved convergence stability and well-balanced performance across objectives.

4 - Two-Stage Decision Tree Optimization Using a GCN-Based Approach

Jose Navarro, University of South Florida, Tampa, FL, United States, Kaixun Hua, Alex Savachkin

We propose a Graph Convolutional Network (GCN) framework to approximate optimal decision tree (ODT) solutions as two-stage Mixed Integer Programming (MIP) problems. This approach utilizes advances in learning-to-optimize and knowledge distillation, featuring a dual GCN architecture: an encoder that learns decision tree structures from first-stage MIP variables and constraints, and a decoder for sample-specific classification. The encoder captures patterns of solver-optimized trees, while the decoder reconstructs leaf assignments, enabling efficient inference with interpretability. Preliminary results demonstrate that the GCN model accurately reconstructs solver outputs and replicates the classification behaviors of traditional MIP solvers.

5 - Formulating Transformers in Mixed-Integer Programming For Sequential Decision-Making

Minseo Lee, Virginia Tech, Blacksburg, VA, United States, Esra Toy

The transformer architecture has demonstrated outstanding performance across domains such as natural language processing, computer vision, and time-series analysis. This paper presents a novel mathematical programming formulation of the transformer, with a focus on integrating it into mixed-integer optimization (MIP) models for decision-making tasks. By explicitly modeling attention mechanisms and feedforward networks, we offer a formulation that captures the nonlinear dependencies inherent in sequential data while enabling provable optimality. We address key challenges, including the non-convexity of the softmax function, through piecewise linear approximations and decomposition strategies. Computational experiments validate substantial efficiency gains and improved solution quality over direct formulations. Furthermore, we demonstrate how this approach can be embedded in broader optimization problems, such as the resource-constrained shortest path problem, to leverage the transformer's representational power in complex combinatorial settings.

1 - An Enhancement of Mixed-Integer Linear Programming Approaches for Resource Allocation in Project Networks

Norbert Trautmann, University of Bern, Bern, Switzerland, Nicklas Klein

An activity-on-node project network consists of nodes representing the project activities and edges representing the prescribed precedence relations between these activities. Executing an activity requires a prescribed amount of time and specific resources of different types. At any given time, the total consumption of each resource type cannot exceed its capacity. We consider the resource-constrained project scheduling problem (RCPSP), which consists in allocating the resources to the project activities over time in order to minimize the time-to-market, i.e. the project duration. A variety of formulations of the RCPSP as a mixed-integer linear programming model have been discussed in the literature. We propose an enhancement to existing models by incorporating a redundant constraint that evaluates the workload to be processed before and after the start of each activity, respectively. Our computational analysis on a standard test set from the literature confirms that this constraint considerably improves the relaxation-based lower bound.

2 - Induced Conflict Formulations for Second-Order K-Clubs

Yajun Lu, Jacksonville State University, Jacksonville, AL, United States, Baski Balasundaram

A k-club is a clique relaxation defined as a vertex subset inducing a subgraph with diameter at most k, originally introduced to model cohesive subgroups in social networks and tightly knit clusters in graph-based data mining. However, k-clubs can be fragile for $k \geq 2$, potentially creating subgraphs with low connectivity, such as those containing a cut vertex. This observation led various authors to introduce second-order k-clubs that require additional properties that endow the induced subgraph with fault tolerance and/or increased vertex connectivity. This talk introduces new induced conflict formulations for several second-order k-club models, offering the very first integer programming formulations for some of them. We compare the new formulations against existing formulations from the recent literature where available, investigate the effectiveness of the proposed formulation through theoretical and empirical means, and report encouraging computational evidence that this approach is favorable over existing approaches for challenging optimization problem instances.

Chair: Arun Akkinepally, Massachusetts Institute of Technology, Cambridge, MA, United States

1 - Modelling Gradual and Cooperative Coverage in Location Models

Mumtaz Karatas, Wright State University, Dayton, OH, United States, Levent Eriskin, Ertan Yakici

Location problems are a fundamental area of study in operations research and decision science, with wide-ranging applications spanning facility location, network design, emergency response, transportation, and defense. One critical aspect of location problems is the coverage of demand or service areas by facilities, which can have significant economic, social, and environmental implications. Conventional models often assume a binary or deterministic coverage, where a facility either fully covers a demand point or does not cover it at all. Such simplifications fail to capture the full complexity of real-world scenarios. This study explores the modeling challenges and solution approaches for location problems in the presence of gradual and cooperative coverage, where multiple facilities provide partial and joint coverage to demand points. We present mathematical formulations, linearization and approximation techniques and solution approaches for a range of models in retail operations and defense.

2 - A Semi-Desirable Modeling Approach for the Vertipoint Location Problem

Zahra Zare, Wright State University, Dayton, OH, United States, Mumtaz Karatas, Levent Eriskin

Abstract

In this study, we focus on the problem of locating vertipoints in the context of Urban Air Mobility (UAM). Vertipoints work as hubs to air-taxis and eVTOL (electric Vertical Take-Off and Landing aircraft) vehicles where passengers start by traveling to a vertipoint, fly between vertipoints using those vehicles, and then complete their trips using ground transportation. Vertipoints not only offer benefits like faster travel but also bring challenges like noise, visual pollution, and safety risks. To account for these conflicting effects, we model the problem as a semi-desirable hub location problem with both push and pull objectives. This approach enables planners incorporate both the positive impacts (better accessibility and connectivity) and negative impacts (disturbance to communities) when designing vertipoint networks. To tackle this problem, we first develop a weighted goal programming model to determine compromise solutions that balances total transportation costs and negative effects on communities. We model the disutility as the degree of impact vertipoints have on nearby neighborhoods using a distance-based function. We demonstrate the applicability of our formulation on a case study for Ohio, USA and perform a series of sensitivity analysis runs to explore the robustness of the solutions.

3 - Data-Driven Stochastic Vehicle Routing Problems with Deadlines

Shanshan Wang, Beihang University, Beijing (北京), China, People's Republic of, Erick Delage, Leandro Coelho

Vehicle routing problems (VRPs) with deadlines have received significant attention around the world. Motivated by a real-world food delivery problem, we assume that the travel time depends on the routing decisions, and study a data-driven stochastic VRP with deadlines and endogenous uncertainty. We use the non-parametric approaches, including k-nearest neighbor (kNN) and kernel density estimation (KDE), to estimate the decision-dependent probability distribution of travel time. To solve the resulting problem efficiently, we employ a logic-based Benders decomposition (LBBD) algorithm with several algorithmic enhancements. In particular, we propose a novel family of optimality cuts that includes the expected delay for all the subroutes. Moreover, we solve a total travel cost minimization problem to warm-start the algorithm. We also use a local search procedure to improve the current routing decision and propose a machine learning-based lower bound heuristic to efficiently solve

problems of realistic size. A practical case study for a food delivery routing problem using real-world data is conducted to show the efficiency of the proposed techniques and the advantage of the data-driven stochastic VRP in reducing the expected delay.

4 - Routing Autonomous Vehicles to Measure Pavement Friction in a Network

Caio Vitor Beojone, University of Illinois at Urbana-Champaign, Urbana, IL, United States, Yanfeng Ouyang

Pavement friction is critical for traffic safety. It is heavily associated with road crashes, notably when weather conditions are not ideal, making roads wet, snowy, or icy. However, accurate pavement friction is still challenging, costly, and slow in most critical spots. Hence, we propose a strategy to perform dynamic pavement friction measurements in a scenario where the authorities compile measurements from uncontrolled regular vehicles (RVs) and controlled autonomous vehicles (AVs). The strategy compiles measurements from different sources with varying methods by weighting their precision and grouping them into a single standardized distribution. The compiled measurements provide error estimates about the number of crashes associated with different arcs in the network. These estimates guide the routing of AVs, which try to minimize the errors of pavement friction measurements by covering the most critical spots in the network. A rolling horizon framework uses new incoming measurements to update routing decisions. This strategy was implemented in a prototype simulation based on Champaign County, reproducing realistic traffic counts for uncontrolled vehicles. Initial results showed that relying solely on uncontrolled RVs provides a sublinear convergence on pavement friction measurement precision. A couple of controlled AVs could cover about 20% of the arcs in the simulated network in three hours at a county level, and, compared with the exclusive use of RVs, they improved estimates by an additional 25%. Finally, further results show that, for planning horizons longer than 10 minutes, improvements in estimates depend mainly on the AV fleet size.

5 - Charge Planning for a Dedicated Electric Delivery Fleet

Arun Akkinipally, Amazon, Austin, TX, United States, Rami Sleiman, Andre Snoeck

We introduce Amazon's Charge Planner, an optimization algorithm designed to efficiently manage the charging of electric delivery vehicles, minimizing energy costs while ensuring operational readiness. As Amazon scales towards deploying 100k electric vehicles by 2030, effective charge planning becomes crucial for successful fleet electrification. We formulate charge planner as a MILP that optimizes for the charge scheduling while respecting infrastructure constraints, vehicle-specific charging requirements, and grid-level power constraints. The planner optimizes across multiple dimensions, including consumption-based spot costs and power-based demand charges, while ensuring that vehicles meet their target energy levels for next-day deliveries. We also enhance the approach to handle practical considerations like—changes in problem state and loss of charger connectivity under power-constraints. The results from simulations demonstrate that the charge planner achieves cost savings of 30-40% compared to baseline charging strategies. Finally, we also discuss future enhancements —like parking assignment and multi-day optimization.

Building Industry Academic Collaborations for Innovations

Panel Session

Practice Track

Co-Chair: Saeid Motevali, Georgia State University, Atlanta, GA, United States

1 - Moderator Panelist

Saeid Motevali, Georgia State University, Atlanta, GA, United States

Strong partnerships between academia and industry can drive innovation, create actionable insights, and deliver meaningful impact. This panel highlights successful models and hard-earned lessons from professionals who have worked across sectors to bridge research and application. Panelists will share strategies for initiating collaboration, aligning incentives, and sustaining momentum across project lifecycles.

The conversation will focus on practical frameworks for building trust, negotiating intellectual property, and balancing academic rigor with business needs. Topics may include applied research programs, joint labs, embedded internships, and data-sharing partnerships. Panelists will speak from experience rather than company-specific examples, offering guidance that applies broadly across sectors and disciplines.

This interactive session invites questions from the audience and encourages thoughtful exchange around mutual benefit, innovation pipelines, and shared goals. Whether you're an academic seeking industry engagement or a practitioner navigating university collaboration, this panel offers actionable insights and new ways to connect ideas with impact.

Chair: Sina Aghakhani

1 - Optimization of Replenishment and Picking Processes in Robotic Mobile Fulfillment Systems with Multiple Picking Stations

Takashi Irohara, Sophia University, Tokyo, Japan, Shinnosuke KAWAHARA

In recent years, robotic mobile fulfillment systems (RMFS) have significantly enhanced the efficiency of the picking process. These systems employ robots to transport racks containing Stock Keeping Units (SKUs) to picking stations, where static pickers are utilized. The frequency of visits to workstations serves as a crucial metric for evaluating the system's effectiveness in terms of cost reduction and makespan compression. Previous studies have demonstrated that warehouses equipped with multiple picking stations can reduce the makespan of picking operations; however, these studies often overlook the tasks performed at replenishment stations. Replenishment activities have largely been neglected in this domain. Consequently, this study aims to minimize the total number of visits to multiple picking stations and a single replenishment station by optimizing both picking and replenishment processes. The proposed model is formulated as an integer linear programming problem. To validate the efficacy of the synchronized model, the outcomes of optimizing solely the picking processes and solely the replenishment processes are compared with those of the integrated model. The integrated model results in fewer visits to the replenishment station compared to the model optimizing only picking processes. Similarly, it results in significantly fewer visits to the picking stations compared to the model optimizing only replenishment processes. Numerical experiments demonstrate that simultaneous optimization of picking and replenishment processes can achieve a reduction in the total number of visits to all workstations, even when multiple picking stations are employed.

2 - Supply Chain Design Principles for SAF Production in Switzerland Using Anylogistix Network Optimization

Marco Aebi, Zurich University of applied Sciences, Winterthur, Switzerland, Maike Scherrer, Joel Weingart

Sustainable aviation fuels (SAF) are one option to reduce GHG emissions in the hard-to-abate aviation sector in the medium term. Among the different pathways that exist for SAF production, experts expect Power-to-Liquid (PtL) to be one of the most relevant ones in the future as it does not rely on limited resources. This pathway uses large amounts of (green) hydrogen and CO₂ as feedstock. As the supply of these feedstocks has not yet been scaled to the necessary quantity, many questions regarding the design of a SAF supply chain remain unanswered.

Using the simulation and optimization software AnyLogistix, this work aims to derive supply chain design principles for the SAF production from a transport perspective for the use-case of SAF production in Switzerland. Questions that will be addressed are for example if it is more beneficial from an environmental and economic perspective to produce SAF in close proximity to the feedstock or rather at the place of consumption, and what transport emissions occur in the SAF supply chain. The results enable informed decisions related to trade-offs in SAF production options. For this, a network optimization model including different modes of transport for the different compounds is used to optimize the SAF production network. Preliminary results show that it is cheaper to produce hydrogen directly at a power plant and then transport liquid hydrogen to the SAF plant compared to transmitting the electricity through the grid and producing hydrogen locally at the SAF plant.

3 - Maximizing Small Dairy Farm Revenues by Simultaneously Selecting Optimal Consolidation Depot Location and Routing Under Co-Mingling Constraints with Heterogeneous Vehicles and Time Windows

Ashesh Kumar Sinha, West Virginia University, Morgantown, WV, United States, John Saldanha, Molly Hughes, Michael Harman

We analyze a milk logistics network problem with heterogeneous vehicles, small farms, consolidation centers and processors. Milk logistics challenges include pickup and milk-grade based co-mingling restrictions and short shelf-life. The primary theoretical drivers for the novel supply chain management solution are transportation economies of density and network economies of scale. Typically, small farms are unable to fill even a small truck and therefore pay less than truckload (LTL) rates to haul their milk to the processor. Relatedly, as LTL rates increase with distance. We propose a novel MILP formulation that models a scenario of a cooperative network of farms and consolidation depots where milk is commingled and aggregated for distribution to processors involving several intermingled decisions: (i) find the optimal number and locations of consolidation depots. (ii) assign farms to each depot. (iii) determine the optimal route to run a truck to each farm to pick up milk and then deliver the milk to the depot. Here the tanker will commingle the milk picked up from each farm before delivery to the depot. (iv) determine transportation decisions for the milk at a much more economical truckload (TL) rate to the processors once the depot that received enough milk.

4 - Integrated Evacuation and Relief Supply Network Design for Foreseen Disasters

Vala Rahmati, Southern Methodist University, Dallas, TX, United States, Halit Uster

This study examines emergency preparedness for foreseen disasters such as hurricanes and floods. Given known evacuee counts for each evacuation zone, we determine the locations of distribution centers (DCs) and shelters, then route both relief supplies and evacuees through transfer nodes on an integrated time-phased network, minimizing cost while meeting arrival deadlines. The problem is formulated as a mixed-integer program and solved with an enhanced Benders decomposition that derives optimality cuts via master-problem modifications and surrogate constraints, further accelerated by solution-modification heuristics and speed-up cuts. Tests on randomly generated instances identify the most effective enhancements, and a GIS-based case study using South Texas data illustrates how key parameters influence network design and real-time operations.

5 - Optimization-Based Consolidation Engine for Last Mile Delivery

Hao Zhou, Amazon, Bellevue, WA, United States

We present an optimization-based approach for the last-mile delivery stop planning problem, where packages must be consolidated into efficient vehicle stops while considering both operational constraints and delivery quality. Current industry solutions often rely on rule-based heuristics, which can lead to suboptimal consolidation and require constant maintenance as delivery patterns evolve. We introduce an Optimization-based Consolidation Engine (OCE) that simultaneously determines stop grouping and optimizes delivery sequences by minimizing total service time across stops. The mathematical model balances the trade-off between parking time overhead and walking time while incorporating critical operational constraints. To address potential data quality issues and capture local delivery patterns, we enhance the base model with a novel hints mechanism that leverages historical delivery data through a cross-entropy loss function. The model is implemented using an efficient local search algorithm suitable for large-scale operations. In initial simulation analysis and pilot testing, we demonstrate improvements in both consolidation quality metrics and service time efficiency, with perfect consolidation rates increasing by 1.53% and under-consolidation decreasing by 2.29%. The approach provides a robust framework for incorporating dynamic features and adapting to real-time conditions. This research contributes to the growing literature on last-mile logistics optimization by presenting a practical solution to a complex operational challenge faced by modern delivery networks.

6 - Awesm: Informing Energy-Aware Last Mile Strategic Network Design

Harry Birnbaum, Amazon, Seattle, WA, United States, Andre Snoeck, Nic Wayand, Daniel Merchan

Amazon co-founded The Climate Pledge in 2019. As part of that Pledge, Amazon also announced to bring 100,000 electric delivery vehicles on the road by 2030. Introducing EVs requires changes across planning horizons, from strategic network design decisions, such as vehicle-to-delivery station allocations, to day-of execution. We propose an approach that quantifies the impact of servicing a specific area with EVs to inform such strategic network design decisions. This Area with EV Suitability Model (AwESM) flexibly defines geographical areas and fleet compositions, making it applicable across multiple strategic planning horizons and use cases.

7 - Improving Linehaul Efficiency with Load Consolidation Models

Jeren Konak, Georgia Institute of Technology, Atlanta, GA, United States, Amira Hijazi, Sikai Cheng, Alan Erera

Designing efficient routes and consolidation strategies for ground transportation between sorting hubs is a major challenge in large-scale logistics networks. Packages move through the system according to primary and alternate flow rules in trailers or other ground freight transportation modes as specified by the load plan. In collaboration with UPS, we analyzed potential partial loads that could feasibly be consolidated using historical load data, yielding insights for future load planning. These consolidations lead to lower overall costs and congestion while meeting service commitments and business practices.

Given the magnitude of the linehaul network, we have approached this problem by creating two robust optimization models – Consolidation by Single Destination (CBD) and Consolidation by Single Origin (CBO). The CBD model groups all partial loads that share a common destination into clusters based on the origin of the load. The model then searched for feasible consolidations within each origin cluster before the trailer reaches the shared destination. On the other hand, the CBO model identifies consolidation opportunities for all partial loads that are leaving from the same origin to different destinations. Both models aim to minimize costs (transportation, package handling/sorting) and the impact on driver schedules while maintaining important business-prioritized constraints, such as service commitments and sort capacities. Our findings offer promising directions for enhancing efficiency in large-scale logistics operations.

8 - A Multi-Objective Optimization Model for Two-Echelon Hybrid Delivery Planning Using Trucks, Robots, and Crowdsourcing

Sina Aghakhani, Oklahoma State University, Stillwater, OK, United States, Mohammad Fili, Guiping Hu

The rapid growth of e-commerce has heightened the demand for last-mile delivery systems that are not only efficient and cost-effective but also environmentally sustainable. This study proposes a multi-objective mathematical model for a hybrid delivery planning framework that integrates trucks, autonomous delivery robots, and crowdsourced drivers to optimize logistics operations. The proposed two-tier model assigns trucks to transport packages to designated parking hubs, from which autonomous robots and crowdsourced drivers complete the final leg of delivery. The model aims to minimize the total delivery costs while also reducing overall operation time. We employ Non-dominated Sorting Genetic Algorithm II (NSGA-II) to find the pareto optimal solutions and compare the performance against the augmented ϵ -constraint method for small instances. Additionally, we introduce and evaluate the algorithm on a large-scale Brazilian E-commerce dataset in São Paulo.

1 - Advances in Budget-Split Experimentation for the Online Ads Marketplace

Shan Ba, LinkedIn, Mountain View, CA, United States

Classical A/B testing on online advertising platforms is often subject to bias, particularly due to cannibalization effects. Budget-Split Testing (BST) is widely regarded as the gold standard for mitigating these biases, as it controls the allocation of campaign budgets across different treatment variants. In this talk, we present recent methodological and system-level advancements that improve the design and analysis of BST. We examine how BST interacts with marketplace dynamics, explore the operational trade-offs of increasing the number of partitions (i.e., splits in BST), and assess the associated cost implications. Additionally, we identify various sources of bias in standard BST setups and introduce a Robust BST design that systematically eliminates partition-related biases. These enhancements make BST more scalable and reliable for high-stakes decision-making in optimizing the online ads marketplace.

2 - Enhancing Geo-Targeted Experimentation: Robust Methodologies for Measuring Advertising Effectiveness in Privacy-Constrained Environments

Malika Korganbekova, The University of Chicago Booth School of Business, Chicago, IL, United States, Jerry Chen, Faith Shin

This paper addresses the challenges of conducting advertising effectiveness experiments in privacy-restricted environments, where data limitations and stringent regulations hinder precise measurement. Platforms increasingly rely on geo-targeted experiments, such as cluster-randomized tests based on geolocations, to navigate these constraints. However, these tests face significant obstacles, including low statistical power, imprecise geolocation matching, and complications arising from dense urban clusters. A key challenge is **interference**, which occurs when individuals in treatment and control groups influence each other's outcomes, often due to overlapping geographies or shared advertising exposure. Interference distorts estimates of treatment effects and reduces the reliability of results.

We partner with a large online retailer in the US and propose a comprehensive framework to enhance the power and precision of geo-targeted experiments. Our methodology includes optimizing geo-split designs to increase sample size, applying synthetic control methods to create robust comparison groups, and introducing switchback testing to improve accuracy in dynamic settings. Clustered randomization is employed to group geographically close areas, minimizing interference while preserving granularity. Re-clustering techniques further balance treatment assignments by accounting for proximity and population density. Simulations are used to model the impact of interference and refine confidence intervals, while observational data aids in reducing measurement biases.

Through simulations, historical data analysis, and new experimental designs, we evaluate the effectiveness of these methods. Our findings contribute to the development of privacy-compliant experimentation frameworks that improve targeting accuracy, boost customer lifetime value, and enhance profitability. Beyond marketing, these approaches have broader applications, such as optimizing logistics and supply chain.

3 - Local Geometric Structure Detection in Random Graphs: Information-Theoretic Limits

Shuangping Li, Yale University, New Haven, CT, United States

We study the problem of detecting a planted random geometric subgraph within an Erdős-Rényi graph. We characterize the information-theoretic limits of detection as a function of the ambient dimension, identifying thresholds where geometric structure becomes distinguishable from randomness.

4 - Choosing the Better Bandit Algorithm Under Data Sharing: when Do A/B Experiments Work?

Jingyan Wang, Toyota Technological Institute at Chicago, Chicago, IL, United States, Shuangning Li, Chonghuan Wang

We study A/B experiments that are designed to compare the performance of two recommendation algorithms. Prior work has shown that the standard difference-in-means estimator is biased in estimating the global treatment effect (GTE) due to a particular form of interference between experimental units. Specifically, units under the treatment and control algorithms contribute to a shared pool of data that subsequently train both algorithms, resulting in interference between the two groups. The bias arising from this type of data sharing is known as "symbiosis bias". In this paper, we highlight that, for decision-making purposes, the sign of the GTE often matters more than its precise magnitude when selecting the better algorithm. We formalize this insight under a multi-armed bandit framework and theoretically characterize when the sign of the expected GTE estimate under data sharing aligns with or contradicts the sign of the true GTE. Our analysis identifies the level of exploration versus exploitation as a key determinant of how symbiosis bias impacts algorithm selection.

5 - Hypothesis Testing for Detecting Network Interference in Randomized Experiments

Christopher Harshaw, Columbia University, New York City, NY, United States, Yitan Wang, Chao Gao, Fredrik Sävje

From political science and economics to public health and corporate strategy, the randomized experiment is a widely used methodological tool for estimating causal effects. In order to meaningfully estimate causal effects, experimenters have to assume structure on the potential outcome functions. The simplest assumption is that of no-interference, although a growing body of work has provided various network interference models under which causal effects can be estimated. Still, this raises the question: to what extent can we test these assumptions? For example, can we detect interference when it is present in the experiment? Can we test between stronger and weaker models of network interference? To this end, a line of previous work has focused on controlling Type I error, but Type II error of these proposed methods remains less well understood.

In this work, we further investigate hypothesis testing frameworks for detecting interference. Our main contribution is a series of negative results. Roughly speaking, we show that there is no test for detecting interference which has small Type I and Type II error, even as the sample size increases. This finding has serious consequences for the epistemological nature of the no-interference and various network interference assumptions: namely, that they are -- in a rigorous sense -- unstable. On the positive side, we show that there exists a uniformly consistent test of no interference when the alternative hypotheses are restricted to a linear-in-means type model and the graph is sufficiently sparse.

Multiserver-job Scheduling and Collusive Learning

Invited Session

Applied Probability Society

Chair: Izzy Grosz, Northwestern University, Evanston, IL, 60201, United States

1 - Half-Batch Multiserver-Job Scheduling

Ziyuan Wang, Northwestern University, Evanston, IL, United States

In large-scale computing systems such as high-performance clusters, jobs often demand heterogeneous server allocations: large jobs that occupy a substantial fraction of the servers are latency-sensitive, while small jobs fill in the remaining capacity to maintain utilisation. To model this dynamic, we introduce the half-batch multiserver-job (MSJ) model, a queueing model in which large jobs arrive according to a Poisson process and require all servers simultaneously, while small jobs, each needing only one server, are always available. We study the resulting trade-off between large-job response time and small-job throughput, define a two-dimensional performance criterion, and aim to characterize the Pareto-optimal frontier.

We analyse a practical family of scheduling policies, the $\$(k,n)\$$ -batch policies and their convex combinations, and propose that they form the Pareto frontier in the half-batch MSJ system. We establish partial structural results about the sample paths of optimal policies and outline the final result needed to complete the proof that convex combinations of $\$(k,n)\$$ -batch policies characterise the full Pareto-optimal frontier.

2 - Multiserver-Job Scheduling with Continuous Requirement Distribution

Heyuan Yao, Northwestern University, Evanston, IL, United States, Izzy Groszof, Jay Kowalik

Multiserver-job systems are a useful model for large-scale computing systems, where different jobs may require different amounts of resources. Existing literature assumes a discrete set of possible job requirements. To better model real-world systems, we study a model where the job requirement distribution is continuous.

In this talk, we will introduce the K-discretized Max-Weight policy, where we equally partition the capacity into K buckets and in each bucket round up the requirement. We prove a full-utilization result when the requirement distribution has a decreasing density. Moreover, we prove throughput-optimality when the requirement density is Lipschitz. We also prove equivalent results for the nonpreemptive K-discretized Markovian Service Rate policy. We also generalize to the adaptive-discretization setting and the multiresource-job setting.

3 - Collusive Pricing Under Oblivious Learning

Yuhang Wu, Columbia University, New York, NY, United States, Assaf Zeevi

There is a growing concern that independent pricing algorithms under competitive market conditions may learn to sustain near-collusive outcomes, a phenomenon called algorithmic collusion. Aside from the regulatory implications, this phenomenon also raises nontrivial questions on how firms should learn and make pricing decisions when it is possible to collude tacitly. To further our understanding of these problems, we propose a novel online multi-agent framework and study the market outcome when sellers are "oblivious" to competitor information. We first provide insights on how sellers' price exploration behaviors affect the market outcome and pinpoint sellers' optimal strategy from a revenue management perspective. Building on these insights, our analysis indicates that, contrary to some existing literature, collusive behaviors do not sustain very naturally. In fact, though significant excursions towards the collusive outcome are possible over finite horizons, the system always converges to the competitive outcome in the long run. We also compare oblivious sellers with "non-oblivious" sellers and illustrate the algorithmic dynamics between these different modeling choices. Supported by both theoretical and numerical evidence, we believe our results shed light on whether sellers should incorporate competitor information in their learning and pricing models. More broadly, our work contributes to the study of algorithmic collusion by showing how revenue management principles can both inform and structure its analysis, paving the way for a deeper understanding of its implications.

4 - Gradient-Based Algorithms for Machine Unlearning

Siqiao Mu, Northwestern University, Evanston, IL, United States, Diego Klabjan

Machine unlearning algorithms aim to efficiently remove data from a model without retraining it from scratch, in order to remove corrupted or outdated data or respect a user's "right to be forgotten." Certified machine unlearning is a strong theoretical guarantee based on differential privacy that quantifies the probabilistic indistinguishability between the unlearned model and the model retained on the retained data samples. We introduce new gradient-based algorithms for certified machine unlearning, emphasizing the importance of *black-box* algorithms that can be applied to trained models without costly precomputation.

5 - Multiserver-Job Response TIME Under Multilevel Scaling

Izzy Groszof, Northwestern University, Evanston, IL, United States

We study the multiserver-job setting in the load-focused multilevel scaling limit, where system load approaches capacity much faster than the growth of the number of servers n . We specifically consider the " 1 and n " system, where each job requires either one server or all n

servers. Within the multilevel scaling limit, we examine three regimes: load dominated by n -server jobs, 1 -server jobs, or balanced.

In each regime, we characterize the asymptotic growth rate of the boundary of the stability region and the scaled mean queue length. We numerically verify our asymptotic results against exact formulae.

1 - The Dynamic Stochastic TIME-Dependent Vehicle Routing Problem with Non-Recurring Congestion Events: a Reinforcement Learning Approach

Fernando Pilleux, Universidad Adolfo Ibañez, Santiago, Chile, Felipe Lagos, Stefano Novellani

In recent times, technological advances and the COVID-19 pandemic have driven a shift in consumer preferences, with a growing demand for faster delivery services. This transformation has led to a significant increase in the global e-commerce market and has forced companies to emphasize last-mile delivery. This study formulates a Dynamic Stochastic Time-Dependent Vehicle Routing Problem with Non-Recurrent Congestion (STDVRPTW-NRC), aiming to minimize the total operational cost. The problem arises from the need to accurately capture real-world traffic conditions using real data from the city of Chengdu, China. The model accounts for speeds and travel times that vary stochastically and depend on the time of day. Additionally, it introduces an extra layer of uncertainty through the inclusion of non-recurrent congestion events. The problem is formulated as a Markov Decision Process and solved using a reinforcement learning approach, specifically through an on-policy Monte Carlo control (MC) method with function approximation. This method employs a linear approximation of the value function, enabling it to effectively adapt to the uncertainty that unfolds during the execution of the problem. The proposed approach is compared with a state-of-the-art metaheuristic that provides a static solution to the problem. To evaluate the performance of these models, four different non-recurrent congestion scenarios are tested, using instances with an average of 150 and 250 customers. Across all scenarios evaluated, the on-policy MC method consistently outperformed benchmark policies, achieving improvements ranging from 11.03% to 41.26% in total costs.

2 - Multi-Agent Reinforcement Learning for Optimizing Relocation in One-Way Electric Car Sharing Systems

Wentao Zhao, University of Southern California, Los Angeles, CA, United States, Maged Dessouky

We study the dynamic relocation problem in an electric vehicle (EV) sharing system that provides on-demand mobility services. The objective of this research is to develop a high-quality, real-time relocation strategy for a widely distributed, large-scale shared EV network, capable of addressing stochastic customer demand and mitigating the computational challenges arising from the curse of dimensionality. To this end, we propose a decentralized two-stage decision-making scheme. In the first stage, we develop a multi-agent reinforcement learning framework that models each EV-sharing station as an independent agent responsible for determining its relocation requests. In the second stage, we transform the decentralized relocation requests into a feasible system-wide relocation strategy that satisfies operational constraints, such as fleet conservation, by solving an optimization problem. Finally, we evaluate the performance of the proposed method by comparing it against several optimization-based benchmarks in terms of profit and service quality, using real-world data from a major EV-sharing system.

3 - Infinite Drive In the City: Scalable Optimization of Dwpt Locations for Urban EV Charging Using Gmns

Yudai Honma, The University of Tokyo, Tokyo, Japan, Xuesong Zhou, Katsuhiro Hata, Takashi Oguchi

We develop a scalable optimization framework for deploying Dynamic Wireless Power Transfer (DWPT) infrastructure to support continuous electric vehicle (EV) operation in urban environments — a concept we call "Infinite Drive." Our mixed-integer programming model minimizes DWPT installation length while ensuring sufficient charging across all travel routes. It incorporates detailed traffic dynamics, including acceleration, deceleration, and signal-induced stopping behavior, and evaluates route-level energy balance using fine-grained segment analysis. Applied first to Kawagoe, Japan, the model identifies just 2,359 meters of DWPT — less than 2% of total road length — as sufficient to support full EV mobility. We extend the model to New York City using the GMNS dataset and find similarly effective results despite increased network complexity. The study demonstrates the feasibility and efficiency of DWPT infrastructure in diverse urban settings, offering a replicable and

data-driven tool for cities seeking to build plug-free, low-emission mobility systems. This research provides a foundation for scalable planning of dynamic EV charging and supports the broader transition to sustainable urban transportation.

4 - Enhancing Online Food Delivery with Transfer Points: a Decompose-Then-Optimize Approach via Hierarchical Reinforcement Learning

Xinwu Qian, Rice University, Houston, TX, United States, Xinyuan Zhang, Qi Luo

Online food delivery services can reduce operational costs and optimize efficiency by consolidating orders with similar origins, destinations, and time windows at intermediate transfer locations.

This research investigates the complexity inherent in the online food delivery problem with transfer (OFDP-T) and assesses how optimized routes and courier assignments involving transfer locations can enhance system delivery performances.

We propose a novel learning-based decompose-then-optimize framework to manage the exponentially growing problem size introduced by transfer and synchronization decisions and enable adaptive decision-making under uncertainty.

This proposed decomposition framework is enabled by a seamless integration between a first-step hierarchical reinforcement learning (HRL) model and the resulting second-step model that can be solved as a linear assignment problem (LAP).

Through comprehensive experiments based on real-world food delivery data, the study demonstrates that the combination of task-agnostic reward design and LAP-guided policy search significantly improve the baseline methods.

Our case study shows that task-agnostic reward design and LAP-guided policy search improve baseline performance by 27.2%, with the reward shaping alone boosting HRL by 37.5% and LAP-guided search adding 6.9%. Notably, even limited use of transfers can yield over 46.6% improvement in route efficiency and a 23.2% gain for remaining orders. This framework offers a deployable, real-time solution and actionable strategies for coordinating complex delivery operations and improving fleet utilization that will empower more sustainable and scalable food delivery systems

5 - Integrated Order Dispatching and Routing via Hierarchical Deep Reinforcement Learning for Last-Mile Delivery

Yida Xu, Tianjin University, Tianjin, China, People's Republic of, Henry Miao, Zhaofang Mao

In recent years, the increasing complexity of last-mile delivery has placed significant demands on the speed and accuracy of decision-making on delivery platforms. Traditional approaches that address the order dispatching and courier routing problems separately often result in sub-optimal solutions and lack coordination between these critical components. To address this gap, we formulate a double-level optimization problem integrating both order dispatching and courier routing, leveraging a dataset of last-mile pickup deliveries provided by Cainiao Logistics (LaDe, 2024). To solve this challenging problem, we propose a hierarchical deep reinforcement learning framework. For the upper-level order dispatching problem, we encode nodes and edges in a heterogeneous graph to distinguish courier nodes from order nodes. To capture the structural similarity of orders from different communities and the dissimilarity among neighboring orders, we design a Spatial Heterophily graph structure to optimize the efficiency of order dispatching. For the lower-level routing problem, a Dynamic Residual Graph Attention Network Encoder is proposed to capture both temporal and spatial features, along with a Look-Ahead Courier Personalized Decoder. Experiments with real-world data confirm the effectiveness of our proposed method. The results show a significant advantage over popular deep reinforcement learning methods and heuristic methods, indicating that our method can effectively help package delivery companies solve the real-time package pickup problem. This research provides a novel integrated approach to optimizing last-mile delivery operations, offering benefits for academics through innovative methodologies, for practitioners through enhanced operational efficiency, and for policymakers through insights into sustainable urban logistics solutions.

Reinforcement Learning with Preference Feedback

Invited Session

Applied Probability Society

Chair: Qiaomin Xie, University of Wisconsin-Madison, Madison, United States

Co-Chair: Yixuan Zhang, University of Wisconsin-Madison, Madison, WI, United States

1 - Zeroth-Order Policy Gradient for Reinforcement Learning from Human Feedback Without Reward Inference

Qining Zhang, University of Michigan, Ann Arbor, MI, United States, Lei Ying

Reward inference (learning a reward model from human preferences) is a critical intermediate step in the Reinforcement Learning from Human Feedback (RLHF) pipeline for fine-tuning Large Language Models (LLMs). In practice, RLHF faces fundamental challenges such as distribution shift, reward model overfitting, and problem misspecification. An alternative approach is direct policy optimization without reward inference, such as Direct Preference Optimization (DPO), which provides a much simpler pipeline and has shown empirical success in LLM applications. However, DPO utilizes the closed-form expression between the optimal policy and the reward function, which is only suitable under the bandit setting or deterministic MDPs. This paper develops two RLHF algorithms without reward inference for general RL problems beyond bandits and deterministic MDPs, and general preference models beyond the Bradley-Terry model. The key idea is to estimate the local value function difference from human preferences and then approximate the policy gradient with a zeroth-order gradient approximator. For both algorithms, we establish polynomial convergence rates in terms of the number of policy gradient iterations, the number of trajectory samples, and human preference queries per iteration. Numerical experiments in stochastic environments validate the performance of our proposed algorithms, outperforming popular RLHF baselines such as DPO and PPO. Our paper shows there exist provably efficient methods to solve general RLHF problems without reward inference.

2 - Beyond Bradley-Terry Models: a General Preference Model for Language Model Alignment

Quanquan Gu, UCLA, Los Angeles, CA, United States

Modeling human preferences is crucial for aligning foundation models with human values. Traditional reward modeling methods, such as the Bradley-Terry (BT) reward model, fall short in expressiveness, particularly in addressing intransitive preferences. In this paper, we introduce preference embedding, an approach that embeds responses into a latent space to capture intricate preference structures efficiently, achieving linear query complexity. Additionally, we propose preference score-based General Preference Optimization (GPO), which generalizes reward-based reinforcement learning from human feedback (RLHF). Experimental results show that our General Preference embedding Model (GPM) consistently outperforms the BT reward model on the RewardBench benchmark and effectively models cyclic preferences where any BT reward model behaves like a random guess. Furthermore, evaluations on downstream tasks such as AlpacaEval2.0, following the language model post-training with GPO and our general preference model, reveal performance improvements over BT models. These findings indicate that our method may enhance the alignment of foundation models with nuanced human values.

3 - Faster Wind: Accelerating Iterative Best-of-N Distillation for LLM Alignment

Tong Yang, Carnegie Mellon University, Pittsburgh, PA, United States

Recent advances in aligning large language models with human preferences have corroborated the growing importance of best-of-N distillation (BOND). However, the iterative BOND algorithm is prohibitively expensive in practice due to the sample and computation inefficiency. This paper addresses the problem by revealing a unified game-theoretic connection between iterative BOND and self-play alignment, which unifies seemingly disparate algorithmic paradigms. Based on the connection, we establish a novel framework, WIN rate Dominance (WIND), with a series of efficient algorithms for regularized win rate dominance optimization that approximates iterative BOND in the parameter space. We provides provable sample efficiency guarantee for one of the WIND variant with the square loss objective. The experimental results confirm that our algorithm not only accelerates the computation, but also achieves superior sample efficiency compared to existing methods.

4 - Online Rlhf with Exploration

Jincheng Mei, Google, St Albans, United Kingdom, Bo Dai

Reinforcement learning (RL) has demonstrated great promise in aligning large language models (LLMs) with human preference, but how to collect samples efficiently for training is still the major bottlenecks. Concretely, while the principles of optimism or pessimism under uncertainty are well-established in standard RL to obtain more effective samples, a practically-implementable and theoretically-grounded form amenable to large language models is not yet available, as standard techniques for constructing confidence intervals become intractable under arbitrary policy parameterizations. In this talk, we introduce value-incentivized preference optimization (VPO), which regularizes the maximum-likelihood estimate of the reward function with the corresponding value function, as a theoretical guarantee implementation of optimism prior for exploration, matching the rates of their standard RL counterparts. Moreover, experiments on text summarization and dialog verify the practicality and effectiveness of VPO.

Recent Advances in Min-Max Optimization

Invited Session

OPT: Nonlinear Optimization

Chair: Mert Gurbuzbalaban, Rutgers, New Brunswick, NJ, United States

Co-Chair: Necdet Aybat, Penn State University, University Park, PA, 16802, United States

1 - High-Probability Complexity Bounds for Stochastic Non-Convex Minimax Optimization

Mert Gurbuzbalaban, Rutgers University, Piscataway, NJ, United States, Yassine Laguel, Yasa Syed, Necdet Aybat

Stochastic smooth nonconvex minimax problems are prevalent in machine learning, e.g., GAN training, fair classification, and distributionally robust learning. Stochastic gradient descent ascent (GDA)-type methods are popular in practice due to their simplicity and single-loop nature. However, there is a significant gap between the theory and practice regarding high-probability complexity guarantees for these methods on stochastic nonconvex minimax problems. Existing high-probability bounds for GDA-type single-loop methods only apply to convex/concave minimax problems and to particular non-monotone variational inequality problems under some restrictive assumptions. In this work, we address this gap by providing state-of-the-art high-probability complexity guarantees for nonconvex/PL minimax problems corresponding to a smooth function that satisfies the PL-condition in the dual variable. We also present numerical results on a nonconvex/PL problem with synthetic data and on distributionally robust optimization problems with real data, illustrating our theoretical findings.

2 - A Stochastic Gradient Ascent Descent Method with Backtracking

Necdet Aybat, Penn State University, University Park, PA, United States, Mert Gurbuzbalaban, Qiushui Xu, Xuan Zhang

We propose a stochastic GDA method with backtracking (SGDA-B) to solve nonconvex-(strongly) concave minimax problems. SGDA-B is agnostic to the Lipschitz constant L , concavity modulus $\mu \geq 0$, and the variance bound of the unbiased stochastic gradient estimator. Within $\mathcal{O}(\epsilon^{-4} \log(1/p))$ and $\mathcal{O}(\epsilon^{-7} \log(1/p))$ stochastic gradient calls, SGDA-B can compute an ϵ -stationary point in terms of gradient-map norm and gradient norm of the Moreau envelope with probability $1-p$ when $\mu > 0$ and $\mu = 0$, respectively.

3 - AGDA+: Proximal Alternating Gradient Descent Ascent Method with A Nonmonotone Adaptive Step-Size Search for Nonconvex Minimax Problems

Qiushui Xu, Penn State University, State College, PA, United States, Xuan Zhang, Necdet Aybat

We consider double-regularized nonconvex-strongly concave (NCSC) minimax problems of the form $(P): \min_{\mathbf{x}} \max_{\mathbf{y}} g(\mathbf{x}) + f(\mathbf{y}) - h(\mathbf{y})$, where g, h are closed convex, f is L -smooth in $(\mathbf{x}, \mathbf{y})$ and strongly concave in $\mathbf{y}$. We propose a proximal alternating gradient descent ascent method `AGDA+` that can adaptively choose nonmonotone primal-dual stepsizes to compute an approximate stationary point for (P) without requiring the knowledge of the global Lipschitz constant L and the concavity modulus μ . Using a nonmonotone step-size search (backtracking) scheme, `AGDA+` stands out by its ability to exploit the local Lipschitz structure and eliminates the need for precise tuning of hyper-parameters. `AGDA+` achieves the optimal iteration complexity of $\mathcal{O}(\epsilon^{-2})$ and it is the first step-size search method for NCSC minimax problems that require only $\mathcal{O}(1)$ calls to ∇f per backtracking iteration. The numerical experiments demonstrate its robustness and efficiency.

4 - Risk-Sensitive Accelerated Gradient Methods with Biased Oracles

Yasa Syed, Rutgers University - New Brunswick, New Brunswick, NJ, United States, Mert Gurbuzbalaban, Necdet Aybat

We study generalized momentum methods (GMMs) for minimizing strongly convex, smooth functions in the presence of potentially biased stochastic gradient noise. This broad class of optimization algorithms includes gradient descent, the heavy ball method, and Nesterov's accelerated gradient method as special cases. Using the risk sensitivity (RS) index from robust control, we examine how step size and momentum parameters influence both convergence behavior and robustness to noise and bias. For quadratic objectives with independent and identically distributed Gaussian noise, we derive a closed-form expression for the RS index and establish large deviation results for the average suboptimality, along with high-probability bounds. We then extend these results to general strongly convex functions under a light-tailed noise assumption, deriving analogous RS index bounds, large deviation bounds, high-probability guarantees, and suboptimality estimates. Finally, we discuss the design of momentum methods that achieve optimal robustness properties in the presence of biased stochastic gradients.

1 - Traffic Reduction Potential of Autonomous Driving Freight Vehicles in Urban Settings

Maïke Scherrer, ZHAW School of Engineering, Winterthur, Switzerland, Joel Weingart

The densification of urban settings will further increase in the near future. The already overcrowded roads will no longer be able to absorb the resulting increase in passenger and freight traffic, which will lead to additional congestion. The study at hand analysis if autonomous driving freight vehicles have the potential to defuse the situation.

We analyse the effect of autonomous driving freight vehicles, which commute between a central warehouse and different city districts, where the freight is handed over to cargobikes for the very last mile. We compare this to traditional direct deliveries using vans and cargobikes.

The analysis bases on a route planning and optimisation model, which is specifically adapted for the different vehicle categories and is tested with real data from Switzerland in two settings: First, in a small and a big city, and second, in the case where a central warehouse is close to the city centre compared to a central warehouse in the outskirt of a city.

The results show that higher traffic reduction potential is given in bigger than in smaller cities and in cases where the central warehouse is in the outskirt of the city.

The results can be used in several ways: First, the model can be used to conduct similar analyses in different urban settings. Second, the results can be used to decide about the modal mix for urban logistics and in which situations a change from traditional deliveries to deliveries with autonomous driving freight vehicles in combination with

cargobikes is beneficial.

2 - Incremental Approximate Single-Source Shortest Paths with Predictions

Aidin Niaparast, Carnegie Mellon University, Pittsburgh, PA, United States, Samuel McCauley, Benjamin Moseley, Helia Niaparast, Shikha Singh

The algorithms-with-predictions framework has been used extensively to develop online algorithms with improved beyond-worst-case competitive ratios. Recently, there is growing interest in leveraging predictions for designing data structures with improved beyond-worst-case running times.

In this paper, we study the fundamental data structure problem of maintaining approximate shortest paths in incremental graphs in the algorithms-with-predictions model. Given a sequence of edges that are inserted one at a time, the goal is to maintain approximate shortest paths from the source to each vertex in the graph at each time step. Before any edges arrive, the data structure is given a prediction of the online edge sequence which is used to "warm start" its state.

As our main result, we design a learned algorithm that maintains $(1+\epsilon)$ -approximate single-source shortest paths, which runs in $O(m \eta \log(W)/\epsilon) \cdot \text{polylog}(n)$ time, where W is the weight of the heaviest edge and η is the prediction error.

Our algorithms are consistent (performing nearly as fast as the offline algorithm) when predictions are nearly perfect, have a smooth degradation in performance with respect to the prediction error and, in the worst case, match the best offline algorithm up to logarithmic factors. That is, the algorithms are "ideal" in the algorithms-with-predictions model.

As a building block, we study the offline incremental approximate single-source shortest-path (SSSP) problem, where the edge sequence is known a priori. Note that the offline problem is defined in the worst-case setting (without predictions) and is of independent interest.

3 - Milp-Based Optimization of Passenger Routing in Urban Air Mobility Systems

DongKyun Kim, Department of Battery-Smart Factory, Korea University, Seongbuk-gu, Korea, Republic of, Taesu Cheong, Min Jei Park

Urban Air Mobility (UAM) is an emerging transportation paradigm that utilizes electric vertical take-off and landing (eVTOL) aircraft to mitigate urban congestion and enhance mobility in dense metropolitan areas. Effective planning and coordination are essential to ensure efficient routing, high service quality, and optimal use of limited aerial infrastructure. This study introduces a Mixed-Integer Linear Programming (MILP) model for passenger routing in a UAM network consisting of vertiports, vertistops, and a constrained fleet of eVTOL aircraft. The formulation jointly optimizes routing and scheduling decisions while accounting for critical operational constraints, including vehicle capacity, time window adherence, selection of charging nodes, and airspace connectivity. The objective function minimizes total operational cost, combining flight distances with passenger delay penalties. Flow variables and binary decision variables are used to model feasible, time-consistent flight paths for each passenger, ensuring that vehicle operations and passenger assignments remain synchronized across the network. Computational experiments conducted on representative urban scenarios show that the proposed model can efficiently generate feasible and high-quality routing plans. The results demonstrate its capability to support strategic planning and tactical operations in UAM systems under realistic constraints.

4 - Distance-Based Discount Policy Optimization for Mobile Charging Vehicles

Hua Li, Yonsei University, Seoul, Korea, Republic of, Bongju Jeong

As cities scale up electric vehicle (EV) adoption, mobile charging vehicles (MCVs) offer a promising alternative to fixed charging infrastructure. This study investigates how tiered, distance-based pricing affects user assignment decisions and operator profit in on-demand MCV services. We propose a discrete pricing scheme where users are charged based on distance intervals to available MCVs, capturing spatial willingness-to-pay heterogeneity. Using a simplified assignment model under fixed MCV locations, we simulate service outcomes under various pricing structures and user distributions. Results reveal a non-trivial trade-off between revenue maximization and service accessibility. Strategic segmentation of distance-based fees leads to increased assignment efficiency and higher total profit compared to uniform pricing. The findings highlight the importance of spatial pricing design in improving both customer coverage and economic performance of mobile EV charging systems. This work provides practical insight for operators aiming to deploy MCVs in urban areas with heterogeneous demand profiles.

1 - Wasserstein Barycenters of Gaussian Processes for Exotic Bayesian Optimization Tasks

Antonio Candelieri, University of Milano-Bicocca, Milano, Italy

Given a set of probability distributions, the Wasserstein Barycenter is a new distribution minimizing the *weighted* Wasserstein distance from those in the original set. The Wasserstein Barycenter shows important properties, such as *shape preservation* and (intrinsic) *geometry awareness*, leading this notion to be at the core of many applications in statistics, mathematics and, more recently, Machine/Deep Learning and Generative Artificial Intelligence.

Exploiting the analogy between Gaussian Processes (GPs) and Gaussian Distributions (GDs) -- for which Wasserstein distance and Barycenter show important properties - the notion of weighted Wasserstein Barycenter is applied into the Bayesian Optimization (BO) framework to naturally deal with *exotic* tasks, specifically: federated/collaborative BO, batch-BO with adaptive batch's size, and multi-fidelity / multiple information source BO.

To achieve these goals, weights of the Wasserstein Barycenter have to be suitably identified depending on the specific application, possibly leading to multiple barycenters (e.g., in batch-BO). Indeed, although assuming equal weights represent a reasonable choice in absence of explicit knowledge about the relevance of each probability distribution in the original set, this choice is not optimal with respect to the specific loss (aka objective) function associated to the target problem, as already reported in the literature.

Empirical results on a set of test problems will be discussed along with theoretical considerations about the impact of the Wasserstein Barycenters of GPs on some of the most widely used acquisition functions.

2 - Clad-Net: Continual Activity Recognition in Multi-Sensor Wearable Systems

Reza Rahimi Azghan, Arizona State University, Tempe, AZ, United States, Gautham Krishna Gudur, Mohit Malu, Edison Thomaz, Giulia Pedrielli, Pavan Turaga, Hassan Ghasemzadeh

The rise of deep learning has significantly advanced human behavior monitoring using wearable sensor data. In particular, human activity recognition (HAR) through deep models has been extensively explored. However, most existing methods assume a stationary data distribution, an assumption that often breaks down in real-world settings. For instance, sensor data collected from one subject performing an activity may differ substantially in distribution from that of another subject. In continual learning settings, this shift is modeled as a sequence of tasks—where each task corresponds to a new subject—which makes the system susceptible to catastrophic forgetting, where previously learned patterns degrade as new ones are acquired. This challenge is further exacerbated by the reliance on labeled data, which is often sparse or inconsistently available in studies involving human participants. To address these challenges, based on the idea of complementary learning systems, we introduce CLAD-Net, Continual Learning with Attention and Distillation. Our model combines a self-supervised transformer, serving as the system's long-term memory, with a supervised CNN trained with knowledge distillation for activity classification. The transformer captures global activity patterns through cross-attention across body-mounted sensors and learns generalizable representations without requiring labels. In parallel, the CNN incorporates knowledge distillation to retain past knowledge during subject-wise

fine-tuning. We evaluate CLAD-Net under a continual stream of data from multiple subjects and demonstrate its strong resilience to forgetting. We also conduct experiments to study the individual contributions of the different components used in each of the models.

3 - Conditional Diffusion Models for Bayesian Optimization

Szu Hui Ng, National University of Singapore, Singapore, Singapore, Yilin Zheng, Haowei Wang

Bayesian Optimization (BO) is a sample-efficient framework for optimizing expensive black-box functions, typically using a Gaussian Process (GP) as a surrogate model and an acquisition function to guide the sequential search. Among various acquisition functions in BO, information-based methods such as Predictive Entropy Search (PES) aim to reduce uncertainty on the location of the global optimum x^* , but often incur high computational cost due to the difficulty of sampling x^* from the GP posterior. To address this issue, we propose a novel framework that integrates diffusion models into BO, enabling efficient approximation of the distribution over the global optimum x^* . Within this framework, we first design a standardized suite of training guidelines for the diffusion models. With the diffusion model, we propose Diffusion-based PES (DPES) algorithm that significantly reduce computational cost. We further introduce Diffusion-based Mode Seeking (DMS), a new acquisition function that directly selects the mode of the learned distribution as the next query, offering a simpler and more efficient alternative to entropy-based strategies. Empirical results on benchmark functions demonstrate the effectiveness of our proposed approaches.

4 - Mixed Pareto Set Learning for Mixed Variable Multi-Objective Bayesian Optimization

Zijian Huang, University of Michigan, Ann Arbor, MI, United States, Weishi Wang, Raed Al Kontar

Real-world optimization often involves simultaneously addressing multiple expensive black-box objectives defined over mixed discrete and continuous variables, known as Mixed Variable Multi-Objective Bayesian Optimization (MVMBO). This context presents notable computational and modeling challenges, particularly due to the non-smooth and potentially infinite mixed Pareto set. To overcome these difficulties, we introduce Mixed Pareto Set Learning (MPSL), a novel framework designed for efficiently recovering the mixed Pareto set within limited evaluation budgets. MPSL employs a relaxed mapping strategy that translates decision-makers' trade-off preferences into Pareto-optimal solutions via probabilistic parameterization of discrete variables, effectively navigating the complexity inherent in mixed design spaces. Additionally, we propose a model-agnostic local search refinement procedure, empirically shown to enhance candidate solution quality and hypervolume performance significantly. Our refinement method demonstrates clear advantages over simply increasing preference sampling and exhibits versatility by benefiting general Multi-Objective Bayesian Optimization (MOBO) scenarios beyond MVMBO. Extensive numerical experiments, including synthetic benchmarks and a real-world electrohydrodynamic (EHD) inkjet printing application, validate that MPSL offers superior Pareto front coverage, improved computational efficiency, and real-time flexibility for decision-makers, underscoring its practical importance across critical engineering and scientific domains.

5 - Bayesian Experimental Design with Generative Input Priors: a KI-Regularized Decision-Theoretic Framework

Raul Astudillo, California Institute of Technology, Pasadena, CA, United States

Bayesian experimental design (BED) is a powerful framework for data-efficient learning and optimization. Yet, standard methods often overlook structural prior knowledge about the input space—such as feasibility constraints or low-dimensional manifolds—that can now be effectively captured by generative models. We introduce a KL-regularized decision-theoretic framework that integrates such generative priors into BED. This formulation yields a simple, principled characterization of one-step Bayes-optimal policies as Boltzmann distributions over the input space, naturally balancing task-specific utility with fidelity to the learned prior. Our perspective unifies and generalizes previous approaches that incorporate generative models into Bayesian optimization, and it lays the groundwork for more advanced developments, including multi-step design strategies and theoretical regret guarantees.

AI for Smart Health: Modeling, Simulation, and Optimization

Invited Session

Health Applications Society

Chair: Bing Yao, The University of Tennessee Knoxville, Knoxville, TN, United States

1 - Simulation Optimization of Spatiotemporal Dynamics in 3D Geometries

Bing Yao, The University of Tennessee Knoxville, Knoxville, TN, United States, Fabio Leonelli, Hui Yang

Many engineering and healthcare systems are featured with spatiotemporal dynamic processes. The optimal control of such systems often involves sequential decision making. However, traditional sequential decision-making methods are not applicable to optimize dynamic systems that involves complex 3D geometries. Simulation modeling offers an unprecedented opportunity to evaluate alternative decision options and search for the optimal plan. In this paper, we develop a novel simulation optimization framework for sequential optimization of 3D dynamic systems. We first propose to measure the similarity between functional simulation outputs using coherence to assess the effectiveness of decision actions. Second, we develop a novel Gaussian Process (GP) model by constructing a valid kernel based on Hausdorff distance to estimate the coherence for different decision paths. Finally, we devise a new Monte Carlo Tree Search (MCTS) algorithm, i.e., Normal-Gamma GP MCTS (NG-GP-MCTS), to sequentially optimize the spatiotemporal dynamics. We implement the NG-GP-MCTS algorithm to design an optimal ablation path for restoring normal sinus rhythm (NSR) from atrial fibrillation (AF). We evaluate the performance of NG-GP-MCTS with spatiotemporal cardiac simulation in a 3D atrial geometry. Computer experiments show that our algorithm is highly promising for designing effective sequential procedures to optimize spatiotemporal dynamics in complex geometries.

2 - Robust Coupled Tensor Decomposition for Shared and Personalized Feature Selection Under Multiple Conditions

Ana Estrada Gomez, Purdue University, West Lafayette, IN, United States, Manni Zhang

Nowadays, complex systems are monitored by hundreds of sensors. How to extract useful information from the multi-modal data for system diagnosis and control is still an open question. In this work, we aim to identify the most relevant information or features collected by the sensors for system diagnosis and control. Different challenges need to be addressed. (1) Systems operate under different conditions. It is critical to differentiate between condition-specific features and system-specific features to account for data heterogeneity. (2) High-dimensional data from different sensors needs to be fused. Features within a data modality offer a partial perspective of the system, whereas fused data yields a comprehensive view of the system. (3) It is common for sensor data to be missing or corrupted. It is critical to develop a robust method for fault isolation and identification. To tackle these challenges, we propose a framework, Missing-value-imputed, RObust, COupled, Sparse and Similar CANDECOMP/PARAFAC Decomposition (MissROCOSS-CPD), that fuses multi-modal data and exploits the similarities and differences across conditions for feature selection. Our method decomposes each modality into a low-rank component that captures the true signal and a sparse component that captures the outliers. We simultaneously learn the joint and individual factor matrices across modalities from the low-rank components and identify the shared and personalized features by adding sparse group Lasso penalties to the individual factor matrices. The performance of the proposed framework is illustrated through simulated datasets and a case study.

3 - Decoding Emotion from Eeg Using Weighted Heterogeneous Recurrence Network Analysis

Yujie Wang, University of Miami, Miami, FL, United States, Cheng-Bang Chen

Emotion recognition from electroencephalography (EEG) signals remains a significant challenge due to the brain's nonlinear, dynamic, and nonstationary activity. This work proposes a novel framework that combines manifold learning, Weighted Heterogeneous Recurrence Network Analysis (WHRNA), and ensemble classification to capture and interpret emotional dynamics in EEG data. High-dimensional EEG signals are first embedded into a low-dimensional manifold using Uniform Manifold Approximation and Projection (UMAP), preserving spatial structure while enhancing computational efficiency. These embedded representations form temporal trajectories, which are segmented via Voronoi tessellation to account for heterogeneous recurrence behaviors across time and space. WHRNA then models multiscale nonlinear dynamics by constructing weighted recurrence networks from these segments. Finally, tree-based ensemble models classify emotional states with an improved accuracy, which achieves 83.7% on SEED and 79.1% on SEED-IV datasets, surpassing prior benchmarks. Sensitivity analyses reveal specific WHRNA-derived features

associated with distinct emotions, offering insights into the neural substrates of affective states. This approach enhances both performance and interpretability, providing a powerful tool for affective computing, mental health assessment, and cognitive neuroscience.

1 - Improving Estimation of Pediatric Mental Health Prevalence in Washington State Under a Marginal Distributions Constrained Optimization Framework

Shan Liu, University of Washington, Seattle, WA, United States, Yinsheng Wang, Kathryn Brandeau

Pediatric mental health disorders, such as depression, anxiety, and behavioral disorders, significantly impact the well-being of children and youth. In Washington state (WA), more than one-third of the population resides in regions lacking adequate mental health providers. Accurately mapping the geographic distribution of mental health demand is thus essential for designing optimal care networks for pediatric services. This study estimates the prevalence of pediatric mental health conditions by integrating multiple data sources, including the National Survey of Children's Health (NSCH), American Community Survey (ACS), and local health surveys and hospital discharge data from WA. Initially, we developed machine learning regression models using NSCH data, incorporating key demographic factors such as age, race, sex, family structure, and poverty status. Subsequently, we constructed a marginal distributions constrained optimization model to recover detailed demographic group proportions by harmonizing regression estimates from the NSCH with corresponding estimates derived from multiple local datasets, constrained by demographic marginal distributions obtained from the ACS. Analysis of surveys and hospital data from WA enabled robust local calibration of prevalence ratios. This integrative modeling approach enhances small-area prevalence estimation by effectively fusing national and local datasets, facilitating precise resource allocation and informing strategic placement decisions for pediatric mental health facilities and programs.

2 - Informing Effective, Efficient, and Equitable Harm Reduction Interventions Through Decision Modeling: Lessons from the ProFOUND/Rescue Project

Xiao Zang, University of Minnesota, Minneapolis, MN, United States

The ongoing overdose crisis in the United States demands urgent, data-driven responses that are not only effective and cost-efficient, but also equitable. This presentation highlights the use of simulation modeling, decision analysis, and optimization methods to inform harm reduction strategies, drawing from the NIH/NIDA-funded PROFOUND/RESCUE project. By integrating epidemiologic and health services data, this project evaluates and optimizes the allocation of naloxone and other harm reduction interventions across diverse populations and geographies in six U.S. jurisdictions.

We developed an individual-based microsimulation model and accompanied decision support tools, including interactive dashboards and Shiny Apps, to assess a wide range of intervention scenarios, varying in geographic targeting, distribution channels, and population reach. Calibrated to local epidemiological data, the model estimates outcomes such as overdose deaths averted, costs, and equity impacts. We also developed novel analytical frameworks to define and measure naloxone availability and saturation, and to optimize its geographic distribution. These frameworks embed simulation-based analysis to identify strategies that maximize public health impact within constrained resources, with extensions that directly incorporate equity considerations into decision-making.

This work illustrates the power of simulation and optimization to guide evidence-based policy decisions in complex and resource-limited environments. The presentation will highlight key insights, methodological innovations, and future research opportunities at the intersection of decision science, optimization, and public health policy.

3 - Building Ethical AI/ML Decision Making Systems for Justice Reform

Aparna Komarla, Redo.io, Berkeley, CA, United States

In 2018, California became the first state in the US to pass a Prosecutor-Initiated Resentencing law, which grants prosecutors the [power](#) to revisit past convictions. In addition, a number of resentencing and second-look laws in the state, such as AB600 and the Racial Justice Act, seek to correct past injustices in the criminal legal system. But given that there are nearly 100,000 people in California's prisons, lawyers and county officials need efficient and accurate ways to identify cases worth a second-look. We estimate that there are hundreds languishing in California's prisons as a result of technological and political barriers. Redo.io (www.redoio.info) is solving this problem with predictive, exploratory and rules-based models for resentencing eligibility determination. Our open-source AI assistant helps attorneys quickly query our dataset and find prison sentences that align with their criteria. Our predictive models embody the principles of fairness, accountability and transparency and help prioritize cases based on violent history and commitment to rehabilitation (education, mental health treatment). Legal experts have helped design and fine-tune eligibility rules in an iterative process. Our model, by design, augments legal knowledge about the applicability of second-look laws as opposed to replacing such expertise. By supplementing a lawyer's decision to examine a case for resentencing instead of automating the end-to-end process, we help stakeholders make high-impact decisions efficiently while preventing existing biases in our society from being exacerbated. We therefore exemplify a framework for meaningful human-computer interactions in high-stakes and high-risk decision making processes.

4 - Adapting Behavioral Health Models Across Policy Shifts: A Transfer Learning Approach to Cannabis Dependence Prediction

Jiyang He, University of Southern California, Los Angeles, CA, United States, Shinyi Wu, Carolyn Wong

Rapid policy changes in cannabis regulation, combined with evolving user demographics, create significant challenges for behavioral health risk models. Patterns learned from older pre-legalization populations may not generalize to younger post-legalization cohorts due to regulatory, market and generational shifts. This study addresses the critical need for adaptive modeling approaches that can efficiently update risk prediction models across these transitions.

We developed a transfer learning (TL) framework to predict problematic cannabis use (PCU) across three distinct contexts using longitudinal data from the CHAYA study (N=506). Our approach employs LSTM networks in a pretrain-fine-tune architecture, transferring knowledge from pre-legalization older cohorts (2014-2018, ages 18-26 at baseline) to post-legalization younger populations (2019-2023, ages 18-21 at baseline). We evaluated model performance across varying amounts of target domain data (0%-100%) and conducted interpretability analysis using SHAP values.

Results demonstrate that direct zero-shot transfer fails dramatically when both policy contexts and population demographics shift (AUC dropping from 0.65 to 0.44). However, fine-tuning with just 25% of new target data rapidly restored performance, achieving AUCs of 0.89-0.92 across transfer scenarios. TL outperformed both training from scratch and pooled modeling approaches. Feature importance analysis revealed significant shifts in risk factors, with relationship status at baseline data collection emerging to show strong association with PCU in post-legalization younger cohorts, while mental health remained as a strong indicator stably across domains.

This work demonstrates that TL enables cost-effective adaptation of behavioral health models to changing contexts, providing a practical approach for ensuring model relevance across market, generational and regulatory shifts.

1 - A Model for Managing Supply Chains with Capacity Investment and Financial Hedging Under Risk from Natural Disasters, Political Conflict**Ismail Civelek, WKU, Bowling Green, KY, United States**

Supply chain management is defined as the efficient integration of manufacturers, suppliers, warehouses, vendors, and customers to maximize value across-the-board by minimizing system wide costs while satisfying customer and fill-rate requirements. Considering recent dramatic disruptions in managing supply chains (i.e., COVID-19, natural disasters, Russian invasion of Ukraine, etc.), supply chain managers must factor in factory shutdowns due to pandemic, conflict, port shutdowns or natural disasters (earthquakes, tsunami, tornadoes, forest fires, etc.). This study proposes an analytical model for a manufacturer, which is under risk due to natural disaster or political risk. A petroleum refinery is a good example because its production mostly depends on the input material, crude oil. A food (or agricultural) processing company or a power plant that uses oil or natural gas would be other motivating examples for this supply chain problem. In addition to related industries, an automotive manufacturer that uses steel, aluminum, and rubber for major material inputs would be another motivating example. The manufacturing company has two joint problems: capacity investment and financial trading. This study models the joint problem and characterizes the optimal policy for single period and finite multi-period settings.

2 - Min-TIME Coverage in Constricted Environments with Heterogeneous Robotic Fleets**Young In Kim, Georgia Institute of Technology, Atlanta, GA, United States, Spiridon Reveliotis**

In a recent research program, we have investigated robotic traffic management problems that arise when a fleet of networked mobile robots is employed to support certain coverage tasks taking place in physically constricted environments.

Our previous studies focused on the case where the employed robots have the same role and capability in the executed task.

In this work, we extend our investigation to the case where robots have distinct roles and capabilities.

We systematically introduce these extensions and formulate the corresponding traffic management problems as integer programs (IPs).

Furthermore, we develop a strong combinatorial relaxation of these IP formulations that significantly reduces the number of integer variables involved without compromising the optimality of the solutions.

Lastly, numerical results demonstrate the effectiveness and the efficiency of the relaxation.

3 - Selling and Leasing Strategies for Perfectly Complementary Products**Wanfen Yang, University of California, Irvine, Irvine, CA, United States, Shuya Yin**

In various industries, we observe a rising trend of hybrid acquisition models in which consumers purchase part of a product bundle while leasing the other part. A prominent example is NIO's Battery-as-a-Service (BaaS) in the electric vehicle industry, where the car body is purchased while the battery is leased. In this paper, we examine a setting involving durable complementary products to explore optimal selling and leasing strategies.

4 - Optimal Replenishment Policy from Dual Supplier with Nonconsecutive Lead TIMES**Chaehoon Han, Seoul National University, Seoul, Korea, Republic of, Kunsoo Park, Byeongkwon Lee**

We study an inventory problem involving dual sourcing from two suppliers with different lead times. While the optimal inventory policy for this problem has been proved only for the case where the lead times of two suppliers are consecutive (i.e. the lead time difference between them is one), this study is, to our best knowledge, the first that proves the optimal replenishment policy with nonconsecutive lead times. We formulate the expected cost function using dynamic programming and verify its convexity through partial optimization and gradient analysis. Then, we demonstrate that the optimal replenishment from the expedited supplier follows the 'pipeline-dependent base-stock policy', where the base-stock level depends on the quantities ordered but not yet received from the regular supplier. Our findings not only address a research gap in dual sourcing inventory system but also introduce a new analytical approach applicable to multi-dimensional inventory problems such as the lost-sales inventory model.

5 - Finding the Optimal Takt Time Group for Individualized Products in Mixed-Model Assemblies**Philipp Pithan, WHU - Otto Beisheim School of Management, Vallendar, Germany, Arnd Huchzermeier**

While assembly lines face increasing pressure to produce locally, customers expect individualized products. These developments are accelerating the shift toward local, mixed-model assembly systems designed to produce highly individualized products — posing new and complex manufacturing challenges. Manufacturers need to balance, schedule, and sequence these products in an efficient yet flexible manner — a impossible challenge with a single fixed takt.

We introduce T-Bars as a simple framework for capturing the variance introduced by selective and additive options and demonstrate how they can be used together with permissible overwork and a variable takt to achieve a perfectly balanced assembly line for multiple individualized products. We analyze the benefits of a variable takt and evaluate the implications of grouping either multiple products or multiple configurations into takt time groups (TTG). The developed mathematical model groups either (i) products or (ii) configurations and selects the best takt time for each group, thus optimizing line utilization.

In a real-world application, we find that the T-Bar framework greatly simplifies the assembly line balancing effort. The use of multiple TTG allows for higher utilization, regardless of whether product- or configuration-based. We show that both have distinct advantages and trade-offs. The former leads to more stable plans, as task-station assignments remain consistent within each product, though lower utilization. The latter allows for higher utilization but results in less stable balancing plans due to frequent changes in task-station allocation. In both cases, the number of TTG should be limited to strike a balance between efficiency and practicability.

6 - Zero-Shot Foundation Model Pipeline for Image Analysis in Biomanufacturing**Rui Qi Chen, Georgia Institute of Technology, Atlanta, GA, United States, Benjamin Joffe, Caroline Serafini, Francisco Robles, Jing Li**

Effective Process Analytical Technology (PAT) in cell therapy manufacturing requires process monitoring and feedback control to ensure product quality. Automated image analysis, leveraging real-time data from non-invasive techniques such as quantitative Oblique Back-illumination Microscopy (qOBM), is integral to achieving this by providing key bioprocess insights. However, current automated image analysis methods face limitations: supervised models demand extensive annotation and struggle with batch effects, while common anomaly detection methods often lack interpretability. Furthermore, the scarcity of comprehensive, well-annotated datasets makes training capable models challenging.

To address these challenges, we propose a novel two-stage pipeline for analyzing qOBM images. First, the Segment Anything Model (SAM) performs zero-shot instance segmentation. Second, a Vision Language Model (VLM) or a multimodal Large Language Model (LLM) with vision capabilities, such as Gemini 2.5 Pro, analyzes these objects within the full image context. This approach leverages pre-trained foundation models to eliminate annotation and training burdens. It enables flexible analysis using prompt-based inputs that embed domain knowledge without requiring model retraining. The broad visual and language understanding of these models improves generalizability and robustness against batch effects and domain shifts. Furthermore, it enhances interpretability by generating natural language explanations and descriptive outputs for detected anomalies. This analytical framework, demonstrated on T-cell cultures, facilitates critical tasks such as real-time cell detection, segmentation, counting, and live/dead classification for viability analysis, alongside explicit identification and description of process deviations like biological contamination. This pipeline is anticipated to advance automated process control and PAT, enabling more reliable, data-efficient biomanufacturing.

7 - The SME Business Maturity Model (SBMM): A Framework for Navigating Growth and Enhancing Operational Effectiveness**Asef Sajjad Abir, North Dakota State University, Fargo, ND, United States, Diana López-Soto**

Small to Medium-sized Enterprises (SMEs), defined as firms with fewer than 249 employees, play a crucial role in the economy, accounting for roughly 95% of global businesses and more than 60% of employment. The global small business market, valued at USD 2,572 billion in 2023, is anticipated to grow to USD 4,985 billion by 2032. Despite its significance, 67% of SME executives identify survival and expansion as key challenges in the face of economic uncertainties, facing difficulties in

transitioning from unstructured operations to sustainable maturity due to insufficient strategic support and funding. This study presents the SME Business Maturity Model (SBMM), a framework that offers a systematic approach for the development of small and medium enterprises (SMEs). The SBMM, based on systematic reviews of SME growth challenges and foundational maturity models, supports advancement from initial stages to established industry leadership. This assessment evaluates critical dimensions such as business model, financial management, operations, technology utilization, and customer acquisition, categorizing SMEs into one of six distinct developmental phases. Each phase exhibits distinct characteristics, challenges, and customized development strategies. The SBMM seeks to systematically improve operational efficiency by identifying areas of attention specific to each phase and recommending actionable strategies. This methodology enables SMEs to develop strong capabilities, enhancing profitability, resilience, and promoting sustainable growth necessary for their survival and expansion.

Online Real-time Intelligent Decision Making Methods and Analysis

Invited Session

Decision Analysis Society

Chair: Mengfan Xu, UMass Amherst, Amherst, MA, United States

1 - Simulation Optimization for Contextually Aware Online Decision Making

Gregory Keslin, New Jersey Institute of Technology, Newark, NJ, United States

Ranking and Selection is a simulation optimization methodology used to solve complex decision problems where each decision is associated with a simulation system. Historically, such problems are static pre-specified problems with a single solution. However, there has been a recent focus on dynamic real-time decision-making problems that utilize real-world contextual information to reduce uncertainty for a better-informed decision-making process. Because classical Ranking and Selection procedures require every decision to be repeatedly simulated, Ranking and Selection procedures are typically ill suited to solve these dynamic problems rapidly or in real time. In this talk, we present a novel approach that runs the entire simulation budget “offline”, prior to observation of the contextual information. A classifier is then fit on the simulation outputs to determine the optimal “online” decision once the contextual information is observed. Associated with the classifier is an assessment of the classifier’s performance. This assessment achieves a finite-sample coverage guarantee under mild conditions.

2 - Sequential Stochastic Combinatorial Optimization Using Hierarchical Reinforcement Learning

Haipeng Chen, William & Mary, Williamsburg, VA, United States, Xinsong Feng, Zihan Yu, Yanhai Xiong

Reinforcement learning (RL) has emerged as a promising tool for combinatorial optimization (CO) problems due to its ability to learn fast, effective, and generalizable solutions. Nonetheless, existing works mostly focus on one-shot deterministic CO, while sequential stochastic CO (SSCO) has rarely been studied despite its broad applications such as adaptive influence maximization (IM) and infectious disease intervention. In this paper, we study the SSCO problem where we first decide the budget (e.g., number of seed nodes in adaptive IM) allocation for all time steps, and then select a set of nodes for each time step. The few existing studies on SSCO simplify the problems by assuming a uniformly distributed budget allocation over the time horizon, yielding suboptimal solutions. We propose a generic hierarchical RL (HRL) framework called wake-sleep option (WS-option), a two-layer option-based framework that simultaneously decides adaptive budget allocation on the higher layer and node selection on the lower layer. WS-option starts with a coherent formulation of the two-layer Markov decision processes (MDPs), capturing the interdependencies between the two layers of decisions. Building on this, WS-option employs several innovative designs to balance the model’s training stability and computational efficiency, preventing the vicious cyclic interference issue between the two layers. Empirical results show that WS-option exhibits significantly improved effectiveness and generalizability compared to traditional methods. Moreover, the learned model can be generalized to larger graphs, which significantly reduces the overhead of computational resources. Our code is released at: <https://github.com/wmd3i/HRL4SSCO>

3 - Probabilistic Non-Negative Factorization with Latent Gaussian Processes

Jialin Li, University of Massachusetts, Amherst, Amherst, MA, United States, Lulu Kang

Developing statistical models for prediction and uncertainty quantification can be unprincipled when we have a priori knowledge about the system (e.g., output non-negativity). In this work, we consider a general modeling problem using expensive observational multi-output data, with recorded configuration/environment parameters for each data point. Within an integrated probabilistic framework, we factorize the non-negative parameter-to-multi-output function into multiple components expressed as “softly censored” latent Gaussian processes. The model is delicately hyperparametrized and we propose a specific variational inference approach to learn the components and hyperparameters. With improved model flexibility and expressive power, we can perform better predictions and correct uncertainty quantification for outputs associated with parameters not yet observed, and the method is compatible with complicated kernel designs.

4 - Asynchronous Decision-Making in Multi-Agent Bandits

Xuchuang Wang, UMass Amherst, Amherst, MA, United States, Yu-Zhen Janice Chen, Xutong Liu, Lin Yang, Mohammad Hajiesmaili, Don Towsley, John C.S. Lui

We study the cooperative asynchronous multi-agent multi-armed bandits problem, where each agent’s active (arm pulling) decision rounds are asynchronous. That is, in each round, only a subset of agents is active to pull arms, and this subset is unknown and time-varying. We consider two models of multi-agent cooperation, fully distributed and leader-coordinated, and propose algorithms for both models that attain near-optimal regret and communications bounds, both of which are almost as good as their synchronous counterparts. The fully distributed algorithm relies on a novel communication policy consisting of accuracy adaptive and on-demand components, and successive arm elimination for decision-making. For leader-coordinated algorithms, a single leader explores arms and recommends them to other agents (followers) to exploit. As agents’ active rounds are unknown, a competent leader must be chosen dynamically. We propose a variant of the Tsallis-INF algorithm with low switches to choose such a leader sequence. Lastly, we report numerical simulations of our new asynchronous algorithms with other known baselines.

5 - Multi-Agent Multi-Armed Bandit with Fully Heavy-Tailed Dynamics

Mengfan Xu, UMass Amherst, Amherst, MA, United States, Xingyu Wang

We study decentralized multi-agent multi-armed bandits, where clients communicate over sparse random graphs with heavy-tailed degree distributions and observe heavy-tailed reward distributions with potentially infinite variance. We are the first to address such fully heavy-tailed scenarios, capturing the dynamics and challenges of communication and inference among multiple clients in real-world systems, and provide regret bounds that match or improve upon existing results developed in even simpler settings. Under homogeneous rewards, we exploit hub-like structures unique to heavy-tailed graphs to aggregate rewards and reduce noises when constructing UCB indices; under M clients and degree distributions with power-law index $\alpha > 1$, we attain a regret (almost) of order $O(M^{1-\frac{1}{\alpha}} \log T)$. Under heterogeneous rewards, clients synchronize by communicating with neighbors and aggregating exchanged estimators in UCB indices; by establishing information delay bounds over sparse random graphs, we attain a $O(M \log T)$ regret.

1 - Multi-Stage Optimization Models for Walmart Private Fleet Driver Scheduling and Tractor Assignment

Loksagar Rudraraju Subramanyam, Walmart Inc, Bentonville, AR, United States, Ian Fraser, KIRAN KUMAR BANDELI, Shitij Gusain, Zabiulla Mohammed, Arun Kannan

Our research focuses on how Walmart optimizes drivers and tractors utilization for hauling loads throughout the network comprising: vendors, distribution centers, consolidation centers, and stores. Each Walmart's Transportation Office (TO) supporting one or multiple DCs is tasked with efficiently managing drivers and tractors to meet the ebbs and flows of the required workload. This raises the need for optimal driver schedules and tractor assignment. The proposed framework consisting of three multi-objective Mixed Integer Linear Programming (MILP) models was built to integrate complex tactical and operational decisions for scheduling over 16,000 drivers across 100 TOs to assign and rotate 12,800 tractors among them, where the components are: (1) a driver scheduler, which generates ideal annual schedules for drivers to cover workload requirements; (2) a driver hiring recommender, which provides ideal schedules for new hire drivers to reduce transportation costs; and (3) a tractor assigner, which assigns tractors to drivers on a weekly basis to haul loads. By leveraging the MILP models, the aforementioned-framework ensures to minimize transportation operational costs, slip-seating (driver switching the tractors in-between the schedules) and maximizes preferred tractor assignment for certain driver types. The Models ability to quickly adapt to changing inputs, such as tractor unavailability, maintenance schedules for tractors, drivers churn, and drivers time off enables Walmart to always steer towards optimal operational conditions. Implementing the suggested framework helps Walmart Transportation yield intangible potential savings with the operational costs by \$9M and maintain the slip-seating below 7% reducing the inefficiencies with driver schedules.

2 - A New Optimization Approach to Multi-Period Planning for A Vertical Farming Supply Chain

SAEED ABDOLMALEKI, Supply Chain & Analytics Department, University of Missouri - St. Louis, Saint Louis, MO, United States, Haitao Li

We consider the tactical-level planning for a vertical farming supply chain, where vertical farming systems using hydroponic and aeroponic growing technologies and artificial lighting are employed to enable year-round crop production in vertically stacked racks under climate-controlled conditions. We develop a new mixed-integer programming (MIP) model to determine decisions related to internal production (growing, harvesting, processing), storage, distribution of multiple produce to markets, and—when necessary—external sourcing from other producers to fulfill market demand. The objective is to maximize total profitability, defined as total revenue minus the costs of setup, energy, labor, storage, procurement, and penalties for unmet demand. Our model and solution provide a data-driven decision-support tool for vertical farms to optimally match their production and supply with fluctuating demand in a sustainable way.

3 - Solving Process Planning and Scheduling Problems Using the Method of Maximum Weighted Independent Set

Kai Sun, University of Maryland, Baltimore County, Baltimore, MD, United States

Process planning and scheduling (PPS) is a critical yet computationally intractable problem in manufacturing systems. It involves determining process plans, and scheduling and allocating limited resources to complete jobs composed of sequenced operations. A common optimization objective is to minimize the makespan, i.e., the total completion time of all jobs. Due to the combinatorial complexity of PPS, traditional approaches such as mixed-integer programming (MIP), metaheuristics, and genetic algorithms often struggle to deliver high-quality solutions within practical runtimes.

To address the dual challenge of high computational cost and solution quality, prior studies have explored graph coloring-based methods aimed at solving the PPS problem more efficiently. However, these formulations are not readily applicable to the generic PPS problem. Therefore, this work proposes a novel graph-based formulation for the generic PPS problem considering the minimum makespan. By representing the PPS problem as an undirected, weighted conflicting graph, the proposed approach leverages the maximum weighted independent set (MWIS) to select the best set of operations and resources for each discrete time slot.

To further improve both solution quality and runtime, we develop an algorithm framework for the exact solutions and improved approximations of the MWIS problem. Validation on real-world PPS applications demonstrates that the graph-based approach consistently yields feasible and optimal/near-optimal solutions with improved runtimes, outperforming a leading commercial MIP solver, i.e., Gurobi. The developed method is generic and can be extended to other resource planning problems, such as wireless sensor network scheduling and timetable scheduling problems.

4 - Advanced Satellite Scheduling Strategy for Snow Water Equivalent (SWE) Monitoring

Hadis Banafsheh, Arizona State University, Tempe, AZ, United States, divya ramachandran, Paul Grogan

Snow plays a critical role in the global hydrological cycle, acting as a natural reservoir that regulates water availability for ecosystems, agriculture, and human consumption. Accurate estimation of Snow Water Equivalent (SWE) is essential for effective water resource management, particularly in regions where seasonal snowmelt influences river flow, reservoir levels, and drought forecasting.

To improve the scientific return of satellite observations for SWE monitoring, we propose a reward-based scheduling framework that integrates publicly owned and operated satellite systems, offering continuous passive microwave coverage, with emerging taskable satellite services, including commercial Synthetic Aperture Radar (SAR) constellations.

This framework combines diverse satellite resources through a structured, data-driven prioritization process, forming the basis for a scalable and adaptive scheduling strategy. At its core is a scientifically grounded reward function that quantifies the value of potential observations based on measurable geophysical features, such as SWE variability, surface temperature, and sensor-specific constraints. These inputs, derived from remote sensing products and environmental monitoring systems, are used to construct geospatial Efficiency layers, which are then used to calculate observation rewards, that dynamically highlight where and when targeted taskable observations will yield the greatest scientific value.

By continuously updating observation priorities in response to evolving environmental conditions and mission needs, the framework enables more responsive and effective deployment of taskable assets. While developed for SWE monitoring, the methodology is broadly applicable across Earth science domains that require agile observation planning and multi-source data integration.

6 - Behavior-Aware Joint Optimization of Fulfillment Network Design and Product Assortment in Substitutable Demand Networks

Ashwin Pothen, Georgia Institute of Technology, Atlanta, GA, United States, Benoit Montreuil

E-commerce fulfillment and distribution networks face complex challenges due to increasingly diverse customer behaviors, high service expectations, and the need for inventory efficiency in a disruption-prone environment. We present a novel simulation-optimization framework that jointly optimizes the selection of fulfillment centers (FCs) and the allocation of substitutable product assortments, explicitly incorporating customer behavioral heterogeneity. Our model integrates two key behavioral dimensions: willingness-to-wait and substitution preferences, each informed by empirical distributions derived from real-world data.

The methodology embeds a multi-agent simulation within a Physical Internet-inspired network design. The optimization layer simultaneously addresses facility location, assortment planning, and fulfillment routing to minimize system-wide inventory and transportation costs, subject to service-level constraints. Substitution utility functions are estimated from historical customer choice data, allowing the model to allocate inventory in a manner that maximizes expected customer satisfaction under stockout conditions.

Applied to a large-scale U.S. distribution network, our preliminary results indicate that the proposed method achieves equivalent levels of demand fulfillment with 20–30% lower inventory compared to conventional approaches. Moreover, we observe that total inventory requirements do not scale with the number of FCs, due to the strategic placement of substitutable assortments and behavior-aware allocation. These findings demonstrate the potential of integrating behavioral operations with physical network optimization to advance resilient and efficient fulfillment strategies.

Optimization and Learning Applications in Healthcare

Invited Session

Health Applications Society

Chair: Yonatan Mintz, University of Wisconsin Madison, Madison, WI, United States

1 - Clinical Trial Enrollment Timing with Information-Sharing

HANWEN LIU, Clemson University, Clemson, SC, United States, Qi Luo, Amin Khademi

Phase II/III clinical trials are critical for evaluating the efficacy and safety of new treatments prior to approval by the Food and Drug Administration (FDA). Recent studies suggest that some patients may strategically delay their enrollment to gain additional information about the trial's progress. To model such behavior, we propose a dynamic game framework incorporating patients' strategic enrollment timing and information sharing, offering nuanced insights into trial enrollment decision-making.

2 - Designing Hospital-at-Home Systems: AI and Optimization for Accessible, Distributed Care

Holly Wiberg, Carnegie Mellon University, Pittsburgh, PA, United States, Peter Zhang, Hao Hao, Shuwei He, Peiyu Wang

As healthcare systems increasingly turn to Hospital-at-Home (HaH) models to expand access and alleviate pressure on facilities, they must simultaneously determine which patients can be safely treated at home and how to deliver timely, cost-effective care outside the hospital. This project presents an AI-enabled framework that jointly makes these clinical and operational decisions---identifying appropriate patients for HaH and designing the staffing and supply strategy needed to serve them.

We leverage machine learning to predict patient suitability for home-based care, and their associated care needs, based on clinical complexity, resource availability, and population characteristics. These predictions feed into a mixed-integer optimization model that determines who to send home and how to meet their care needs. The model considers tradeoffs between aggregation and personalization and how these choices affect costs, access, and responsiveness under operational constraints and uncertainty in patient trajectories.

Rather than separating clinical assignment and logistics planning, our framework treats them as interdependent choices. We evaluate system performance under varied geographic distributions, patient profiles, and capacity limits to identify the conditions under which HaH is most effective. Our results offer actionable insights for designing scalable, equitable HaH programs that adapt to uncertainty while balancing efficiency and patient-centered care.

3 - Prescriptive Optimization for Adaptive Auto-Insurance Pricing with Telematics Data

Qinyang He, University of Wisconsin Madison, Madison, WI, United States, Yonatan Mintz

The automotive insurance industry is undergoing fundamental transformation as telematics and decision science enable sophisticated, personalized risk assessment to replace traditional one-size-fits-all pricing models. We present a novel prescriptive optimization framework for personalizing insurance premiums through a two-stage process: first, tailored machine learning models predict individual driver claim risk and expected amounts using telematics data; second, an optimization problem incorporating driver behavioral patterns and price sensitivity determines personalized discount rates. Our experimental results demonstrate this framework creates a win-win scenario where insurers experience increased revenue while drivers benefit from safety-based incentives and fair pricing. Notably, the approach improves individual outcomes and enhances overall social welfare by promoting safer driving behaviors across the insured population.

4 - A Power Constrained Posterior Sampling Algorithm for Nonstationary Bandits with Habituation and Recovery Dynamics

Fengxu Li, University of Wisconsin-Madison, Madison, WI, United States, Yonatan Mintz

Multiarmed bandits (MABs) are a widely used framework for sequential decision-making under uncertainty, with significant applications in personalized healthcare. While traditional MAB methods typically assume stationary reward distributions, real-world settings are often nonstationary. For instance, in personalized interventions, treatment effectiveness may decline due to habituation and later recover, creating complex nonstationary behaviors that standard methods fail to capture.

In addition to adapting to these evolving reward structures, a critical challenge—especially in clinical trial contexts—is preserving statistical power for reliable inference. Existing bandit algorithms generally optimize cumulative rewards but often neglect adequate exploration which is necessary for detecting meaningful treatment effects.

We propose a novel Posterior Sampling algorithm explicitly designed to tackle this dual challenge. Our method adapts to nonstationary environments characterized by habituation and recovery dynamics, while simultaneously satisfying specified power constraints through controlled exploration.

We provide theoretical guarantees via sublinear regret bounds and validate the approach on two real-world datasets by simulation: a bipolar disorder clinical trial and a microrandomized trial promoting workplace standing. Results demonstrate the method's effectiveness in personalizing interventions while maintaining accurate statistical inference.

Flexibility and Sustainable Operation of Data Centers

Invited Session

ENRE: Energy-Climate

Chair: Grant Ruan, MIT, Boston, MA, United States

1 - Reliability Issues of Grid-Connected Data Centers

Grant Ruan, MIT, Boston, MA, United States

The surge of data center energy use has been broadly recognized, but electric grid operators have limited experience and understanding of the reliability risks. One of the major concerns of infrastructure reliability and fault tolerance is on the sub-synchronous resonance (SSR) incidents triggered by data centers. It remains largely uncertain whether and how the interactions between data centers and the grid may trigger undesirable disturbances and potential stability risks.

Here, I will conduct an in-depth investigation from the grid operator perspective to study the impedance characteristics of data center systems, with a special focus on the magnitude and phase variations within the sub-synchronous frequency range. The sensitivity analysis will be conducted to reveal the most critical control parameters or structural settings in data center systems. Scanning through diverse working conditions, these sensitivity models provide useful information for mitigation strategies such as active impedance shaping. Extensive simulations validate that the proposed model and algorithms successfully identify the sub-synchronous risks and outperform the benchmarks in terms of modeling precision and robustness performances.

2 - Toward Sustainable Data Centers for Artificial Intelligence

Benjamin Lee, University of Pennsylvania, Philadelphia, PA, United States

As the impact of artificial intelligence (AI) continues to proliferate, computer architects must assess and mitigate its energy demands and environmental impact. This talk will survey strategies for mitigating the energy used by AI computation and datacenter infrastructure, drawing on data and experiences from industrial, hyperscale systems. First, we analyze the energy and carbon implications of super-linear AI growth. Second, we re-think datacenter infrastructure and define a solution space for sustainable computation with renewable energy, utility-scale batteries, and job scheduling. Finally, we develop strategies for datacenter demand response, incentivizing workloads to modulate power usage in ways that reflect their performance goals. In summary, the talk provides a broad perspective on sustainable computing and outlines the many remaining directions for future work.

3 - Fine-Grained Carbon Accounting for Serverless Cloud Computing

Prateek Sharma, Indiana University, Bloomington, IN, United States

Serverless computing, or Functions as a Service (FaaS), has emerged as a key cloud abstraction which is enabling rapid deployment of AI, IoT, and scientific computing applications. Cloud functions are ephemeral and small—with millisecond-scale execution times. This necessitates /fine-grained/ accounting and optimization of carbon footprint of individual function invocations.

This talk will present the challenges and recent developments in statistical disaggregation and fair accounting for function-level carbon footprint measurement. For cloud applications, the energy and carbon footprint is diffused across many local and remote software and hardware components. For instance, virtualization and containerization software layers which execute and orchestrate applications (functions in our case) can themselves be significant energy consumers. As a result, existing energy profilers only provide a small and incomplete picture. We show how Shapley value principles can be used for fairly dividing this shared overhead among highly heterogeneous and dynamic functions, improving accuracy significantly. For fine-grained applications like serverless functions, we also develop new validation techniques and metrics, such as marginal energy, which provide a practical approach to obtain the "ground truth" energy and carbon footprint.

4 - Theoretical Foundations of Carbon-Aware Workload Scheduling

Mohammad Hajiesmaili, UMass Amherst, Amherst, MA, United States

As efforts to reduce the environmental impact of computing grow, *carbon-aware workload scheduling* has emerged as a promising approach for improving the sustainability of data centers. In this talk, we introduce a new online decision-making problem inspired by this setting: the *pause-and-resume problem*. Here, the goal is to select the k lowest prices (e.g., carbon intensity levels) from a sequence that is revealed one step at a time. At each time step, a decision-maker must choose whether to accept or reject the current price, while also managing *switching costs* incurred when changing decisions—such as the cost of pausing or resuming a workload.

This problem is motivated by real-world scenarios where computational tasks can be deferred during periods of high carbon intensity and resumed when cleaner energy is available—but doing so incurs operational overhead. The problem shares features with classical models in online optimization but also presents new challenges that render existing solutions insufficient. We propose and analyze a class of *double-threshold algorithms*, extending previous work on threshold-based strategies. We show that these algorithms achieve optimal competitive performance among all deterministic online methods.

This talk will highlight the interplay between sustainability goals, algorithm design, and online decision-making, with implications for broader areas such as carbon-aware and real-time resource management.

Stochastic Programming and Distributionally Robust Optimization Under Decision-Dependent Uncertainty

Invited Session

OPT: Optimization Under Uncertainty

Chair: Miguel Lejeune, George Washington University, Washington, DC, United States

1 - Chance-Constrained Set Multicover Problem

Pavlo Krokhmal, University of Arizona, TUCSON, AZ, United States, Shunyu Yao, Neng Fan

We consider a version of the set covering problem with uncertain parameters, which we refer to as the chance-constrained set multicover problem (CC-SMCP). In this problem, we assume that there is uncertainty regarding whether a selected set can cover an item, and the objective is to determine a minimum-cost combination of sets that covers each item i at least k_i times with a prescribed probability. To tackle CC-SMCP, we construct exact equivalent deterministic reformulations that feature a hierarchy of bounds and develop the corresponding outer-approximation (OA) algorithm. Additionally, we consider reducing the number of chance constraints via vector dominance relations and reformulate special cases of CC-SMCP using the "log-transformation" method and binomial distribution properties. Theoretical results on sampling-based methods, i.e., the sample average approximation (SAA) method and the importance sampling (IS) method, are also developed to approximate the true optimal value of CC-SMCP under a finite discrete probability space. Our numerical experiments demonstrate the effectiveness of the proposed OA algorithm, particularly in scenarios with sparse probability matrices, outperforming sampling-based approaches in most cases and validating the practical applicability of our solution approaches.

2 - Distributionally Robust Chance-Constrained Optimization Under Decision-Dependent Distributional Shift

Miguel Lejeune, George Washington University, Washington, DC, United States

We study distributionally robust chance-constrained optimization problems under decision-dependent uncertainty. The focus is on decision-dependent uncertainty of Type 1 in which the support of the random variables is decision-dependent and shifted. We study various types of coupling functions and ambiguity. We derive computationally tractable equivalent reformulations and a cutting-plane algorithm. Computational tests are reported.

3 - Distributionally Robust Performative Optimization

Zhuangzhuang Jia, University of Illinois Urbana-Champaign, Champaign, IL, United States, Yijie Wang, Roy Dong, Grani Adiwenana Hanasusanto

In performative stochastic optimization, decisions can influence the distribution of random parameters, rendering the data-generating process itself decision-dependent. In practice, decision-makers rarely have access to the true distribution map and must instead rely on imperfect surrogate models, which can lead to severely suboptimal solutions under misspecification. To address this challenge, we propose a distributionally robust framework for performative optimization that explicitly accounts for ambiguity in the decision-dependent distribution. Our framework introduces two modeling paradigms that capture a broad range of applications in machine learning and decision-making under uncertainty. This latter setting has not previously been explored in the performative optimization literature. To tackle the intractability of the resulting nonconvex objectives, we develop an iterative algorithm named repeated robust risk minimization, which alternates between solving a decision-independent distributionally robust optimization problem and updating the ambiguity set based on the previous decision. This decoupling ensures computational tractability at each iteration while enhancing robustness to model uncertainty. We provide reformulations compatible with off-the-shelf solvers and establish theoretical guarantees on convergence and suboptimality. Extensive numerical experiments in strategic classification, revenue management, and portfolio optimization demonstrate significant performance gains over state-of-the-art baselines, highlighting the practical value of our approach.

4 - Stackelberg Games with K-Submodular Function Under Distributional Risk-Receptiveness and Robustness

Sunghoon Park, Virginia Tech, Blacksburg, VA, United States, Manish Bansal

We study submodular optimization in adversarial context, applicable to machine learning problems such as feature selection using data susceptible to uncertainties and attacks. We focus on Stackelberg games between an attacker (or interdictor) and a defender where the attacker aims to minimize the defender's objective of maximizing a k -submodular function. We allow uncertainties arising from the success of attacks and inherent data noise, and address challenges due to incomplete knowledge of the probability distribution of random parameters. Specifically, we introduce Distributionally Risk-Averse k -Submodular Interdiction Problem (DRA k -SIP) and Distributionally Risk-Receptive k -Submodular Interdiction Problem (DRR k -SIP) along with finitely convergent exact algorithms for solving them. The DRA k -SIP solution allows risk-averse interdictor to develop robust strategies for real-world uncertainties. Conversely, DRR k -SIP solution suggests aggressive tactics for attackers, willing to embrace (distributional) risk to inflict maximum damage, identifying critical vulnerable components, which can be used for the defender's defensive strategies. The optimal values derived from both DRA k -SIP and DRR k -SIP offer a confidence interval-like range for the expected value of the defender's objective function,

capturing distributional ambiguity. We conduct computational experiments using instances of feature selection and sensor placement problems, and Wisconsin breast cancer data and synthetic data, respectively.

5 - A Successive Refinement Algorithm for Tri-Level Stochastic Defender-Attacker Problems with Decision-Dependent Probability Distributions

Hugh Medal, University of Tennessee, Knoxville, TN, United States, Samuel Affar

Tri-level defender-attacker game models are a well-studied method for determining how best to protect a system (e.g., a transportation network) from attacks. Existing models assume that defender and attacker actions have a perfect effect, i.e., system components hardened by a defender cannot be destroyed by the attacker, and attacked components always fail. Because of these assumptions, these models produce solutions in which defended components are never attacked, which may not be realistic in some contexts. This study considers an imperfect defender-attacker problem in which defender decisions (e.g., hardening) and attacker decisions (e.g., interdiction) have an imperfect effect such that the probability distribution of a component's capacity depends on the amount of defense and attack resources allocated to the component. Thus, this problem is a stochastic optimization problem with decision-dependent probabilities and is challenging to solve because the deterministic equivalent formulation has many high-degree multilinear terms. To address the challenges in solving this problem, we propose a successive refinement algorithm that dynamically refines the support of the random variables as needed, leveraging the fact that a less-refined support has fewer scenarios and multilinear terms and is, therefore, easier to solve. A comparison of the successive refinement algorithm versus the deterministic equivalent formulation on a tri-level stochastic maximum flow problem indicates that the proposed method solves many more problem instances and is up to 66 times faster. These results indicate that it is now possible to solve tri-level problems with imperfect hardening and attacks.

Contributed

Chair: Zhongling Xu, The University of Texas at Austin, Austin, TX, United States

1 - Convergence and Bound Computation for Chance Constrained Distributionally Robust Models Using Sample Approximation

Jiaqi Lei, Northwestern University, Evanston, IL, United States, Sanjay Mehrotra

This paper considers a distributionally robust chance constraint model with a general ambiguity set. We show that a sample based approximation of this model converges under suitable sufficient conditions. We also show that upper and lower bounds on the optimal value of the model can be estimated statistically. Specific ambiguity sets are discussed as examples.

2 - Multi-Stage Stochastic Optimization on Perishable Goods Inventory from Retailers Perspective

Weiliang Deng, University of Arizona, Tucson, AZ, United States

An increasing number of households are struggling with food insecurity, while a significant amount of food is wasted in the supply chain. Multi-parties within the entire supply chain are now collaborating to reduce waste. However, there is a lack of effective inventory management strategies for perishable goods from the retailer's perspective, particularly addressing food waste and donation. This study presents a multi-product, multi-period inventory control model, considering quality- and price-dependent demand and tax incentives to maximize the retailer's overall profit. This model can provide the retailer with an optimal inventory control plan, determining the optimal initial inventory, donation amount, re-order time and re-order amount. Algorithm is designed to solve the problem and numerical experiments are performed to validate the effectiveness of the model.

3 - Mean-Risk Stochastic Mixed-Integer Programs with Endogenous Uncertainty: Deterministic Equivalent Problem Formulations and Decomposition

Lina Villa, Texas A&M University, College station, TX, United States, Lewis Ntaimo

Mean-risk stochastic mixed-integer programs (MR-SMIPs) incorporate risk measures into classical stochastic programming to account for both expected outcomes and variability. Two-stage MR-SMIPs with decision-dependent (endogenous) uncertainty involve here-and-now first-stage decisions that affect the realization of uncertain parameters in the second stage. This work focuses on decision-dependent uncertainty where the first-stage decisions influence the availability of future information. We apply this modeling framework to optimal fuel (vegetation) treatment planning (FTP) under uncertainty, a critical problem in wildfire management. FTP includes methods such as prescribed burning and mechanical thinning to reduce hazardous fuels and thus influence future fire occurrence and behavior, which are both uncertain and driven by weather conditions. We derive two-stage MR-SIP models for the FTP problem with the expected excess (EE) risk measure, conditional value-at-risk (CVaR), and quantile deviation (QDEV), respectively, and create deterministic equivalent problem (DEP) formulations. Due to endogenous uncertainty, the DEP models are nonlinear and challenging to solve. To address this issue, we propose a linearization of the models that preserves the structure and improves tractability. We perform a computational study based on real-life data to evaluate the performance of the DEP models relative to a decomposition approach. The study offers practical guidance for selecting the solution method to use based on instance characteristics and the scalability of the method.

4 - Novel Stratified Algorithms for Sustainable Decision-Making Under Uncertainty

Shayan Sharifi, Wayne State University, Detroit, MI, United States, Melike Yildirim

In the rapidly evolving landscape of public healthcare, decision-makers face complex challenges due to conflicting objectives and dynamic weights for each objective. Traditional decision-making methods often fall short in such dynamic and uncertain environments. This study introduces two novel algorithms—Multi-Objective Stratified Decision-Making (MOSDM) and Sustainable Stratified Decision-Making (SSDM)—developed based on the Concept of Stratification (CST), aimed at addressing these challenges in public healthcare. The MOSDM algorithm significantly reduces computational complexity, making it suitable for large-scale applications and overcoming the limitations of existing stratification methods. Building on MOSDM, the SSDM algorithm incorporates sustainability principles, allowing decision-makers to consider future scenarios and fluctuating criteria—an essential feature in healthcare, where long-term sustainability is critical. These algorithms were validated through real-world case studies, where their performance was benchmarked against traditional decision-making approaches. The results demonstrate the algorithms' superior ability to integrate multiple objectives, adapt to changing environments, and promote sustainability. Key findings highlight their scalability, efficiency, and adaptability, showcasing their potential to enhance decision-making in healthcare policy, resource allocation, and long-term strategic planning.

5 - Sequentially Eliciting Distributional Information from a Human for Stochastic Integer Programs

John Nichols, Rensselaer Polytechnic Institute, Troy, NY, United States, Jennifer Pazour, Sandipan Mishra, John Mitchell

Stochastic programming problems have uncertain parameters, which can be represented as probability distributions. Expert elicitation protocols can be used to reveal additional information about these uncertain parameters. In this work, we develop a method to guide expert elicitations used to update stochastic input parameters. The method is designed to balance the need to create high-quality solutions without overburdening the human expert. This method uses statistical distances measures in a one-dimensional line search to determine how much an uncertain parameter's probability distribution can be perturbed before the objective function value changes. This is the stability region. The method recommends querying the human about the stochastic parameter with the smallest stability region. This is a general, numerical approach for stochastic integer programs. This method is compared to benchmark methods, including eliciting a human expert for information about all uncertain parameters.

6 - Defining and Solving Stochastic Programs with Equilibrium Recourse

Beau Groom, University of Tennessee, Knoxville, TN, United States, Mingzhou Jin

Applications of stochastic programming that involve modeling human behavior generally assume that independent agents choose to act in ways that are beneficial on the societal level. However, game theory shows that people follow their incentives to reach Nash equilibria at suboptimal societal outcomes. These interactions of self-interested human actors can cause large degradations in system performance that are not accounted for in traditional stochastic programming. To better model these

interactions and their impact on optimal first-stage decisions, we introduce stochastic programs with equilibrium-constrained recourse problems, along with a portfolio of exact and heuristic solution techniques. These algorithms are demonstrated and validated for an infrastructure investment planning problem with user equilibrium traffic assignment recourse.

7 - Managing Distributional Ambiguity in Stochastic Optimization Through a Statistical Upper Bound Framework

Shixin Liu, University of Michigan - Dearborn, Dearborn, MI, United States, Jian Hu

Stochastic optimization is often hampered by distributional ambiguity, where critical probability distributions are poorly characterized or unknown. Addressing this challenge, we introduce a new framework that targets the minimization of a statistical upper bound for the expected value of uncertain objectives, facilitating more statistically robust decision-making. Central to our approach is the Average Percentile Upper Bound (APUB), a novel construct that simultaneously delivers a statistically rigorous upper bound for the population mean and a meaningful risk metric for the sample mean. The integration of APUB into stochastic optimization not only fortifies the process against distributional ambiguity but also reinforces key data-driven decision-making attributes, such as reliability, consistency, and comprehensibility. Notably, APUB-enriched optimization problems feature tractability, with particular advantages in two-stage stochastic optimization with random recourse. Empirical demonstrations on two-stage product mix and multi-product newsvendor benchmark problems reveal the benefit of the APUB optimization framework, in comparison with conventional techniques such as sample average approximation and distributionally robust optimization.

8 - Learning Robust Decisions: Data-Driven Distributionally Robust Optimization with Neural Decision Rules

Zhongling Xu, The University of Texas at Austin, Austin, TX, United States

Traditional optimization often assumes perfect knowledge of underlying data distributions, a luxury rarely afforded in real-world applications. Data-driven distributionally robust optimization (DRO) offers a powerful framework to address this uncertainty by optimizing against the worst-case distribution within an ambiguity set, defined by available data. This talk will explore a novel approach to solving data-driven DRO problems by leveraging the expressive power of neural networks to represent optimal decision rules. Specifically, we will discuss how to parameterize the decision rule as a neural network, allowing us to learn complex, nonlinear, and robust policies directly from data. This methodology not only enhances the flexibility and applicability of DRO to high-dimensional and intricate problems but also provides a computationally tractable pathway to derive robust solutions. We will delve into the theoretical underpinnings and practical benefits of this neural network-based approach, demonstrating its effectiveness in generating decisions that are resilient to distributional shifts and model misspecification.

Invited Session

Revenue Management

Chair: Jiashuo Jiang, HKUST, Hong Kong, Hong Kong

1 - Taming the Curse of Dimension in Multi-Stage Decision-Making

Yifan Hu, Rutgers Statistics, New Brunswick, NJ, United States

We revisit the empirical approximation of multi-stage stochastic programming studied in Shapiro, 2006. For 3-stage problems, the previous results obtain an $O(\epsilon^{-4})$ complexity bound to obtain an ϵ approximation. It was thus inferred that the sample complexity of T-stage problem admits an exponential dependence on T, i.e., $O(\epsilon^{-2T+2})$. Such a conjecture forms a long-standing belief that multi-stage stochastic programming suffers from the curse of dimensionality. In this talk, we discuss a novel method for 3-stage problem that achieves an $O(\epsilon^{-2})$ complexity bound, indicating that the complexity bounds for T-stage problem can be improved. We further construct a novel empirical approximation of T-stage problem and establish a polynomial complexity bound in terms of $O(1/\epsilon)$.

2 - Online Order Fulfillment with Replenishment

Zi (Elaine) Ling, Booth School of Business, University of Chicago, Chicago, IL, United States, Jiashuo Jiang, Linwei Xin

In modern e-commerce and service operations, firms must jointly manage *inventory replenishment policies* and *real-time fulfillment algorithms* to maximize revenue under uncertainty. While each component has been studied extensively in isolation, their interaction remains underexplored. This paper investigates a fundamental operational question: **Which lever has a greater impact on system performance—replenishment or fulfillment?**

We model the system as a one-location fulfillment problem (equivalently, a multi-secretary problem) with lost sales and stochastic customer arrivals, each offering heterogeneous rewards. Replenishment follows either a base-stock or constant-order policy, while real-time fulfillment decisions are made using online algorithms. Our core performance metric is the long-run average revenue per replenishment cycle, evaluated across all combinations of these policies and algorithms.

We show that, when the replenishment cycle length is large, the *total regret of online fulfillment* remains in the same order as in a single-cycle problem—even in the presence of replenishment—revealing a form of *regret stability*, which also extends to the multi-location setting. We further develop a regret-based framework for quantitatively comparing fulfillment and replenishment decisions, characterizing when optimizing the replenishment policy has greater impact on revenue than improving the fulfillment algorithm alone. Motivated by examples where online myopic algorithms underperform, we introduce a novel *look-ahead online algorithm* that anticipates future replenishment and demand. Numerical experiments verify that this algorithm outperforms myopic baselines.

Our results offer both theoretical and managerial insights into situations where inventory replenishment policies are more influential and vice versa.

3 - Beyond Non-Degeneracy: Revisiting Certainty Equivalent Heuristic for Online Resource Allocation

Wenjia Wang, HKUST (GZ), Guangzhou, China, People's Republic of, Yilun Chen

The Certainty Equivalent (CE) heuristic is a widely-used algorithm for various online resource allocation problems in OR and OM. Despite its popularity, existing theoretical guarantees of CE are limited to settings satisfying restrictive fluid regularity conditions, particularly, the non-degeneracy conditions, under the widely held belief that the violation of such conditions leads to performance deterioration and necessitates algorithmic innovation beyond CE.

In this work, we conduct a refined performance analysis of CE within the general framework of online linear programming. We show that CE achieves uniformly near-optimal regret (up to a polylogarithmic factor in T) under only mild assumptions on the underlying distribution, without relying on any fluid regularity conditions. Our result implies that, contrary to prior belief, CE effectively beats the curse of degeneracy for a wide range of problem instances with continuous conditional reward distributions, highlighting the distinction of the problem's structure between discrete and non-discrete settings. Our explicit regret bound interpolates between the mild $(\log T)^2$ regime and the worst-case $\sqrt{T}$ regime with a parameter β quantifying the minimal rate of probability accumulation of the conditional reward distributions, generalizing prior findings in the multisecretary setting.

To achieve these results, we develop novel algorithmic analytical techniques. Drawing tools from the empirical process theory, we establish strong concentration analysis of the solutions to random linear programs, leading to improved regret analysis under significantly relaxed assumptions. These techniques may find potential applications in broader online and offline stochastic decision-making contexts.

4 - Empowering LLM Alignment with Choice Modeling

Yuxuan Tang, National University of Singapore, Singapore, Singapore, Yifan Feng

LLM alignment is the process of making LLMs behave in ways that are consistent with human intentions and values. It's crucial because unaligned models may produce harmful, biased, or undesired outputs. Human preference data is central to alignment, helping steer models toward more desirable responses. While traditional approaches

like RLHF and DPO rely on pairwise preference data, our work explores a more expressive format—ranked choice data—which allows for more efficient and informative training.

1 - Adaptive Two-Sided Assortment Optimization: Revenue Maximization

Mohammadreza Ahmadnejadsaein, Cornell Tech, Cornell University, New York, NY, United States, Omar El Housni

We study adaptive two-sided assortment optimization for revenue maximization in choice-based matching platforms. The platform has two sides of agents, an initiating side, and a responding side. The decision-maker sequentially selects agents from the initiating side, shows each an assortment of agents from the responding side, and observes their choices. After processing all initiating agents, the responding agents are shown assortments and make their selections. A match occurs when two agents mutually select each other, generating pair-dependent revenue. Choices follow Multinomial Logit (MNL) models. This setting generalizes prior work focused on maximizing the number of matches under submodular demand assumptions, which do not hold in our revenue-maximization context.

Our main contribution is the design of polynomial-time approximation algorithms with constant-factor guarantees. In particular, for general pairwise revenues, we develop a randomized algorithm that achieves a $(\frac{1}{2} - \epsilon)$ -approximation in expectation for any $\epsilon > 0$. The algorithm is static and provides guarantees under various agent arrival settings, including fixed order, simultaneous processing, and adaptive selection. When revenues are uniform across all pairs involving any given responding-side agent, the guarantee improves to $(1 - \frac{1}{e} - \epsilon)$. In structural settings where responding-side agents share a common revenue-based ranking, we design a simpler adaptive deterministic algorithm achieving a $\frac{1}{2}$ -approximation. Our approach leverages novel linear programming relaxations, correlation gap arguments, and structural properties of the revenue functions.

2 - Contextual Markov Chain Choice Model

Kai Tan, Stanford University, Stanford, CA, United States, Elynn Chen, Gustavo Vulcano, Jiawei Zhang

In this work, we propose a contextual Markov Chain Choice Model (MCCM) that captures heterogeneity in customer purchasing behavior by incorporating both customer and product features. We develop an Expectation-Maximization (EM) algorithm to perform maximum likelihood estimation and establish the convergence of the log-likelihood function. In addition, we introduce a linear programming approach to compute revenue-maximizing assortments, enabling personalized assortment decisions for individual customers. Extensive simulation studies show that our contextual MCCM is noticeably competitive with existing benchmark methods in both modeling customer choices and revenue optimization.

3 - On the Estimation of a Markov Choice Model from Partial Inventory Data

Gustavo Vulcano, Universidad Torcuato Di Tella, Buenos Aires, Argentina, Charles Thraves, Ivan Vidal

A seller observes the inventory levels of substitute products at the beginning and end of each day over multiple days. Each day, customers arrive sequentially and either purchase one product or opt for the no-purchase alternative. Each customer has a probability distribution over first-choice preferences and, if their preferred product is unavailable, transitions to another option according to a Markov chain discrete choice model. While the total number of arriving customers is known, neither the specific product purchased by each customer nor the choice set they faced is observed. This work extends previous studies by relying on less detailed information about customer behavior and observed outcomes. We use the Expectation-Maximization (EM) algorithm to estimate the model parameters, using Metropolis-Hastings (MH) methods in the E-step to sample purchase paths consistent with inventory observations. The M-step admits closed-form solutions. We solve numerical instances to assess the accuracy and performance of the parameter estimates. Our results show that, although the true parameters are not always identifiable, the log-likelihood achieved with the estimated parameters is very close to that obtained using the true parameters. This finding also holds when evaluating simulated data in terms of final inventories, stock-out probabilities, and fill rates.

4 - Blind and near-Optimal Dynamic Assortment Optimization with Reusable Resources

Zerui Wu, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Ran LIU, Xu Sun

We study dynamic assortment optimization with reusable resources in blind settings, where both customer arrival rates and resource rental durations are unknown. This challenge arises in environments such as cloud computing, healthcare, and hospitality, where resources are rented for random durations and demand patterns may fluctuate. We propose a simple, blind, state-dependent policy that selects assortments based solely on the current system state and known resource attributes, such as expected revenue and customer choice probabilities. The policy requires no estimation of arrival or rental return rates and adapts naturally to slowly time-varying conditions. It achieves an absolute revenue loss of $O(\sqrt{n})$ in general systems and a constant $O(1)$ loss in overloaded regimes, where n is the total number of resources, matching the best-known performance bounds in the literature under comparable assumptions. Theoretical guarantees are derived using an exponential potential function that induces self-correcting behavior without explicit learning. Numerical experiments support the theoretical bounds and demonstrate robust performance across a range of operating regimes.

Learning in Games and Strategic Environments

Invited Session

Auctions and Market Design

Chair: Kunhe Yang, UC Berkeley, Berkeley, CA, United States

1 - Calibrated Stackelberg Games: Learning Optimal Commitments Against Calibrated Agents

Chara Podimata, MIT, Newton, MA, United States, Nika Haghtalab, Kunhe Yang

In this paper, we introduce a generalization of the standard Stackelberg Games (SGs) framework: Calibrated Stackelberg Games (CSGs). In CSGs, a principal repeatedly interacts with an agent who (contrary to standard SGs) does not have direct access to the principal's action but instead best-responds to calibrated forecasts about it. CSG is a powerful modeling tool that goes beyond assuming that agents use ad hoc and highly specified algorithms for interacting in strategic settings and thus more robustly addresses real-life applications that SGs were originally intended to capture. Along with CSGs, we also introduce a stronger notion of calibration, termed adaptive calibration, that provides fine-grained any-time calibration guarantees against adversarial sequences. We give a general approach for obtaining adaptive calibration algorithms and specialize them for finite CSGs. In our main technical result, we show that in CSGs, the principal can achieve utility that converges to the optimum Stackelberg value of the game both in finite and continuous settings, and that no higher utility is achievable. Two prominent and immediate applications of our results are the settings of learning in Stackelberg Security Games and strategic classification, both against calibrated agents.

2 - Learning Local Stackelberg Equilibria from Repeated Interactions with a Learning Agent

Nivasini Ananthkrishnan, University of California, Berkeley, Berkeley, CA, United States, Yuval Dagan, Kunhe Yang

Motivated by the question of how a principal can maximize its utility in repeated interactions with a learning agent, we study repeated games between a principal and an agent employing fictitious play. Prior work has shown that computing or even approximating the global Stackelberg value in similar settings can require an exponential number of rounds in the size of the agent's action space, making it computationally intractable. In contrast, we shift focus to the computation of local Stackelberg equilibria and introduce an algorithm that, within the smoothed analysis framework, constitutes a Polynomial Time Approximation Scheme (PTAS) for finding an ϵ -approximate local Stackelberg equilibrium. Notably, the algorithm's runtime is polynomial in the size of the agent's action space yet exponential in $(1/\epsilon)$ —a dependency we prove to be unavoidable.

3 - Nearly-Optimal Bandit Learning in Stackelberg Games with Side Information

Keegan Harris, Carnegie Mellon University, School of Computer Science, Pittsburgh, PA, United States

We study the problem of online learning in Stackelberg games with side information between a leader and a sequence of followers. In every round the leader observes contextual information and commits to a mixed strategy, after which the follower best-responds. We provide learning algorithms for the leader which achieve $O(T^{1/2})$ regret under bandit feedback, an improvement from the previously best-known rates of $O(T^{2/3})$. Our algorithms rely on a reduction to linear contextual bandits in the utility space: In each round, a linear contextual bandit algorithm recommends a utility vector, which our algorithm inverts to determine the leader's mixed strategy. We extend our algorithms to the setting in which the leader's utility function is unknown, and also apply it to the problems of bidding in second-price auctions with side information and online Bayesian persuasion with public and private states. Finally, we observe that our algorithms empirically outperform previous results on numerical simulations.

4 - Full Swap Regret and Discretized Calibration

Princewill Okoroafor, Cornell University, Ithaca, NY, United States, Maxwell Fishelson, Robert Kleinberg, Renato Paes Leme, Jon Schneider, Yifeng Teng

We study the problem of minimizing swap regret in structured normal-form games. Players have a very large (potentially infinite) number of pure actions, but each action has an embedding into d -dimensional space and payoffs are given by bilinear functions of these embeddings. We provide an efficient learning algorithm for this setting that incurs at most $O(T^{(d+1)/(d+3)})$ swap regret after T rounds.

To achieve this, we introduce a new online learning problem we call *full swap regret minimization*. In this problem, a learner repeatedly takes a (randomized) action in a bounded convex d -dimensional action set $\mathcal{K}$ and then receives a loss from the adversary, with the goal of minimizing their regret with respect to the *worst-case* swap function mapping $\mathcal{K}$ to $\mathcal{K}$. For varied assumptions about the convexity and smoothness of the loss functions, we design algorithms with full swap regret bounds ranging from $O(T^{d/(d+2)})$ to $O(T^{(d+1)/(d+2)})$.

Finally, we apply these tools to the problem of online forecasting to minimize calibration error, showing that several notions of calibration can be viewed as specific instances of full swap regret. In particular, we design efficient algorithms for online forecasting that guarantee at most $O(T^{1/3})$ ℓ_2 -calibration error and $O(\sqrt{\epsilon} T, T^{1/3})$ *discretized-calibration* error (when the forecaster is restricted to predicting multiples of ϵ).

1 - A Patient-Centered Hospital Procurement of Physician Preferred Implants

Renato de Matta, University of Iowa, Iowa City, IA, United States

This paper studies the hospital's procurement of physician preferred implants where both hospital surplus (profit) and patient surplus (value) are maximized. For better flexibility with minimal revision risk to patients, we introduce the substitution of another device that belongs in the category of the physician-preferred implant. This allows for improving the hospital surplus through larger revenues and volume discounts, although it implies that there is an additional cost to train the physician who may need to use the substituted implant and associated surgical procedure for safety and quality assurance. We model the procurement problem as a single period multiproduct stochastic programming problem with substitution. The problem is NP-hard. We propose two heuristic procedures for finding good feasible solutions and for estimating the optimality bound. The results of our experiments using patient-reported costs and total hip replacement outcomes from the medical literature show that a modest increase in flexibility can improve the hospital's financial performance, produce better patient outcomes, and reduce the negative effects of demand uncertainty.

2 - Streamlining Hospital Operations with Interactive Optimization and AI-Powered BI Tools

Deepti Bahel, VigourSoft Global Solutions, San Jose, CA, United States, Vinay Manglani

This presentation showcases an interactive hospital business intelligence (BI) application developed using Streamlit, designed to support real-time, data-driven decision-making in healthcare operations. The tool enables stakeholders to explore and analyze hospital data across key areas such as billing, patient length of stay, and anomaly detection—without requiring programming expertise.

At its core, the application offers optimization capabilities using linear programming (LP), integer programming (IP), and greedy heuristics to help hospital administrators identify cost-efficient patient management strategies. Users can apply constraints like long-stay thresholds, weekend admission limits, and anomaly risk to simulate and compare different approaches.

The platform integrates machine learning models—such as XGBoost and Random Forest—to classify patient stays and predict outcomes, while Isolation Forest algorithms help detect potential billing anomalies. Model explainability is enhanced with SHAP values, making it easier to understand the drivers behind predictions.

What makes this tool particularly accessible is its conversational AI interface. Users can query the data in plain English, and the system returns executable Python code, visualizations, and narrative summaries generated by GPT. With features like CSV upload, filters, and result exports, the app provides a seamless user experience.

This talk will walk through the design, key features, and practical use cases of the tool, demonstrating how operations research, machine learning, and explainable AI can work together to improve transparency and efficiency in hospital management.

3 - The Impact of DIP Policy on Patient Hospitalization Costs and Hospital Admission Practices

Nuotong Yang, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Hui Lin, Guohua Wan

Based on inpatient data from DIP pilot regions, this study employs a difference-in-differences approach to empirically examine the policy's impact on medical costs and their structure, while analyzing adjustments in hospital admission practices. The findings reveal that the DIP policy significantly reduces hospitalization costs in secondary hospitals and decreases examination and testing expenses for inpatients in tertiary hospitals, demonstrating notable heterogeneity across hospital tiers. The study suggests that the DIP policy can leverage economic incentives to motivate healthcare institutions to control costs endogenously, thereby curbing unreasonable growth in medical expenditures.

4 - Designing Specialist-Response Policies in Hospital Emergency Departments

Emily Fainman, Texas State University, San Marcos, TX, United States, Beste Kucukyazici, Zhankun Sun

Emergency Department (ED) overcrowding is a global healthcare challenge, significantly exacerbated by delays in specialist consultations (SCs). These delays, measured as Request-to-Realization (R2R) times—the interval from SC request to specialist arrival—often exceed targets and prolong ED length of stay (LoS), thereby compromising patient outcomes and operational efficiency. This study addresses the design of specialist-response policies to mitigate R2R delays without increasing staffing burdens. Leveraging data from over one million ED visits across eleven hospitals in Montreal, we employ empirical analysis, stochastic modeling, and simulation to assess the impact of SC delays and develop optimal specialist scheduling strategies.

We model SC processes as $Mt/G(T)/1$ queues to capture time-varying arrival patterns and derive an analytical, closed-form solution for optimal fixed-time specialist schedules. These are evaluated against conventional on-call and on-site policies to identify the most efficient policy mix for each hospital setting. Furthermore, we integrate specialist availability into triage prioritization by developing a predictive model to assess SC needs at triage, aligning patient assessment with scheduling constraints.

Simulation studies in both tertiary and secondary hospitals validate the approach, demonstrating reductions in R2R times by 25–42% and ED LoS by over 10%, without increasing the frequency of specialist visits. This research introduces a novel, time-dependent queuing framework for healthcare operations, offering actionable decision-support tools for hospital administrators. Our findings have broad applicability in managing shared or rotating medical staff, thereby enhancing ED responsiveness and patient care across diverse hospital environments.

5 - Nurse Staffing and Hospital Outcomes: a Strategic Investment in Quality and Sustainability

Esmail Bahalkeh, University of New Hampshire, Durham, NH, United States, Dinesh Pai

Rising healthcare costs and the ongoing shift toward value-based care necessitate a thoughtful and critical reassessment of how hospitals allocate their resources—particularly in relation to nursing staff, who remain the backbone of high-quality patient care. This longitudinal study (2000–2023) analyzes data from acute care hospitals across Pennsylvania to explore the complex, multidimensional relationships between nurse staffing levels (RN ratio), skill mix (proportion of RN), financial performance, quality of care, and length of stay (LOS). Using robust statistical methods, we examine how variations in staffing influence key clinical and economic outcomes over time. Our findings reveal a nuanced and often paradoxical landscape. Hospitals with a higher RN ratio experience significantly better quality outcomes. However, these clinical benefits are accompanied by increased operational costs and diminished operating margins, highlighting a financial trade-off that administrators must carefully consider. Meanwhile, a higher skill mix is associated with favorable impacts on readmissions and length of stay but does not show a statistically significant relationship with financial performance, suggesting that improvements in workforce composition may enhance care efficiency without clear cost consequences. By illuminating both the clinical advantages and financial implications of investing in a skilled nursing workforce, this research offers timely, data-driven insights for healthcare leaders and policymakers. It emphasizes the importance of strategic, evidence-based staffing decisions to achieve both financial sustainability and optimal patient outcomes within an increasingly demanding and value-conscious healthcare environment.

1 - Explaining Black Box Models: a Framework Comparison on Loan Data Using Prosper Marketplace Loan Data

Rongbin Ye, Synchrony Bank(Self Representing), Chicago, IL, United States, Jiaqi Chen

Assessing credit risk in finance is challenging due to the need to balance powerful machine learning (ML) predictions with regulatory demands for transparency and fairness (e.g., OCC, CFPB). While simple models are transparent but less accurate, complex "black-box" models lack explainability. This project tackles this by developing and comparing Logistic Regression, Random Forest, and Neural Network models for credit risk on the Prosper Marketplace dataset, enhanced with macroeconomic data. We used LIME to explain individual predictions, especially for the Neural Network. Results show complex models predict better, particularly for defaults, and LIME effectively reveals their decision processes. We also propose a new five-part framework (Inherent Interpretability, Global Explanations, Local Explanations, Consistency, Complexity) to evaluate model explainability beyond just accuracy. This research demonstrates that high-performance ML models can be used in regulated finance by employing modern explainability methods and provides a structured way to weigh performance against interpretability.

3 - Data Driven Delivery Delay Prediction Using a Deep Learning Framework

Stefan Faulkner, Georgia Institute of Technology, Atlanta, GA, United States, Reza Zandehshahvar, Vahid Eghbal Akhlaghi, Pascal Van Hentenryck

Accurate and timely predictions of delivery times play a crucial role in enhancing supply chain operational efficiency and ensuring customer satisfaction. Yet, numerous challenges exist in making precise predictions, including complex logistics data, geographical differences, and imbalanced delivery status distributions. This paper introduces a two-phase deep learning approach for predicting delivery delays using a classification-then-regression setting. The models are equipped with uncertainty quantification through conformal prediction to enhance the trustworthiness and enable informed-decision making.

The approach begins by analyzing historical delivery data to develop a classification system that categorizes shipments into three forms of groups: on-time, delayed, and those with uncertain status. For shipments identified as potentially delayed or uncertain, a second-phase regression model calculates the expected delay time. Both stages include conformal prediction to ensure well-calibrated predictions with reliable confidence levels. The framework accounts for geographical variations by training location-specific models based on the shipment sources.

The proposed method employs deep learning with specialized embedding layers for numerical and categorical variables and is compared against conventional machine learning approaches. Testing on an extensive real-world dataset containing over 10 million shipment records from an industry logistics provider demonstrates that multi-layer perceptron model with linear embeddings surpasses alternative approaches, yielding F1-scores ranging from 0.35 to 0.49 across various locations despite significant class imbalances. The regression component also performs effectively, achieving mean absolute errors under 1 day for delayed shipments and under 1.5 days across all shipments.

4 - An Xr-Enabled Deep Learning Framework for Driver Distraction Detection and Monitoring

Amirarash Kashaf, Mississippi State University, Starkville, MS, United States, Junfeng Ma

According to the World Health Organization (WHO), approximately 1.19 million people die annually in road traffic accidents, with an additional 20 to 50 million sustaining non-fatal injuries, often leading to long-term disabilities. A significant portion of these accidents is attributed to driver distraction, particularly from mobile phone use and drowsiness—two of the most pressing safety concerns in modern transportation. This study addresses these challenges by utilizing the publicly available *Distracted Driver Dataset V2*, which includes side-view RGB images of 44 drivers performing 10 distinct actions related to distracted driving. To enhance the dataset's coverage and relevance, we introduce an additional class representing drowsy drivers, acknowledging that drowsiness was involved in approximately 17.6% of fatal crashes between 2017 and 2021. We implement transfer learning using a lightweight Deep Convolutional Neural Network (DCNN) based on the MobileNet architecture. The proposed model achieves a classification accuracy of 93.60% and an F1-score of 0.94 across all classes. Beyond training and evaluation, we deploy the trained model on an Extended Reality (XR) headset to enable real-time driver monitoring from a passenger-side view. The XR integration offers enhanced situational awareness and posture visibility, improving detection accuracy for subtle or partially occluded distractions. By fusing lightweight AI models with immersive sensing platforms, our

approach offers a practical and scalable solution for real-time distracted driver classification. The results highlight the potential of combining transfer learning with XR technologies for advanced, adaptive, and context-aware driver safety systems.

5 - A Human-on-the-Loop LLM Framework for Adaptive Quality Prediction Systems for Industry 5.0

Minsik Kim, Kyung Hee University, Yongin, Korea, Republic of, Jae-Yoon Jung

To realize autonomous manufacturing, it is essential to develop technologies that minimize human intervention across the production process. This study proposes a semi-autonomous and adaptive quality prediction system using large language models (LLMs). The proposed framework aims to address two key challenges in intelligent manufacturing environments: real-time adaptability to data distribution shifts and model interpretability.

This study designs an LLM-based pipeline that learns from production data and extracts rule-based explanations for quality prediction. The system offers clear reasoning behind predictions through explainable AI, while its automated quality monitoring mechanism continuously observes model performance. Upon detecting data shifts, the model is dynamically updated to maintain long-term prediction accuracy.

This approach demonstrates that LLMs can be effectively applied not only to natural language tasks but also to mission-critical domains such as manufacturing. Experimental results using real-world production datasets show that the proposed system maintains robust predictive performance under changing conditions, while also providing human-understandable explanations.

These findings highlight the potential of integrating industrial AI with LLMs to develop interpretable and adaptive autonomous quality control systems. Ultimately, the proposed method supports greater automation and resilience in manufacturing by reducing dependency on manual oversight.

6 - Improving Targeting Policies Using Transfer Learning

Marat Ibragimov, Emory University, Atlanta, GA, United States, Duncan Simester, Artem Timoshenko

Firms can enhance the profitability of marketing campaigns by targeting different customers with different actions based on the incremental effects. However, firms typically estimate the incremental effects using training data that closely resembles the focal campaign, and this data is often scarce. We propose a method to augment focal training data with information from different marketing campaigns, even when the campaigns differ in content, audience, and timing. Our approach accounts for campaign and customer differences and explicitly incorporates uncertainty in the measurement of treatment effects using a Bayesian probabilistic matrix factorization framework. Scalability and computational efficiency are achieved through a combination of closed-form conditional distributions and gradient-based MCMC sampling. We validate the method using simulated data and a large-scale field experiment, and demonstrate substantial improvements in predictive accuracy and campaign profitability. By leveraging information across campaigns, the proposed approach amplifies the value of firms' marketing data and offers a scalable and robust solution for designing targeting policies.

1 - Treemark++: Robust and High-Capacity Image Watermarking for Diffusion Models

Yaopeng Wang, Southeast University, Nanjing, China, People's Republic of

As diffusion-based generative models are increasingly applied in content creation, image watermarking has become a critical tool for ensuring traceability and copyright protection. However, existing methods struggle to balance robustness, imperceptibility, and information capacity. In this work, we propose TreeMark++, an enhanced watermarking framework built upon Tree-Ring Watermarking. TreeMark++ introduces a single-layer ring structure with multi-bit embedding, significantly improving capacity and matching efficiency in multi-user scenarios. To address synchronization issues under geometric transformations, we incorporate a header-aware design and redundancy encoding, enabling accurate information extraction even under distortions such as JPEG compression, cropping, and large-angle rotation. Experimental results demonstrate that TreeMark++ achieves high watermark detection and extraction accuracy while preserving semantic fidelity across diverse datasets.

2 - Smart Home Service System Development Framework Based on Generative AI

JAESEOK YUN, Korea University, Sejong, Korea, Republic of, Sung Yeon Kim, Seonghyeon Han, Jinmin Kim

This study proposes a development framework for smart home service systems based on generative artificial intelligence (Generative AI) and analyzes its effects. Traditional smart home systems have faced limitations in providing personalized services due to a lack of interoperability among devices, command-based interaction, and non-standardized data management. Focusing on the rapid advancement of Generative AI technologies, this research presents a framework that enables more intelligent and integrated smart home services. The proposed framework incorporates data standardization, user requirement-based system design, and personalized service strategies, while also aligning with global smart home standards such as Matter. Additionally, the study empirically examines the impact of Generative AI-based smart home systems on users' intention to use the services and their residential satisfaction. The analysis reveals perceptual structures based on differences in product-service quality across smart home components, suggesting the potential for a new classification framework from the perspective of Product-Service Systems (PSS). Notably, the proposed framework also supports the advancement of smart home testing and certification systems, contributing to enhanced interoperability and system reliability. This study not only highlights the applicability of Generative AI in the smart home domain but also provides technological and policy implications for implementing sustainable smart homes, improving user experience, and enabling data-driven decision-making.

3 - Comparing Deep Learning Models and LLMs for Airport Sentiment Analysis on Twitter Data

Dirk Van den Poel, Ghent University, Ghent, Belgium, Belgium, Maxim Devriendt, Valentin Janclaes

This study presents a structured and scalable pipeline for extracting actionable insights on airport service experiences from unstructured Twitter data. We use a staged setup to filter over two million tweets into a curated subset of relevant, airport-specific content, enabling fine-grained sentiment evaluation per airport service category.

We benchmark both deep learning models (e.g., ModernBERT, BiLSTM) and a range of large language models (LLMs), including lightweight (e.g., Mistral 7B, Qwen 2.5 3B) and heavyweight variants (e.g., LLaMa 3.3 70B, DeepSeek 67B). In early pipeline tasks, such as relevance filtering and entity classification, ModernBERT (an encoder-based model) outperforms LLMs in both F1-score and computational efficiency. However, in the airport service topic modeling stage, where multi-label complexity and semantic nuance are essential, LLMs, particularly heavyweight ones, exceed deep-learning baselines. The final stage performs sentiment analysis across the airport service topics.

Our approach differs from prior work in three ways: (1) it enables multi-label classification across multiple airport service topics per tweet, rather than restricting to a single label; (2) it introduces a modular, step-by-step pipeline tailored to noisy Twitter data, transferable to other social media sources; and (3) it provides comprehensive benchmarking of LLMs versus deep learning throughout the pipeline.

We demonstrate that social media data, when processed via a structured pipeline, may yield rich, near real-time insights into passenger experience, offering a valuable complement to traditional airport service survey methods and enabling more agile, data-driven airport management.

4 - Generative AI-Based Optimization Agent for Nonlinear Programming

Saif Kazi, Los Alamos National Laboratory, Santa Fe, NM, United States

Nonlinear Constrained Optimization a.k.a Nonlinear Programming (NLP) is an important tool in solving engineering problems [Optimal Control, Optimal Power Flow, Nonlinear Model Predictive Control etc.] with applications in multiple domains such as operations research, finance etc. Deterministic methods to solve NLPs are generally based on using the optimality criterion known as Karush-Kuhn-Tucker (KKT) conditions. Algorithms such as Interior-point methods (IPM) use Newton-Raphson to solve the nonlinear KKT conditions. This particular approach suffers from convergence issues due to the local convergence property of Newton's algorithm making it extremely important to provide good initial guess to the optimization algorithm for fast convergence.

In this study, we propose building an optimization agent based on mix of LLM and Neural Network architecture which first transforms NLP problems written in text format to the KKT conditions. In second step, the Nonlinear KKT Equation system is solved using the Neural network architecture and an adaptive learning rate. This step doesn't require training of neural network using artificial dataset and also overcomes the local convergence issue associated with the classical Newton-Raphson method. We test our approach on benchmark NLP problems to showcase and compare it's performance with conventional NLP solvers.

5 - Multi-Agent Language Agent Tree Search for Adaptive Financial Decision-Making

Sorouralsadat Fatemi, University of Illinois at Chicago, Chicago, IL, United States

In this work, we introduce **Language Agent Tree Search (LATS)**, a novel multi-agent framework that integrates the reasoning power of large language models (LLMs) with structured decision-making for adaptive financial tasks. LATS extends Monte Carlo Tree Search (MCTS) by embedding language agents at decision nodes, allowing each agent to generate, reflect, and critique financial actions—such as buy/hold/sell strategies—based on textual, tabular, and temporal data. Unlike prior agent-based approaches that rely on static heuristics or black-box models, our architecture coordinates multiple specialized agents, including reflection and forecasting agents, to dynamically explore and prune the decision tree through iterative, language-guided rollouts

6 - Transmode-LLM: Feature-Informed Natural Language Modeling with Domain-Enhanced Prompting for Travel Behavior Modeling

Meijing Zhang, Singapore University of Technology and Design, Singapore, Singapore, Ying Xu

Understanding traveler behavior and accurately predicting travel mode choice are at the heart of transportation planning and policy making. Traditional methods relying on raw numbers and structured feature representations have limitations on capturing the complex interdependency and qualitative factors that may impact on travel behavior in the real-world, particularly the rich contextual nuances underlying individual decision-making processes. Large language models (LLMs) with promising capabilities for understanding contextual information across domains provides new pathways for travel behavior modeling. In this study, we propose, TransMode-LLM, an innovative framework designed to predict travel modes from natural language descriptions of travelers and their trips. We start by analyzing the importance of features to identify and select key impacting factors (i.e. individual, household and trip characteristics) to enrich context for decision-making. To enhance the performance of LLMs for transportation-specific tasks, we propose a domain-enhanced prompting strategy that incorporates standardize mode definitions. We further explore various learning paradigms (zero-shot and one/few-shot learning) to understand their impact on travel mode prediction using natural language. Finally, we build an evaluation system to compare the performance of the proposed LLM-based approach against state-of-the-art traditional models. Extensive experiments are conducted on the real-world travel survey dataset and the results demonstrate the competitive performance of LLM-based approach such as prediction accuracy compared to the traditional methods. This study advances the application of LLMs in travel behavior modeling, providing promising and valuable insights for both academic research and transportation policy-making in the future.

1 - Balancing Cost and Carbon Emissions: Smart Scheduling with Non-Identical Parallel Machines and Mixed Energy Sources in Manufacturing

Sang Jin Kweon, Yonsei University, Seoul, Korea, Republic of

In this talk we address a production scheduling problem involving non-identical parallel machines in a high-mix, low-volume manufacturing setting. We focus on two key objectives: minimizing production-related costs and reducing carbon emissions, while also accounting for machines powered by various energy sources, each with different costs and emission profiles. To tackle this, we develop a bi-objective mixed-integer programming model that supports green manufacturing strategies by finding cost-effective, low-emission production schedules. The proposed model is tested using real data from a manufacturer in Ulsan, South Korea, demonstrating how flexible machine assignments and energy source choices can jointly optimize cost and environmental impact. Our analysis reveals key trade-offs, such as shifts in energy preference under varying carbon emission limits. We also conduct sensitivity analyses on energy prices, showing that coal tends to offer more cost stability than natural gas during price fluctuations. Ultimately, we identify optimal energy source combinations under different emission constraints, providing insights for decision-makers striving to balance economic and environmental goals in production planning.

2 - When and How Should South Korea Achieve Carbon Neutrality? Understanding Public Preferences and Generation Differences for Carbon Neutrality Policy

Sukhoon Lee, Kyung Hee University, Yongin, Korea, Republic of, Hyunhong Choi

This study quantitatively examined public preferences and generational differences related to South Korea's carbon neutrality policy. The survey focused on three key attributes, including the target year (which included levels such as 2045, 2050, 2060, or 2070), the strategy (such as front-loaded, evenly distributed, or back-loaded), and the annual carbon neutrality tax (ranging from about 7 to 50 USD). An online survey was conducted in May 2024 with 645 adults aged 20 to 69 nationwide, utilizing a choice experiment and a hierarchical Bayesian logit model. Results showed the public most preferred 2050 as the target year, followed by 2045, 2060, and 2070. Similarly, the back-loaded strategy was least preferred. Additionally, the relative importance revealed that the combined weight of the target year and strategy accounted for approximately 40%, demonstrating that the public places significant emphasis on the strategic combination of when and how carbon neutrality should be achieved. A distinct generational pattern emerged, showing that older adults (aged 30 to 69) were even less likely than younger adults (aged 20 to 29) to prefer postponing both the target year and the achievement strategy, which would shift the burden to future generations. These findings suggest that implementing an additional carbon neutrality tax should involve differential tax rates by generation to ensure intergenerational equity is reflected in policy design. By analyzing generational differences in preferences for carbon neutrality policies, this study enhances understanding of intergenerational disparities and provides a foundation for developing more valid and participatory carbon neutrality policies in South Korea.

3 - Mitigating Disruptions in Semiconductor Supply Chains: Stability Improvement vs. Backup Procurement

Zhili Yuan, Shanghai Jiao Tong University, Shanghai, China, People's Republic of, Xiaofeng Shao, Jian Wang

Semiconductor supply chain disruptions often lead to prolonged recovery. Manufacturers face strategic trade-offs between stabilization improvement investments and backup procurement activation to enhance supply resilience. This study employs a game-theoretic approach to examine the optimal decision-making strategies under emergency procurement constraints. Results show that when emergency procurement is not allowed, investment only is viable under low stabilization costs and the disruption risk below an upper threshold, while reservation only becomes preferable when costs are high and the risk exceeds a lower threshold. Our findings further reveal that investment can sometimes deter backup procurement initiation, with a combined strategy optimal only under high-risk conditions. Notably, when permissible, emergency procurement proves incompatible with reservation and is adopted only if the disruption probability is below a defined value. Additionally, while investment increases the preference for emergency procurement, it does not affect purchase volumes. We extend assumptions yielding consistent insights. Moreover, when the supply

stability level is endogenous, a combined investment and emergency procurement strategy may surprisingly be optimal under high-risk scenarios. In contexts with risk-averse manufacturers and product competition, the risk threshold for selecting backup supply based solely on reservation increases, whereas it remains unchanged when backup supply offers procurement flexibility.

1 - Physics-Centric Machine Learning to Improve Fatigue Performance Prediction of Laser Powder Bed Fusion

Jia Liu, Auburn University, Auburn, AL, United States

Understanding the fatigue performance and accurately predicting the fatigue life of laser powder bed fusion (L-PBF) parts remains a pressing challenge due to its complex failure mechanisms, time-consuming tests, and limited fatigue testing data. Meanwhile, machine learning provides a promising alternative approach to investigating such complex relationships and using surrogate models to enable sufficient prediction. With previous knowledge in both fracture mechanics and machine learning, we propose a physics-centric machine learning method to investigate the relationship between fatigue performance and surface quality and improve fatigue life prediction. The fatigue life of additively manufactured metallic parts in the unmachined surface condition is typically shorter than those in machined surfaces, primarily due to the presence of surface micro-notches. Specifically, we utilize a fracture mechanics-based approach to identify the key surface features, which include the geometry of surface micro-notches, such as width, depth, opening angle, and radius of curvature, from Ti-6Al-4V L-PBF coupons. Then, we leverage the structure of a linear mixed model and point process to create a novel, interpretable, and generalizable machine-learning model to model the complex relationships between fatigue performance and surface quality, aiming to achieve a better interpretation, smaller scatter, and more accurate prediction.

2 - Enhanced Counterfactual Explanations for Optimizing 3D Printing Parameters Using Shap and Nearest-Neighbor Constraints

Samar Saleh, Rutgers, The State University of New Jersey, Piscataway, NJ, United States, Weihong Guo, Yuebin Guo

Overheating in additive manufacturing (AM), particularly in Laser Powder Bed Fusion, impacts part quality and reliability. This study presents a novel framework for optimizing 3D printing parameters (power, speed, and printing sequence) using enhanced counterfactual explanations (CE).

The framework incorporates SHapley Additive exPlanations (SHAP) to identify key features influencing overheating, quantified by the Consolidated Overheating Ratio (COR), a metric representing localized thermal excess. SHAP values guide the model to prioritize impactful adjustments that reduce COR while improving interpretability.

To ensure practicality, the method integrates nearest neighbor constraints during counterfactual generation, yielding parameter suggestions that are realistic and data grounded. We introduce SHAP and Neighbor-Enhanced Counterfactual Explanations (SHANCE), which addresses the limitation of conventional CE methods that may propose infeasible recommendations.

A key innovation lies in the addition of a physics-based constraint: volume energy density (VED). This constraint ensures that any suggested power and speed combination remains within manufacturable bounds, aligning with material and process requirements. It acts as a filter to exclude counterfactuals that could result in under- or over-exposure, bridging the gap between data-driven insights and physical feasibility.

The framework was validated using both MNIST and real-world AM datasets. On MNIST, SHANCE improved the realism and diversity of counterfactuals. Applied to AM data, it successfully reduced COR while maintaining process constraints, demonstrating its potential for practical parameter optimization.

By combining interpretability, data proximity, and physical validation, this framework offers a robust and explainable tool for mitigating overheating in AM and improving manufacturing outcomes.

3 - Enabling Comparability: a Benchmarking Framework for Reinforcement Learning in Manufacturing Systems

Lingxiang Yun, University of North Carolina at Charlotte, Charlotte, NC, United States

Reinforcement Learning (RL) has emerged as a promising approach for real-time decision-making in manufacturing systems under uncertainty. However, the lack of standardized simulation environments has hindered the comparability and reproducibility of RL-based methods developed by different research groups. This project introduces a benchmarking framework designed to address this gap by providing a modular, Python-based simulation environment tailored for manufacturing system control tasks. The framework is compatible with popular RL libraries such as Stable-Baselines3 and supports integration with custom algorithms built in PyTorch or TensorFlow. By offering a shared platform for experimentation, this benchmark aims to accelerate progress in RL research for manufacturing and promote fair, transparent evaluation across studies.

1 - An Empirical Investigation of Efficient Anomaly Detection Techniques for Resource-Constrained Systems

Hyungkwon Lee, KAIST, Daejeon, Korea, Republic of, Hyewon Ryu, Youngho Kim, Hangeong Park, Jinuk Oh, Jong-Seok Lee

As anomaly detection has been actively studied, industrial and defense applications increasingly seek to implement anomaly detection systems. However, these systems are typically well-maintained, making anomalies extremely rare or nonexistent in operational data. This scarcity complicates training supervised machine learning models, thus unsupervised methods trained solely on normal data often remain the only practical solution. Additionally, strict hardware constraints in real-world settings—such as security-sensitive systems, thermally restricted equipment, and low-performance computing devices—often make modern deep learning methods with high computational demands impractical. This research aims to support practitioners by examining anomaly detection methods characterized by low computational complexity and quantitatively evaluating their efficiency. We analyze several lightweight algorithms across diverse anomaly scenarios, utilizing both synthetic and limited real anomaly datasets. Our study compares detection performance and computational resource usage under constrained hardware conditions. We also empirically investigate whether the frequently mentioned trade-off between detection accuracy and computational efficiency truly exists. The findings of this study provide practical insights for practitioners designing effective anomaly monitoring systems within resource-limited environments.

2 - An Uncertainty-Aware Physics-Integrated Mixture of Experts for Melt Pool Prediction in Metal Additive Manufacturing

Kyudong Kim, University at Buffalo, Buffalo, NY, United States, Yuxin Yang, Yu Jin

Accurate prediction of melt pool dynamics is essential for ensuring product quality and process reliability in metal additive manufacturing (AM). While laser scan strategies (i.e., laser trajectory) and process parameters significantly influence melt pool behavior, many existing models did not fully capture the relationship between the scan strategy and quality. To address this gap, we propose an uncertainty-aware, physics-integrated Mixture of Experts (UP-MoE) framework tailored for melt pool size prediction for a laser power bed fusion process. The architecture comprises multiple specialized experts, dedicated to capturing distinct aspects of the underlying physics: spatio-temporal melt pool evolution, energy density, radiation pressure, and power distribution. These experts collectively learn the complex interactions between process parameters and melt pool size. To enable principled uncertainty quantification, a Gaussian Process (GP) is integrated with the MoE output, offering reliable confidence estimates critical for process monitoring and control. Numerical studies demonstrate the accuracy and precision of the proposed approach by explicitly modeling scan strategy variations and embedding domain-informed physics into the learning process.

3 - A Comparative Study of Fractional Grey Models for Time Series Forecasting

Gazi Duman, University of New Haven, West Haven, CT, United States, Elif Kongar

Fractional Grey Models represent a significant advancement in Grey System Theory, offering improved flexibility and forecasting accuracy in environments characterized by limited and uncertain data. This study conducts a systematic comparative analysis of several fractional grey models, employing distinct definitions of fractional derivatives, including the Caputo, Riemann-Liouville, Hausdorff and Conformable approaches. The models are evaluated using a benchmark time series dataset, with performance assessed across various criteria such as prediction accuracy, robustness, and computational efficiency. The findings contribute to a deeper understanding of the theoretical and practical implications of fractional calculus in grey modeling and offer evidence-based recommendations for model selection in various applications.

4 - Identifying Key Attributes Influencing Short-Term Rental Occupancy Rates: Case of Airbnb

Ehsan Ahmadi, Mercer University, Atlanta, GA, United States, Sanelisiwe Amanda Nkomo, Reza Maihami

Optimizing the profitability of listings on platforms such as Airbnb is essential in the evolving housing and rental market. Occupancy rates can change due to various factors, such as price, location, host practices, property features, and guest engagement. This study explores the key attributes of higher occupancy rates by analyzing Airbnb listing data. Utilizing data mining and machine learning techniques, the study explores patterns and insights that reveal the most significant factors influencing short-term rental occupancy rates. High occupancy rates, an average of 58% are strongly associated with guest engagement efforts such as the number of reviews, average low prices of \$180, and limiting listing capacity to at least 3 guests. These insights help as a guide for short-term rental hosts in improving occupancy rates and property performance through strategic decisions.

5 - A Patent Location Model for Identifying New Technology Opportunities

Jinseob Kim, Seoul National University, Seoul, Korea, Republic of, Sungjoo Lee

The growing emphasis on evidence-based R&D strategy necessitates determining which patents constitute the core of a technology domain, which actors possess the most extensive and valuable patent portfolios, and where latent R&D opportunities remain. The existing approaches rely heavily on citation, co-classification, or text information; they rarely consider the location of patents within a patent landscape considering technology coverage of patented inventions, which is essential to evaluate the value of patents. This study closes that gap by embedding patent corpora in a high-dimensional semantic space and fulfills the research objective with a facility-location problem. First, a p-center formulation selects a set of patents that minimizes the maximum distance to all others, thereby operationalizing core-technology detection with respect to technological content coverage. Here, the core technology is defined as a patent that can best represent the technological content within technological fields. Next, aggregating the resulting coverage regions by assignee and its country yields quantitative metrics of the actor's technological influence, weighted by forward citations, family size, and claim breadth to measure the technological values. Finally, to identify white-space opportunities, we solve a continuous k-median problem whose coverage gaps highlight candidate coordinates for future invention; each coordinate is reconverted to text via large language model prompting and nearest-neighbor patent sampling, turning abstract vectors into interpretable concept sketches. The framework integrates the facility-location concept with modern language AI to deliver reproducible, content-aware analytics, enabling a novel approach to strategic innovation planning.

6 - Improving Few-Shot Tabular Regression via Latent Task Discovery and Meta-Learning

Yujung Byun, KAIST, Daejeon, Korea, Republic of, Jong-Seok Lee

In many real-world tabular regression problems, data points may actually come from multiple latent tasks or domains, even if we initially treat the dataset as a single task. This hidden heterogeneity can degrade a model's performance and hamper generalization, especially when adapting to new tasks with only a few samples. If the task or domain labels were known, one could apply meta-learning techniques to train models that adapt quickly to each task. However, in our scenario these task structures are not observed, making it challenging to directly use meta-learning. To overcome this challenge, we propose a two-stage framework that discovers latent task structures from data and then leverages meta-learning for improved few-shot regression. In the first stage, our method clusters the training samples into pseudo-tasks based on their prediction error patterns, without using any ground-truth task labels. Samples with similar error behavior are grouped together, as they likely share an underlying function or domain. In the second stage, each pseudo-task is treated as a separate task for meta-learning, training the model to quickly adapt its predictions to each discovered task structure. Through this two-stage process, the model effectively captures task-specific patterns in the data and generalizes better to unseen data or new tasks with only a few examples for adaptation.

7 - Solar Flare Detection Based on Multiple Wavelengths Data

Seungye Lee, Ewha Womans University, Seoul, Korea, Republic of, Dongil Kim

Solar phenomena are observed once every few seconds and stored as a large amount of data. The stored data is used for space environment forecasts. Solar flares, which are solar phenomena that emit strong energy and bright light, can cause fatal damage to social network systems. So accurate detection is necessary. Most of the existing studies use single-form data and basic deep learning models, so it is essential to introduce a new method for improving automatic detection. In this study, we trained a multimodal flare-detection model using solar full-disk images acquired at multiple wavelengths. The proposed method is expected to enable efficient data accumulation with high accuracy by learning solar flare observation data from various aspects.

1 - Dynamic Operating Envelopes for Flexible Management of Distributed Energy Resources

Zhaoyu Wang, Iowa State University, Ames, IA, United States

The increasing penetration of distributed energy resources (DERs) brings both flexibility and uncertainty to power distribution system operations. Under traditional firm interconnection rules, DERs are either allowed full access to the grid or denied interconnection altogether, based on the hosting capacity. Conventional hosting capacity ignores time-varying operational conditions of distribution networks, leading to underutilization of DERs and grid infrastructure. Dynamic operating envelope (DOE) allows the flexible interconnection of DERs. Utilities can dynamically adjust DER power export/import power limits according to real-time grid conditions, such as load fluctuation, voltage level, etc. This talk will introduce a mathematical formulation of DOE, which is widely implemented in commercial advanced distribution management systems of major software vendors. Solving such problems for large-scale distribution grids is extremely challenging due to the non-convexity,

computational burden, and the online operation requirements. In this talk, we will discuss and compare different solution algorithms such as gradient-based, linear programming, and AI-based methods.

2 - Attention is All You Need to Optimize Wind Farm Operations and Maintenance

Iman Kazemian, Wayne state university, Detroit, MI, United States, Murat Yildirim, Paritosh Ramanan

Operations and maintenance (O&M) is a fundamental problem in wind energy systems with far reaching implications for reliability and profitability. Optimizing O&M is a multi-faceted decision optimization problem that requires a careful balancing act across turbine level failure risks, operational revenues, and maintenance crew logistics. The resulting O&M problems are typically solved using large-scale mixed integer programming (MIP) models, which yield computationally challenging problems that require either long-solution times, or heuristics to reach a solution. To address this problem, we introduce a novel decision-making framework for wind farm O&M that builds on a multi-head attention (MHA) models, an emerging artificial intelligence method that are specifically designed to learn in rich and complex problem settings. The development of proposed MHA framework incorporates a number of modeling innovations that allows explicit embedding of MIP models within an MHA structure. The proposed MHA model (i) significantly reduces the solution time from hours to seconds, (ii) guarantees feasibility of the proposed solutions considering complex constraints that are omnipresent in wind farm O&M, (iii) results in significant solution quality compared to the conventional MIP formulations, and (iv) exhibits significant transfer learning capability across different problem settings.

3 - Distributionally Robust Planning of Hydrogen-Electrical Microgrids for Sea Islands

Yuchen Dong, Xi'an Jiaotong University, Xi'an, China, People's Republic of, Zhengwen He, Xiaoyu Cao, Bo Zeng

This paper presents a distributionally robust planning method for hydrogen-electrical microgrids over islands, where the cross-island energy exchange is supported by a maritime hydrogen transport network. This planning problem is complicated due to heterogeneous off-shore wind-driven uncertainties (i.e., renewable power, transport availability, demand fluctuations, and grid faulting), a subset of which exhibit endogenous uncertainty, as they can be affected by proactive measures (e.g., grid hardening) or infrastructure investment. To capture these features, a two-stage distributionally robust optimization (DRO) model is developed considering decision-dependent uncertainty (DDU), which encompasses variation of the underlying distributional ambiguity due to the change of the first stage decisions. Notably, the complete recourse property is missing, which is often neglected in existing DRO studies. Nevertheless, different from the case for land-based microgrids, this issue is critical and fundamental for sea island systems due to their particular physical and logistical requirements. To address these issues, we develop a C&CG algorithm that is customized with strong cutting planes to handle DRO with a varying DDU ambiguity set and feasibility requirements. Numerical results demonstrate the cost-effectiveness and resilience of the proposed planning framework, along with the nontrivial improvements of the algorithm in both solution accuracy and computational efficiency.

4 - Adaptive Robust Optimization with Data-Driven Uncertainty for Enhancing Distribution System Resilience

Shuyi Chen, Carnegie Mellon University, Pittsburgh, PA, United States, Shixiang Zhu, Ramteen Sioshansi

Extreme weather events are placing growing strain on electric power systems, exposing the limitations of purely reactive responses and prompting the need for proactive resilience planning. However, existing approaches often rely on simplified uncertainty models and decouple proactive and reactive decisions, overlooking their critical interdependence. This paper proposes a novel tri-level optimization framework that integrates proactive infrastructure investment, adversarial modeling of spatio-temporal disruptions, and adaptive reactive response. We construct high-probability, distribution-free uncertainty sets using conformal prediction to capture complex and data-scarce outage patterns. To solve the resulting nested decision problem, we derive a bi-level reformulation via strong duality and develop a scalable Benders decomposition algorithm. Experiments on both real and synthetic data demonstrate that our approach consistently outperforms conventional robust and two-stage methods, achieving lower worst-case losses and more efficient resource allocation, especially under tight operational constraints and large-scale uncertainty.

1 - Epidemic Time Series Forecasting in the Era of Machine Learning

Wei Jin, Emory University, Atlanta, GA, United States

As machine learning continues to revolutionize various scientific domains, its impact on epidemic time series forecasting has become increasingly significant. This talk explores the intersection of advanced machine learning techniques with the pressing needs of epidemic forecasting. We will address three key challenges in this field: computational efficiency, data scarcity, and the accurate modeling of spatial-temporal dynamics. First, I will present a solution to enable lighter, faster models to perform at the level of more complex models, crucial for timely epidemic responses. Next, I will discuss the utilization of extensive pre-training on epidemic data to improve the model's predictive accuracy and generalization across varied epidemic scenarios. Finally, I will introduce a graph neural ODE approach for accurately modeling the continuous and dynamic spread of diseases across regions, and outline future research directions in this evolving field of machine learning for epidemic forecasting.

2 - Dynamic Delegation to Achieve Human-AI Complementarity

Wei Gu, Carnegie Mellon University, Pittsburgh, PA, United States, Shixiang Zhu, Michael Lingzhi Li

Humans bring judgment and oversight, while AI offers scale and efficiency. To utilize the complementary strength of both human and AI, we develop a dynamic delegation strategy for adaptive agents that intelligently manage human-AI collaboration. The proposed method optimizes when to act autonomously, defer to humans, or involve human oversight based on the tradeoff between system accuracy and cost. The interaction between human and AI is modeled as a generalized Nash equilibrium and reformulated as a quasi-variational inequality to capture human behavioral adaptation. We provide the conditions under which human and AI can cooperate, and show when the proposed dynamic delegation strategy will outperform static delegation such as fully automated decision-making or mandatory human review. The effectiveness of the proposed method is validated in numerical experiments. Our results offer insights on balancing automation with human input toward building responsible, efficient, and deployable agentic AI systems.

3 - A Semidefinite Relaxation for Copositive Dual Pricing in Discrete Energy Markets

Lauren Henderson, Clemson University, Clemson, SC, United States, Cheng Guo, Ryan Cory-Wright, Boshi Yang

Electricity markets often rely on solving unit commitment (UC) problems to determine generator dispatch and pricing, but non-convexities in these problems lead to challenges in deriving efficient prices. We propose a new pricing scheme, derived from relaxing the completely positive program (CPP) formulation of the UC problem to a semidefinite program (SDP). We show that our SDP is at least as strong as an alternative UC SDP formulation in the literature (Fattahi et al., 2017). We introduce coordination agents that model cross-terms in the semidefinite relaxation, which gives our pricing scheme economically desirable properties like revenue adequacy and cost recovery. Additionally, we provide perturbation bounds using the envelope theorem, which describes the optimal UC value as a function of the cost of starting up or shut down a generator. We perform numerical experiments on a variety of IEEE UC instances to demonstrate the efficacy of our pricing scheme. Specifically, we show that our SDP relaxation yields a much tighter approximation to the UC value function than the linear programming-based relaxation. We also see promising results of lower uplift payments compared with the commonly-used fixed binary pricing scheme.

4 - Operator Learning for Human-Centered Indoor Air Quality Control in Smart Buildings

Yuxin Bian, University of California San Diego, La Jolla, CA, United States, Oliver Schmidt, Yuanyuan Shi

Ensuring healthy indoor air quality while minimizing energy consumption is a central challenge in smart building control. Traditional ventilation strategies often overlook fine-grained airflow dynamics, leading to inefficient or suboptimal performance. While Computational Fluid Dynamics (CFD) provides high-fidelity modeling of airflow, its prohibitive computational cost hinders real-time decision-making. In this work, we propose a data-driven operator learning framework that captures complex indoor airflow patterns and supports intelligent, health-aware ventilation control. Leveraging high-resolution CFD data, we train a neural operator transformer to learn the mapping from control inputs—such as vent angles and supply rates—to full-field airflow and CO₂ distributions. This learned operator enables gradient-based, real-time

optimization of ventilation settings to simultaneously ensure occupant health and reduce energy use. We evaluate our method across various indoor scenarios and compare it with rule-based control, data-driven approaches based on average CO₂ modeling, and reduced-order modeling techniques. Our approach consistently maintains safe air quality levels while achieving substantial energy savings, demonstrating its promise for scalable, human-aware smart building management.

Plenary - Learning to Optimize: Foundations and Industrial Impact

Plenary Keynote

Plenary

1 - Learning to Optimize: Foundations and Industrial Impact

Pascal Van Hentenryck, ISyE Georgia Tech, Atlanta, GA, United States

In many industry settings, the same optimization problem is solved repeatedly for instances taken from a distribution that can be learned or forecasted. Indeed, such parametric optimization problems are ubiquitous in applications over complex infrastructures such as electrical power grids, supply chains, manufacturing systems, and transportation networks. The scale and complexity of these applications, and increasingly volatile environments they operate on, have grown significantly in recent years, challenging traditional optimization approaches. This talk studies how to fuse machine learning and optimization for speeding up these parametric optimization problems and meeting real-time constraints present in practice. It first reviews the concept of optimization proxies that learn the input/output mappings of parametric optimization problems, computing near-optimal feasible solutions and providing quality guarantees orders of magnitude faster. The talk also presents how to “learn to optimize” highly complex optimization problems, fusing optimization methodologies with supervised learning and reinforcement learning. The impact of the methodologies are highlighted on industrial problems in grid optimization, end-to-end supply chains, logistics, and transportation systems. The talk should reveal beautiful connections between machine learning and optimization, that leverage fundamental theoretical results to push the practice of optimization.
